Viewer Guide

Navigation Tips:

- Use the outline/bookmarks pane (left side in most PDF viewers) to jump between sections.
- Click links at the bottom of each question to switch between Part A (questions) and Part B (answers).
- Master Index links take you to topic parts.

Viewer Settings:

- Adobe Reader: View > Show/Hide > Navigation Panes > Bookmarks
- Chrome: Install PDF viewer extension if needed.
- Mobile: Use apps like Adobe Acrobat or Xodo for outline support.

Q1: A 52-year-old male presents with worsening shortness of breath and fatigue. An echocardiogram shows left ventricular dilation and significant aortic regurgitation. Which of the following are the possible conditions causing Aortic regurgitation? Ankylosing Spondylitis Aortic Dissection Marfan's Syndrome Syphilis (Q850418)

A. 1,2,3

B. 2,3,4

C. 1,3,4

D. 1,2,3,4

See Answer in Part B → Q1

@Neet_pg_bot

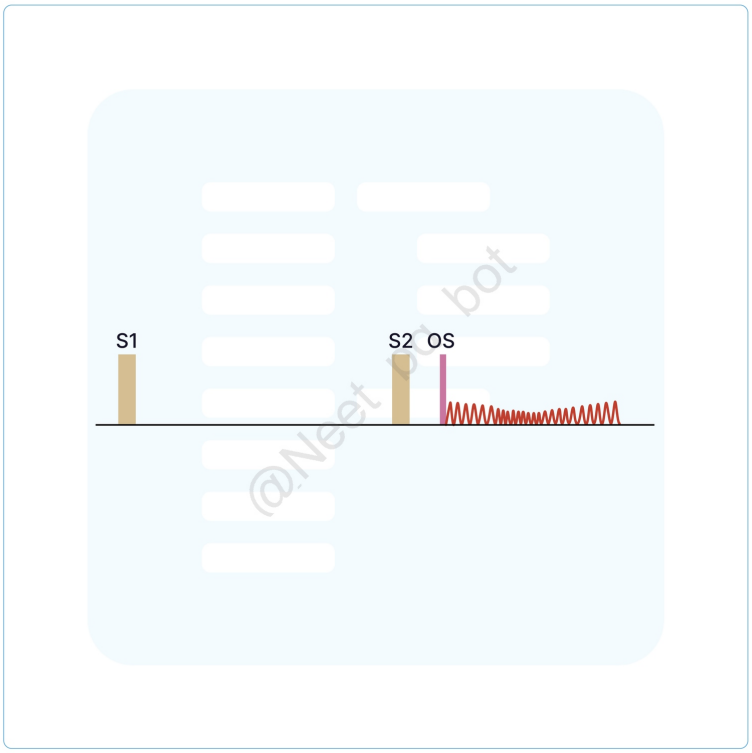
Q2: Match the following murmurs with the respective conditions. S.No Murmur Condition 1) a) Mitral Stenosis 2) b) Aortic Stenosis 3) c) Mitral Regurgitation 4) d) Aortic Regurgitation (Q850444)

A. 1-a, 2-b, 3-c, 4-d

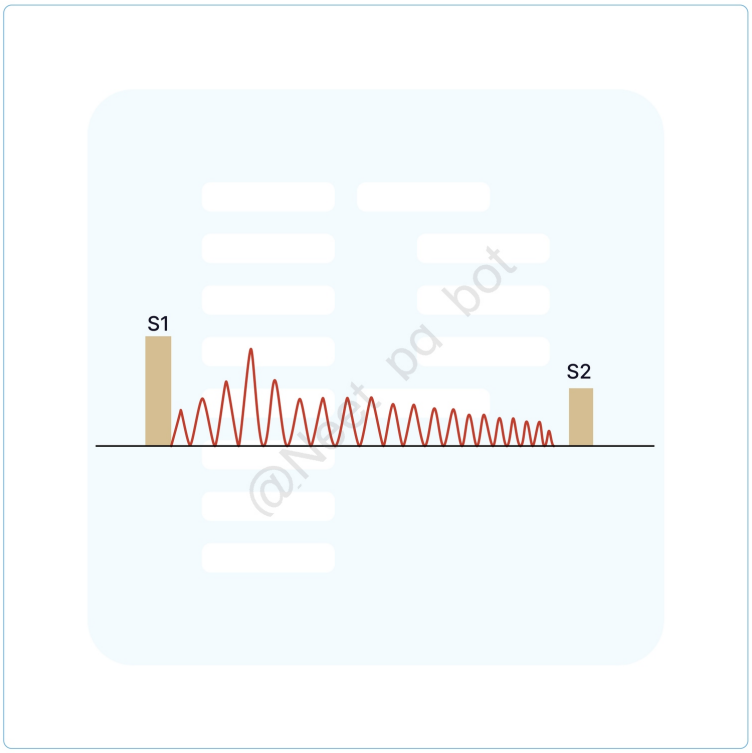
B. 1-c, 2-a, 3-d, 4-b

C. 1-a, 2-c, 3-b, 4-d

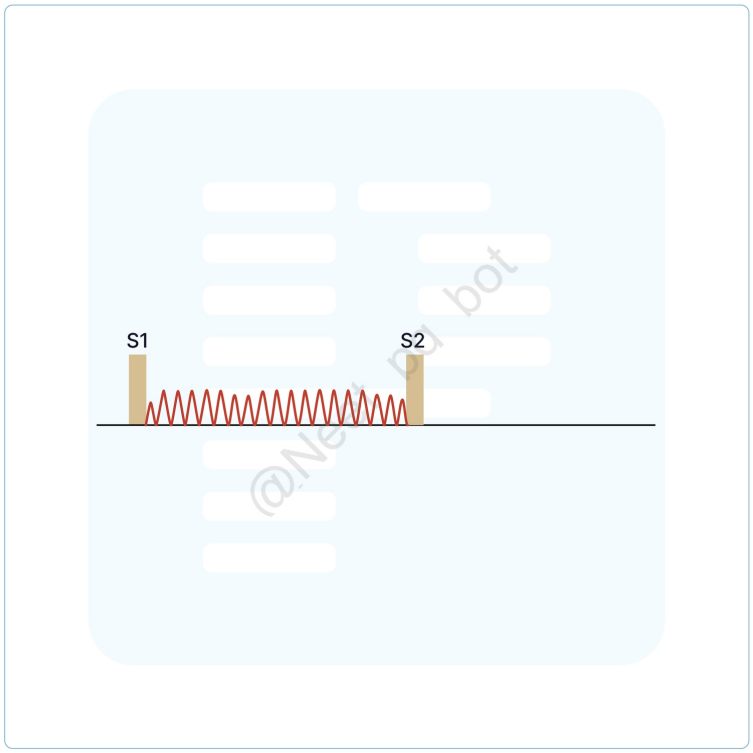
D. 1-d, 2-b, 3-c, 4-a



@Neet_pg_bot



@Neet_pg_bot



@Neet_pg_bot

Q3: A 25 year old woman diagnosed with scleroderma presents with exertional dyspnea. You auscultate a high-pitched, decrescendo diastolic murmur at the second left intercostal space, radiating along the left sternal border that increases with inspiration. Which of the following is correct about this case? (Q850440)

A. Graham Steell murmur

B. Austin Flint murmur

C. Carey-Coombs murmur

D. Gibson's murmur

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 65-year-old male presents to the clinic with complaints of left arm pain and intermittent dizziness. O/E, you find a notable difference in blood pressure readings: 150/90 mmHg in the right arm and 100/60 mmHg in the left arm. Which condition is least likely to cause this variation? (Q850438)

A. Coarctation of the aorta

B. Aortic dissection

C. Supravalvular aortic stenosis

D. Takayasu arteritis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Match the following cardiac valvular disorders with their specific murmur type: Valvular defect Murmur 1. Aortic stenosis a. Pansystolic murmur increasing with inspiration 2. Mitral regurgitation b. Mid-diastolic rumble with opening snap 3. Mitral stenosis c. Harsh systolic murmur radiating to the carotids 4. Tricuspid

regurgitation d. Holosystolic murmur radiating to the axilla (Q850436)

A. 1-b, 2-a, 3-d, 4-c

B. 1-c, 2-b, 3-a, 4-d

C. 1-c, 2-d, 3-b, 4-a

D. 1-d, 2-a, 3-c, 4-b

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 6-year-old girl with a history of Tetralogy of Fallot repair 12 months ago presents with abdominal swelling and pedal oedema. Cardiac auscultation reveals an early diastolic murmur, and ECG shows right ventricular and atrial enlargement. Considering the suspicion of pulmonary regurgitation, which investigation is most appropriate for further evaluation? (Q850433)

A. Transthoracic echocardiography

B. Cardiac magnetic resonance imaging

C. Transesophageal echocardiography

D. Cardiac catheterisation

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 10-year-old girl presents with exercise intolerance and occasional chest pain. Examination reveals a systolic ejection murmur at the left upper sternal border and elevated jugular venous pressure. An echocardiogram shows a peak systolic gradient of 70 mmHg across the pulmonary valve, raising suspicion for pulmonary valve stenosis. Which of the following set of statements is true regarding this condition? Pulmonic stenosis is always congenital. Dysplastic valves leading to pulmonary stenosis are seen in Noonan syndrome. Severe PS is defined by peak systolic gradient across the PV>64 mmHg Percutaneous balloon valvuloplasty is indicated for all

patients. Pulmonic stenosis usually leads to right ventricular hypertrophy. (Q850431)

A. 2 and 5

B. 3 and 4

C. 2,3 and 5

D. 1,2 and 5

See Answer in Part B → Q7

@Neet_pg_bot

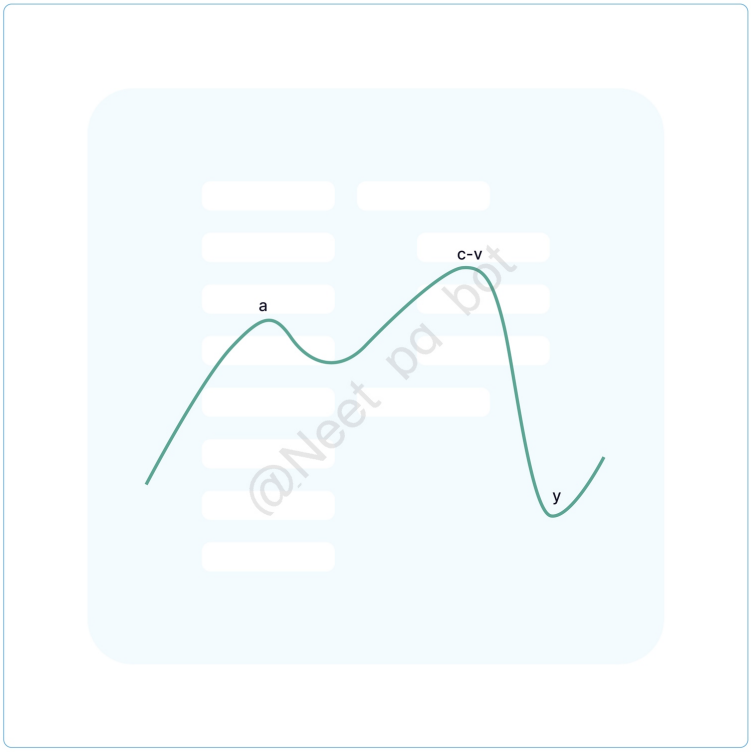
Q8: A 75-year-old male with a history of long-standing hypertension and atrial fibrillation presents with progressive fatigue & bilateral leg swelling. O/E, the patient has distended neck veins with the following waveform with a blowing holosystolic murmur that increases with inspiration and radiating to epigastrium. What is the most likely diagnosis? (Q850429)

A. Pulmonary hypertension

B. Tricuspid regurgitation

C. Pulmonary stenosis

D. Mitral regurgitation



@Neet_pg_bot

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 66-year-old female presents with fatigue, abdominal discomfort, and swelling in her legs. On examination, she has jugular venous distention with giant ‘a’ waves, hepatomegaly, and ascites. Auscultation reveals a diastolic murmur at the lower left sternal border, which increases in intensity with inspiration. What’s the most likely diagnosis? (Q850426)

A. Mitral stenosis

B. Tricuspid stenosis

C. Constrictive pericarditis

D. Aortic stenosis

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 69-year-old man presents with severe aortic regurgitation. He reports increasing fatigue, breathlessness, and episodes of dizziness. On auscultation, a diastolic murmur is heard along with a water-hammer pulse, and an echocardiogram shows significant left ventricular dilation and an ejection fraction of 55%. What is the most appropriate management for this patient? (Q850425)

A. Medical management

B. Transcatheter aortic valve implantation

C. Intra-aortic balloon counterpulsation

D. Aortic valve replacement

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Match the following signs with specific features Signs Features 1. Muller Sign a) Systolic pulsations of the Spleen 2. Rosenbach sign b) Visible systolic pulsation of the uvula 3. Gerhardt's sign c) Jarring motion of the head with each heartbeat 4. De-Musset sign d) Systolic pulsations of the Liver (Q850421)

A. 1-b, 2-d, 3-a, 4-c

B. 1-a, 2-c, 3-b, 4-d

C. 1-c, 2-a, 3-d, 4-b

D. 1-d, 2-b, 3-c, 4-a

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 72-year-old male presents with complaints of worsening dyspnea, angina and orthopnea. Physical examination reveals a loud diastolic murmur at the left sternal border and a widened pulse pressure. An echocardiogram indicates significant left ventricular dilation. What is the likely estimated regurgitant volume in this condition

to label as severe valvular dysfunction? (Q850419)

A. < 35 ml/beat

B. > 35 ml/beat

C. < 60 ml/beat

D. > 60 ml/beat

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 32-year-old female presents with palpitations, chest discomfort, and fatigue. A mid-systolic click and late systolic murmur are heard at the apex. Echocardiography shows mitral valve leaflets billowing into the left atrium during systole. Which of the following is leading cause of this presentation? (Q850397)

A. Inflammation of the mitral valve due to rheumatic fever

B. Fibrotic changes affecting the mitral valves

C. Rupture of the tendinae of the mitral valve

D. Myxomatous degeneration of mitral valve apparatus.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 65-year-old woman reports experiencing mild chest pain and shortness of breath on exertion. On examination, harsh ejection- systolic murmur is noted, best heard at the right second intercostal space and radiating to the carotids. An Echocardiogram shows an aortic valve area of 0.9 cm^2. Which stage of aortic stenosis is present and what is the ideal management? (Q850417)

A. Stage B and TAVR

B. Stage D and Statins

C. Stage B and Statins

D. Stage D and TAVR

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 72-year-old patient presents with angina and shortness of breath on exertion. Physical examination reveals a slow-rising carotid pulse and a systolic ejection murmur. Which of the following is most likely to be observed in this patient? (Q850415)

A. Triple vessel disease

B. Right atrial enlargement

C. Medial displacement of heaving apex

D. Junctional Tacycardia

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 65-year-old patient presents to the clinic with increasing fatigue and shortness of breath on exertion. O/E a harsh, systolic crescendo-decrescendo ejection murmur is noted at the right second intercostal space. Which of the following is not seen in this condition ? (Q850413)

A. Left axis deviation

B. Angina pectoris

C. Syncope on exertion

D. Water Hammer pulse

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 72-year-old woman presents with fatigue and progressive shortness of breath, particularly when climbing stairs. During the physical examination, a harsh, systolic ejection murmur is heard at the right second intercostal space, radiating to the carotids. Which of the following factors is least likely to be associated with the development of the condition? (Q850412)

A. Mediastinal irradiation

B. Mutation in NOTCH1

C. Prior rheumatic inflammation

D. Systemic lupus erythematosus

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 65-year-old male presents with recurrent syncopal episodes. Auscultation reveals an ejection systolic murmur heard at the right 2 nd intercostal space and radiates to the carotids. The murmur also becomes higher-pitched when heard at the apex. ECG shows left axis deviation with a normal sinus rhythm. Which condition is most likely in this patient? (Q850410)

A. Sick Sinus syndrome

B. Aortic stenosis

C. Complete heart block

D. Pulmonary stenosis

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 50-year-old female patient presents with exertional dyspnea and a history of rheumatic fever. Echocardiogram shows severe mitral stenosis with calcification. Which of the following is the most appropriate management strategy for her

condition? (Q850408)

A. Initiate warfarin therapy

B. Percutaneous mitral balloon commissurotomy (PMBC)

C. Schedule for mitral valve replacement

D. Start beta-blockers and diuretics

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 48-year-old female presents with worsening exertional dyspnea and fatigue. She has a history of rheumatic fever during her childhood. Examination shows diastolic murmur at the cardiac apex with pronounced opening snap. Which of the following findings is least likely to be present in this case? (Q850406)

A. Left atrial enlargement

B. Reduced mitral valve area

C. Right ventricular hypertrophy

D. Heaving apex beat

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 40-year-old female with a history of rheumatic heart disease comes to the OPD for a regular follow-up. Echocardiography confirmed the presence of severe mitral regurgitation . When considering her treatment options, which of the following interventions should not be included in her management plan? (Q850404)

A. Use of Apixaban if her CHA2DS2-VASc score ≥2

B. Cardiac resynchronization therapy, when indicated

C. Mitral valve repair if EF < 60%

D. Vitamin K antagonists

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 65-year-old female presents to the clinic with complaints of fatigue, shortness of breath on exertion, and palpitations. On physical examination, a systolic thrill is palpable at the cardiac apex. Echocardiography showed severe backflow of blood from the left ventricle to the left atrium during ventricular systole. What kind of murmur is most likely to be heard during cardiac auscultation of this patient? (Q850401)

A. Continuous murmur

B. An opening snap followed by a diastolic murmur

C. Holosystolic murmur, best heard at the apex

D. Crescendo decrescendo systolic murmur best heard at the base

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following is not a cause of primary chronic mitral regurgitation? (Q850400)

A. Ischemic cardiomyopathy

B. Rheumatic fever

C. Infective endocarditis

D. Radiation

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 65-year-old diabetic male with mitral valve prolapse presents with palpitations. Pulse 130/min irregular, BP on admission is 160/100 mmHg. He also has a history of infective endocarditis. Which of the following statements regarding his management is not true? (Q850398)

A. Anticoagulation therapy should be avoided due to low CHADS2Vasc score

B. Beta-blockers should be initiated for his palpitations

C. Mitral valve repair is preferred over mitral valve replacement

D. Prophylactic antibiotics should be initiated

See Answer in Part B → Q24

Q25 (p. 43)					

Q1: A 55-year-old man presents with gradually worsening shortness of breath and fatigue. He has a history of tuberculosis treated 10 years ago. Physical examination reveals elevated jugular venous pressure (JVP) that rises paradoxically with inspiration. Which of the following is the most likely diagnosis? (Q850497)

A. Pulmonary embolism

B. Restrictive cardiomyopathy

C. TB pericardial effusion

D. Constrictive pericarditis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following statements is correct about grades of murmurs? (Q850755)

A. Grade 1 murmur is very loud and audible even without a stethoscope

B. Grade 2 murmur is faint but audible with a stethoscope

C. Grade 4 murmur has a loud intensity without thrill

D. Grade 6 murmur is very faint and heard with difficulty

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Match the following murmurs to their characteristics Murmurs Characteristics 1. Mitral Stenosis A. High-pitched, crescendo-decrescendo murmur best heard at the right upper sternal border. 2. Aortic Stenosis B. Holosystolic murmur radiating to the axilla, often with a displaced apical impulse. 3. Patent Ductus Arteriosus C. Early diastolic decrescendo murmur best heard along the left sternal border. 4. Hypertrophic Cardiomyopathy D. "Machine-like" continuous murmur heard best at the left infraclavicular area. 5. Mitral Regurgitation E. Loud S1, opening snap, and low-pitched diastolic murmur heard best at the apex. 6. Aortic Regurgitation F. Systolic ejection murmur, often with a crescendo-decrescendo pattern, best heard at the right upper sternal border, radiating to the carotids. (Q850756)

A. 1 - E, 2 - F, 3 - D, 4 - A, 5 - B, 6 - C

B. 1 - E, 2 - F, 3 - A, 4 - D, 5 - C, 6 - B

C. 1 - F, 2 - E, 3 - D, 4 - A, 5 - C, 6 - B

D. 1 - F, 2 - E, 3 - A, 4 - D, 5 - B, 6 - C

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 35-year-old male presents with exertional chest pain and dyspnea. On physical examination, you note a harsh mid systolic murmur that is loudest at the left sternal border and increases in intensity with the Valsalva maneuver. Which of the following is the most likely cause? (Q850752)

A. Hypertrophic Cardiomyopathy

B. Aortic Stenosis

C. Pulmonary Stenosis

D. Atrial Septal Defect

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45-year-old male presents shortness of breath on exertion. Examination reveals a pansystolic murmur heard best at the apex of the heart, radiating to the axilla. The intensity of the murmur does not change with inspiration. Which of the following is the most likely diagnosis? (Q850753)

A. Chronic Mitral Regurgitation

B. Chronic Tricuspid Regurgitation

C. Aortic Stenosis

D. Acute Mitral Regurgitation

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 7-year-old child is brought to the clinic for evaluation of high blood pressure detected during a routine check-up. On physical examination, the blood pressure is higher in the arms compared to the legs. A continuous murmur is heard over the back, near the left scapula. Which of the following is the most likely diagnosis? (Q850754)

A. Takayau Arteritis

B. Coarctation of the Aorta

C. Atrial Septal Defect

D. Aortic Dissection

See Answer in Part B → Q6

@Neet_pg_bot

Q7: In aortic regurgitation, capillary pulsations can be seen in the nail beds. What is this sign called? (Q850751)

A. Quincke’s sign

B. Duroziez’s sign

C. de Musset’s sign

D. Hill sign

See Answer in Part B → Q7

@Neet_pg_bot

Q8: From the list of ECG findings given below which will not be seen in mitral stenosis? (Q850749)

A. Tall R waves in V1-V3

B. Bifid P wave

C. Atrial fibrillation

D. Tall tented T-waves

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following schematic represents murmur of mitral stenosis? (Q850748)

See Answer in Part B → Q9

@Neet_pg_bot

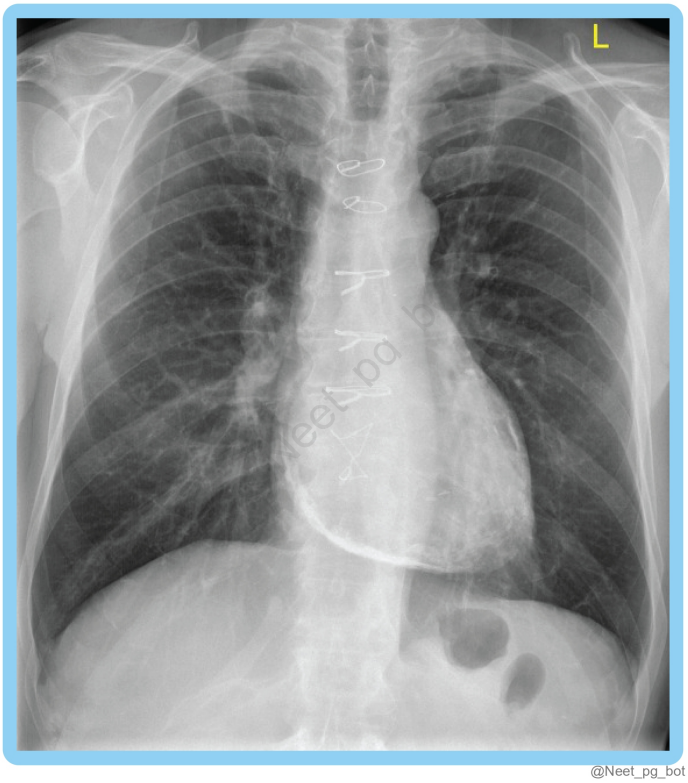
Q10: A 60-year-old male with presents with shortness of breath and pedal edema. Auscultation reveals a loud diastolic sound. Chest X-ray is given below. What is the treatment? (Q850746)

A. Diuretics

B. Pericardiocentesis

C. Beta-blockers

D. Glyceryl trinitrate



See Answer in Part B → Q10

@Neet_pg_bot

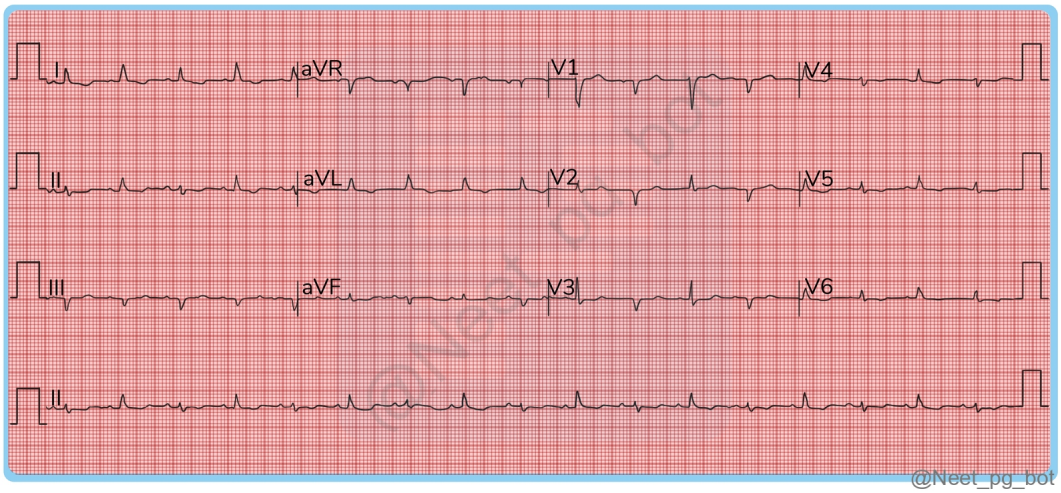
Q11: A 45-year-old woman recently diagnosed with adenocarcinoma lung presents with sudden dyspnoea, tachycardia, and hypotension. Examination reveals elevated JVP and an abnormal drop of 15mm Hg in systolic blood pressure during inspiration. An ECG was performed and is given below. What is the most appropriate next step in management? (Q850745)

A. Intravenous diuretics

B. Pericardiocentesis

C. Start vasopressors

D. Schedule elective cardiac surgery



See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 60-year-old man with a history of heart failure presents with worsening edema and jugular venous distention. You observe a steep x and steep y descent in the jugular venous waveform. Which of the following conditions is most likely responsible for these findings? (Q850500)

A. Constrictive pericarditis

B. Tricuspid regurgitation

C. Pericardial tamponade

D. Acute Pericarditis

See Answer in Part B → Q12

@Neet_pg_bot

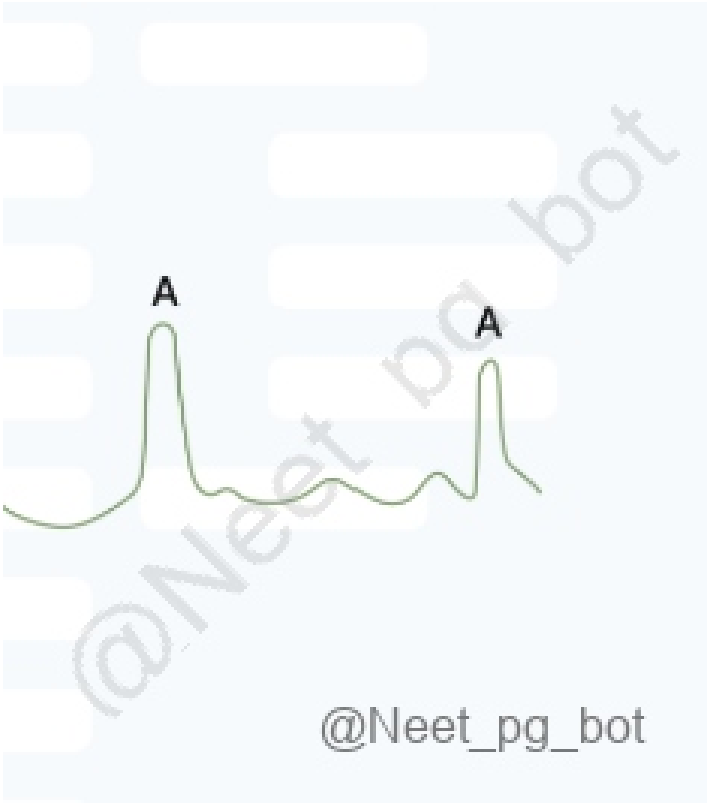
Q13: A 65-year-old man presents with palpitations and lightheadedness. His ECG shows an unequal number of P waves and R waves and his jugular venous pressure tracing is shown below. Which of the following conditions is responsible for this finding? (Q850498)

A. Atrial fibrillation

B. Complete heart block

C. Tricuspid stenosis

D. Electromechanical dissociation



See Answer in Part B → Q13

@Neet_pg_bot

Q14: Loud first heart sound (S1) in mitral stenosis indicates? (Q850476)

A. Reduced LV compliance

B. Increased left atrial pressure

C. Severe calcified mitral stenosis

D. Hypertrophy of the right ventricle

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 70-year-old woman with a history of ischemic cardiomyopathy, hypertension, and diabetes presents with worsening shortness of breath and fatigue. On physical examination, you hear both an S3 and an S4 heart sound. Which of the following best explains the presence of both heart sounds in this patient? (Q850495)

A. Atrial fibrillation with mitral stenosis

B. Acute mitral regurgitation

C. Combined systolic and diastolic heart failure

D. Severe aortic stenosis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 35-year-old woman presents with palpitations. On examination, hyperdynamic precordium is noted with soft S1 and pansystolic murmur. Which of the following is the most likely cause? (Q850494)

A. Hyperthyroidism

B. Mitral stenosis

C. Mitral regurgitation

D. Myxedema heart

See Answer in Part B → Q16

@Neet_pg_bot

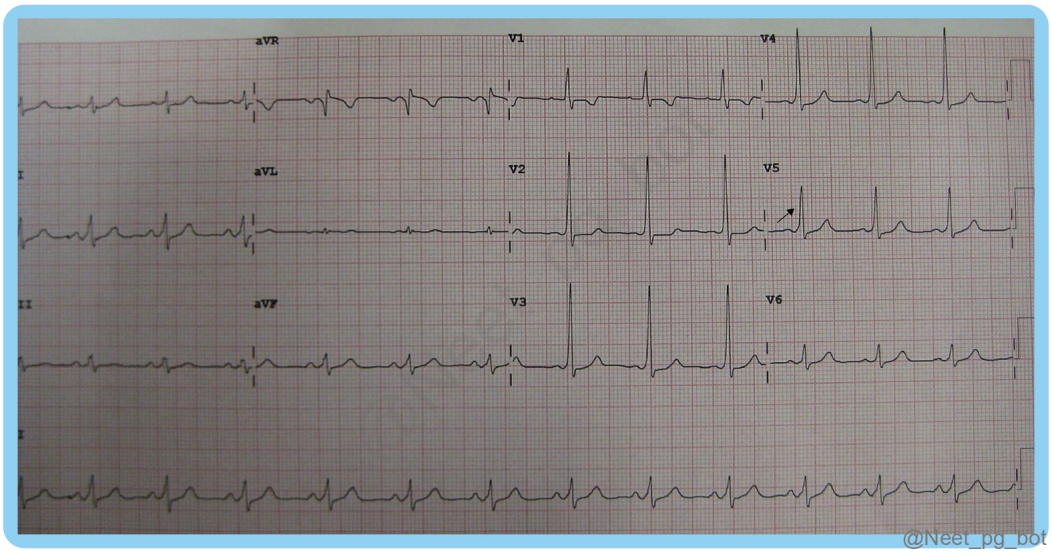
Q17: A 25-year-old man presents to the ER with recurrent episodes of palpitations, dizziness, and occasional chest discomfort. Auscultation shows loud S1 and normal split S2. An ECG of the condition is given below. What is the most likely diagnosis for this patient's condition? (Q850491)

A. Atrial Fibrillation

B. Wolff-Parkinson-White (WPW) Syndrome

C. Myocardial Infarction

D. Brugada syndrome



See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 6-year-old boy is brought my mother as he gets very breathless during physical activities and had hospitalization for recurrent pneumonia episodes. Inspection shows a right parasternal heave, no cyanosis and auscultation reveals a systolic ejection murmur. Which is correct auscultatory finding seen in this case? (Q850488)

A. Narrow split S2

B. Paradoxical split S2

C. Wide split fixed S2

D. Wide split variable S2

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 3-year-old girl presents to the clinic with a history of recurrent respiratory infections and exercise intolerance. On physical examination, a holosystolic murmur is noted at the left lower sternal border. Which of the following is correct about heart sound finding in this case? (Q850487)

A. Wide Fixed split S2

B. Paradoxical split S2

C. Narrow split S2

D. Wide split variable S2

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 45-year-old man presents with progressive dyspnea and occasional dizziness. On auscultation, a harsh crescendo-decrescendo systolic murmur is noted at the left sternal border, which increases with the Valsalva maneuver. There is also evidence of a jerky carotid pulse. Which of the following will be heard on auscultation in this case? (Q850485)

A. Wide split S2

B. Fixed split S2

C. Paradoxical split S2

D. Physiological split S2

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Narrow split S2 heart sound is heard in which of the following conditions? (Q850484)

A. Mitral regurgitation

B. Aortic stenosis

C. Atrial septal defect

D. Pulmonary hypertension

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Match the following Heart sound Condition seen 1) Wide Split S2 a) RBBB 2) Paradoxical Splitting S2 b) Mitral regurgitation 3) Fixed Splitting S2 c) LBBB 4) Narrow Split S2 d) Hypertrophic cardiomyopathy e) ASD (Q850482)

A. 1-b, 2-c, 3-e, 4-d

B. 1-a, 2-e, 3-b, 4-c

C. 1-b, 2-d, 3-b, 4-e

D. 1-c, 2-a, 3-b, 4-e

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 28-year-old woman comes with a history of fever, chest pain, weight loss, and night sweats. During cardiac auscultation, the physician notes a characteristic sound that persists on breath holding. ECG shows global ST segment elevation with concavity upwards. What is this finding called on auscultation known as? (Q850481)

A. Opening snap

B. Pericardial friction rub

C. Pericardial knock

D. Pleural rub

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following features would raise suspicion for a diagnosis of Carney complex? (Q850480)

A. Association with tuberous sclerosis

B. Presence of skin pigmentation abnormalities

C. Restrictive cardiomyopathy

D. A-V nodal block

See Answer in Part B → Q24

@Neet_pg_bot

Q25: During the cardiac cycle, the closing of the aortic valve takes place at ? (Q850478)

A. End of isovolumetric contraction

B. End of rapid filling phase

C. Start of isovolumetric relaxation

D. Start of ejection

See Answer in Part B → Q25

Q31 (p. 57)					

Q1: A 78 year old man, three months after undergoing transcatheter aortic valve replacement presents with high grade fever with chills and rigors. What is the most common causative organism in TAVR-associated infective endocarditis? (Q850454)

A. Streptococcus viridans

B. Enterococcus spp

C. Staphylococcus aureus

D. Candida spp.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is a minor criterion for diagnosing infective endocarditis based on 2023 Duke-ISCVID criteria? (Q850473)

A. Two negative blood cultures

B. Echocardiogram showing valve perforation

C. PCR from a sterile body site identifying a typical pathogen

D. Two positive blood cultures

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is a typical organism causing infective endocarditis based on 2023 Duke-ISCVID criteria? (Q850472)

A. Enterococcus faecalis

B. Streptococcus pneumoniae

C. Pseudomonas aeruginosa

D. Streptococcus pyogenes

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 70 year old man with a prosthetic aortic valve has a fever, positive blood cultures for Enterococcus faecalis, valve vegetations visualized on echocardiography. Cardiac Computed Tomography shows a valve abscess. Which finding is a new major criterion for infective endocarditis in the 2023 Duke-ISCVID criteria? (Q850471)

A. Direct visual evidence of vegetations during surgery

B. Echocardiogram revealing vegetation

C. Positive blood cultures with Enterococcus faecalis

D. Development of a new onset murmur

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 65 year old male patient with a history of rheumatic heart disease presents to the dental clinic for a tooth extraction. He has a prosthetic heart valve placed two

years ago and reports a penicillin allergy. Which of the following prophylactic antibiotic regimens should be administered to this patient before his dental procedure to prevent infective endocarditis? (Q850470)

A. Amoxicillin 2g orally 1 hour before the procedure

B. Ampicillin 2g IV or IM within 1 hour before the procedure

C. Clarithromycin 500 mg orally 1 hour before the procedure

D. Cefazolin 1g IV or IM 30 minutes before the procedure

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 55 year old man with a history of prosthetic valve deployment presents with fever, chills, and fatigue. Blood cultures reveal methicillin-resistant Staphylococcus aureus. The patient has a prosthetic valve and shows evidence of vegetation on echocardiography. What is the appropriate antibiotic regimen for managing this patient's infection? (Q850469)

A. Vancomycin + Gentamicin + Rifampin

B. Vancomycin + Daptomycin

C. Nafcillin + Gentamicin + Rifampin

D. Ampicillin + Gentamicin

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is a minor criterion under the Modified Duke's Criteria for infective endocarditis? (Q850468)

A. Positive echocardiographic findings of vegetation

B. Two positive blood cultures with a typical organism

C. Presence of a prosthetic valve

D. Abscess formation on echocardiogram

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 60 year-old man with a mechanical aortic valve presents with 2 weeks of fever, fatigue, and shortness of breath. He has a history of a dental procedure done 3 weeks back. Blood cultures are negative. FDG-PET/CT shows abnormal uptake around the valve. Which major criterion from the Modified Duke's Criteria does this patient meet? (Q850467)

A. Negative blood culture for a typical organism

B. Evidence of endocardial involvement by FDG-PET/CT

C. Osler nodes and Janeway lesions

D. Recent history of dental procedure

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 30 year old woman who is known case of rheumatic heart disease and mitral regurgitation presents with complaints of fever for past 2 weeks.Echo showed vegetations on both surfaces of mitral valve.Blood cultures grew staphylococcus aureus. Which of the following would be immunological phenomenon seen in these patient? (Q850464)

A. Janeway lesions and Osler's nodes

B. Roth spots and Osler nodes

C. Carditis and Arthritis

D. Splinter hemorrhages in nails and clubbing

See Answer in Part B → Q9

@Neet_pg_bot

Q10: In the context of infective endocarditis, what role do MSCRAMMs play in the disease process? (Q850463)

A. They enhance the immune response against pathogens during bacteremia.

B. They facilitate bacterial adherence to nonbacterial thrombotic endocarditis (NBTE) or injured endothelium.

C. They are responsible for the formation of emboli that lead to tissue infarction.

D. They promote the breakdown of vegetation formed in the heart.

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 65 year old male with ischemic cardiomyopathy and a history of benign prostatic hyperplasia presents with fever, malaise, and a new heart murmur. He recently underwent a urinary catheterisation for urinary retention. Blood cultures are positive for gram-positive cocci. What is the most likely causative organism of his infective endocarditis? (Q850461)

A. Staphylococcus aureus

B. Streptococcus gallolyticus

C. Enterococcus faecalis

D. Haemophilus species

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 68 year old farmer with a prosthetic valve presents with fever, night sweats, and fatigue 6 months post-surgery. Blood cultures are negative. He has goats and cows on his farm . Which organism is most likely responsible for his prosthetic valve

endocarditis? (Q850460)

A. Staphylococcus epidermidis

B. Coxiella burnetii

C. Mycobacterium chimaera

D. Enterococcus faecalis

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 3 year girl with a history of patent ductus arteriosus presents with high grade fever. Her recent echocardiogram shows vegetations along the inner lining of her aorta. Which of the following conditions is the most likely diagnosis for this patient based on her symptoms and history? (Q850459)

A. Acute bacterial endocarditis

B. Subacute bacterial endocarditis

C. Infective endarteritis

D. Fungal endocarditis

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 72 year female with a history of mitral valve prolapse presents with a fever and fatigue for last > 2 weeks. Physical examination reveals a new heart murmur and petechiae on her extremities. Blood cultures are sent. What is the leading organism associated with this patient's probable condition? (Q850458)

A. Staphylococcus aureus

B. Streptococcus viridans

C. Enterococcus faecalis

D. HACEK organisms

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following lists the valves in order of frequency of involvement in infective endocarditis, from most to least commonly affected? (Q850456)

A. Mitral valve > Aortic valve > Tricuspid valve > Pulmonic valve

B. Aortic valve > Mitral valve > Pulmonic valve > Tricuspid valve

C. Tricuspid valve > Mitral valve > Aortic valve > Pulmonic valve

D. Pulmonic valve > Aortic valve > Tricuspid valve > Mitral valve

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following statements is false regarding right-sided infective endocarditis (IE)? (Q850455)

A. Right-sided infective endocarditis is more commonly associated with enterococci than left-sided infective endocarditis.

B. Staphylococcus aureus is the most common pathogen in right-sided infective endocarditis

C. Injecting particles are more likely to reach the right-sided valves compared to the left-sided valves

D. Right-sided infective endocarditis has a better long-term prognosis compared to left-sided infective endocarditis

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 72 year old woman presents with severe chest pain and shortness of breath after the death of her husband. She has no history of heart disease. ECG shows STE of 2 mm in lead I , aVL, V2-V4. Bedside echocardiogram shows left ventricular

ballooning and cardiac biomarkers are elevated. What is the most likely diagnosis? (Q850403)

A. Anterior wall MI

B. Takotsubo Cardiomyopathy

C. Inferior wall MI

D. Pulmonary Embolism

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following is the most common echocardiographic finding associated with rheumatic carditis in children? (Q850453)

A. Aortic regurgitation

B. Mitral regurgitation

C. Aortic stenosis

D. Mitral stenosis

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 12 year old girl presents with involuntary, jerky movements in her hands and feet, worsening with stress or purposeful tasks and does not interferes with eating. Her mother tells that for 3 months she had developed arthritis that caused her to limp for a week with swelling of knee and ankle joints. Work up shows increased PR interval, What is the most appropriate initial treatment? (Q850451)

A. Penicillin prophylaxis

B. Haloperidol

C. Intravenous immunoglobulin (IVIG)

D. Carbamazepine

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 25 year woman presents with a history of exertional dyspnea, palpitations, and episodes of syncope. She recalls experiencing multiple episodes of sore throat as a child, followed by joint pains, for which she received no definitive treatment. On auscultation, there is a diastolic murmur at the apex and a loud S1. An echocardiogram reveals mitral valve orifice < 1.5 cm 2 with left atrial enlargement. What is the next most appropriate step in management? (Q850450)

A. Mitral balloon valvotomy

B. Mitral valve repair

C. ACE Inhibitors and rate control drugs

D. Immediate mitral valve replacement

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 35-year-old woman presents with progressive exertional dyspnea, fatigue, and occasional palpitations. O/E, she has an irregular pulse, a loud S1, an opening snap, and a low-pitched diastolic rumble at the apex. She recalls a childhood illness with fever and joint pain requiring hospitalization. Which of the following investigations is NOT primarily used in diagnosing her condition? (Q850449)

A. Echocardiography

B. Electrocardiogram

C. Blood cultures

D. Chest X-ray

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following is not a part of the major criteria for a low-risk population? (Q850445)

A. Carditis

B. Polyarthritis

C. Chorea

D. Polyarthralgia

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following is correct about St Vitus's dance? (Q850443)

A. It is an early manifestation of rheumatic fever

B. It occurs in all patients with rheumatic fever

C. It is associated with emotional lability

D. It is a minor diagnostic criteria

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 5 year old boy presents with fever and migratory joint pain. On auscultation, a soft mid-diastolic murmur is heard at the apex. Echocardiography reveals mitral valve inflammation. Which of the following is most likely present in this patient? (Q850442)

A. Mitral stenosis murmur

B. Austin Flint murmur

C. Carey Coombs murmur

D. Graham Steele Murmur

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following clinical features is most commonly associated with Acute Rheumatic fever in the Indian population? (Q850437)

A. Polyarthritis

B. Erythema Marginatum

C. Subcutaneous Nodules

D. Pulmonary Hypertension

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 10 y/o boy presents with fever, joint pain, and a recent history of sore throat. Examination reveals a heart murmur suggestive of mitral regurgitation. Laboratory tests show elevated antistreptolysin O titers. Which of the following best explains the pathogenesis of his condition? (Q850435)

A. Direct invasion of heart valves by Streptococcus bacteria

B. Immune response triggered by molecular mimicry between bacterial antigens and heart tissue

C. Autoimmune destruction of heart valves due to viral infection

D. Genetic mutations in heart muscle proteins

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 11 year boy with a history of acute rheumatic fever without carditis presents for follow-up. Based on the AHA guidelines, what is the recommended duration for continuing secondary prophylaxis in this patient? (Q850432)

A. Continue prophylaxis for 1 more year

B. Continue prophylaxis until the age of 25

C. Continue prophylaxis on lifelong basis

D. Continue prophylaxis until the age of 21

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which of the following is not an indication for ICD implantation? (Q850430)

A. Chagas disease

B. Wolff-Parkinson-White syndrome

C. Hypertrophic cardiomyopathy

D. Long QT syndrome

See Answer in Part B → Q28

@Neet_pg_bot

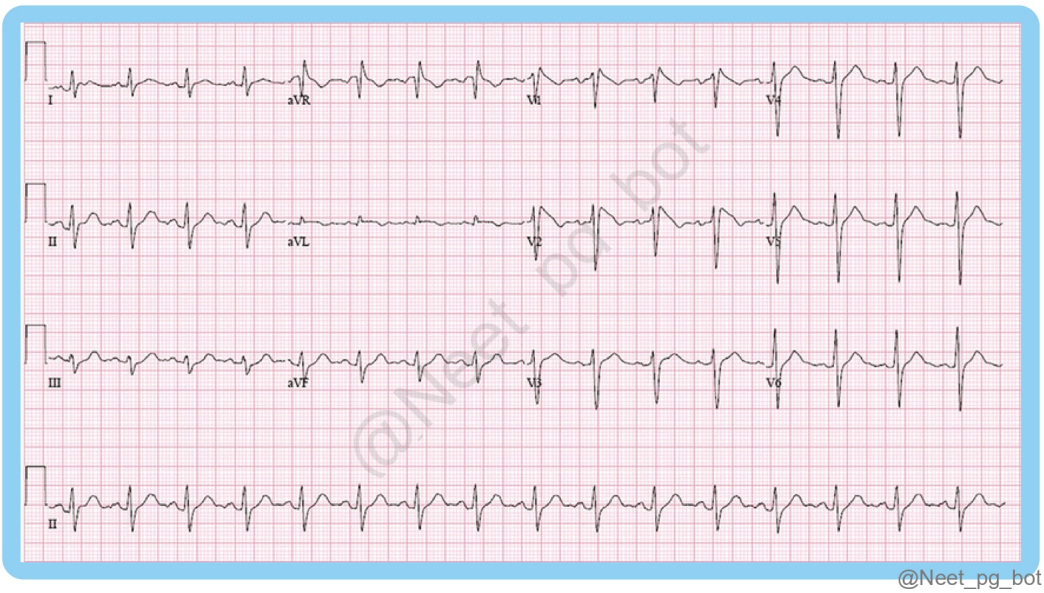
Q29: A 13 year old male is brought to ER by his father who noticed agonal breathing at 5 am in morning. He is the only child in family. Urgent ECG is done. What finding is noted? (Q850423)

A. Delta waves

B. Deep Q waves

C. Coved ST elevation

D. Epsilon waves



See Answer in Part B → Q29

@Neet_pg_bot

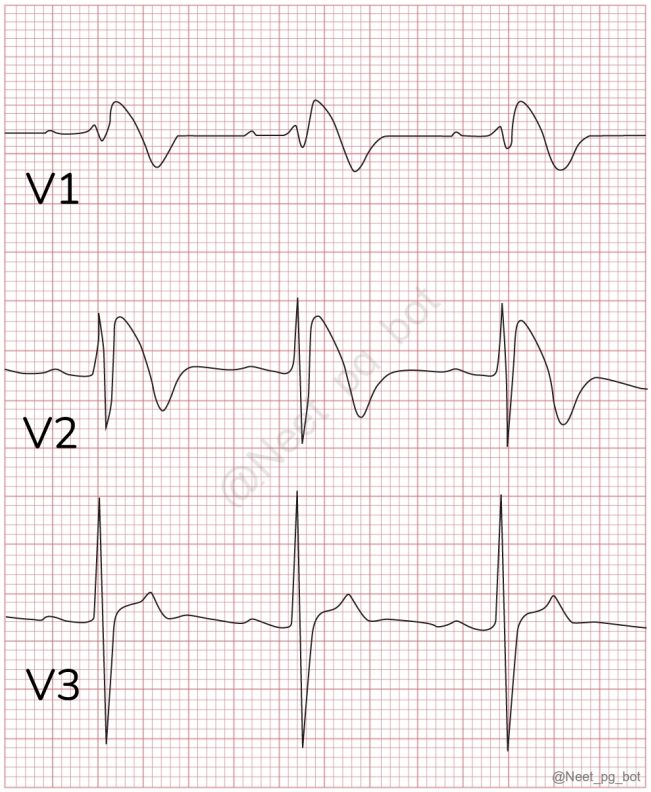
Q30: A 15-year-old male presents to the ED after experiencing a brief episode of syncope. He reports occasional palpitations and dizziness. His family history is significant for sudden cardiac death at a young age. An ECG of leads V1-V3 is given below. Which of the following management options is most appropriate for this patient, given the findings? (Q850411)

A. Prescribe a beta-blocker and advise lifestyle modifications

B. Perform Troponin I levels

C. It is also called Broken heart syndrome

D. Deploy implantable cardioverter-defibrillator.



See Answer in Part B → Q30

@Neet_pg_bot

Q31: A 68 year old postmenopausal woman presents to the emergency department with chest pain and dyspnea after a recent stressful event. Her ECG shows ST-segment elevation and cardiac biomarkers are elevated. What is the most appropriate next step in management of this patient? (Q850407)

A. Administer intravenous anticoagulation therapy

B. Implant an implantable cardioverter-defibrillator.

C. Initiate inotropic support immediately.

D. Perform coronary angiography

See Answer in Part B → Q31

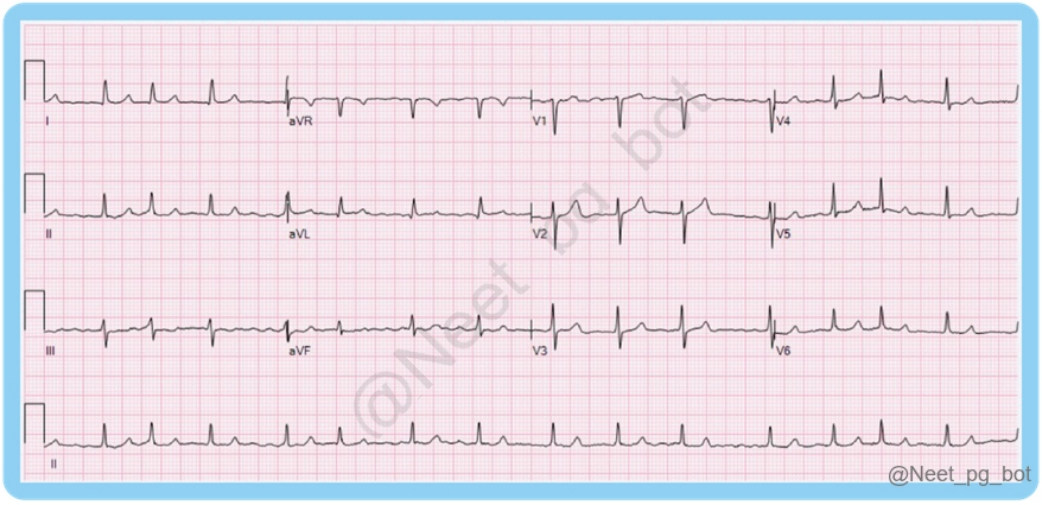
Q1: A 68-year-old smoker man with a history of hypertension presents to the ER with complaints of palpitations and shortness of breath for the past 2 hours. On examination, his pulse is irregularly irregular with a rate of 140 beats per minute. An ECG of the patient is given below. He has poorly controlled COPD. Which of the following statements about his condition is incorrect? (Q850694)

A. Multiple ectopic foci due to structural damage to heart

B. Start beta blockers followed by warfarin

C. CHADS2VASc score is used to decide the need for anticoagulation

D. Amiodarone is used for chemical cardioversion



See Answer in Part B → Q1

Q2: A 68-year-old male patient with a history of hypertension presents to the emergency department in acute distress. He is diaphoretic, tachycardic, and complains of severe chest pain. BP is 90/60 mm Hg. His ECG is given below. Given the patient's condition, what is the most appropriate immediate management for this patient? (Q850728)

A. Amiodarone

B. Radiofrequency catheter ablation

C. Digoxin

D. Synchronized cardioversion

See Answer in Part B → Q2

@Neet_pg_bot

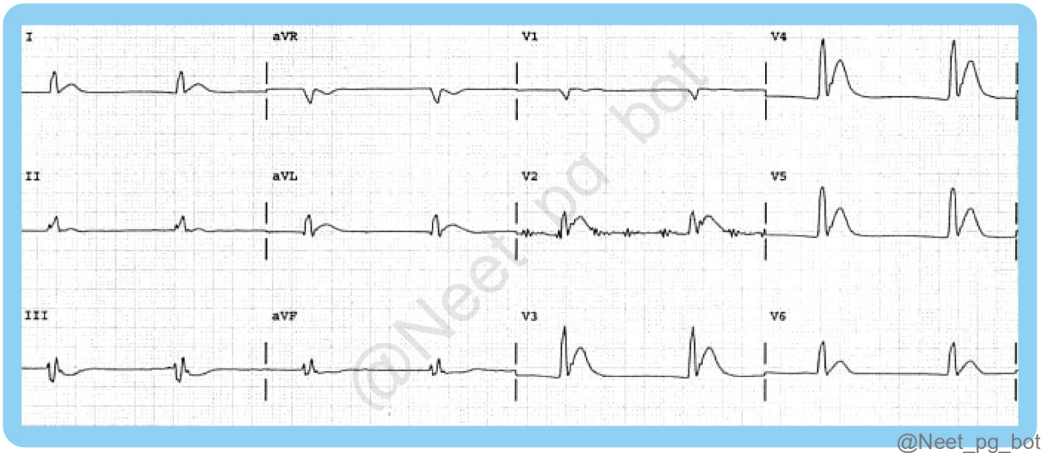
Q3: A 42-year-old woman diagnosed with stage IV breast cancer presents to the emergency department with confusion and breathing difficulty. BP on admission is 80/60 mm Hg. The ECG is attached below. Which of the following would be the most likely diagnosis in this patient? (Q850726)

A. Malignant pericardial effusion

B. Cardiac tamponade

C. Acute pericarditis

D. Constrictive pericarditis



See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old man is brought to the emergency department with confusion and muscle weakness. His laboratory results show a serum potassium level of 7.2 mEq/L.Which of the following T-wave morphologies is most likely to be seen on this patient's ECG? (Q850722)

See Answer in Part B → Q4

@Neet_pg_bot

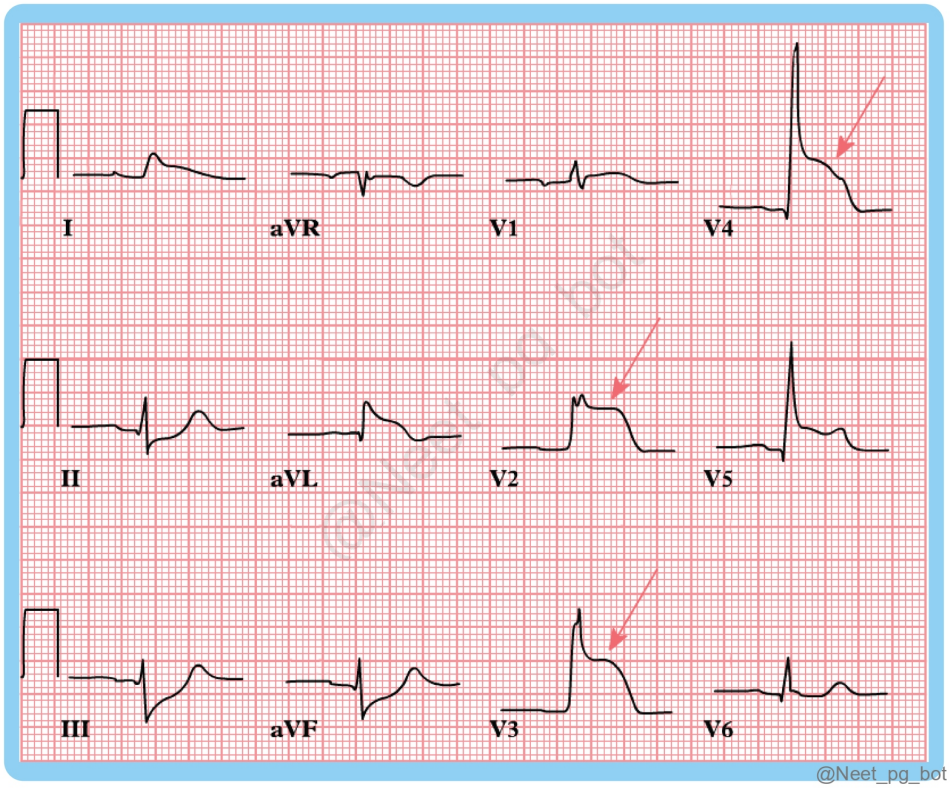
Q5: A 55-year-old alcoholic presents to the emergency department with sweating and palpitations. He is a known case of T2DM on metformin and Glipizide. Labs show plasma glucose 65 mg/dl, serum creatinine 2.0 mg/dl, BUN 70 mg/dl and serum potassium of 5.8 meq/dl. ECG is shown below. What is the next best step in the management of this patient? (Q850714)

A. Call nephrology for urgent hemodialysis

B. Stop metformin

C. Give IV dextrose with thiamine

D. Send to cath lab



See Answer in Part B → Q5

@Neet_pg_bot

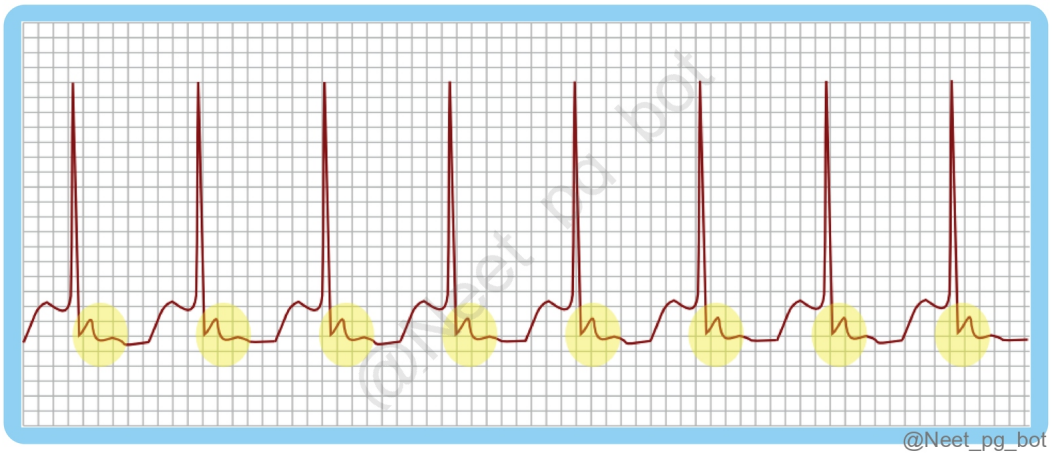
Q6: A 62-year-old man presents to the emergency department with palpitations and lightheadedness. His ECG shows a rapid, regular rhythm with a rate of 150 beats per minute, as shown below Which of the following conditions is most likely to be associated with this ECG finding? (Q850708)

A. Ventricular tachycardia

B. AV nodal re-entrant tachycardia

C. Wolf-Parkinson-White syndrome

D. Hypothermia



See Answer in Part B → Q6

@Neet_pg_bot

Q7: Match the following tachyarrhythmias with their respective pharmacological interventions Tachyarrhythmia Treatment 1. Atrial Fibrillation in Hypertension A. Adenosine 2. Stable Monomorphic Ventricular Tachycardia B. Esmolol followed by Anticoagulation 3. Torsades de Pointes C. Magnesium Sulfate 4. AV nodal re-entrant tachycardia D. Amiodarone (Q850706)

A. 1-B, 2-D, 3-C, 4-A

B. 1-B, 2-A, 3-D, 4-C

C. 1-D, 2-B, 3-A, 4-C

D. 1-A, 2-C, 3-B, 4-D

See Answer in Part B → Q7

@Neet_pg_bot

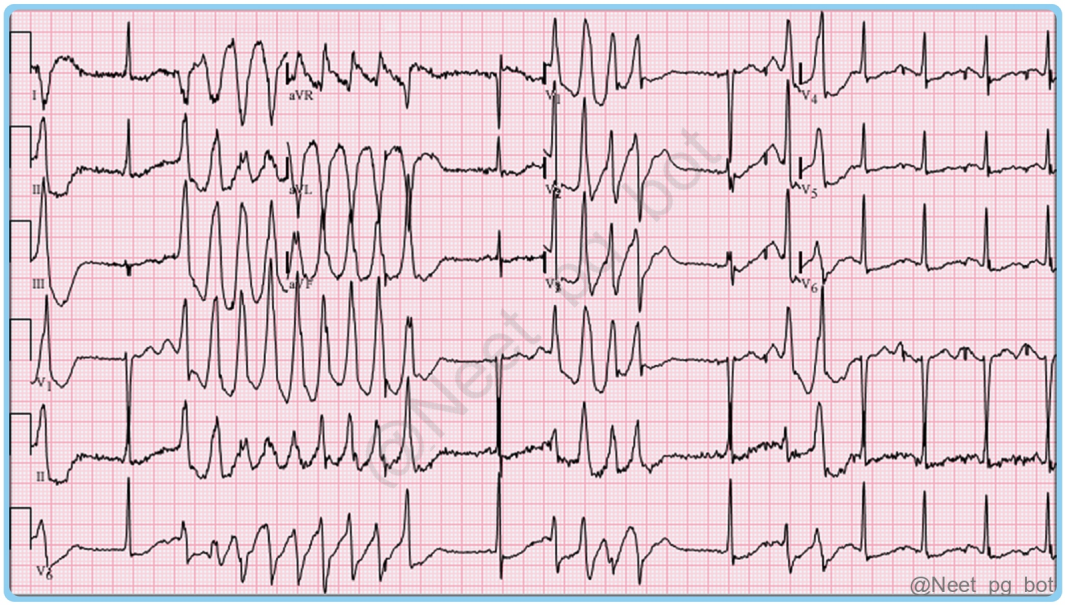
Q8: A 62-year-old woman presents to the ER with palpitations and lightheadedness. She is on azithromycin and cough syrup by her GP. BP on admission is 100/60 mm Hg. Her ECG is given below: Which of the following is the most appropriate immediate management for this patient? (Q850703)

A. Administer intravenous amiodarone

B. Perform immediate electrical cardioversion

C. Administer intravenous magnesium sulfate

D. Start oral beta-blocker therapy



See Answer in Part B → Q8

@Neet_pg_bot

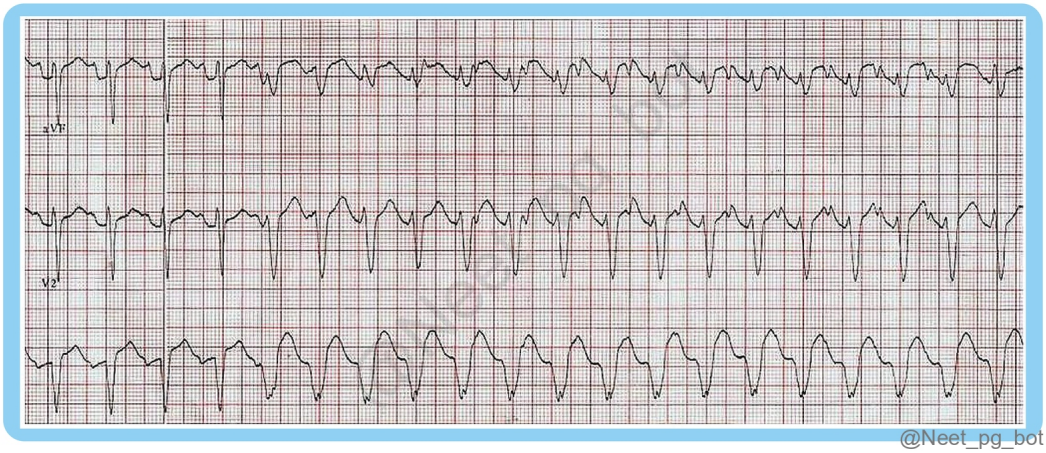
Q9: A 65-year-old male with a history of prior myocardial infarction presents to the emergency department with severe palpitations, dizziness, and chest pain. He suddenly becomes pulseless and BP is unrecordable. An ECG shows wide QRS complexes, a regular rhythm, and a ventricular rate of 160 bpm. What is the most appropriate initial treatment for this patient? (Q850701)

A. Intravenous Adenosine

B. Intravenous Magnesium Sulfate

C. Defibrillation

D. Intravenous Procainamide



See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is correct about Wolff-Parkinson-White syndrome? Accessory pathway between the atria and ventricles that lacks the decremental property Prolonged PR interval, delta waves, and narrow QRS complexes. Short PJ interval The drug of choice for an acute episode of palpitations is procainamide (Q850699)

A. 1 and 4 only

B. 2 and 3 only

C. 4 only

D. 1, 2, 3, and 4

See Answer in Part B → Q10

@Neet_pg_bot

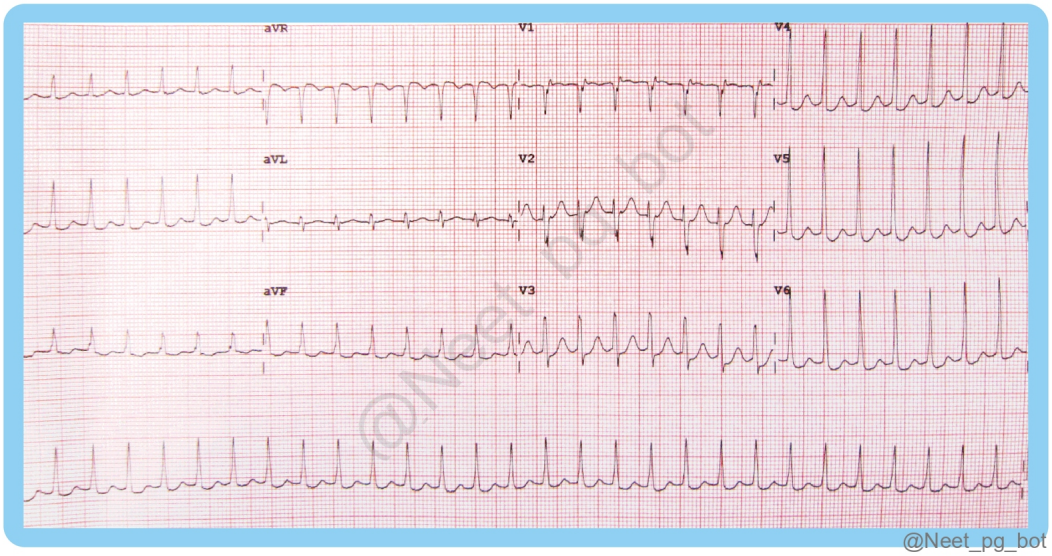
Q11: A 25-year-old female presents with sudden onset palpitations. ECG is shown below. You successfully terminated the arrhythmia using the Valsalva maneuver. Which of the following best describes the primary mechanism by which this maneuver terminates the arrhythmia? (Q850697)

A. Vagus induced decreased firing of the sinoatrial node

B. Vagus induced an increased sympathetic tone to the heart

C. Transient block in AV node conduction

D. Mechanical disruption of accessory pathways



See Answer in Part B → Q11

@Neet_pg_bot

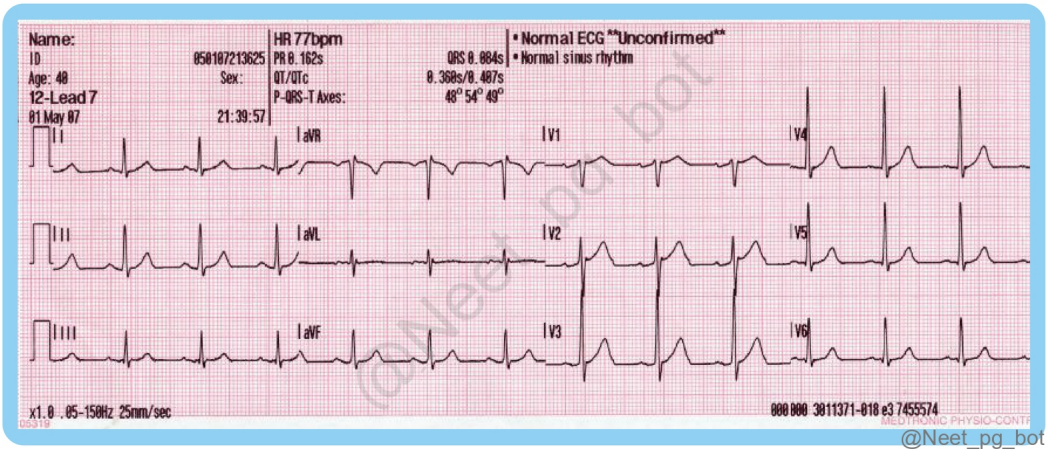
Q12: A 50-year-old man comes to your clinic for a annual medical check-up. He has Hypertension and takes Ramipril and Amlodipine. Office BP recording is 124/ 80 mm Hg. What is the ECG findings shown below? What is the most likely finding based on this ECG? (Q850534)

A. Left ventricular hypertrophy

B. Normal sinus rhythm

C. Second-degree AV block

D. Right bundle branch block



See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 70-year-old patient is diagnosed with stokes adam syndrome. Which is correct about management of this patient? (Q850692)

A. Dual chamber pacemaker

B. Triple chamber pacemaker

C. Transcutaneous pacemaker

D. Transvenous pacemaker

See Answer in Part B → Q13

@Neet_pg_bot

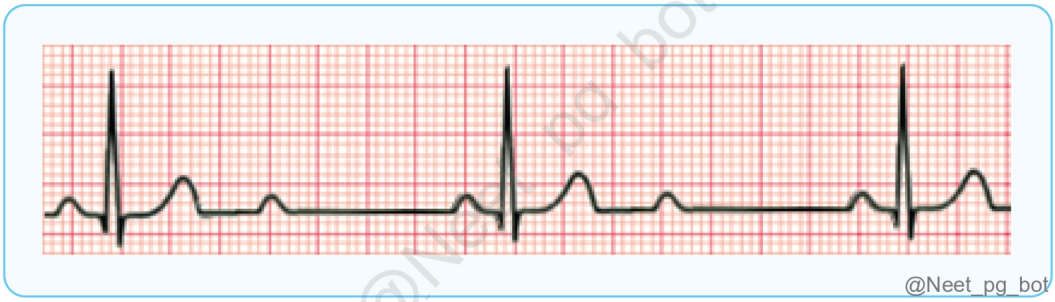
Q14: A 74-year-old patient comes to the emergency department with complaints of intermittent dizziness and lightheadedness. An electrocardiogram (ECG) is performed, as shown below. Based on the ECG findings and the clinical scenario, what type of atrioventricular block is most likely present in this patient? (Q850687)

A. Mobitz Type I - Wenckebach

B. Infranodal conduction defect

C. First-degree AV block

D. Third-degree AV block



See Answer in Part B → Q14

@Neet_pg_bot

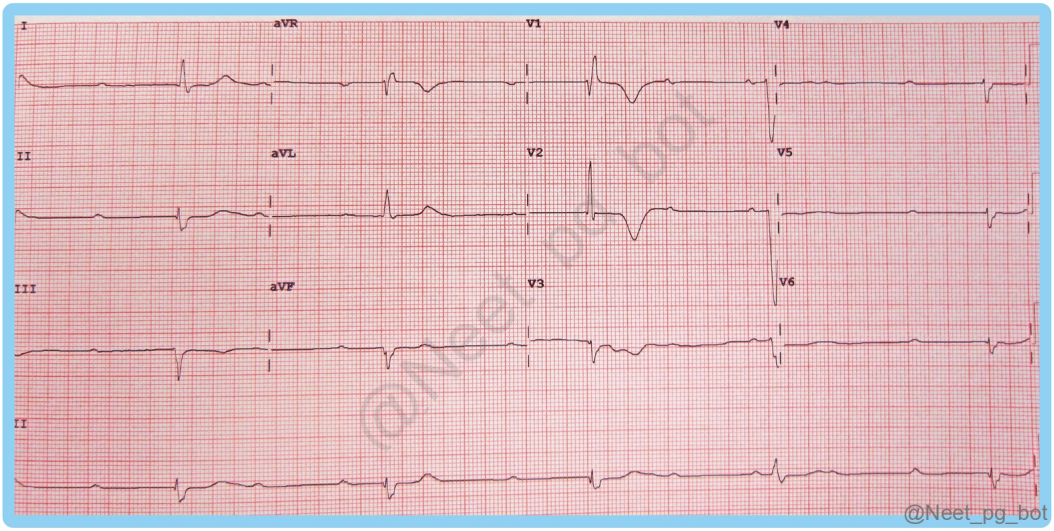
Q15: A 72-year-old man is brought to the ER due to sudden onset syncope in the bathroom. His medical history includes hypertension and a prior myocardial infarction. ECG of the patient is given below. What is the most appropriate initial management for this patient? (Q850685)

A. Oral beta-blockers

B. Temporary pacing

C. Permanent pacemaker placement

D. IV atropine 0.4 mg



See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 68-year-old male patient presents to the ER with complaints of fatigue and occasional lightheadedness. He has a history of hypertension and coronary artery disease. During the examination, he describes episodes of near-syncope. The physician performs an ECG to evaluate his symptoms. What is the most likely diagnosis based on the ECG findings? (Q850668)

A. First-degree heart block

B. Mobitz Type I

C. Mobitz Type II

D. Complete heart block

See Answer in Part B → Q16

@Neet_pg_bot

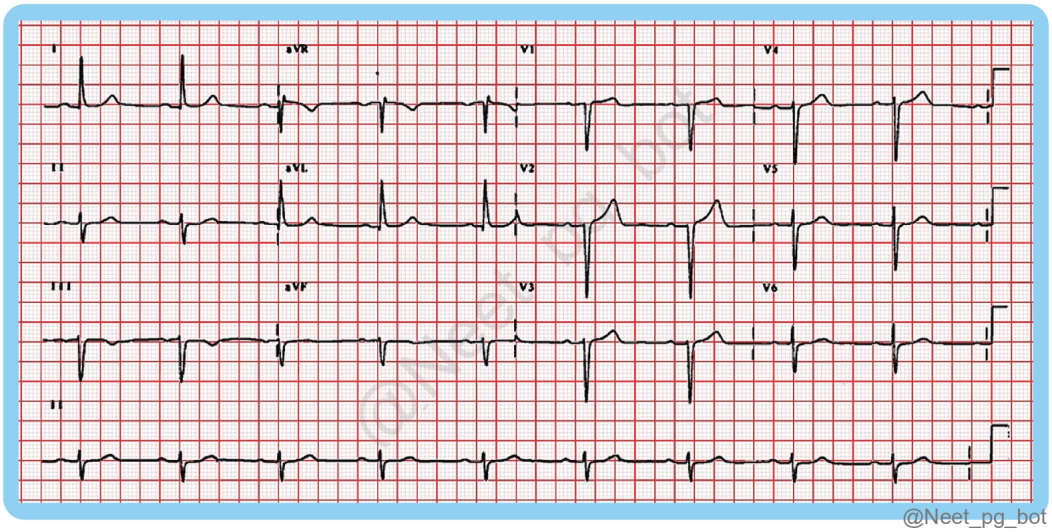
Q17: A 58-year-old woman comes to the clinic for an annual medical check up. She has a history of mild hypertension, which is well-controlled with medication. She reports no symptoms such as palpitations, dizziness, or chest pain. An ECG of the patient is given below. What is the most likely diagnosis based on the ECG findings? (Q850631)

A. Second-Degree AV Block

B. First-Degree AV Block

C. Third-Degree AV Block

D. Bundle Branch Block



See Answer in Part B → Q17

@Neet_pg_bot

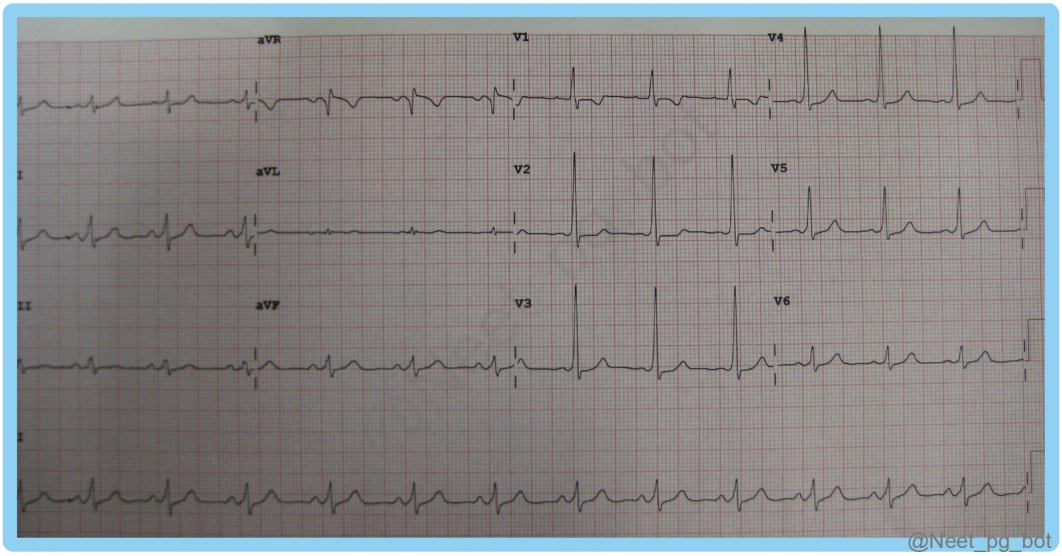
Q18: A 25-year-old male presents with recurrent palpitations and dizziness. An ECG of the patient is given below. Which of the following statements is true regarding this patient's diagnosis? (Q850625)

A. He is at risk for pre-excited atrial fibrillation leading to dangerously fast ventricular rates

B. The accessory pathway is the Bundle of James, facilitating rapid conduction.

C. ECG shows prolonged PR interval with delta waves

D. Adenosine is drug of choice for this condition



See Answer in Part B → Q18

@Neet_pg_bot

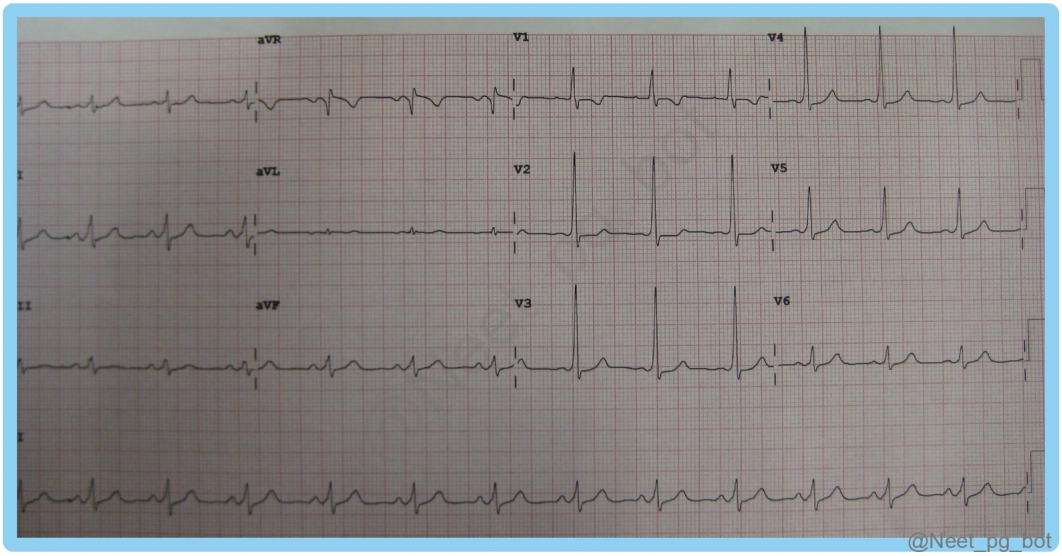
Q19: A 28-year-old male presents to the emergency department with palpitations and lightheadedness. He has no significant past medical history and is otherwise healthy. After a thorough examination, an ECG is obtained. Based on the patient's presentation and the findings of the ECG, what is the most likely diagnosis? (Q850619)

A. Atrial Fibrillation

B. Wolff-Parkinson-White (WPW) Syndrome

C. First-degree AV Block

D. Second degree heart block



See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 2-year-old child is referred to your hospital for a suspected congenital heart condition due to central cyanosis. On examination, there is a prominent jugular venous pulsation and a pansystolic murmur at the left lower sternal border. ECG shows Himalayan P waves. Which condition will you suspect? (Q850611)

A. Ebstein’s Anomaly

B. Atrial septal defect

C. Ventricular septal defect

D. Tetralogy of Fallot

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 60-year-old woman with a history of hypertension and diabetes presents with a one-month history of mild exertional dyspnea. She denies chest pain but has noticed some occasional palpitations. Physical examination reveals a blood pressure of 140/90 mmHg and regular heart sounds. You order an ECG, which is shown below. What is

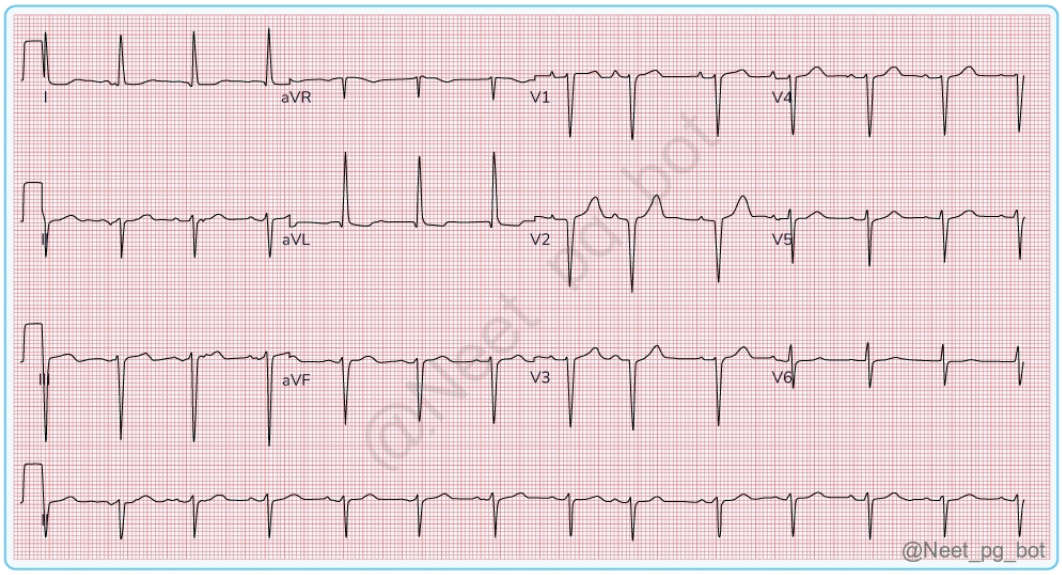
the most likely diagnosis based on this ECG? (Q850602)

A. Normal axis

B. Right axis deviation

C. Left axis deviation

D. Extreme axis deviation



See Answer in Part B → Q21

@Neet_pg_bot

Q1: A 35-year-old woman comes at 8 am to the ER with chest pain that started last evening and has progressively worsened. She describes the pain as a burning sensation accompanied by a sour taste in her mouth, which began shortly after dinner. She has had similar experiences previously. This morning she passed a black stool. ECG and Echocardiography shows normal results. What is next investigation to be performed in this patient? (Q850457)

A. 24 hour pH monitoring

B. Endoscopy

C. hs-CTn

D. Coronary CT angiography

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 70-year-old male presents with an acute onset of severe dyspnea and shock 5 days after receiving fibrinolysis for STEMI. On examination, an early systolic murmur is heard at the apex. Echocardiography reveals valvular dysfunction. What is the most likely cause of his condition? (Q850499)

A. Ventricular septal rupture

B. Papillary muscle rupture

C. Ventricular aneurysm

D. Ventricular rupture

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 65-year-old male patient presents 6 weeks after experiencing an ST-elevation myocardial infarction . He reports malaise, fever, and chest discomfort that worsens with deep breathing. On examination, a pericardial friction rub is heard. Laboratory tests reveal leukocytosis and an elevated ESR. What is the most appropriate initial treatment for this condition? (Q850496)

A. Glucocorticosteroids

B. Aspirin

C. Colchicine

D. Rescue PCI

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 60-year-old female with a history of hypertension and hyperlipidemia presents with severe chest pain for 3 hours. She has a blood pressure of 180/110 mmHg and a history of active peptic ulcer disease. Her ECG shows ST-elevation in leads V2-V4. What is the most appropriate treatment option for this patient? (Q850493)

A. Streptokinase

B. Tissue plasminogen activator

C. Coronary artery bypass surgery

D. Percutaneous coronary intervention

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 60-year-old male with a history of hypertension and hyperlipidemia presents with chest pain lasting 45 minutes. His ECG shows STE in lead I, avL, V5, V6. Which of the following statements about his management is correct? (Q850490)

A. Beta blockers should be avoided in all patients with STEMI.

B. First line drug for the management of STEMI is Streptokinase

C. LMWH provides more reliable anticoagulation than UFH.

D. Leading cause of death after 24 hours of hospitalization is cardiac rupture

See Answer in Part B → Q5

@Neet_pg_bot

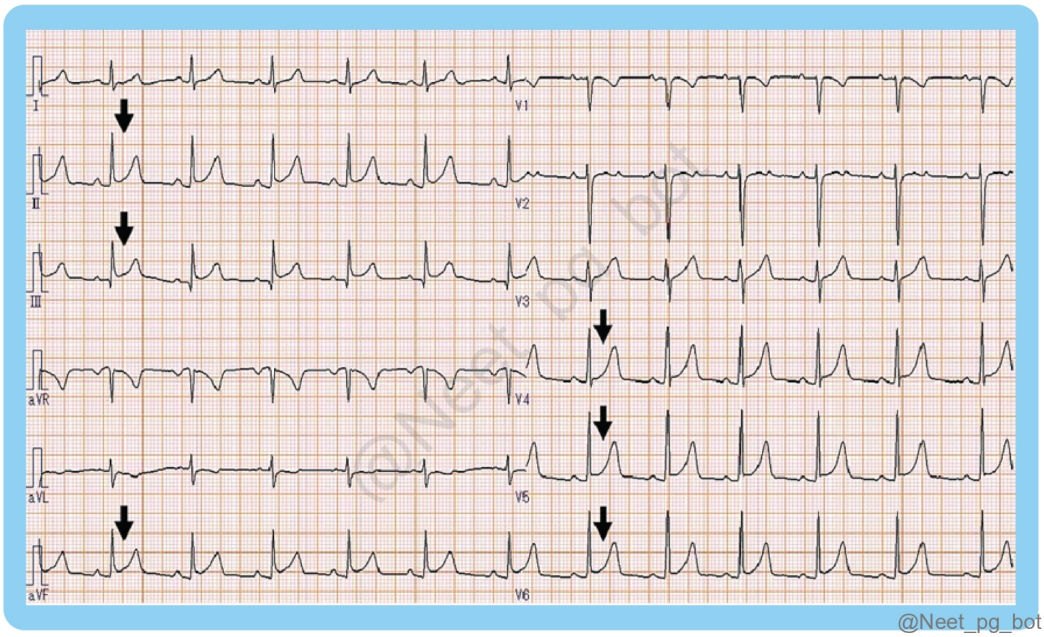
Q6: A 65-year-old male presents with central chest pain for the last 3 hours radiating to the left shoulder. On admission, blood pressure is 150/100 mmHg, and his oxygen saturation is 95% on room air. Which of the following drugs should be avoided in this patient? (Q850486)

A. Administer morphine IV for pain relief

B. Administer nifedipine to relieve chest pain

C. Administer clopidogrel loading dose for platelet inhibition

D. Administer sublingual nitroglycerin (0.4 mg) to reduce myocardial oxygen demand



See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following would provide the least accurate diagnosis of Myocardial infarction? (Q850483)

A. Echocardiography

B. Coronary angiography

C. High sensitivity Troponin I

D. Radionuclide ventriculography

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 58-year-old male smoker was managed with primary PCI for STEMI 4 days ago. On the day of planned discharge he again develops central chest pain. Which of the following should be done in this patient to identify a reinfarction? (Q850479)

A. Troponin T

B. Creatine Kinase-MB

C. Lactate Dehydrogenase

D. Heart fatty acid-binding Protein

See Answer in Part B → Q8

@Neet_pg_bot

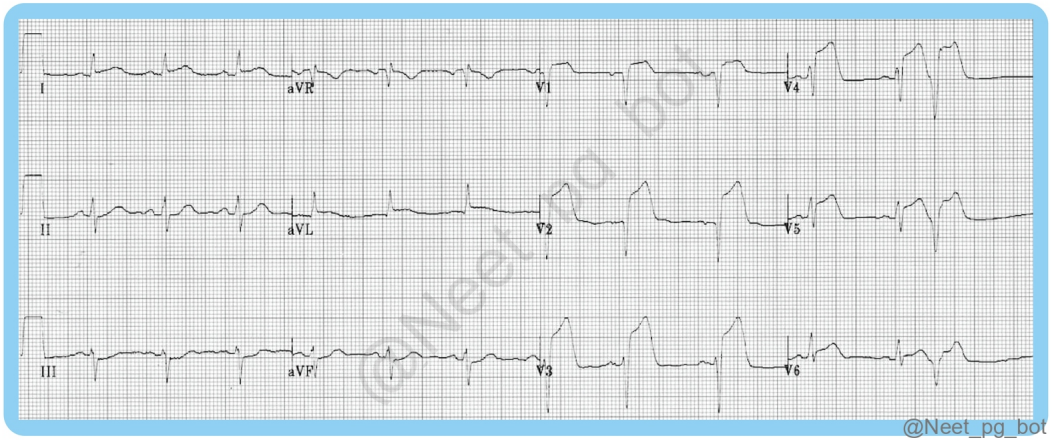
Q9: A 58-year-old male presents with chest pain, and an ECG reveals the following changes Based on these findings, which coronary artery is most likely affected? (Q850477)

A. Left Circumflex Artery

B. Right Coronary Artery

C. Anterior Interventricular Artery

D. Posterior Descending Artery



See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 65-year-old male patient with a history of coronary artery disease undergoes angiography, which reveals a thrombus in the right coronary artery (RCA). Based on this finding, which area of the heart is most likely to be affected by an infarct?

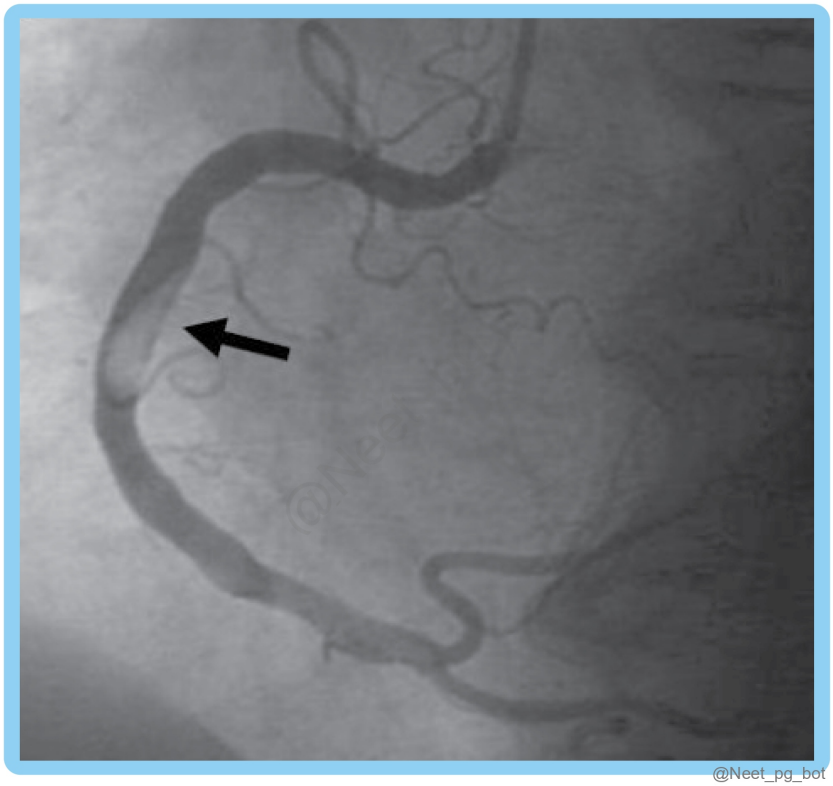
(Q850475)

A. Anterior wall

B. Lateral wall

C. Inferior wall

D. Septal wall



See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is correct placement for Lead II on the ECG? (Q850474)

A. Left arm (+) to Left arm (–)

B. Right arm (+) to Left arm (–)

C. Left arm (–) to Left leg (+)

D. Right arm (–) to Left leg (+)

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 56-year-old smoker male presented to the emergency department with chest pain radiating to interscapular area. On examination unequal radial artery pulse is palpated with BP of 180/110 mm Hg. Clinical diagnosis is: (Q850466)

A. Aortic dissection

B. Preductal coarctation of aorta

C. Aortic transection

D. Postductal coarctation of aorta

See Answer in Part B → Q12

@Neet_pg_bot

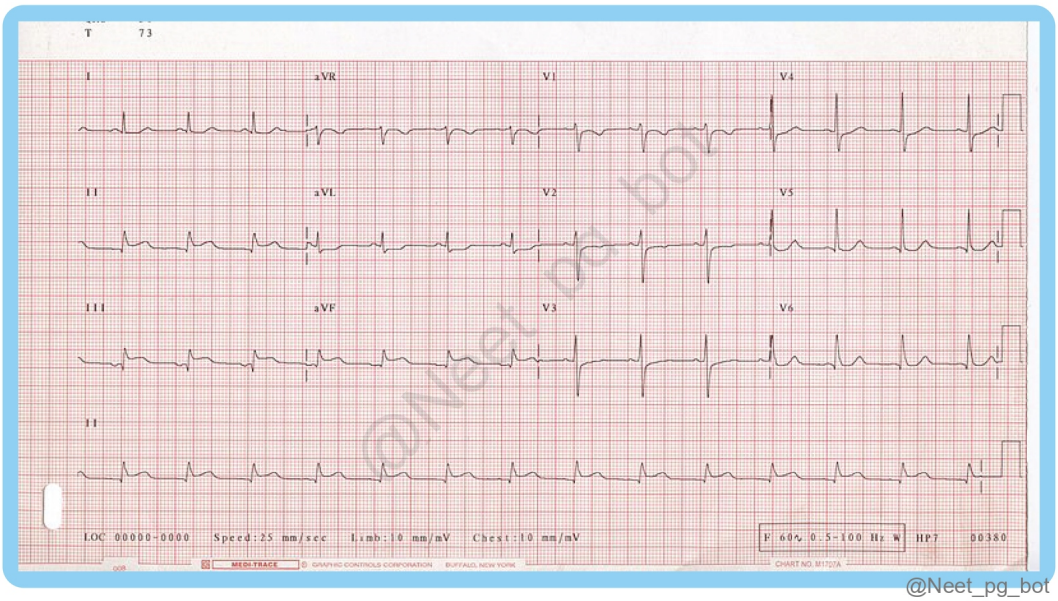
Q13: A 60-year-old male presents with a sudden onset of severe chest pain that radiates to his left arm. This pain started about 60 minutes ago while he was having his breakfast. His medical history includes hypertension and hyperlipidemia. An ECG has been performed and cardiac biomarkers are significantly elevated. What is the most likely cause of his presentation? (Q850465)

A. Coronary artery spasm

B. Coronary artery embolism

C. Spontaneous coronary artery dissection

D. Plaque rupture



@Neet_pg_bot

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 72-year-old man underwent PCI with drug-eluting stents for double vessel disease yesterday. Today he develops chest pain with ECG showing ST-segment depression and cTn levels rising to five times the 99th percentile of the upper limit. What type of MI is seen in this case? (Q850462)

A. Type 1

B. Type 2

C. Type 3

D. Type 4

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following is correct about predisposition to atherosclerosis in these vessels? (Q850396)

A. Popliteal arteries > Coronary arteries > Circle of Willis > Abdominal aorta

B. Coronary arteries > Abdominal aorta > Circle of Willis > Popliteal arteries

C. Abdominal aorta > Coronary arteries > Popliteal arteries > Circle of Willis

D. Coronary arteries > Circle of Willis > Abdominal aorta > Popliteal arteries

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 58-year-old man presents with chest pain at rest for the past 4 hours. He has a history of hypertension and hyperlipidemia. ECG shows ST-segment depression in lead II, III, aVF and his cardiac troponin levels are elevated. What is the most appropriate next step in managing this patient's condition? (Q850452)

A. Immediate coronary artery bypass grafting

B. Thrombolysis

C. High-intensity Atorvastatin and ACEI

D. Aspirin and Ticagrelor

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 59-year-old woman with T2DM presents to ER with chest discomfort at rest radiationg to jaw and nausea for past 2 hours. ECG shows T wave inversion and ST depression in lead II, III, aVF. Trop I value is greater than 99th centile of upper reference limit. Which of the following is the most likely diagnosis? (Q850448)

A. Stable angina

B. Unstable angina

C. Non-ST elevation MI

D. ST elevation MI

See Answer in Part B → Q17

@Neet_pg_bot

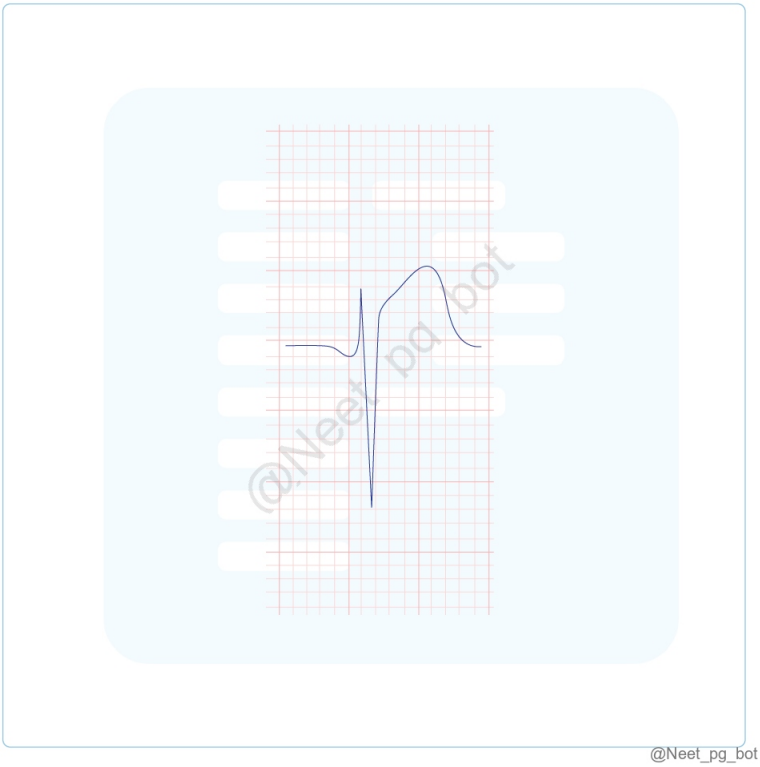
Q18: Check out this ECG finding and select the condition(s) that can present with this change? Hyperkalemia Variant Angina Digoxin (Therapeutic doses) Left Ventricular Hypertrophy (LVH) Chronic Stable Angina (Q850441)

A. 1 and 3

B. 1 and 2

C. 2, 3, and 5

D. 1, 2 and 5



See Answer in Part B → Q18

@Neet_pg_bot

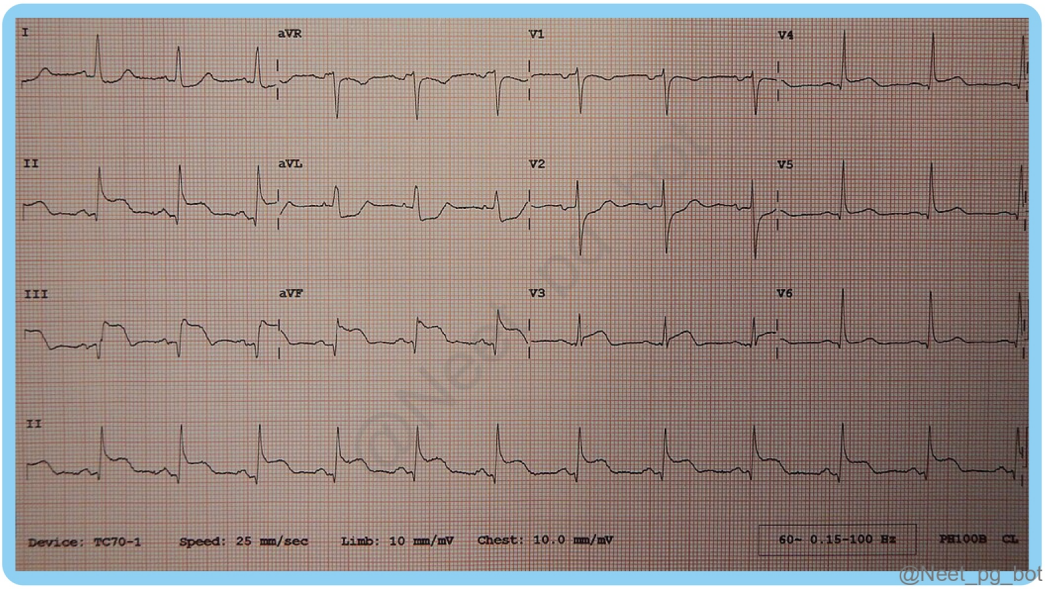
Q19: A 65-year-old woman presents to the ER with early morning episode of chest pain lasting 15 minutes which is relieved by sublingual nitroglycerin. She has had similiar episodes in past and her husband says that metoprolol was started which worsend her chest pain episodes so they stopped the medication. Past medical history is significant for Raynaud phenomenon. ECG is given below. There is no elevation of cardiac markers on serial evaluation. Which of the following is the most likely diagnosis? (Q850434)

A. Stable angina

B. Unstable angina

C. Prinzmetal angina

D. Myocardial infarction



See Answer in Part B → Q19

@Neet_pg_bot

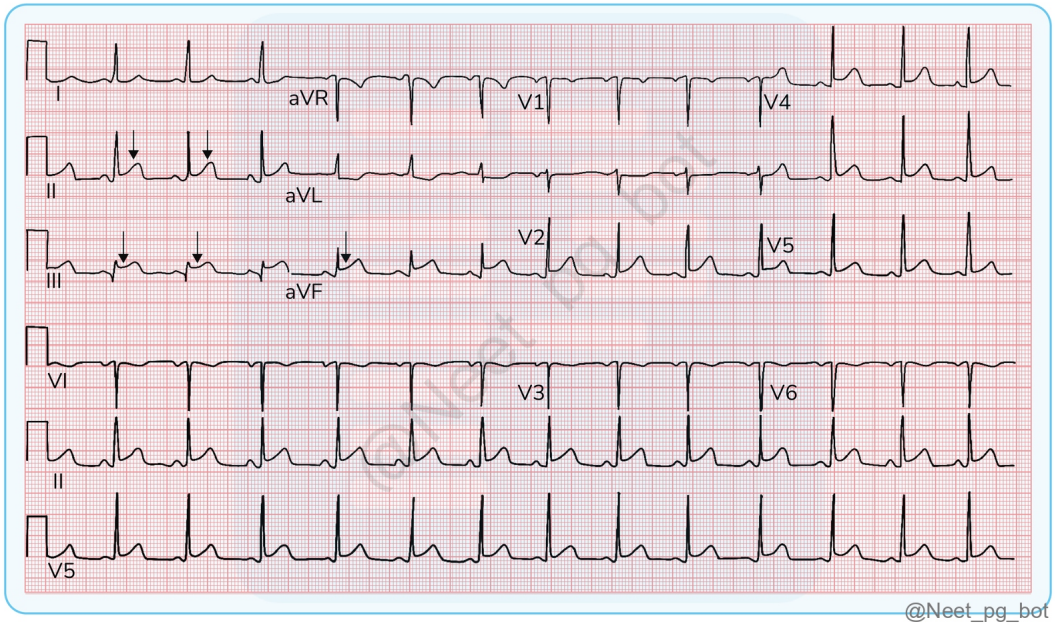
Q20: A 62-year-old male presents to ER central chest pain at rest and shortness of breath for last one hour. His medical history includes hypertension and hyperlipidemia. Troponin I is elevated. Which of the following is the most appropriate initial management for this patient's condition? (Q850428)

A. Send for PCI

B. Chewable Aspirin and Atorvastatin

C. Enoxaparin and Eptifibatide

D. IV atropine followed by temporary pacing



See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 65-year-old woman is known case of chronic stable angina and has undergone PCI with stenting last year. Today morning, she presents to the ER with a 60-minute episode of chest discomfort that occurred while she was watching television. She describes the pain as a tightness in his chest, radiating to her left arm. She has a history of T2DM and has deranged lipid profile. An ECG reveals inverted T-waves. Which of the following is the best next step in the management of this patient? (Q850422)

A. Cardiac biomarkers

B. Send to Cath lab for PCI

C. Treadmill test

D. Myocardial perfusion imaging

See Answer in Part B → Q21

@Neet_pg_bot

Q22: What is the revascularization procedure of choice for two different cases, Patient A with triple vessel disease and Patient B with left anterior descending artery blockage with EF < 40%? (Q850420)

A. A: CABG; B: PCI with stenting

B. CABG for both A and B

C. A: PCI with stenting; B: CABG

D. A: PCI with Bare metal stenting ; B: PCI with drug eluting stenting

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 65-year-old male with chronic stable angina presents with chest pain during routine activities. His current medications include aspirin, metoprolol, isosorbide mononitrate and atorvastatin, but his symptoms persist. Coronary angiography reveals 90% stenosis of the right coronary artery. and 70% in LCX. What is the most appropriate intervention? (Q850416)

A. Increase the dose of beta-blockers

B. Increase the dose of Long acting nitrates

C. PCI with drug-eluting stenting

D. Refer for coronary artery bypass grafting

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 60-year-old man with a history of CAD presents with recurrent syncope. Considering his intermediate to high risk for CAD, which imaging modality would be most appropriate for further evaluation? (Q850414)

A. Myocardial Perfusion Imaging

B. Stress Echocardiography

C. Multigated Acquisition (MUGA) Scanning

D. Treadmill test

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 60-year-old male smoker presents with chest pain on climbing stairs. He is started on low-dose aspirin, statins and metoprolol by his GP. His symptoms have worsened despite medical therapy. What is the next best step in diagnosing the extent of his coronary artery disease? (Q850409)

A. Stress echocardiography

B. Myocardial perfusion imaging

C. Coronary angiography

D. Coronary computed tomography angiography

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 60-year-old male undergoes a treadmill ECG stress test and develops 2 mm of horizontal ST-segment depression after 12 minutes of exercise. He reports non-limiting chest pain (angina index = 1). What is his Duke Treadmill Score (DTS) and his risk category? (Q850405)

A. DTS = 0; Intermediate risk

B. DTS = 5; Low risk

C. DTS = -2; Intermediate risk

D. DTS = -8; High risk

See Answer in Part B → Q26

@Neet_pg_bot

Q27: An elderly male with a history of cigarette smoking and hypertension develops chest pain after an evening walk. The pain is relieved after lying down for a few minutes. A treadmill stress test reveals ST-segment depression. What is the most likely cause attributed to this clinical presentation? (Q850402)

A. Hypertrophic Cardiomyopathy

B. Prinzmetal Angina

C. Non-ST-Elevation Myocardial Infarction (NSTEMI)

D. Chronic Stable Angina

See Answer in Part B → Q27

@Neet_pg_bot

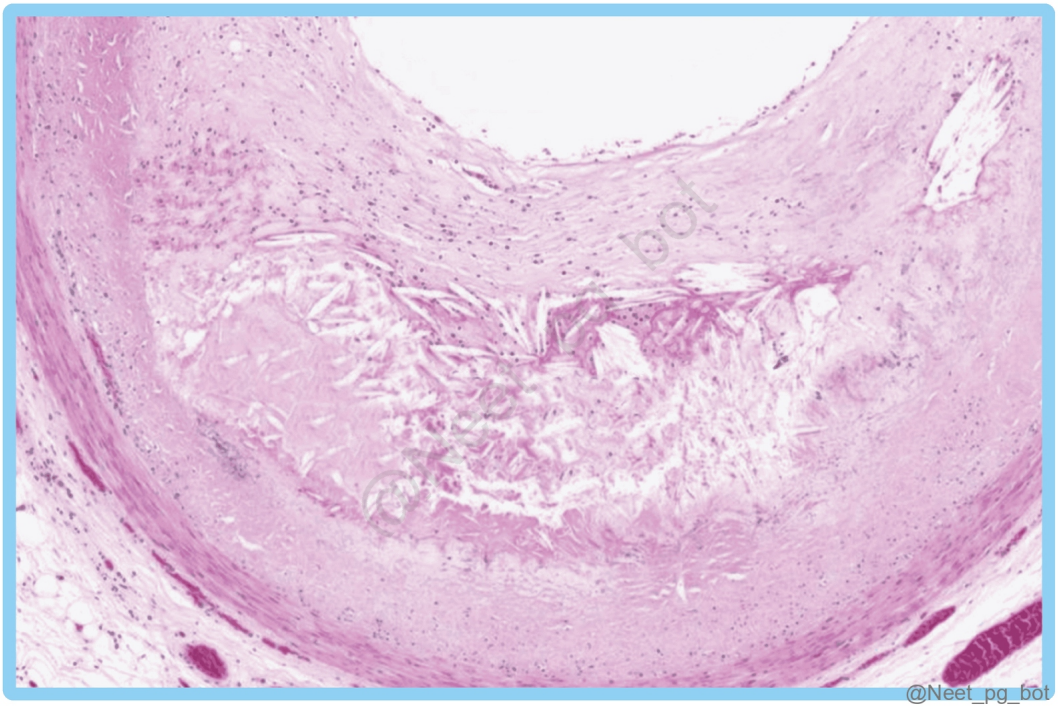
Q28: Arrange the following structures of an atherosclerotic plaque inside a blood vessel from the innermost to the outermost layer: Fibrous cap Necrotic core Foam cell layer Media (Q850399)

A. Fibrous cap → Foam cell layer→ Necrotic core → Media

B. Necrotic core → Media → Foam cell layer → Fibrous cap

C. Foam cell layer → Fibrous cap → Media→ Necrotic core

D. Foam cell layer → Necrotic core → Fibrous cap → Media



See Answer in Part B → Q28

@Neet_pg_bot

Q1 (p. 89) *Q2 (p. 89)* *Q3 (p. 90)* *Q4 (p. 90)* *Q5 (p. 90)* *Q6 (p. 91)*
Q7 (p. 91) *Q8 (p. 92)* *Q9 (p. 92)* *Q10 (p. 93)*

Q1: A 55-year-old male presented to the clinic for a routine check-up last week. Automated Office Blood Pressure (AoBP) readings of 142/94, 138/86, and 138/90 mmHg. Ambulatory blood pressure monitoring (ABPM) was advised and the average 24-hour blood pressure is 138/86 mmHg. According to the ACC/AHA hypertension classification, what category does his blood pressure fall into? (Q850501)

A. Normal blood pressure

B. Elevated blood pressure

C. Stage 1 hypertension

D. Stage 2 hypertension

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 60-year-old male with a BMI of 30 presents with frequent headaches and dizziness. His office blood pressure is recorded as 126/74 mmHg, but home readings range between 150/94 mmHg and 156/90 mmHg. Ambulatory blood pressure monitoring confirms these findings with higher readings outside the office. Which of the following is the most appropriate management plan for this patient? (Q850503)

A. Lifestyle modifications alone is sufficient

B. Initiate antihypertensive therapy

C. Increase clinic visit frequency to monitor blood pressure

D. Diagnosis to be reconfirmed in 3 to 6 months

See Answer in Part B → Q2

@Neet_pg_bot

Q3: During a lecture on cardiovascular physiology, a professor explained that conditions causing unequal arm blood pressure often involve branches of the aortic arch. Which of the following conditions is not likely to cause a difference in blood pressure between the arms? (Q850504)

A. Aortic dissection involving the ascending aorta

B. Coarctation of the aorta distal to the left subclavian artery

C. Takayasu arteritis affecting the aortic arch

D. Subclavian artery stenosis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 28-year-old male with a history of resistant hypertension and periodic muscle cramps is being investigated. Lab tests show hypokalemia, low plasma renin activity, and low aldosterone levels. Genetic testing reveals a mutation in the epithelial sodium channel (ENaC). What is the most likely diagnosis? (Q850505)

A. Gordan syndrome

B. Liddle syndrome

C. Congenital adrenal hyperplasia (CAH)

D. Pheochromocytoma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 65-year-old man with a long-standing history of hypertension presents with occasional episodes of dizziness and transient visual disturbances. Neurological examination and fundoscopy are normal. A carotid doppler is performed to visualize the carotid arteries. Which of the following findings is not expected to be seen in this patient? (Q850507)

A. Increased peak systolic velocity

B. Normal intima-media thickness

C. String sign

D. Turbulent blood flow in the carotid arteries

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 70-year-old male with a history of hypertension and not on medications has chronic kidney disease . His laboratory tests indicate an estimated glomerular filtration rate of 60 mL/min and elevated protein in his urine. His present blood pressure is 142/90 mmHg. Considering his condition, which of the following antihypertensive medications is most appropriate to initiate? (Q850508)

A. Amlodipine

B. Lisinopril

C. Hydrochlorothiazide

D. Metoprolol

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is most appropriate step cabout management of poorly controlled asthmatic on daily Formoterol and medium dose inhaled steroids and is still having nocturnal attacks daily? (Q850509)

A. Start Oral corticosteroids

B. Add LAMA

C. Start high dose inhaled corticosteroids

D. Start IV steroids

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old male presents with severe headache, nausea, and confusion. His blood pressure is recorded at 190/130 mmHg. Neurological examination reveals altered mental status, and the patient appears distressed. A fundoscopic exam shows retinal haemorrhages. What is the most appropriate classification of this patient's condition? (Q850510)

A. Hypertensive urgency

B. Hypertensive emergency

C. Malignant hypertension

D. Essential hypertension

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 65-year-old man with a history of type 2 diabetes and hypertension presents to his primary care physician for a follow-up appointment. His blood pressure is 160/95 mmHg. The physician wants to start an antihypertensive medication. What is the target blood pressure for this patient? (Q850512)

A. < 140/90 mmHg

B. < 135/85 mmHg

C. < 130/80 mmHg

D. < 150/90 mmHg

See Answer in Part B → Q9

@Neet_pg_bot

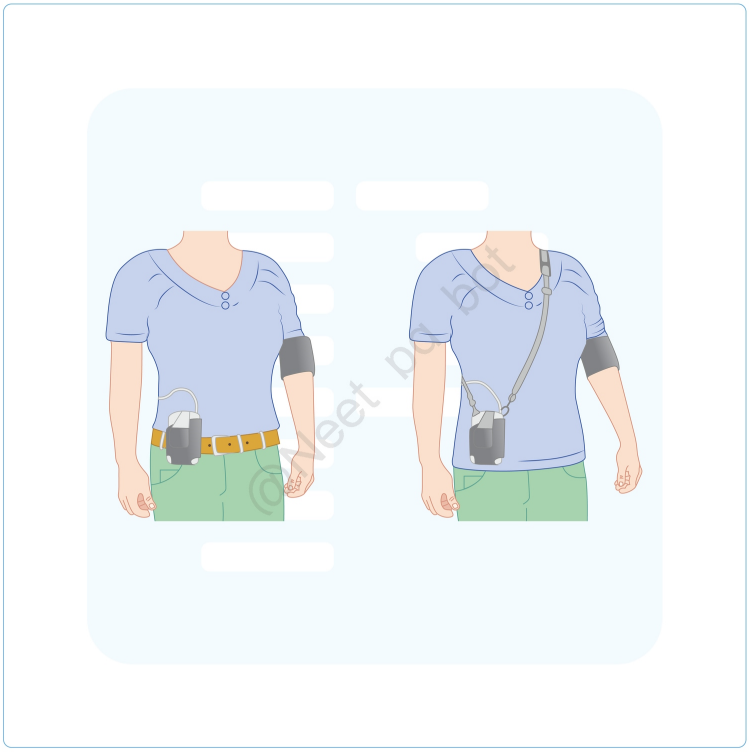
Q10: Which of the following is incorrect regarding the image given? (Q850513)

A. Can help identify the white-coat effect in patients

B. Continuous readings for a full 24-hour period

C. Measures both awake and sleep averages

D. Used to investigate hypertension only



@Neet_pg_bot

Q1: Which of the following statements is false about first-degree atrioventricular block? (Q850536)

A. Minor Jones criteria in Rheumatic fever

B. Serial prolongation of PR interval

C. Can be physiological

D. Consistent PR interval with no missed beats

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 65-year-old man treated with PCI for STEMI develops syncope and is found to have a 2:1 AV block with broad QRS on his ECG. Which of the following is the most likely mechanism behind his AV block, and how would atropine administration affect his condition? (Q850573)

A. The block is most likely in the AV node, and atropine will improve AV conduction.

B. The block is most likely in the His-Purkinje system, and atropine will improve AV conduction.

C. The block is most likely in the AV node, and atropine may increase the degree of AV block.

D. The block is most likely in the His-Purkinje system, and atropine may increase the degree of AV block.

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which among the following are included in the criteria for Metabolic syndrome 1) Waist circumference > 102 cm in men 2) Waist circumference > 88 cm in women 3) HDL > 50 mg/dL in men 4) BP 115/80 mm Hg 5) Fasting plasma glucose > 100 mg/dL 6) LDL > 200 mg/dL (Q850570)

A. 1, 2, 3, 4, 5

B. 1, 4, 5, 6

C. 1, 2, 5

D. 2, 4, 5, 6

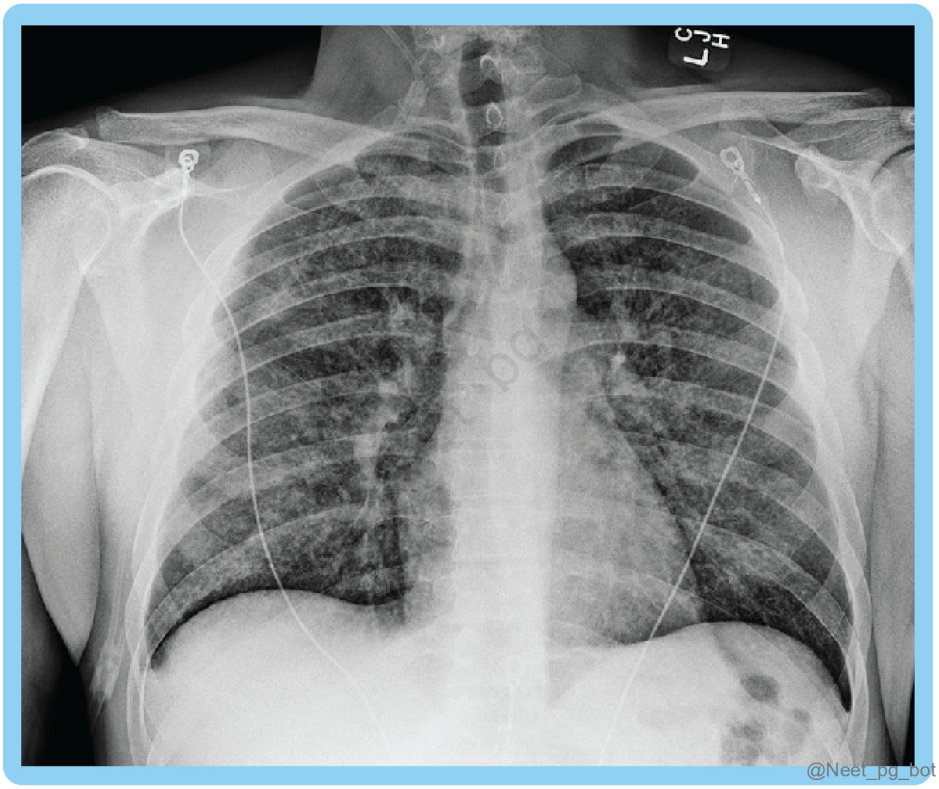
Q5: A patient presents with sudden onset breathlessness. On arrival his vitals were, PR- 130 bpm, BP- 180/110 mmHg and spO 2 - 82% in room air. X-ray done is as shown below.What is the most appropriate next step in managing this patient? (Q850562)

A. Furosemide and Esmolol

B. Furosemide and NTG

C. Furosemide and Diltizaem

D. Furosemide and Digoxin



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 75-year-old man is a known case of triple vessel disease, presented with fatigue. Echocardiography done showed global reduction in contractility and reduced ejection fraction. What is the most likely electrolyte disturbance seen in this patient? (Q850555)

A. Hyponatremia and Hypokalemia

B. Hypernatremia and Hyperkalemia

C. Hyponatremia and Hyperkalemia

D. Hypernatremia and Hypokalemia

See Answer in Part B → Q6

@Neet_pg_bot

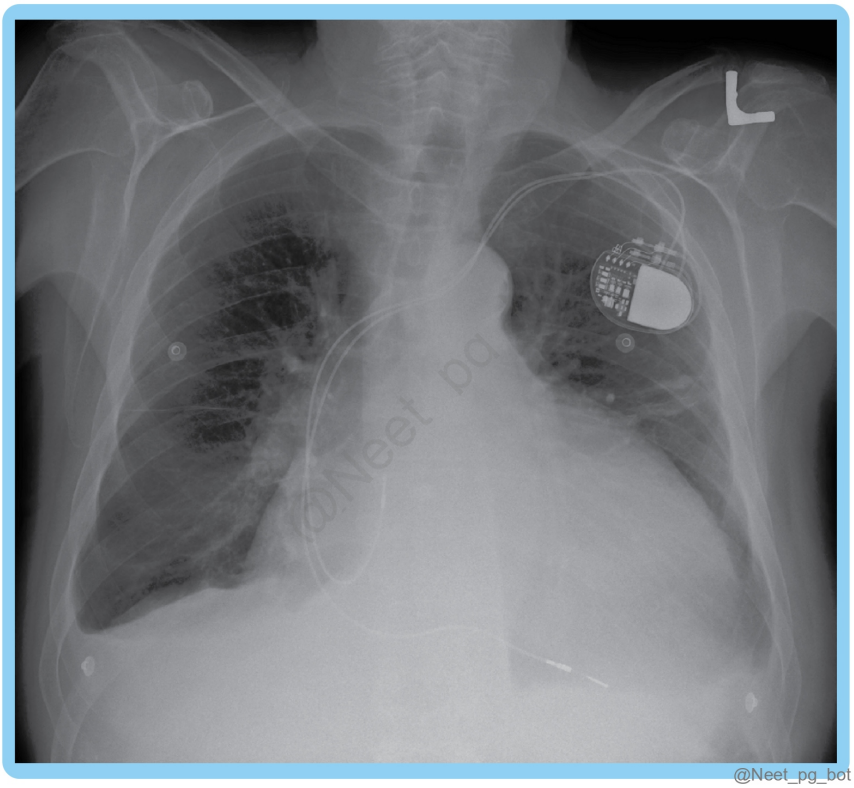
Q7: A 50-year-old male comes with complaints of shortness of breath that worsens upon lying down for the past 1 week. On examination, pulse-130 bpm, BP-150/90 mmHg, neck veins are distended, S3+ on cardiac auscultation. He had developed MI last year and was treated. CXR is shown below. Which among the following is not part of the major Framingham's criteria? (Q850549)

A. Dyspnoea worse upon lying down

B. Neck vein distention

C. HR-130 bpm

D. S3



See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 68-year-old male is presented with sudden loss of consciousness and collapses. ECG on arrival at ER is shown below and significant perioral pallor was noted while tracing was being done. What is the diagnosis? (Q850544)

A. Third-degree atrioventricular block

B. Mobitz II heart block

C. Mobitz I block

D. First degree heart block

See Answer in Part B → Q8

@Neet_pg_bot

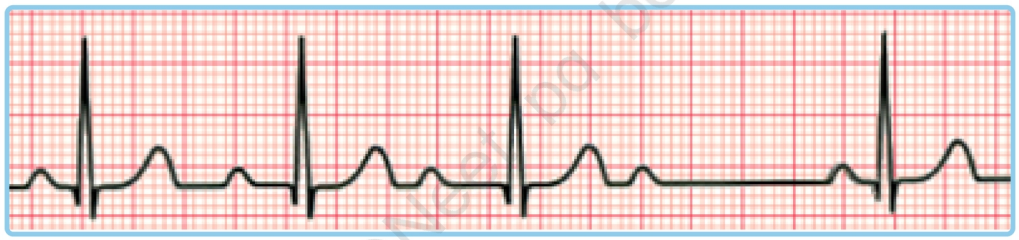
Q9: Identify the type of heart block from the ECG given below. (Q850539)

A. First-degree AV block

B. 2nd degree heart block, intra nodal conduction delay

C. 2nd degree heart block, Infra nodal conduction delay

D. Third-degree atrioventricular block



See Answer in Part B → Q9

@Neet_pg_bot

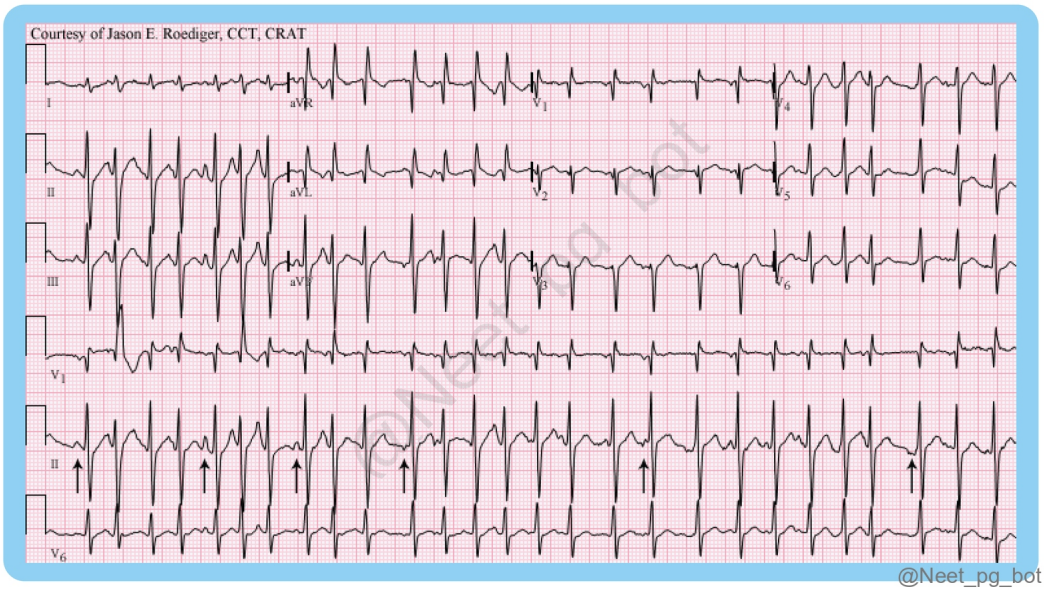
Q10: A 68-year-old smoker presents with breathing trouble and sudden onset palpitations. The ECG is given below and has an irregular rhythm with an average heart rate of 150 beats per minute. What is the most likely diagnosis based on the ECG findings? (Q850516)

A. Atrial Fibrillation

B. Multifocal Atrial Tachycardia

C. Atrial Flutter

D. Sinus Tachycardia



See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following statements on transvenous pacing is wrong? (Q850532)

A. Central venous access is needed

B. Intracardiac lead placement is done

C. Permanent method of pacing

D. Required in inferior wall MI

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 72-year-old male presents with an inferior wall STEMI. He starts developing altered mental status and heart rate is 38 bpm, blood pressure 80/50 mmHg. Which of the following will be used to manage his bradycadia? (Q850530)

A. IV atropine 1 mg every 3-5 minutes

B. IV atropine 2 mg every 3-5 minutes

C. IV atropine 0.5 mg every 3-5 minutes

D. IV atropine 0.6 mg every 3-5 minutes

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 38-year-old man with a history of fatigue and daily headaches is found to have a blood pressure 150/100 mmHg on multiple occasions. His chest X-ray shows cardiomegaly and echocardiography shows reduced mitral inflow with concentric hypertrophy of heart. Which of the following is correct about this patient? (Q850529)

A. Systolic malfunction of left ventricle

B. Mitral stenosis

C. Diastolic dysfunction of Left ventricle

D. Mitral regurgitation

See Answer in Part B → Q13

@Neet_pg_bot

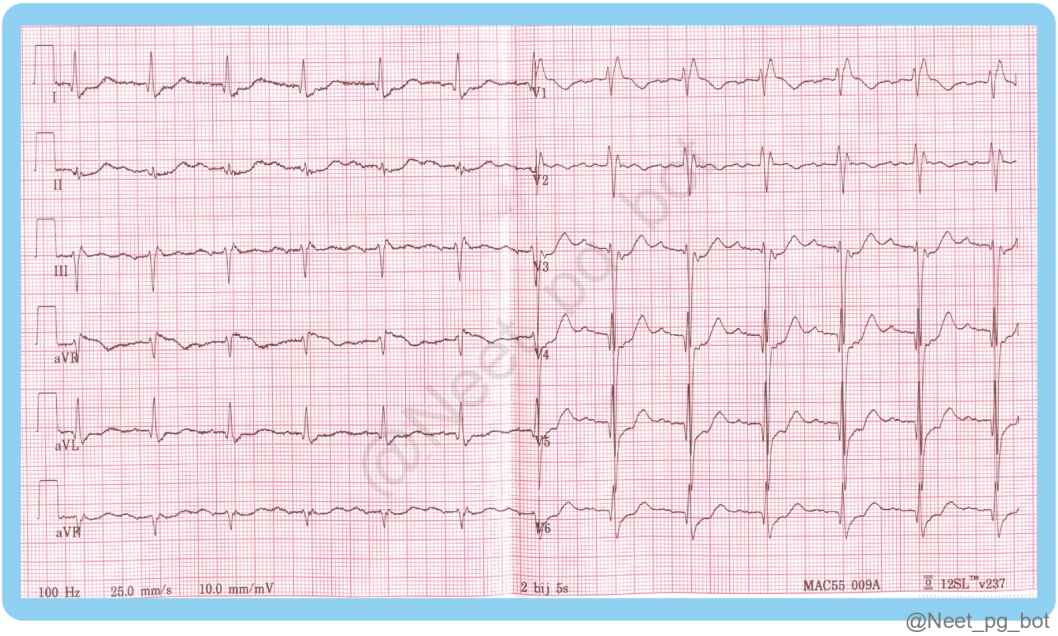
Q14: You are performing an annual medical check up of a 48-year-old man corporate executive. What is the most likely diagnosis based on the ECG findings? {{caption_text}} (Q850526)

A. Brugada Syndrome

B. Ventricular Tachycardia

C. Left Bundle Branch Block (LBBB)

D. Right Bundle Branch Block (RBBB)



@Neet_pg_bot

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 60 year old man presents with central chest pain and breathing difficulty for the last 6 hours. He had tested positive for RT-PCR SARS COV-2 yesterday. Auscultation shows bilateral basal crepitations. ECG shows non-specific ST segment changes. Both NT pro-BNP levels and Troponin I levels are elevated. In cath lab coronary angiography is normal. Diagnosis is? (Q850524)

A. Myocarditis

B. Anterior wall Myocardial infarction

C. Broken heart syndrome

D. Acute pericarditis

See Answer in Part B → Q15

@Neet_pg_bot

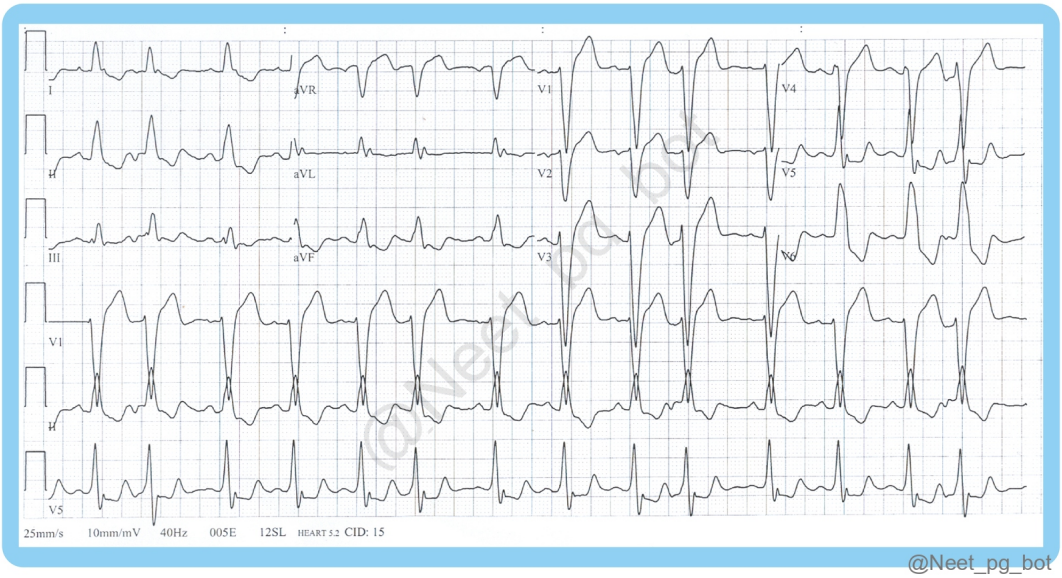
Q16: A 65-year-old diabetic male develops MI and is taken up for thrombolysis in the district hospital. ECG shows which of the following? (Q850523)

A. Ventricular tachycardia

B. Premature Ventricular Contractions (PVCs)

C. Right Bundle Branch Block (RBBB)

D. Left Bundle Branch Block (LBBB)



See Answer in Part B → Q16

@Neet_pg_bot

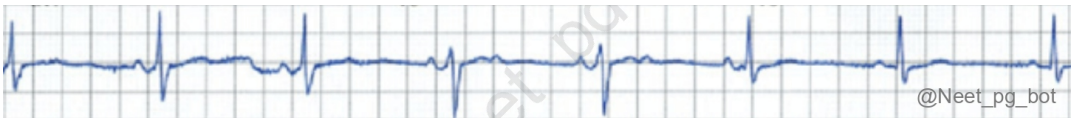
Q17: Calculate the heart rate of the ECG shown below (Q850522)

A. 60 beats per minute

B. 75 beats per minute

C. 100 beats per minute

D. 50 beats per minute



See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 65-year-old smoker with COPD presents to the ER with palpitations and shortness of breath. His ECG shows an irregular rhythm with at least three distinct P-wave morphologies and a heart rate of 120 beats per minute. BP 100/60 mm Hg. Which of the following is the most appropriate management to prevent recurrence of

this rythm disorder (Q850520)

A. Electrical cardioversion

B. Intravenous Diltiazem

C. LTOT with LAMA and LABA

D. IV amiodarone

See Answer in Part B → Q18

Q1: A 25 year old male presents with exertional dyspnea and chest pain while playing table tennis. Echocardiography shows systolic anterior movement of mitral valve with LV free wall thickness of 30 mm. He informs you about the sudden death of his elder brother while dancing at a marriage party. Which of the following is the best intervention for management of this patient? (Q850596)

A. Mitral valvotomy

B. Implantable cardioverter defibrillator

C. Propranolol with Disopyramide

D. Surgical myomectomy

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 55 year old woman presents with acute chest pain and difficulty breathing after learning of the death of her daughter in an air crash. Her ECG shows ST-segment elevation in lead I, aVL, V2-V4. Cardiac biomarkers are elevated. Bed side echocardiography reveals ballooning of the left ventricular apex. What is the most likely diagnosis? (Q850637)

A. Myocardial Infarction

B. Takotsubo Cardiomyopathy

C. Aortic Dissection

D. Brudaga syndrome

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55-year-old patient presents with sharp chest pain, fever, and inspiratory catch on taking deep breath 3 weeks after undergoing coronary artery bypass surgery. Which of the following is the most likely underlying mechanism? (Q850635)

A. Constrictive pericarditis

B. Post cardiac injury syndrome

C. Electro-mechanical dissociation

D. Autoimmune myocarditis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A post-mortem study reveals deposits between the pericardial layers with a “bread and butter” appearance. Which of the following is most consistent with this form of pericarditis? (Q850633)

A. Hemorrhagic pericarditis

B. Purulent pericarditis

C. Fibrinous pericarditis

D. Caseous pericarditis

See Answer in Part B → Q4

@Neet_pg_bot

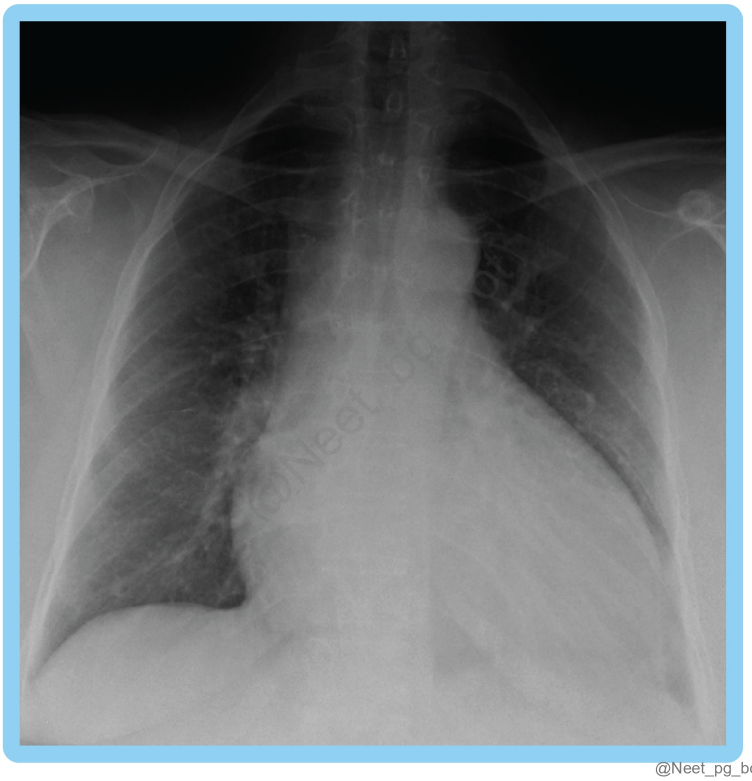
Q5: A 50 year old alcoholic presents with worsening fatigue, shortness of breath, and leg swelling. The Chest X-ray and Cardiac MRI of the patient are given below. Which of the following statements regarding the treatment of her condition is false? (Q850624)

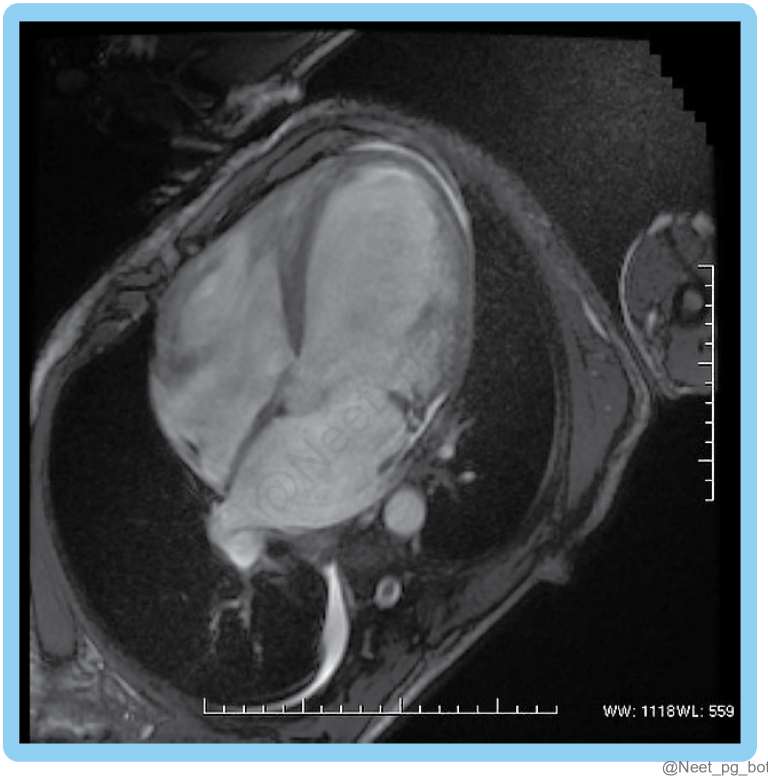
A. Low dose diuretics should be administered to maintain an euvolemic state.

B. ACE inhibitors are recommended for heart failure with reduced ejection fraction.

C. Beta-blockers should not be used in patients with chronic heart failure.

D. Cardiac resynchronization will reduce symptoms





See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 50 year old alcoholic presents with shortness of breath and finding shown in the image. Auscultation reveals pan-systolic murmur. Which of the following findings is most consistent with the diagnosis of this patient? (Q850622)

A. Increased dynamic LV outflow tract obstruction

B. Increased Left ventricular diastolic dimension

C. Double Apical impulse

D. Point of maximum impulse displaced medially

See Answer in Part B → Q6

@Neet_pg_bot

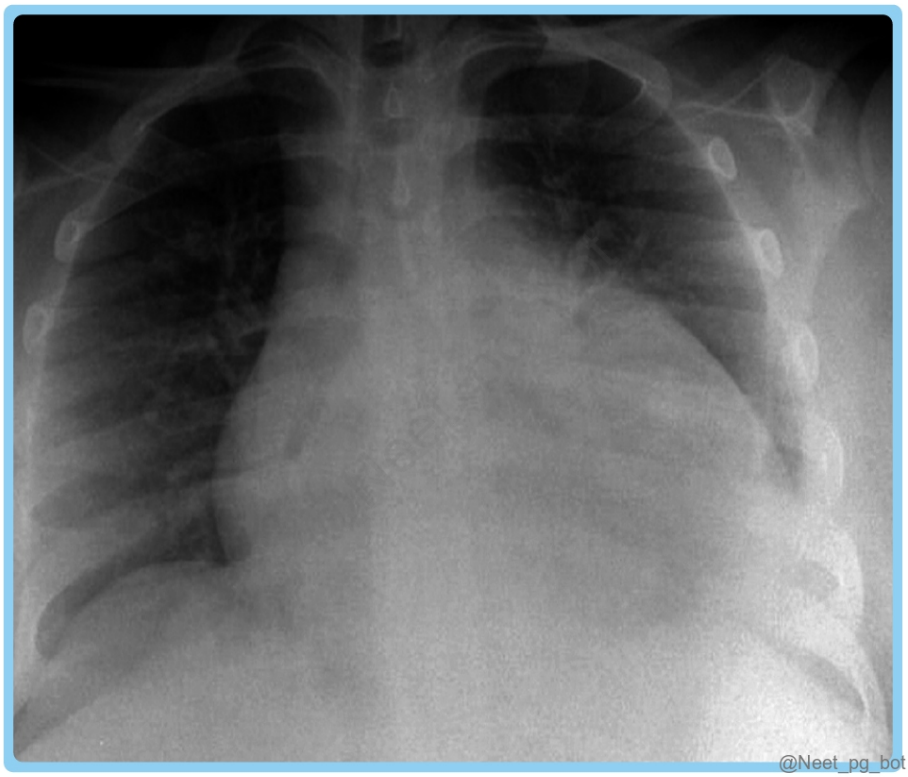
Q7: A 55 year old male presents to the emergency department with fatigue, shortness of breath, and swollen legs. CXR is shown below. Echocardiography shows global hypokinesia with reduced thickness of cardiac chambers. Which of the following is NOT a recognised cause of this patient's diagnosis? (Q850620)

A. Sarcoidosis

B. Chagas disease

C. Scleroderma

D. Heavy metal exposure to lead



See Answer in Part B → Q7

@Neet_pg_bot

Q8: All of the following are correct about restrictive cardiomyopathy except? (Q850616)

A. Echo shows dilated atria with normal size ventricles and increased LV and RV end diastolic pressures

B. Cardiac MRI shows starry sky appearance due to amyloidosis

C. Absent y descent and steep x descent

D. Endomyocardial biopsy is the gold standard for diagnosing cardiac amyloidosis.

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 60-year-old male presents with ascites, shortness of breath, and bilateral ankle edema. Kussmaul's sign is noted. An echocardiogram shows normal systolic function but diastolic dysfunction with a speckled pattern in the ventricular wall. The chest X-ray of the patient is given below. Which of the following statements is correct about the diagnosis of this patient? (Q850610)

A. Thinned out, small-size atria

B. Rapid y descent in JVP

C. Atrial fibrillation is rare in these patients.

D. Endomyocardial Fibroelastosis is the leading cause

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45-year-old man presents with worsening fatigue, shortness of breath, and ankle swelling. His medical history includes joint pain, elevated liver enzymes, hyperpigmentation, and diabetes. He has recently been diagnosed with a metabolic

disorder. An echocardiogram reveals elevated filling pressures and bilateral atrial enlargement. Which of the following best explains the underlying pathophysiology of this patient's condition? (Q850607)

A. Increased contractility due to myocardial hypertrophy

B. Impaired diastolic filling due to stiffened ventricular walls

C. Dilated ventricular chambers leading to heart failure

D. Obstruction of blood flow through the left ventricle

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 30-year-old female marathon runner collapses and is found unresponsive during a race. Despite attempts at resuscitation, she is pronounced dead in the ER. Her family reports that she had previously experienced episodes of dizziness and palpitations during training. You re-evaluate her ECG done at time of admission which shows epsilon waves. Which of the following conditions is most likely to contribute to sudden cardiac death in this young athlete? (Q850603)

A. Arrhythmogenic RV dysplasia

B. Commotio cordis

C. HCM

D. Atherosclerotic coronary artery disease

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following medications is not contraindicated in patients with hypertrophic cardiomyopathy? (Q850601)

A. Amlodipine

B. Verapamil

C. Furosemide

D. Digoxin

See Answer in Part B → Q12

@Neet_pg_bot

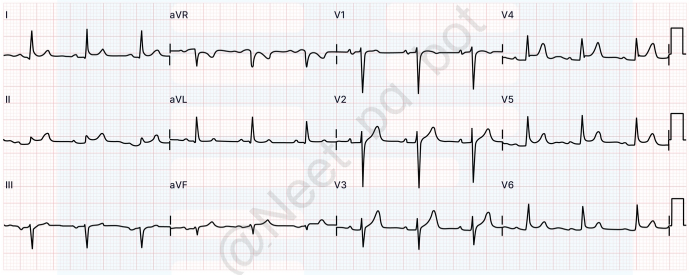
Q13: A 45-year-old male presents with sharp chest pain worsened by lying down and relieved by sitting up. He had a recent viral illness. A friction rub is heard on cardiac auscultation, and the ECG shows the following. What is the most likely diagnosis? (Q850515)

A. Myocardial infarction

B. Pulmonary embolism

C. Acute pericarditis

D. Aortic dissection



@Neet_pg_bot

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 30-year-old male presents with exertional chest pain and occasional fainting spells. His family history includes a relative who experienced sudden cardiac death. An echocardiogram reveals asymmetric septal hypertrophy. Which of the following is not a characteristic investigatory finding in this condition? (Q850592)

A. Brockenbrough-Braunwald-Morrow sign

B. Deep, narrow Q waves in the lateral leads

C. Left ventricle free wall thickness >10 mm

D. Increased precordial voltages

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 15-year-old male presents to the ED after experiencing syncope while playing basketball. He has a palpable double impulse at the apex, and an ECG shows signs of left ventricular hypertrophy. An echocardiogram reveals asymmetric septal thickening with left ventricular outflow tract obstruction. Which of the following examination findings would not be expected in this patient? (Q850589)

A. Palpable double impulse at the apex

B. Late-peaking ejection systolic murmur best heard at the left sternal border

C. Pulsus bisferiens on peripheral pulse examination

D. Prominent y descent in jugular venous pressure (JVP)

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 30-year-old athlete presents with recurrent syncope and exertional chest pain. Exam shows a hyperdynamic apex beat and a mid-systolic murmur at the left lower sternal border. Echocardiography reveals asymmetric septal hypertrophy and systolic anterior motion of the mitral valve. What is the most likely mechanism of his symptoms? (Q850584)

A. Diastolic heart failure due to a dilated left ventricle

B. Mitral valve prolapse

C. Left ventricular outflow tract obstruction

D. Aortic stenosis

See Answer in Part B → Q16

@Neet_pg_bot

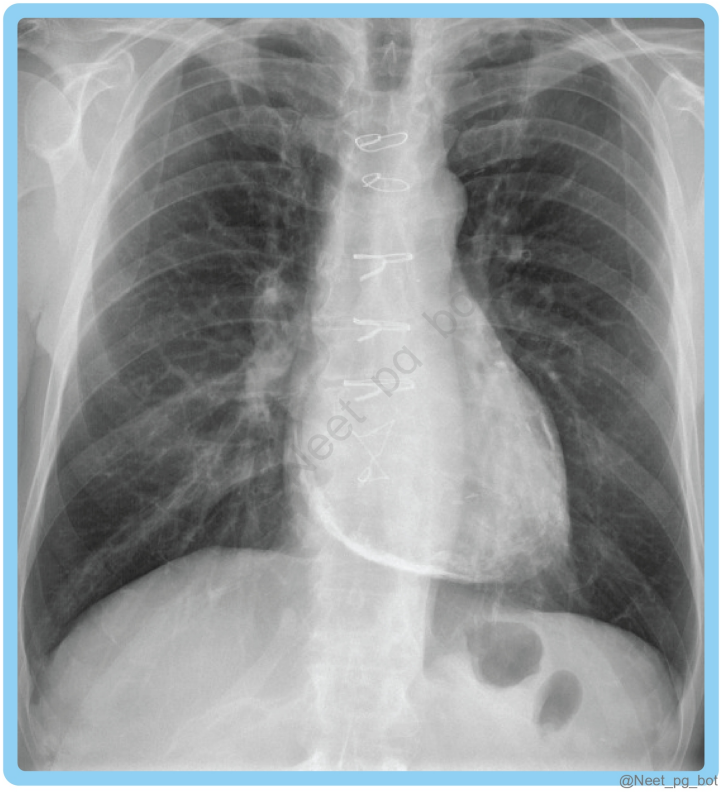
Q17: A 60-year-old male presents with signs of peripheral oedema and ascites. A chest X-ray reveals the following, and echocardiography confirms a thickened pericardium. Which of the following is not correct regarding his likely condition? (Q850580)

A. Diastolic collapse of the ventricles

B. JVP shows a prominent “y” descent

C. Commonly caused by tuberculosis in endemic regions

D. CT scan can assist in visualizing pericardial calcification



See Answer in Part B → Q17

@Neet_pg_bot

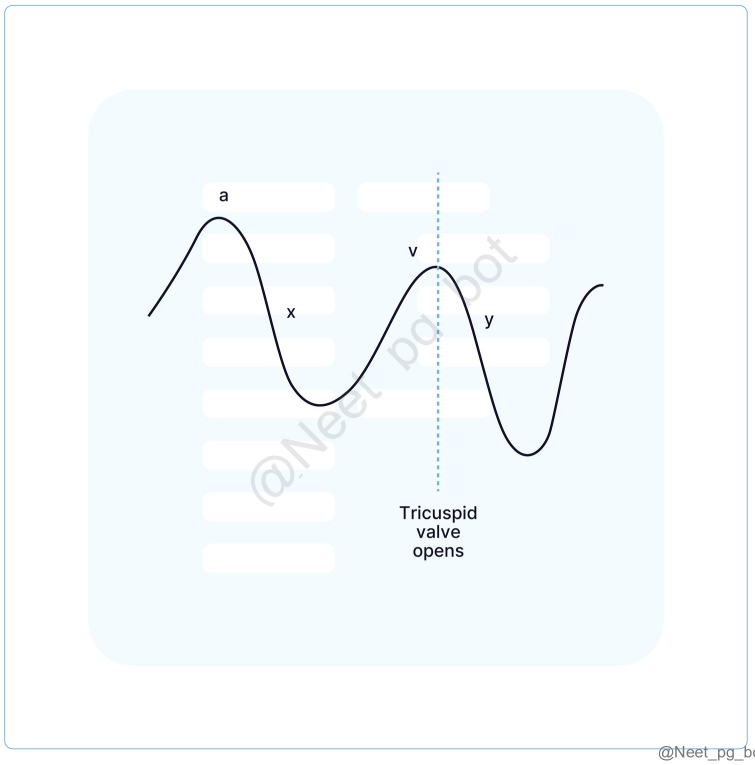
Q18: A 45-year-old male presents with fatigue, abdominal swelling, and peripheral oedema. On examination, he has elevated jugular venous pressure, hepatomegaly, and a loud diastolic sound. There is also a rise in JVP during inspiration. Which of the following is the most likely diagnosis? (Q850579)

A. Cardiac Tamponade

B. Constrictive pericarditis

C. Dilated cardiomyopathy

D. Restrictive cardiomyopathy



See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 25-year-old male is brought to the emergency department after a high-speed car accident. His vitals are heart rate of 120 bpm, blood pressure of 80/50 mmHg, and he is pale with cold, clammy skin. He has a deep laceration on his lower thigh and is actively bleeding. Which of the following is the most appropriate initial management step? (Q850578)

A. Echocardiography guided pericardiocentesis

B. Emergency resuscitative thoracotomy

C. Start intravenous fluid resuscitation

D. Apply a tourniquet to the thigh

See Answer in Part B → Q19

@Neet_pg_bot

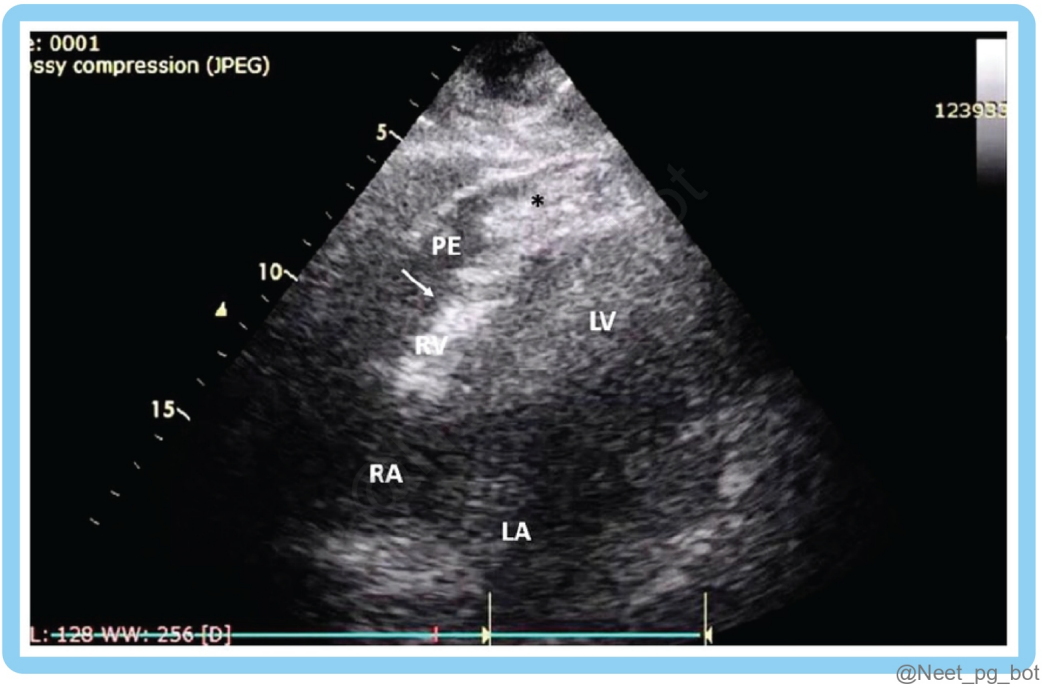
Q20: A 60 year old woman with stage 4 carcinoma breast presents to the ED with severe shortness of breath. On examination, she is hypotensive with a blood pressure of 80/60 mmHg, has distended neck veins with a jugular venous pressure of 12 cm H2O, and her heart sounds are muffled. An echocardiogram shows the following: What is the most appropriate immediate and definitive treatment for this patient? (Q850572)

A. Intravenous saline infusion

B. Pericardiocentesis

C. Diuretics

D. Surgical drainage (pericardiotomy)



@Neet_pg_bot

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following is a classic finding in cardiac tamponade? (Q850571)

A. Pulsus paradoxus

B. S3 heart sound

C. Pulsus alternans

D. High-pitched systolic murmur

See Answer in Part B → Q21

@Neet_pg_bot

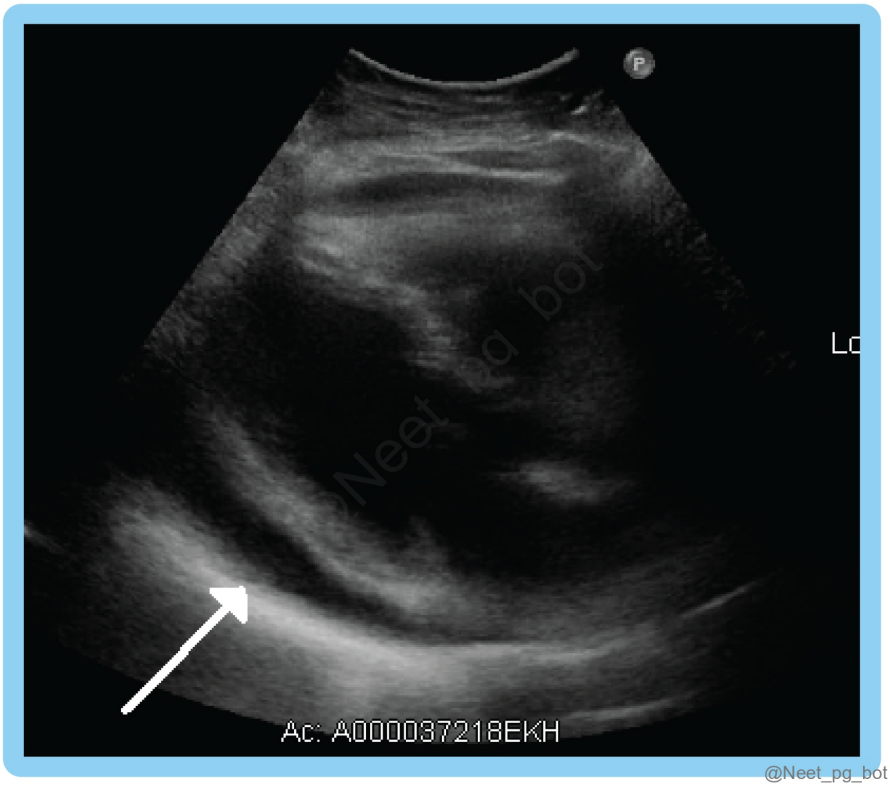
Q22: A 65-year-old man presents to the emergency department with complaints of shortness of breath, fatigue, and mild chest discomfort. On examination, his blood pressure is low, and his heart sounds are faint on auscultation. The physician orders an echocardiogram, which shows the following Based on these findings, which of the following ECG pattern would you most likely expect to see? (Q850557)

A. High-voltage QRS complexes

B. ST-segment elevation in all leads

C. Prolonged PR interval

D. Electrical alternans



See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 60 y/o male with acute pericarditis who has not responded to NSAIDs and colchicine is now experiencing frequent recurrences. He does not tolerate glucocorticoids well. What additional treatment can be considered? (Q850553)

A. Increase the dose of NSAIDs

B. Start azathioprine

C. Begin a higher dose of colchicine

D. Stop all medications and monitor

See Answer in Part B → Q23

Q1: An alcoholic patient presents with palpitations, dizziness, and syncopal attacks. On examination, irregularly irregular pulse is seen. What will be seen on JVP? (Q866781)

A. Absent a wave

B. Large a wave

C. Canon a wave

D. Steep y descent

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 25-year-old female with a previous history of rheumatic fever. Examination shows a loud S1 and mid-diastolic murmur is having which of the following valvular heart disease? (Q866784)

A. TS

B. MR

C. MS

D. AR

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A female patient complains of chest pain while waking up in the morning. Pain is more in winter months. Which of the following best describes this patient? (Q866827)

A. Fixed plaque obstruction

B. Ach-induced coronary vasoconstriction

C. Subendocardial ischemia due to increased demand of myocardium

D. Increased sympathomimetic drive in morning hours

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which type of pulse is based on the Frank-Starling law? (Q865309)

A. Pulsus bisferiens

B. Pulsus paradoxus

C. Pulsus alternans

D. Pulsus parvus

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Mitral stenosis murmur corresponds to which wave of ECG? (Q865310)

A. QRS complex

B. T wave

C. P wave

D. ST segment

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 62-year-old male presents with sudden onset of shortness of breath and B/L pedal edema. He is compliant with his antihypertensive medications, and blood pressure is well controlled. ECG reveals an ejection fraction of 60%, concentric left ventricular hypertrophy, left atrial enlargement, and grade 2 diastolic dysfunction. Which of the following is the most appropriate next step to improve his condition? (Q865331)

A. Perform coronary angiography to rule out ischemic cardiomyopathy

B. Initiate loop diuretics and SGLT2 inhibitors for management of HFpEF

C. Start digoxin to enhance myocardial contractility

D. Initiate ivabradine to reduce heart rate and improve diastolic filling

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is not a symptom of cardiac failure? (Q865338)

A. Right hypochondriac pain

B. Non-pulsatile elevation of JVP

C. Orthopnea

D. Paroxysmal nocturnal dyspnea

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old male presents to a PHC for a routine check-up. His blood pressure readings on two separate occasions are 148/90 mmHg and 152/96 mmHg. He is asymptomatic and has no known comorbidities. What is the most appropriate next step in management according to current hypertension guidelines? (Q865381)

A. Initiate treatment only if BP exceeds 160/100 mmHg

B. Start Amlodipine 5 mg once daily and advise follow-up in 1 month

C. Refer to a higher center for further evaluation

D. Start the patient on IV anti-hypertensive drugs

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 30 year old man with 6 month past history of PND and SOB. On examination, JVP is elevated with irregularly irregular pulse and tender hepatomegaly and MDM. past medical history of ARF. Which of the following is not seen in this patient? (Q866488)

A. Presystolic accentuation of mid-diastolic murmur is hallmark feature

B. Patient has increased risk of embolic stroke

C. Absent a wave in JVP

D. Right heart failure

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A patient presents with palpitations and an irregularly irregular pulse. He presents within 2 hours of symptom onset, and has no history of diabetes or other comorbidities. What is the most appropriate initial management? (Q866489)

A. TEE for starting anticoagulation

B. Cardioversion

C. Control ventricular rate with verapamil

D. Wait and watch

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A patient presents with frothy sputum, dyspnea, and paroxysmal nocturnal dyspnea (PND) and subsequently dies. Autopsy lung histopathology shows hemosiderin-laden macrophages. Which of the following is least likely to occur in this patient? (Q866493)

A. Volume overload

B. RV failure

C. Pulmonary vein obstruction

D. Protein losing enteropathy

See Answer in Part B → Q11

@Neet_pg_bot

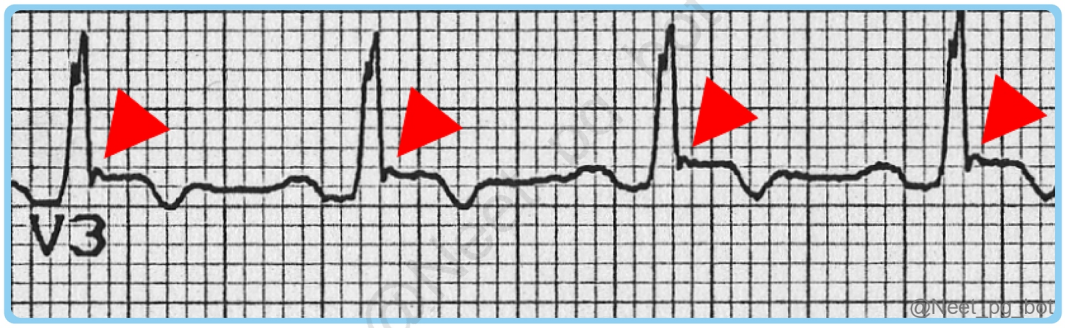
Q12: A female patient comes to the ER with palpitations and syncopal attacks following exercise. She has had similar episodes in the past. An ECG was performed as follows. What is the most probable diagnosis? {{caption_text}} (Q853362)

A. Uhl's disease

B. Arrhythmogenic Right Ventricular Dysplasia

C. Hypertrophic Cardiomyopathy

D. Brugada's syndrome



See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is associated with a Graham-Steel murmur? (Q852672)

A. Ventricular septal defect (VSD)

B. Hypertrophic obstructive cardiomyopathy (HOCM)

C. Pulmonary regurgitation

D. Aortic regurgitation

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 65-year-old male with chronic stable angina presents with worsening chest pain during routine activities. His current medications include aspirin, clopidogrel, metoprolol, and atorvastatin, but his symptoms persist. ECG shows ST-segment depression in V5-V6, and coronary angiography reveals 80% stenosis of the left anterior descending (LAD) artery. What is the most appropriate intervention? (Q852747)

A. Increase the dose of beta-blockers

B. Add Ranolazine

C. Percutaneous coronary intervention (PCI) with drug-eluting stent (DES)

D. Refer for coronary artery bypass grafting (CABG)

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 72 y/o woman presents with severe chest pain and shortness of breath after a stressful argument. She is post-menopausal with no history of heart disease. O/E, she is slightly tachycardic with normal blood pressure. An echocardiogram shows left ventricular ballooning during systole, and cardiac enzymes are minimally elevated. What is the most likely diagnosis? (Q852748)

A. Hypertensive Heart Disease

B. Takotsubo Cardiomyopathy

C. Coronary Artery Disease

D. Pulmonary Embolism

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 68-year-old man with long-standing hypertension presents to the emergency department with severe chest pain, profuse sweating, and marked tachycardia. He appears acutely ill and hypotensive. His ECG finding is given below. What is the most

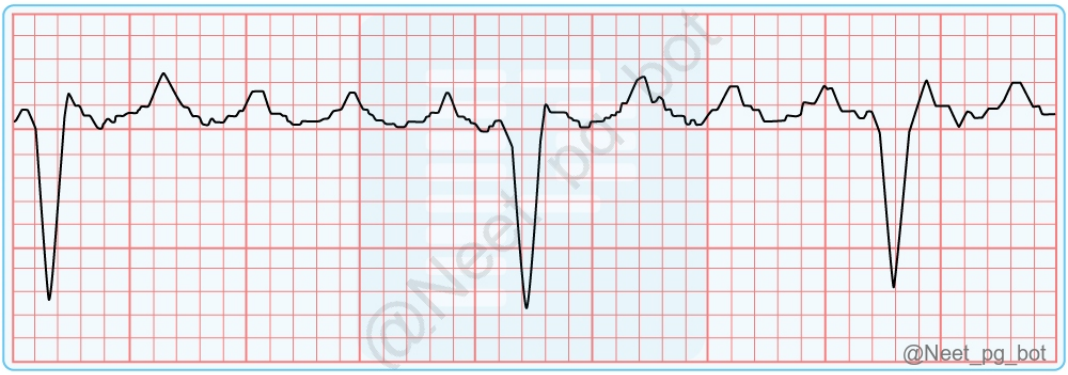
appropriate immediate management? (Q852749)

A. Amiodarone

B. Radiofrequency catheter ablation

C. Digoxin

D. Synchronized cardioversion



See Answer in Part B → Q16

@Neet_pg_bot

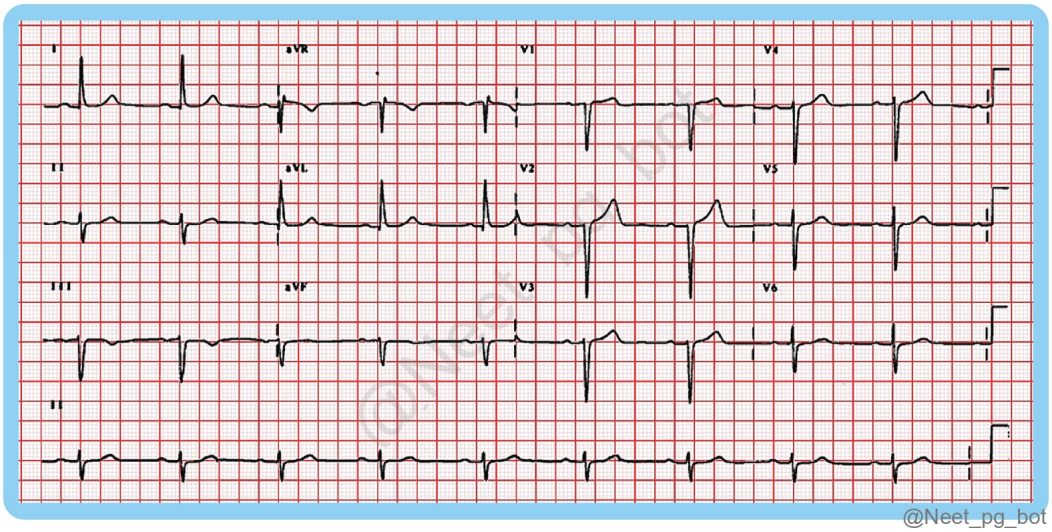
Q17: A 58-year-old woman comes to the clinic for a routine follow-up. She has a history of mild hypertension, which is well-controlled with medication. She reports no symptoms such as palpitations, dizziness, or chest pain. An ECG of the patient is given below. What is the most likely diagnosis based on the ECG findings? {{caption_text}} (Q852750)

A. Second-Degree AV Block

B. First-Degree AV Block

C. Third-Degree AV Block

D. Bundle Branch Block



See Answer in Part B → Q17

@Neet_pg_bot

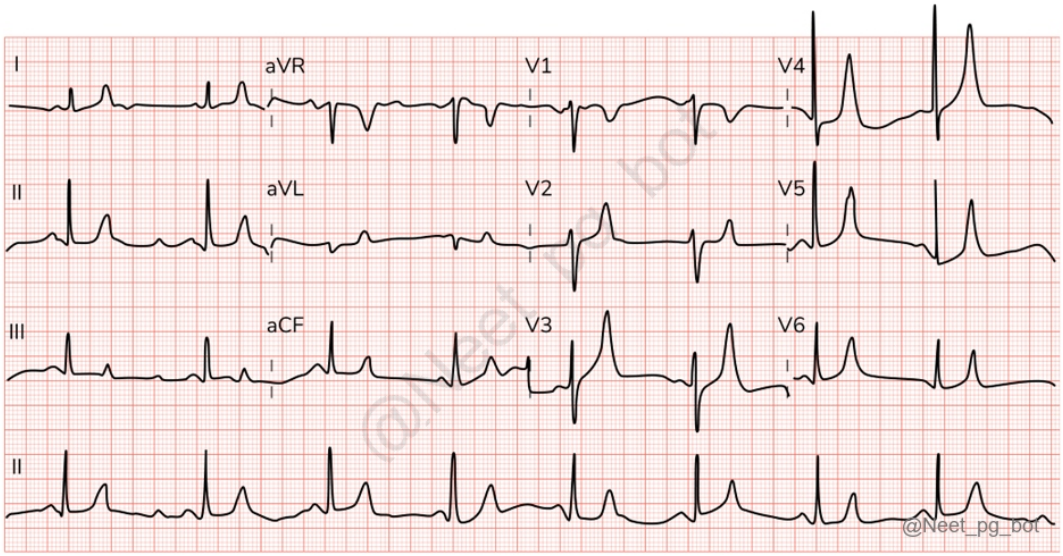
Q18: A patient of CKD has tachycardia. An ECG is taken and shown below. What's the most likely diagnosis? (Q844166)

A. Hyperkalemia

B. Hypokalemia

C. Hypercalcemia

D. Hypocalcemia



See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 60-year-old lady presents with SOB and angina pectoris episodes. Work up shows aortic stenosis. Which of the following is the reason behind these chest pain episodes? (Q844172)

A. Increased pressure in aorta

B. Decreased pressure in aorta

C. Increased oxygen consumption in heart

D. Increase in volume overload of heart

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Patient presents with features of right heart failure and exhibits a rapid Y descent on cardiac examination. What is the most likely diagnosis? (Q844245)

A. Constrictive pericarditis

B. Cardiac tamponade

C. Pulmonary hypertension

D. Right ventricular infarction

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A pulmonary artery hypertension patient presented with an irregularly irregular pulse with loud P2 on auscultation. Which JVP finding will be seen in this patient? (Q844316)

A. Absent a waves

B. Cannon a waves

C. Rapid x descent

D. Rapid y descent

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A young athlete underwent testing for a competition and was found to have hypertrophic cardiomyopathy. Which of the following will increase the murmur in this condition? (Q844250)

A. Handgrip

B. Valsalva maneuver

C. Squatting

D. Leaning forward

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following drugs will cause Torsades de pointes if given with erythromycin? (Q844254)

A. Astemizole

B. Levofloxacin

C. Amoxicillin

D. Ceftriaxone

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A patient presents with shortness of breath. Vitals are HR= 120/min, BP= 90/60. Echo shows diastolic collapse of ventricles. CT showed money bag appearance. Which is best for management of this patient? (Q844256)

A. Start diuretic with BP monitoring

B. Intra aortic balloon pump

C. Pericardiocentesis

D. Ventricular assist device

See Answer in Part B → Q24

@Neet_pg_bot

Q25: What is the next best step in management of a pulseless patient with the following rhythm? (Q844260)

A. Defibrillate and continue chest compression

B. Defibrillate and check pulse

C. Check pulse and give synchronized DC

D. Give synchronized DC and continue chest compression

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A patient with a history of hypertension presents with atrial fibrillation, shortness of breath and Bilateral basal crackles on auscultation. Least important in management would be: (Q844277)

A. Start on anticoagulants like warf or Doac

B. Start beta blocker

C. Cardioversion to correct rhythm if hemodynamically remain unstable even after medical management

D. Iv Digoxin to control rate

See Answer in Part B → Q26

@Neet_pg_bot

Q27: The PR interval was measured at 0.21 seconds in a routine ECG of the patient. What is the correct Interpretation? (Q844281)

A. Second degree HB

B. First degree HB

C. Normal rhythm

D. Complete HB

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 70 year old male patient presents to the OPD with multiple, recurrent fainting episodes. An ECG was taken and it shows P waves at a rate of 75 bpm and qrs complexes at a rate of 35 bpm. What is the diagnosis? (Q860467)

A. Mobitz type II heart block

B. Stokes adams syndrome

C. First degree heart block

D. Wolf parkinson white syndrome

See Answer in Part B → Q28

@Neet_pg_bot

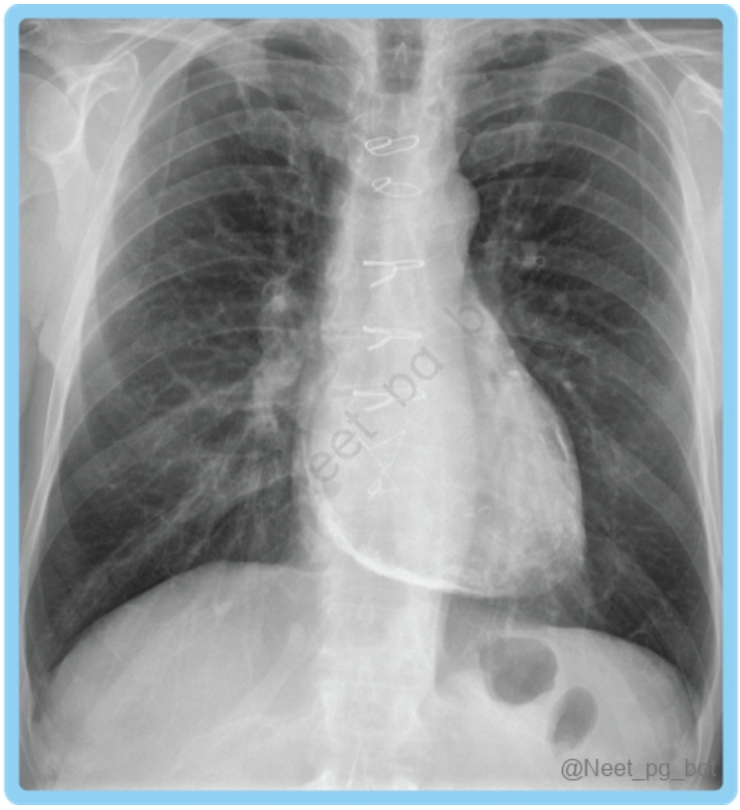
Q29: A 48-year-old man presents with progressive fatigue and breathlessness. On examination, he has distended neck veins, hepatomegaly, ascites, and peripheral edema. Chest X-ray is shown below. Which of the following is the most likely diagnosis? (Q860471)

A. Acute pericarditis

B. Bronchial asthma

C. Constrictive pericarditis

D. Atrial myxoma



See Answer in Part B → Q29

@Neet_pg_bot

Q30: A patient has muffled heart sounds with low blood pressure. What is the correct JVP finding? (Q860477)

A. Steep x descent

B. Absent y descent

C. Steep y descent

D. Blunted x descent

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A young male patient presents with sudden onset chest pain for one hour with ECG showing STE in lead 2,3 and aVF. Which is the best treatment for this case of inferior wall MI in a multispecialty hospital? (Q860480)

A. Alteplase

B. Streptokinase

C. Primary angioplasty

D. Dabigatran

See Answer in Part B → Q31

@Neet_pg_bot

Q32: "A 45-year-old female presents to the emergency department with breathlessness. She has a history of a viral infection and chest pain from 7 days ago. A chest X-ray reveals a "water bottle" heart. All of the following statements are true except:" (Q840110)

A. Pulsus paradoxus is observed

B. Loud S1

C. Emergency pericardiocentesis may be required

D. ECG showing RA and RV collapse requires immediate intervention

See Answer in Part B → Q32

@Neet_pg_bot

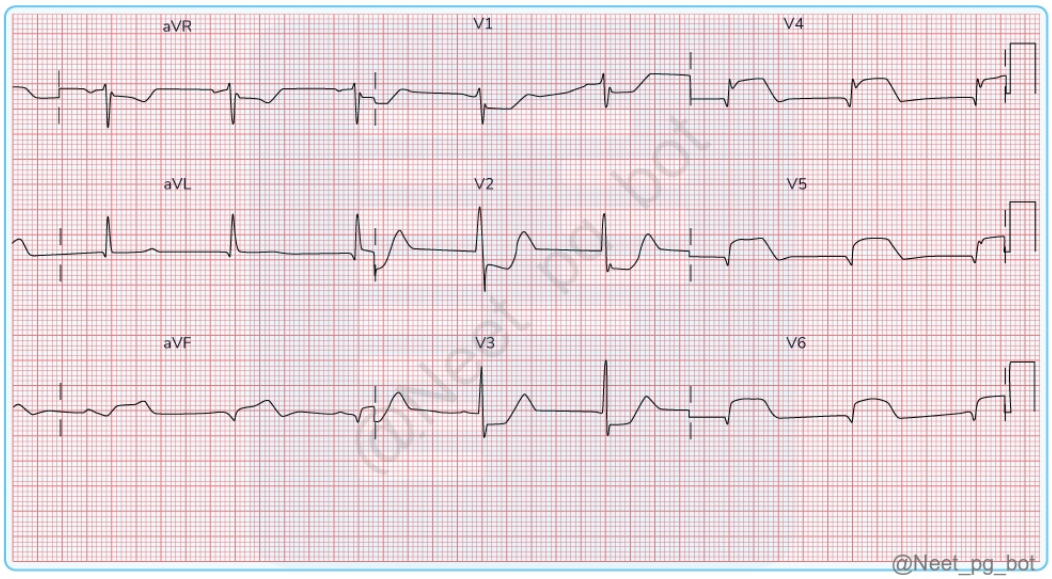
Q33: Which of the following conditions is indicated by the symptoms of chest pain and breathlessness in a 55-year-old male, as revealed by the provided ECG? (Q840116)

A. Unstable angina

B. Non-ST elevation myocardial infarction (NSTEMI)

C. Acute myocarditis

D. Posterior wall myocardial infarction (MI)



See Answer in Part B → Q33

@Neet_pg_bot

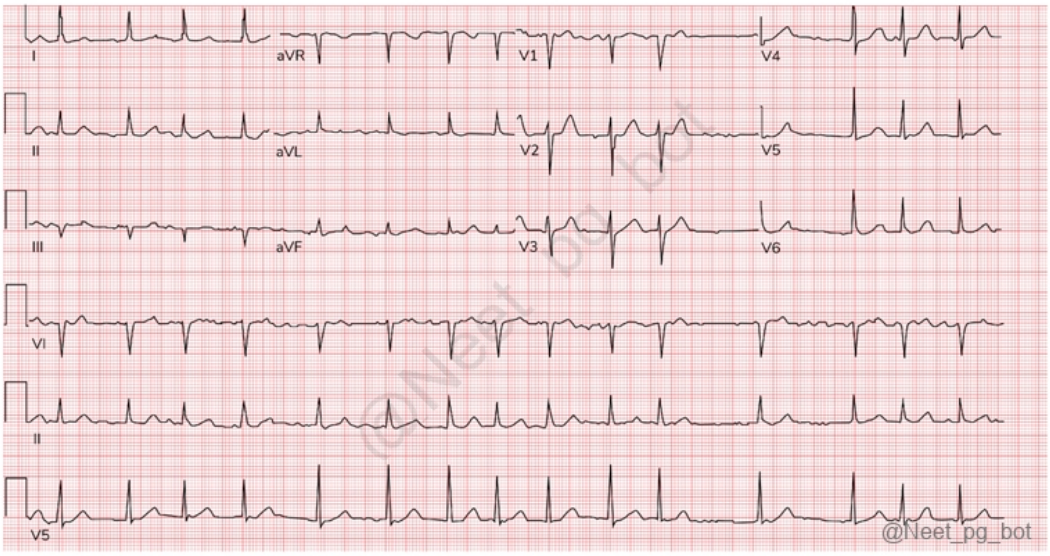
Q34: Which of the following statements is false regarding a 35-year-old male presenting to the emergency department with unconsciousness and the given ECG findings? (Q840119)

A. Atrial fibrillation can occur in structurally normal hearts

B. Direct current cardioversion should always be performed immediately

C. IV digoxin can be used when AF is associated with heart failure

D. Pulse deficit is a useful clinical clue in AF



See Answer in Part B → Q34

@Neet_pg_bot

Q35: A 21-year-old man presents with episodes of chest pain. Physical examination reveals a bisferiens pulse and a heaving apex. What is the most likely diagnosis? (Q860218)

A. Dilated Cardiomyopathy (DCM)

B. Hypertrophic Cardiomyopathy (HCM)

C. Mitral Stenosis

D. Aortic Stenosis

See Answer in Part B → Q35

@Neet_pg_bot

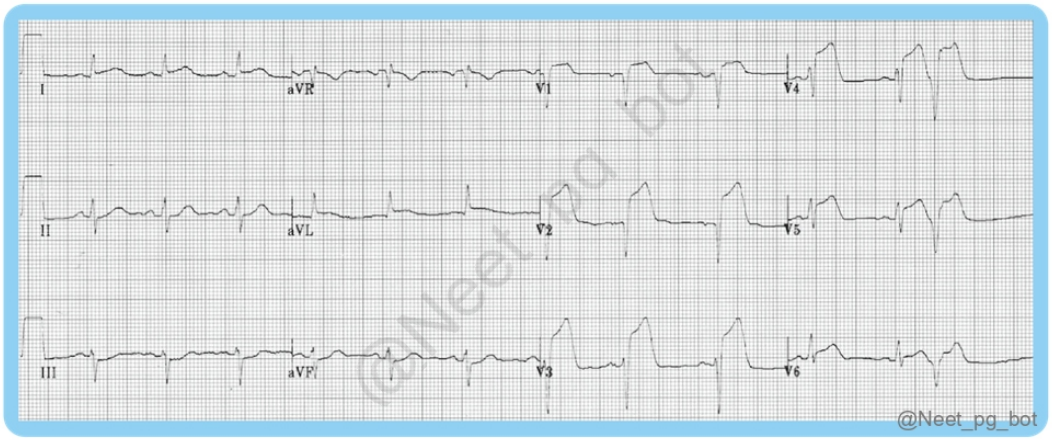
Q36: Based on the given ECG, identify which wall of the myocardium was affected in this patient? (Q860223)

A. Inferior wall

B. Anterior wall

C. Posterior wall

D. Lateral wall



See Answer in Part B → Q36

@Neet_pg_bot

Q37: In which of the following scenarios is Rescue Percutaneous Coronary Intervention (PCI) indicated? (Q860242)

A. Failed thrombolysis

B. Chronic stable angina

C. Prinzmetal's angina

D. NSTEMI

See Answer in Part B → Q37

@Neet_pg_bot

Q38: A 30-year-old man with a past history of tuberculosis now complains of abdominal distension and pedal edema. On examination, his neck veins are

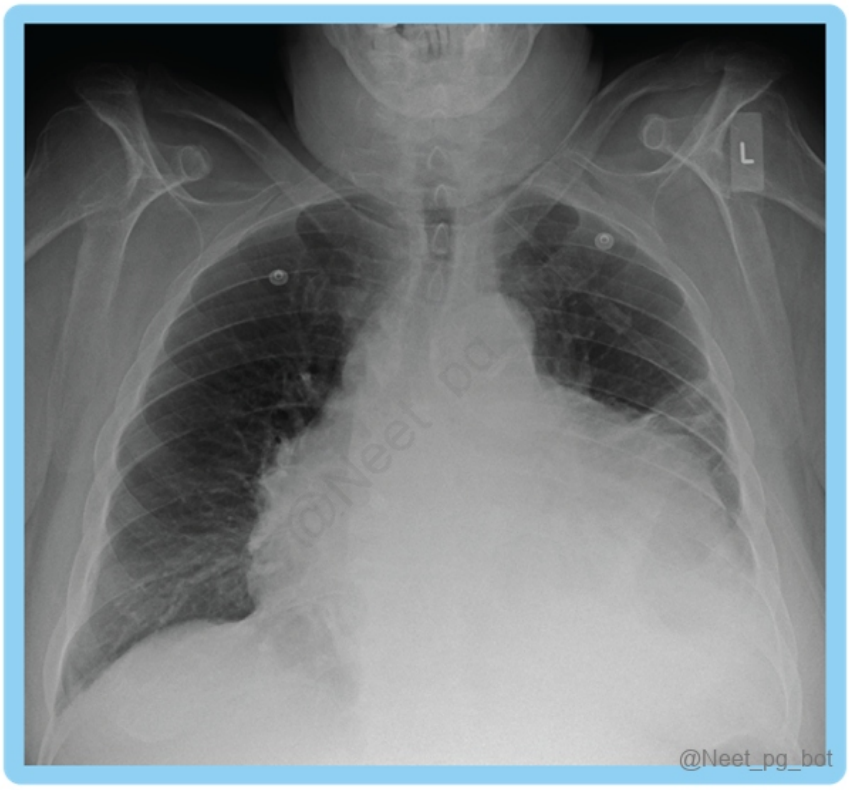
prominent. His chest x-ray is given below. Which of the following findings will be seen in this patient? (Q860246)

A. Pulsus bisferiens

B. Kussmaul sign

C. Non pulsatile elevated JVP

D. SBP rises from 80 mmHg to 60 mmHg



See Answer in Part B → Q38

@Neet_pg_bot

Q39: Which of the following is seen in subclinical acute myocarditis? (Q857252)

A. Palpitations

B. Elevated pro-BNP, Trop T

C. Low LVEF on 2D ECHO

D. Elevated creatinine levels

See Answer in Part B → Q39

@Neet_pg_bot

Q40: Which of the following describes an aortic regurgitation murmur? (Q857263)

A. Ventricular contraction

B. Ejection systolic murmur

C. Diastolic murmur

D. Systolic murmur

See Answer in Part B → Q40

@Neet_pg_bot

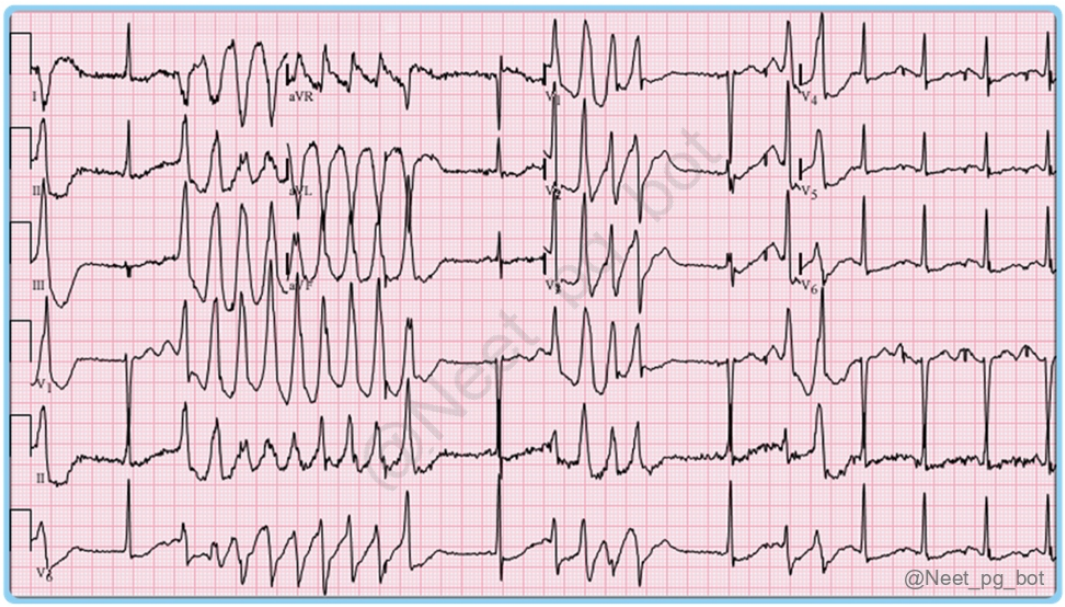
Q41: What does the ECG in the following image depict? (Q857267)

A. Pericarditis

B. Viral myocarditis

C. Torsades de pointes

D. Cardiac tamponade



See Answer in Part B → Q41

@Neet_pg_bot

Q42: What is the correct order for cardiac auscultation, from superior to inferior? a. Pulmonary b. Tricuspid c. Mitral (Q857280)

A. a > b > c

B. b > a > c

C. c > a > b

D. c > b > a

See Answer in Part B → Q42

@Neet_pg_bot

Q43: Which of the following jvp findings seen in a patient with muffled heart sounds, hypotension and raised JVP? (Q820395)

A. Absent x descent

B. Absent y descent

C. C waves are enlarged

D. A waves are absent

See Answer in Part B → Q43

@Neet_pg_bot

Q44: Which of the following is correct regarding Wolf Parkinson's white syndrome? (Q820427)

A. Short PJ Interval

B. Broad QRS interval

C. Tall Tented T waves

D. Prolonged PR interval

See Answer in Part B → Q44

@Neet_pg_bot

Q45: The patient presented with pedal oedema, raised JVP till mandible and ascites. What is the most likely diagnosis? (Q820445)

A. Cardiac failure

B. Renal failure

C. Liver failure

D. Brain injury

See Answer in Part B → Q45

@Neet_pg_bot

Q46: A 20 year old male who is an IV drug user. on examination, a temperature of 38.5 C, and some spots can be noted over the fundus. CBC showed a leukocyte count of 20,000/cu mm. Blood has been sent for culture. Infective endocarditis is suspected.

How many minor duke's criteria are satisfied for the diagnosis? (Q830821)

A. 1

B. 2

C. 3

D. 4

See Answer in Part B → Q46

@Neet_pg_bot

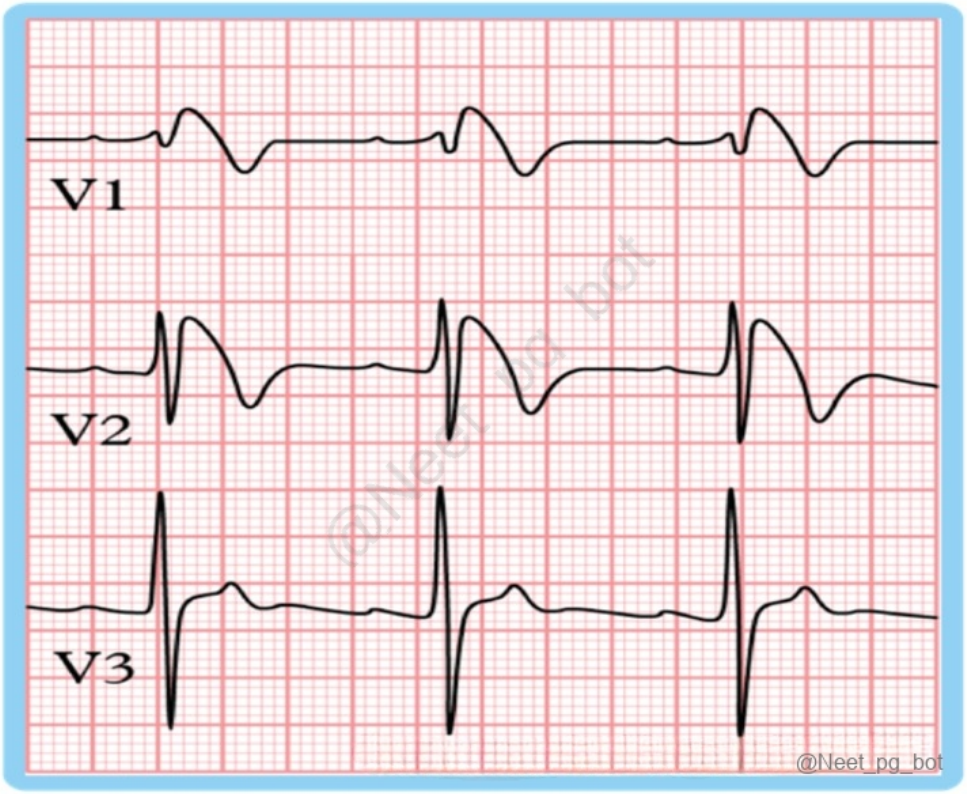
Q47: A 10-year-old boy's father noticed agonal respiration at 5 AM while he was asleep. He was rushed to the ER where an ECG was performed as given. What could be the diagnosis? (Q854656)

A. Early repolarization syndrome

B. Brugada Syndrome

C. Hypertrophic cardiomyopathy

D. Atrial fibrillation



See Answer in Part B → Q47

@Neet_pg_bot

Q48: All of the following are the causes of high-output cardiac failure, except? (Q854694)

A. Cor pulmonale

B. Beri Beri

C. Anemia

D. Systemic AV shunt

See Answer in Part B → Q48

@Neet_pg_bot

Q49: What does the ECG depict in the following image? (Q854707)

A. First-degree heart block

B. Second-degree intra-nodal heart block

C. Complete heart block

D. AV dissociation

See Answer in Part B → Q49

@Neet_pg_bot

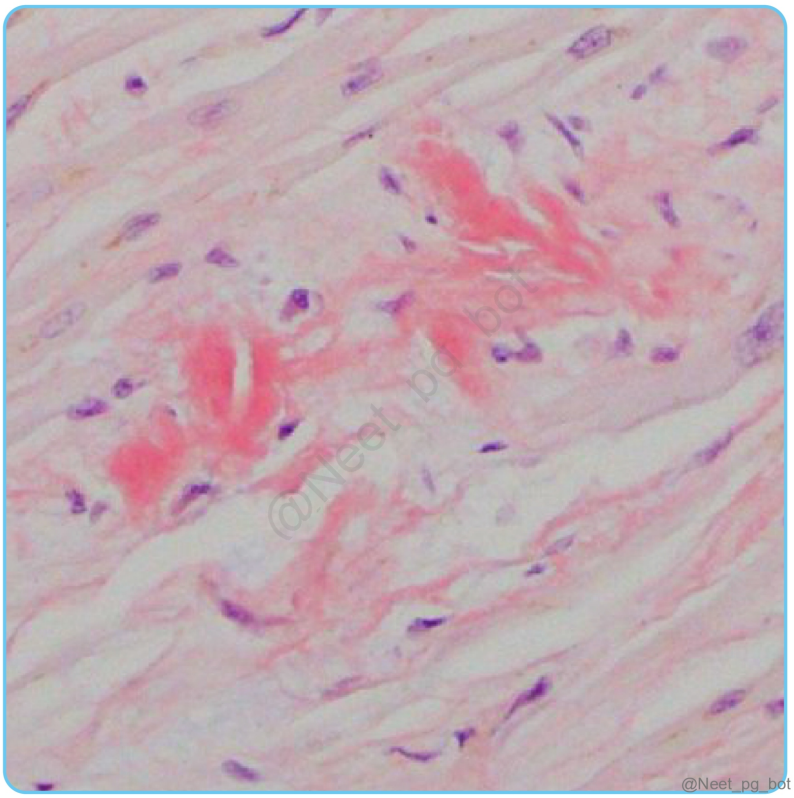
Q50: A 75-year-old woman with Type 2 diabetes mellitus and hypertension, developed features of heart failure and expired. The post-mortem cardiac biopsy slide is given below. What is the likely diagnosis? (Q854713)

A. Dilated Cardiomyopathy

B. Restrictive cardiomyopathy

C. Hypertrophic cardiomyopathy

D. Takotsubo cardiomyopathy



See Answer in Part B → Q50

@Neet_pg_bot

Q51: A 60-year-old diabetic male with central chest pain, shortness of breath and palpitations came to the emergency department. An ECG was taken, which showed NSTEMI. Which of the following is the right treatment? (Q854724)

A. Aspirin + Clopidogrel

B. Aspirin + Statin

C. Aspirin + Clopidogrel + LMWH

D. Aspirin + LMWH

See Answer in Part B → Q51

@Neet_pg_bot

Q52: Which of the following statements about the culture taken in a suspected case of infective endocarditis is correct? (Q854726)

A. Two samples from peripheral lines 30 minutes apart

B. Three samples from peripheral lines 1 hour apart

C. One sample only from the peripheral line

D. Two peripheral samples, two days apart

See Answer in Part B → Q52

@Neet_pg_bot

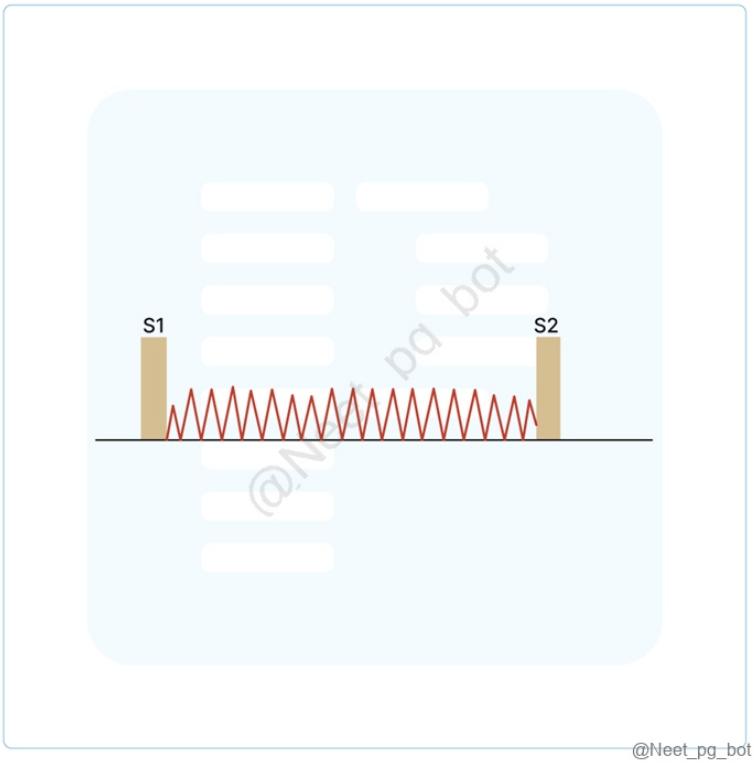
Q53: Identify the condition associated with the murmur depicted in the image below. (Q855412)

A. Mitral Regurgitation

B. Aortic Regurgitation

C. Aortic Stenosis

D. Mitral Stenosis



See Answer in Part B → Q53

@Neet_pg_bot

Q54: A 40-year-old female patient came with complaints of chest pain, palpitation, and shortness of breath. On examination, a mid-diastolic murmur was heard, and a prominent 'a' wave was found on JVP. What is the most likely diagnosis? (Q855479)

A. Mitral stenosis

B. Tricuspid stenosis

C. Mitral regurgitation

D. Tricuspid regurgitation

See Answer in Part B → Q54

@Neet_pg_bot

Q55: A patient who is a known case of hypertension on multiple antihypertensive medications came to the OPD. His ECG finding is given below. Which of the following drugs is responsible for the ECG finding? (Q855489)

A. Prazosin

B. Metoprolol

C. Hydrochlorothiazide

D. Spironolactone

See Answer in Part B → Q55

@Neet_pg_bot

Q56: A patient presents with dyspnea and distended neck veins that increase on inspiration. There is no murmur. What is the diagnosis? (Q858032)

A. Constrictive pericarditis

B. Aortic regurgitation

C. Tricuspid stenosis

D. Pulmonary arterial hypertension

See Answer in Part B → Q56

@Neet_pg_bot

Q57: Which of the following drugs reduce mortality in a patient with heart failure? (Q858361)

A. Metoprolol

B. Furosemide

C. Prazosin

D. Torsemide

See Answer in Part B → Q57

@Neet_pg_bot

Q58: A 65-year-old man with known lung cancer presents with acute shortness of breath and chest discomfort. On examination, percussion over the left infrascapular area is dull, and breath sounds are markedly decreased. He has hypotension, tachycardia, elevated JVP, and muffled heart sounds. What is the most likely diagnosis? (Q793802)

A. Cardiac tamponade

B. Chronic constrictive pericarditis

C. Pulmonary embolism

D. Left-sided pleural effusion

See Answer in Part B → Q58

@Neet_pg_bot

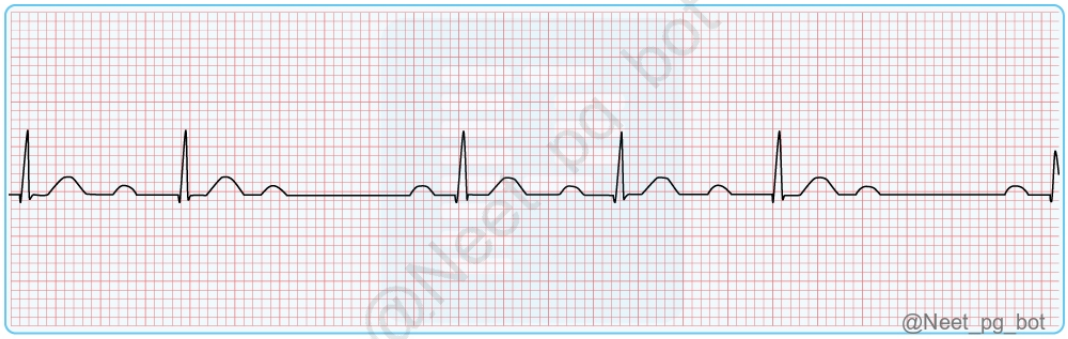
Q59: Identify the conduction abnormality from the ECG given below? (Q855705)

A. First degree heart block

B. Ventricular tachycardia

C. Third degree heart block

D. Second degree heart block



See Answer in Part B → Q59

@Neet_pg_bot

Q60: A 45-year-old patient with suspected mitral stenosis is found to have a soft or absent first heart sound on auscultation. Which of the following conditions is least likely to cause a soft or absent S1? (Q855710)

A. Severe mitral valve calcification

B. Aortic regurgitation

C. First degree heart block

D. Advanced mitral stenosis

See Answer in Part B → Q60

@Neet_pg_bot

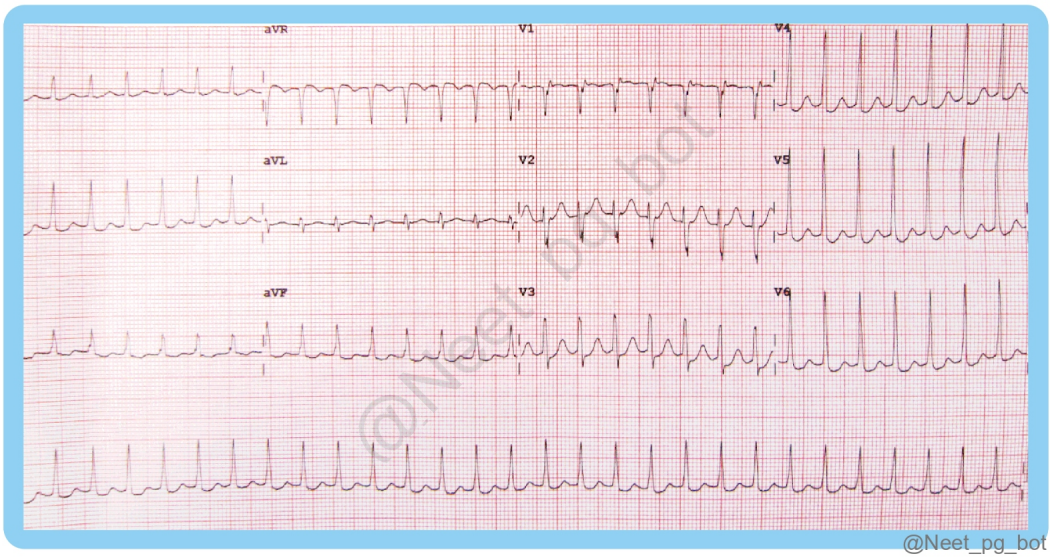
Q61: Which of the following is the initial treatment of choice for managing the condition in a female patient who comes to the hospital with palpitations, having stable vital signs and an ECG showing the following? (Q855330)

A. Amiodarone

B. Adenosine

C. DC cardioversion

D. Primary PCI



See Answer in Part B → Q61

@Neet_pg_bot

Q62: A patient with heart disease has breathlessness when going to the bathroom. What grade does he belong to? (Q855360)

A. NYHA 3

B. NYHA 4

C. mMRC 4

D. mMRC 5

See Answer in Part B → Q62

@Neet_pg_bot

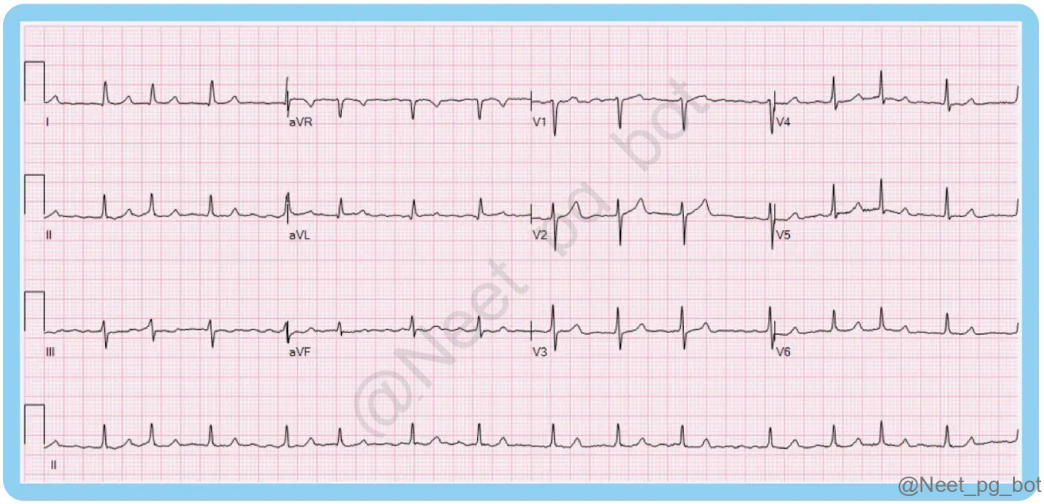
Q63: Based on the ECG given below, which of the following is not used in the management of the condition? (Q855364)

A. Verapamil

B. Metoprolol

C. Amiodarone

D. Non-synchronised DC shock



See Answer in Part B → Q63

@Neet_pg_bot

Q64: Which of the following foods is not included in the DASH diet? (Q857042)

A. Rich in potassium

B. Rich in calcium

C. Rich in sodium

D. Rich in magnesium

See Answer in Part B → Q64

@Neet_pg_bot

Q65: A patient has presented with features of cardiac tamponade. Which of the following is correct regarding this condition? (Q857043)

A. Pulsus Paradoxus is always present

B. Kussmaul sign is always present

C. Tall A wave is present

D. Jugular veins column is visibly distended without pulsations

See Answer in Part B → Q65

@Neet_pg_bot

Q66: What is the clinical diagnosis for a young male who has no symptoms but is found to have a wide fixed split S2 during auscultation? (Q857046)

A. ASD

B. VSD

C. TOF

D. BAV

See Answer in Part B → Q66

@Neet_pg_bot

Q67: Which of the following is contraindicated in a patient with Wolff–Parkinson–White (WPW) syndrome presenting with atrial fibrillation? (Q857052)

A. Treadmill test

B. Electrophysiological studies

C. Oral beta blocker

D. Procainamide

See Answer in Part B → Q67

@Neet_pg_bot

Q68: Which of the following is not correct about Defibrillation? (Q857055)

A. Only be used by a trained person

B. Decrease in success rate with delay in initiation

C. Improve prognosis

D. 1 minute gap between 2 shocks

See Answer in Part B → Q68

@Neet_pg_bot

Q69: Modified duke criteria are used for diagnosis of? (Q857066)

A. Infective endarteritis

B. Infectious mononucleosis

C. Inflammatory myopathy

D. Infective endocarditis

See Answer in Part B → Q69

@Neet_pg_bot

Q70: Which of the following indicators shall be seen with use of a small-sized BP cuff? (Q857069)

A. False elevation of BP

B. Falsely low value of BP

C. Cancels the effects of calcified arteries

D. Increases trans arm impedance

See Answer in Part B → Q70

@Neet_pg_bot

Q71: Elderly male patient has presented with recurrent falls. Which of the following medicines is responsible? (Q857070)

A. Prazocin

B. Metformin

C. Acarbose

D. Thiazide

See Answer in Part B → Q71

@Neet_pg_bot

Q72: What is the waist to hip ratio that is associated with an increased risk of heart disease? (Q857072)

A. > 0.80 in males

B. > 0.80 in females

C. > 0.85 in males

D. > 0.85 in females

See Answer in Part B → Q72

@Neet_pg_bot

Q73: Best management of a hemodynamically stable patient with ECG showing Broad QRS complex with antidromic tachycardia is? (Q857074)

A. Oral verapamil

B. Oral Beta-blocker

C. Cardioversion

D. Intravenous Procainamide

See Answer in Part B → Q73

@Neet_pg_bot

Q74: What is the diagnosis for a 23-year-old female who has been experiencing fever for the past week and displays the following rhythm on the monitor? {{caption_text}} (Q857095)

A. Atrial fibrillation

B. Atrial flutter

C. Supra ventricular tachyarrhythmia

D. Ventricular tachyarrhythmia

See Answer in Part B → Q74

@Neet_pg_bot

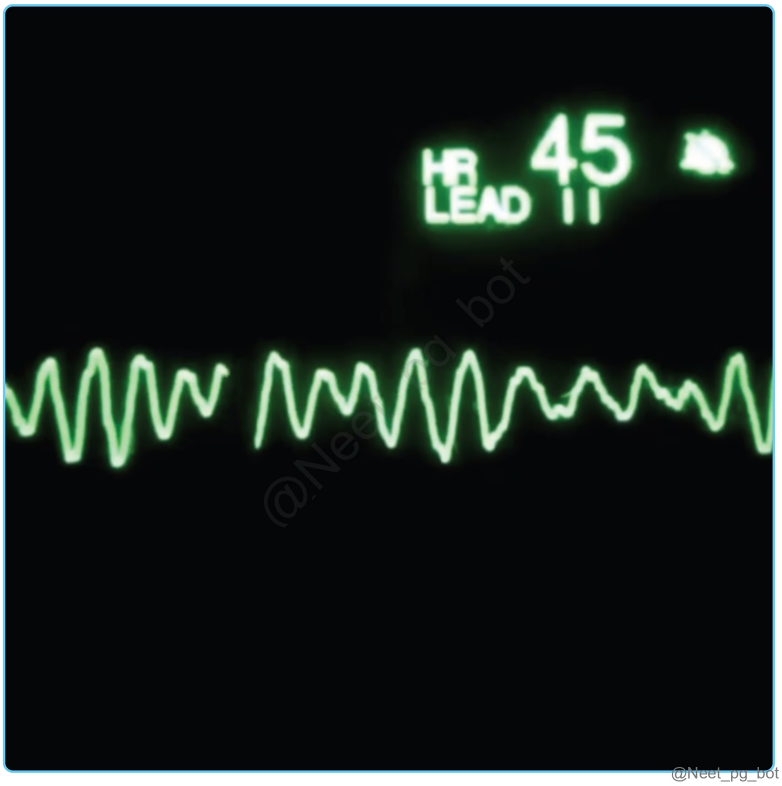
Q75: An intern observed that a patient in the ward was unresponsive, and an ECG which was performed urgently showed a rhythm as depicted below. DC shock was delivered but the arrhythmia persisted and the patient is still unresponsive. What is the next best step in the management of this patient? (Q857615)

A. Synchronized cardioversion

B. Start CPR

C. Deliver another DC shock

D. 1 mg epinephrine



See Answer in Part B → Q75

@Neet_pg_bot

Q76: Pulsus paradoxus is seen in: (Q857626)

A. Coronary artery disease

B. Severe Asthma or Chronic Obstructive Pulmonary Disease

C. Atrial Fibrillation

D. Right ventricular myocardial infarction

See Answer in Part B → Q76

@Neet_pg_bot

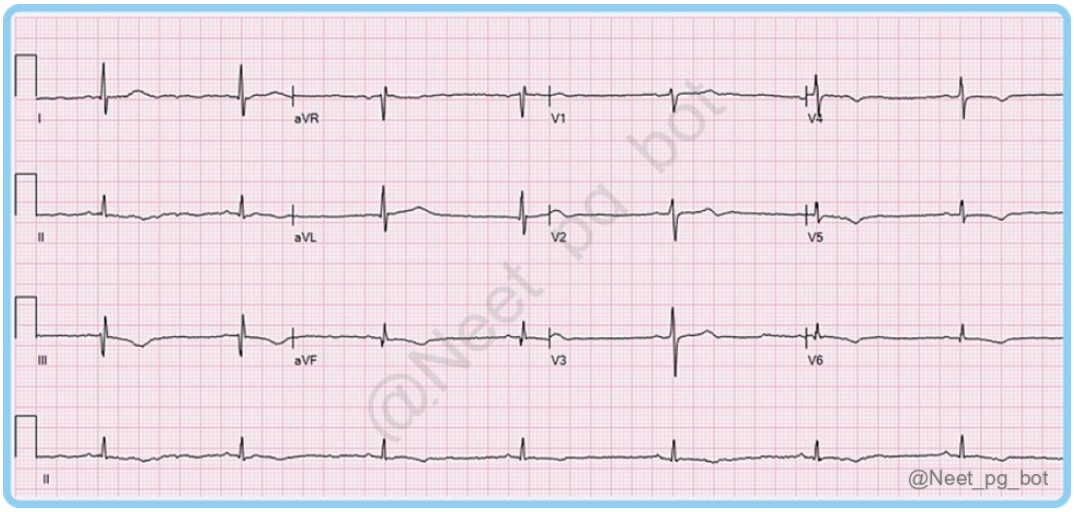
Q77: A 64-year-old man presents with complaints of palpitations and syncope. He has a history of inferior-wall myocardial infarction a year ago. Holter study was done and his 24 hour ECG strip obtained is given below. What is the long-term treatment for this condition? (Q857641)

A. Amiodarone

B. Atropine only

C. Permanent pacemaker

D. Atropine and isoproterenol



See Answer in Part B → Q77

@Neet_pg_bot

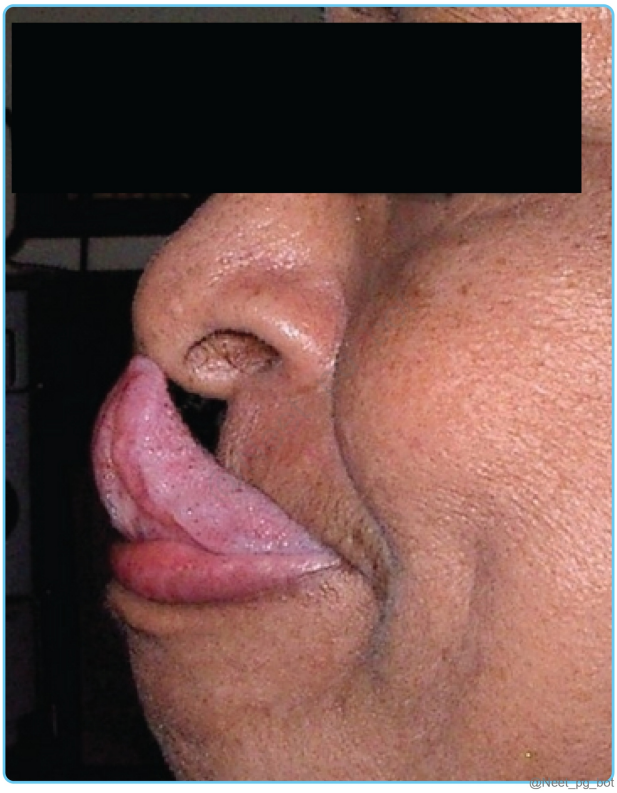
Q78: A 5 year old child has flexible fingers and can even touch the back of his hand with his wrist extended. The child also demonstrates the sign shown in the image below. On auscultation, a click is heard after S1, followed by a late systolic murmur. What is the probable diagnosis? (Q857653)

A. Ehlers-Danlos syndrome

B. Marfan’s syndrome

C. Loeys-Dietz syndrome

D. Osteogenesis imperfecta



See Answer in Part B → Q78

@Neet_pg_bot

Q79: Which of the following is the most appropriate position for placement of single lead pacemaker ? (Q857654)

A. Right ventricle

B. Left atrium

C. Left ventricle

D. Superior vena cava

See Answer in Part B → Q79

@Neet_pg_bot

Q80: What is the most probable diagnosis for a female patient, aged 65, who visits the outpatient department with symptoms of breathlessness and fatigue? During examination, the patient's neck veins were engorged, and her jugular venous pulse displayed a swift X and Y descent. (Q857667)

A. Constrictive pericarditis

B. Cardiac tamponade

C. Dilated cardiomyopathy

D. Restricted cardiomyopathy

See Answer in Part B → Q80

@Neet_pg_bot

Q81: A 35 year old female patient with fever and malar rashes was found to have vegetations on either side of the heart valves. What can be the diagnosis of the patient? (Q857674)

A. Infective endocarditis

B. Libman sacks endocarditis

C. Rheumatic Heart Disease

D. None of the above

See Answer in Part B → Q81

@Neet_pg_bot

Q82: PR segment in ECG indicates: (Q857686)

A. Atrial depolarization

B. Atrioventricular nodal conduction

C. Ventricular depolarization

D. Ventricular repolarization

See Answer in Part B → Q82

@Neet_pg_bot

Q83: Most sensitive and specific marker for MI is? (Q857691)

A. Troponin

B. Cytokeratin

C. Myoglobin

D. CPK-MM

See Answer in Part B → Q83

@Neet_pg_bot

Q84: Which of the following is given lifelong for patient receiving prosthetic mitral valve replacement? (Q857693)

A. Aspirin

B. Clopidogrel

C. Atorvastatin

D. Warfarin

See Answer in Part B → Q84

@Neet_pg_bot

Q85: A 68-year-old male presents with palpitations and shortness of breath. His medical history includes hypertension, diabetes, and coronary artery disease. On examination, irregularly irregular heartbeats are noted. An electrocardiogram (ECG) reveals irregularly irregular rhythm , no P waves, and absence of an isoelectric baseline. His blood pressure is 132/84 mmHg, heart rate 130 bpm, and oxygen saturation 94% on room air. Given the patient's clinical presentation and history,

which of the following treatment options should be considered as a first-line approach for managing this case? (Q855706)

A. Amiodarone

B. Metoprolol

C. Electrical cardioversion

D. Direct oral anticoagulant (DOAC) therapy

See Answer in Part B → Q85

@Neet_pg_bot

Q86: All are true regarding heart failure except: (Q855713)

A. Regardless of ejection fraction and the type of heart failure, the 5-year mortality rate is around 50%

B. Non-cardiovascular death is more in HFrEF-30-40% as compared to HFpEF-15%

C. Angiotensin converting enzyme (ACE) inhibitors cause cough in 15% and angioedema in 1%

D. Atrial fibrillation is common in elderly and is the cause of stroke in quarter of the stroke cases

See Answer in Part B → Q86

@Neet_pg_bot

Q87: In atrial fibrillation, choose the correct statements: Novel oral anticoagulants (NOACs) used in the treatment of moderate to severe MS Anticoagulants should be given in patients with ischemic stroke due to atrial fibrillation NOACs are contraindicated in prosthetic valves All patients with atrial fibrillation who are not candidates for cardiac surgery can be started on beta-blockers (Q855730)

A. 1,2,3 and 4 correct

B. 1,2 and 3 correct

C. 2 and 3 correct

D. 1 and 4 correct

See Answer in Part B → Q87

@Neet_pg_bot

Q88: A 60 year old male patient with critical mitral stenosis presented with atrial fibrillation. He has a history of multiple episodes of transient ischemic attacks. Which of the following are true regarding the prevention of stroke in this patient? Only aspirin is given Warfarin is given Direct oral anticoagulants are not indicated Mitral valvotomy should be recommended (Q855731)

A. 1 only

B. 2 and 3

C. 2,3 and 4

D. 1,2,3 and 4

See Answer in Part B → Q88

@Neet_pg_bot

Q89: For the diagnosis of resistant hypertension, the patient should have uncontrolled hypertension despite taking three antihypertensive drugs. This should include at least one: (Q856598)

A. Calcium channel blocker

B. Beta blocker

C. Alpha blocker

D. Diuretic

See Answer in Part B → Q89

@Neet_pg_bot

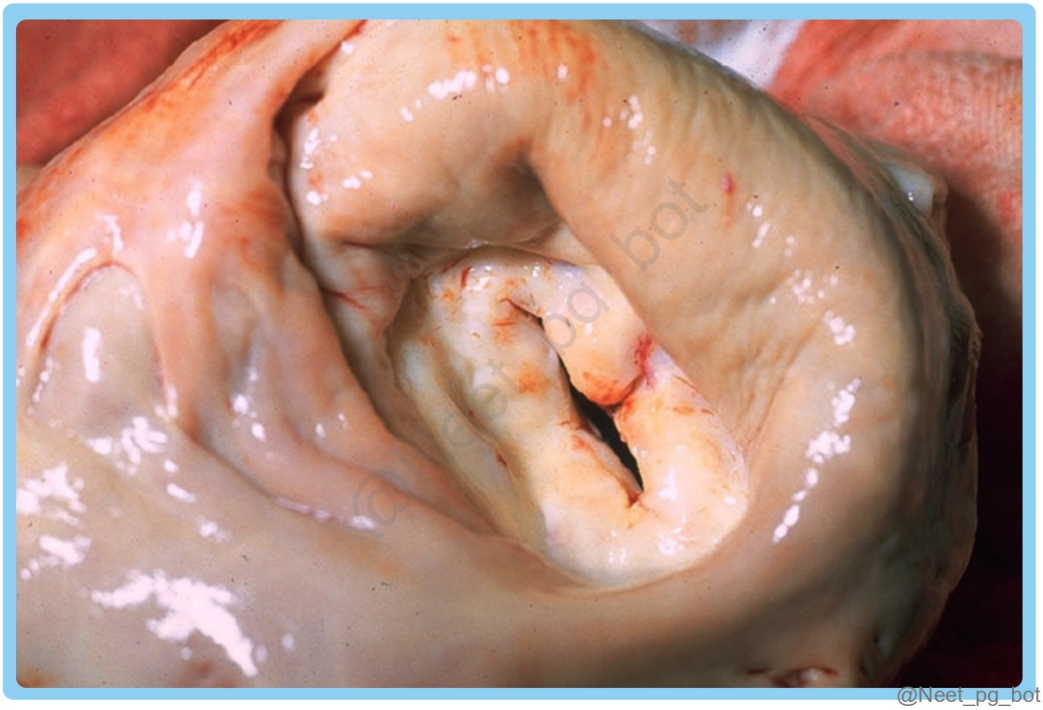
Q90: Identify the disease? (Q856617)

A. Tricuspid stenosis

B. Mitral stenosis

C. Dilated cardiomyopathy

D. Hypertrophic obstructive cardiomyopathy



See Answer in Part B → Q90

@Neet_pg_bot

Q91: A patient who is a known case of atherosclerosis underwent a circumflex artery bypass. The stent is now placed successfully. He's already taking lisinopril, verapamil, and metoprolol. Which drug should be added? (Q856117)

A. PDE 3 inhibitor

B. Direct oral anticoagulant

C. P2Y12 receptor blocker

D. PDE 5 inhibitor

See Answer in Part B → Q91

@Neet_pg_bot

Q92: A male patient had feeble femoral pulses with an upper-limb blood pressure of 186/90 mmHg. Chest x-ray showed enlarged intercostal arteries. What is the likely diagnosis? (Q856118)

A. Coarctation of aorta

B. Atrial septal defect

C. Bicuspid aortic valve

D. Patent ductus arteriosus

See Answer in Part B → Q92

@Neet_pg_bot

Q93: A 45-year-old woman with a history of hypertension presented to the emergency room with loss of consciousness, chest pain, and diaphoresis. On examination, she was grossly unstable, and the bilateral pulses were unequal. ECG showed nonspecific ST-T changes. What is the next best investigation? (Q856130)

A. MRI

B. Transoesophageal echocardiography

C. Cardiac enzymes

D. X-ray

See Answer in Part B → Q93

@Neet_pg_bot

Q94: A 50-year-old man presents with a history of recurrent retrosternal chest pain, with each episode lasting for 3-5 min and subsiding with sublingual nitrate. ECG

shows left ventricular hypertrophy and flat T-wave. He has a known case of hypertension, diabetes mellitus, and hypercholesterolemia and is currently on aspirin, atenolol, metformin, and lovastatin. What is the next best step in management? (Q856171)

A. IV glyceryl trinitrate infusion

B. Injection enoxaparin

C. Add clopidogrel

D. Increase the dose of beta blocker

See Answer in Part B → Q94

@Neet_pg_bot

Q95: Evaluation of a patient revealed the presence of a mid-diastolic murmur. JVP showed prominent a-waves. What is the likely diagnosis? (Q856199)

A. Mitral stenosis

B. Tricuspid stenosis

C. Mitral regurgitation

D. Tricuspid regurgitation

See Answer in Part B → Q95

@Neet_pg_bot

Q96: A 20-year-old woman presents with breathlessness and chest pain. She is a known case of mitral stenosis. Her pulse is irregularly irregular. No thrombus is seen on echocardiography. What is the best agent to prevent future thrombotic events? (Q856202)

A. Dabigatran

B. Aspirin 150mg

C. Oral warfarin

D. Aspirin + Clopidogrel

See Answer in Part B → Q96

@Neet_pg_bot

Q97: Resistant hypertension is defined as? (Q856945)

A. BP >160/90 mmHg with one antihypertensive

B. BP >140/90 mmHg with one antihypertensive

C. BP >160/90 mmHg with three or more antihypertensive

D. BP >140/90 mmHg with three or more antihypertensive

See Answer in Part B → Q97

@Neet_pg_bot

Q98: Which among the following investigations is the most suitable for diagnosing myocardial infarction (MI) within a timeframe of 2-4 hours of onset of chest pain? (Q856953)

A. LDH

B. CKMB

C. Troponin-T

D. BNP

See Answer in Part B → Q98

@Neet_pg_bot

Q99: Which of the following treatment options is not suitable for managing a patient with non-ST-elevation myocardial infarction (NSTEMI)? (Q856335)

A. Aspirin

B. Clopidogrel

C. Streptokinase

D. Prasugrel

See Answer in Part B → Q99

@Neet_pg_bot

Q100: A 65 year old male patient presented to the emergency room with symptoms of palpitation, dizziness. On examination pulse is 180 beats per minute and his blood pressure is 70 mmHg systolic. The electrocardiogram (ECG) reveals a narrow QRS complex tachycardia with a regular heart rate. What should be the next course of action in managing this patient? (Q856342)

A. DC cardioversion

B. Adenosine

C. Valsalva Maneuver

D. Verapamil

See Answer in Part B → Q100

@Neet_pg_bot

Q101: What would be the most appropriate approach for a patient experiencing chest pain for the past 3 hours, where an ECG shows ST depression in anterior chest leads and T wave inversion? (Q856351)

A. Intra aortic balloon pump(IABP)

B. Thrombolysis with alteplase

C. Prophylaxis for arrhythmia

D. Aspirin with heparin

See Answer in Part B → Q101

@Neet_pg_bot

Q102: A 45-year-old female patient presents to the clinic with complaints of increasing fatigue and shortness of breath. Upon auscultation, the physician detects a pan systolic murmur that is best heard at the right side of the heart. The murmur radiates to the axilla and is louder during inspiration. The patient denies any history of fever, chest pain, or recent infections. What is the most probable diagnosis for this patient's condition based on the described findings? (Q856358)

A. Aortic stenosis

B. Mitral valve prolapse

C. Ventricular septal defect

D. Tricuspid regurgitation

See Answer in Part B → Q102

@Neet_pg_bot

Q103: Correct sequence after p wave: A - ‘a’ wave B - 1 st heart sound C - Rapid filling of ventricles D - ‘t’ wave (Q856377)

A. ABCD

B. ABDC

C. CABD

D. ACBD

See Answer in Part B → Q103

@Neet_pg_bot

Q104: Water hammer pulse is seen in which of the following conditions? (Q855002)

A. Aortic stenosis

B. Aortic regurgitation

C. Aortic stenosis and aortic regurgitation

D. Mitral regurgitation

See Answer in Part B → Q104

@Neet_pg_bot

Q105: A 70-year-old man with a known history of DM and HTN on regular medications presents with a history of progressively worsening dyspnoea on exertion. On examination, there's elevated JVP, positive hepatojugular reflux, crackles at the lung bases, hepatomegaly, ascites and pedal oedema. What is your provisional diagnosis? (Q855008)

A. Heart failure

B. Hypertrophic cardiomyopathy

C. Mitral regurgitation

D. Portal hypertension

See Answer in Part B → Q105

@Neet_pg_bot

Q106: Which of the following is not a radiological finding in a patient with left heart failure? (Q855046)

A. Kerley B lines

B. Focal oligemia

C. Increased venous blood in lung

D. Change in upper lobe circulation

See Answer in Part B → Q106

@Neet_pg_bot

Q107: A 60-year-old man presented with an episode of acute onset dizziness and loss of consciousness, which lasted for a few seconds, followed by a regain of full consciousness. There were no similar episodes in the past. Which of the following is a true statement regarding this scenario? (Q855052)

A. ECG to rule out atrial fibrillation

B. If ECG is normal, CT scan should be done

C. Tilt-table testing

D. Vestibular neuritis is a possible condition that can cause these symptoms

See Answer in Part B → Q107

@Neet_pg_bot

Q108: A 58-year-old male patient has been diagnosed with hypertension. On examination, there is no existing cardiovascular disease, no hypertension-mediated organ damage (HMOD), and renal function is normal. He should be immediately started on pharmacological management if his blood pressure is more than (Q855064)

A. >130/80 mmHg

B. >160/100 mmHg

C. >150/100 mmHg

D. >140/90 mmHg

See Answer in Part B → Q108

@Neet_pg_bot

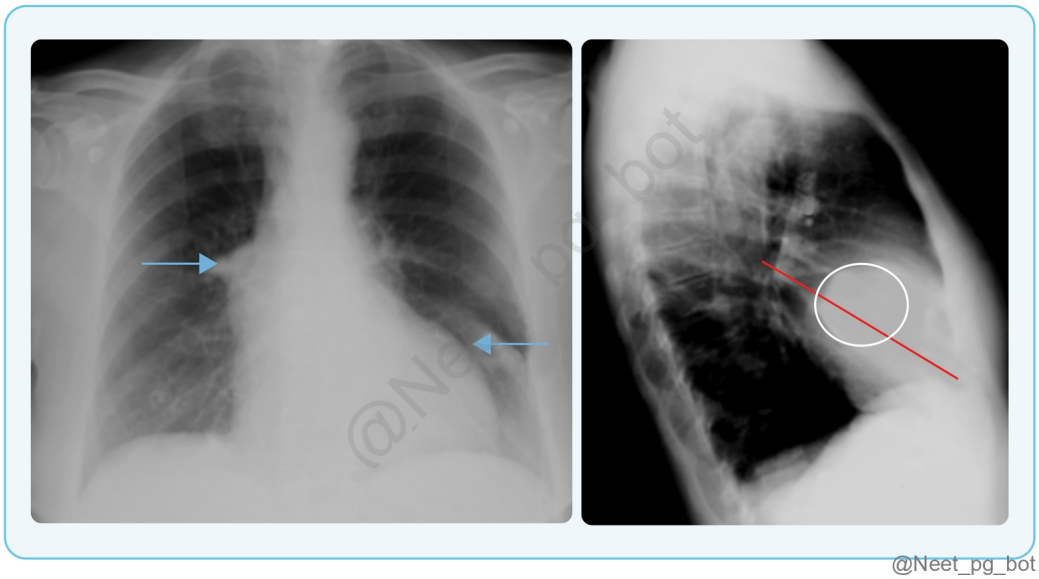
Q109: A 65-year-old male patient presented with chest pain, exertional dyspnea and syncope. He was diagnosed with a case of aortic stenosis and his chest x-ray was taken which is shown below. What is the most likely diagnosis? (Q859523)

A. Dilated aortic root

B. Widening of aortic knob

C. Widening of the vascular pedicle

D. Post stenotic dilatation of aorta



See Answer in Part B → Q109

@Neet_pg_bot

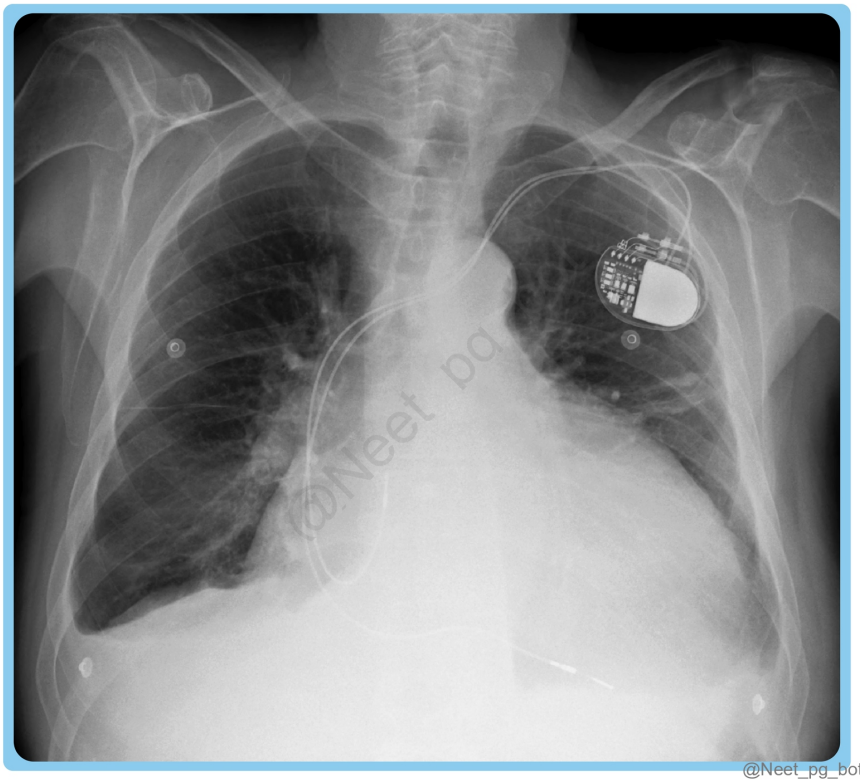
Q110: The device seen in the following image is? (Q859525)

A. Cardiac pacemaker

B. Chemo port device

C. Travel tract for accessory

D. Chest X-ray artefact



See Answer in Part B → Q110

@Neet_pg_bot

Q111: A 55-year-old male patient came to the hospital complaining of palpitations. During the examination, a diastolic murmur is detected in the left third intercostal space, along with the presence of a pistol shot sound over the femoral arteries. What is the diagnosis here? (Q859528)

A. Aortic regurgitation

B. Aortic stenosis

C. Tricuspid regurgitation

D. Mitral regurgitation

See Answer in Part B → Q111

@Neet_pg_bot

Q112: A person with dyspnea has a slight limitation in physical activity and doing ordinary activity causes symptoms but he is asymptomatic at rest. To which class does he belong, based on the New York Heart Association functional classification? (Q859529)

A. Class I

B. Class II

C. Class III

D. Class IV

See Answer in Part B → Q112

@Neet_pg_bot

Q113: A 56-year-old woman who had a heart attack 2 years ago is currently experiencing a cough and difficulty breathing while walking short distances. Physical examination revealed dullness upon percussion and reduced breath sounds on the right side. A chest x-ray indicated the presence of moderate pleural effusion. Thoracocentesis, guided by ultrasound, was performed and the laboratory results are provided below. Pleural fluid findings: Appearance: turbid pH: 7.1 Protein: 3.2 g/dL Lactate dehydrogenase: 80 U/L (normal serum LDH- 50-150 U/L) Pleural fluid protein/serum protein ratio: 0.34 Pleural fluid LDH /serum LDH: 0.3 Glucose: 54 mg/dL WBC count: 4000 cells/µL with >50% lymphocytes Adenosine deaminase: 30 U/L AFB smear microscopy: Negative Gram staining and microscopy: No organisms, no pus cells (Q859532)

A. Parapneumonic pleural effusion

B. Malignant pleural effusion

C. Congestive heart failure

D. Tubercular pleural effusion

See Answer in Part B → Q113

@Neet_pg_bot

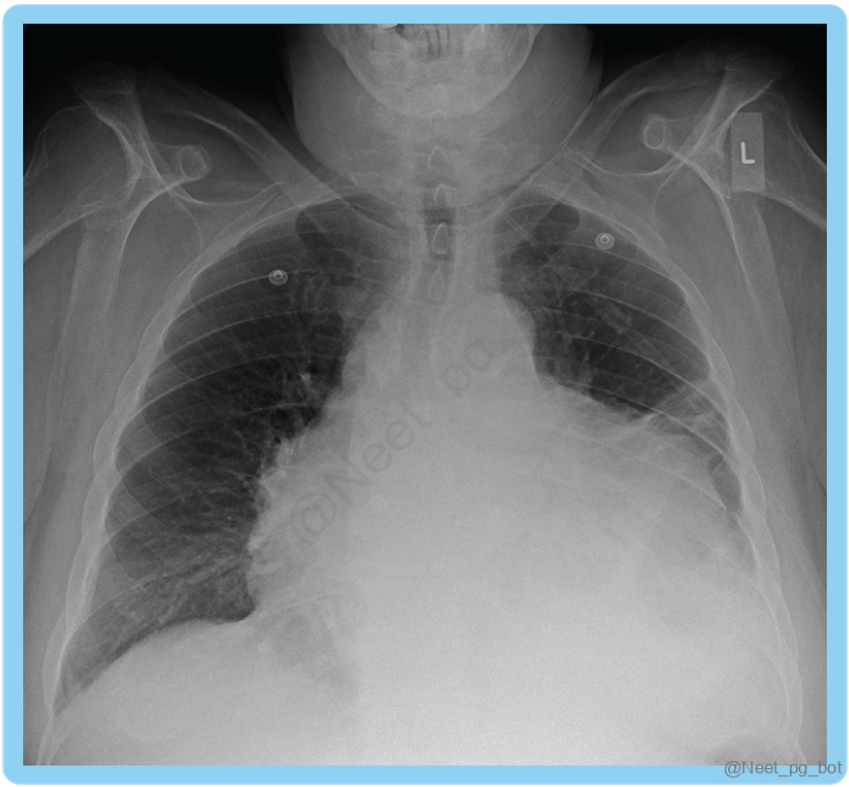
Q114: What is the most likely diagnosis for a 45-year-old man who experiences chest pain and difficulty breathing that worsens when lying down but improves when sitting upright, and has muffled heart sounds during examination? (Q859534)

A. Pericardial effusion

B. Tetralogy of Fallot

C. Transposition of great arteries

D. Pulmonary hypertension



See Answer in Part B → Q114

@Neet_pg_bot

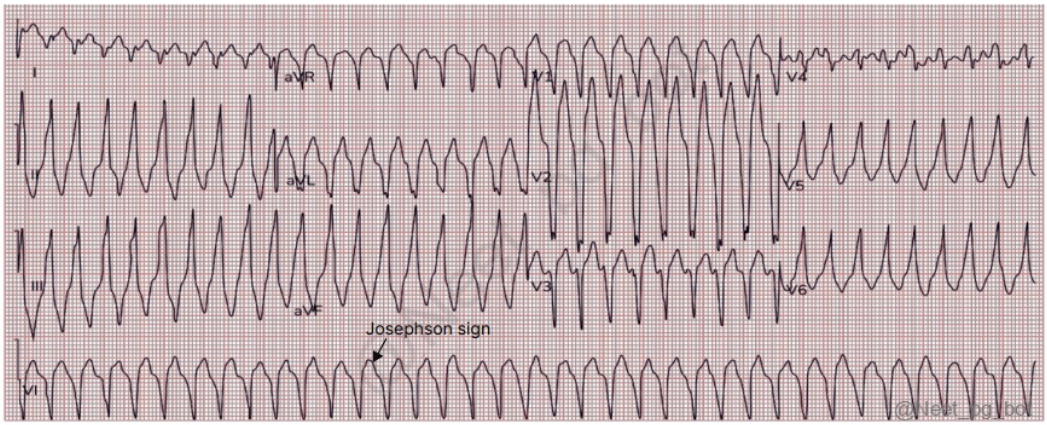
Q115: A 62-year-old man with a history of coronary artery disease presents with sudden onset palpitations, dizziness, and mild chest discomfort. His blood pressure is 90/60 mmHg and ECG is given below. What is the most likely diagnosis? (Q859535)

A. Atrial fibrillation

B. Atrial flutter

C. Ventricular tachycardia

D. Ventricular fibrillation



See Answer in Part B → Q115

@Neet_pg_bot

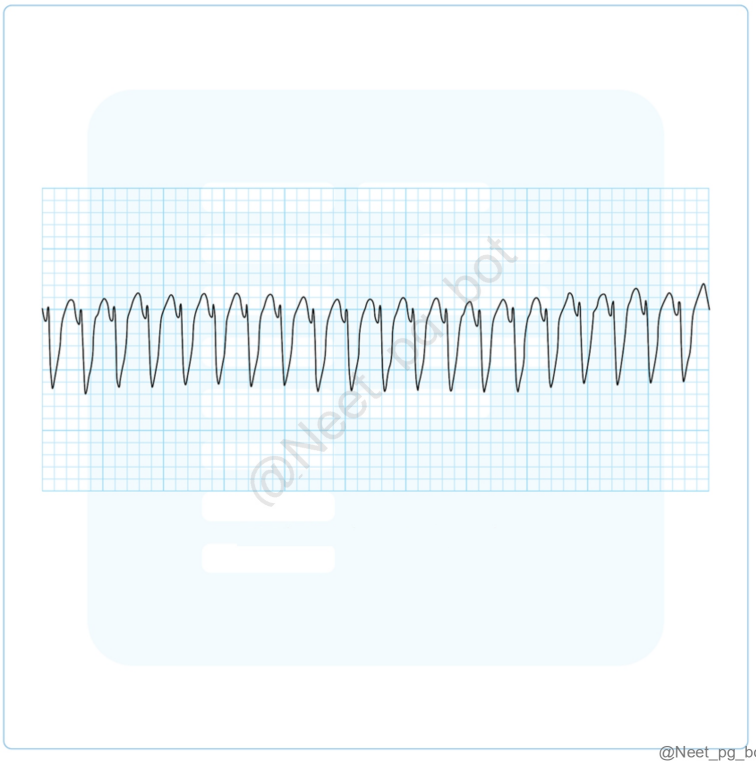
Q116: Based on the ECG given below, what is the most likely diagnosis? (Q859537)

A. Normal ECG

B. Ventricular fibrillation

C. Ventricular tachycardia

D. Misplaced leads



See Answer in Part B → Q116

@Neet_pg_bot

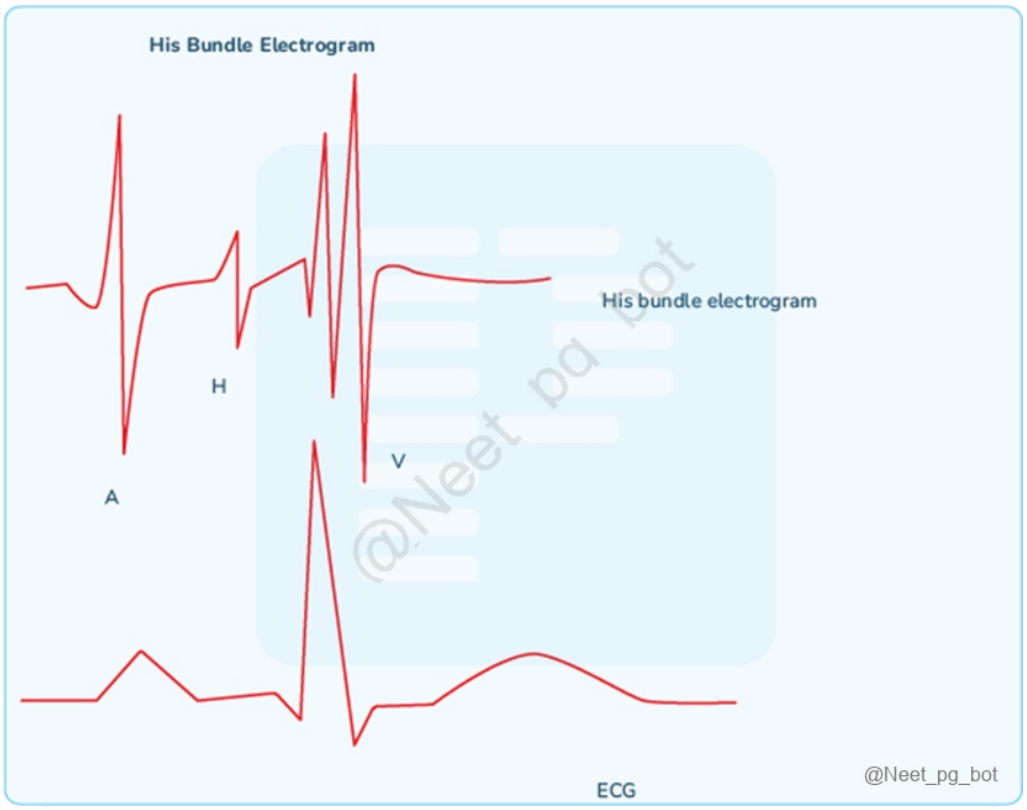
Q117: HV interval in the below given His bundle electrogram is for conduction: (Q859559)

A. Through the His-Purkinje system

B. From AV node to bundle of His

C. Purkinje to ventricular fibres

D. From a bundle of His and bundle branches to ventricles



See Answer in Part B → Q117

@Neet_pg_bot

Q118: A 50-year-old man presents with recurrent episodes of chest pain which is seen only on exertion or exercise and lasts 2-5 minutes. He was assessed and was diagnosed with a case of stable angina however his BP was consistently elevated. What is the most appropriate antihypertensive for this patient (Q859560)

A. Atenolol

B. Thiazides

C. Enalapril

D. Amlodipine

See Answer in Part B → Q118

@Neet_pg_bot

Q119: A postoperative cardiac surgery patient developed sudden hypotension, raised central venous pressure, and pulsus paradoxus at the 4 th postoperative hour. The most probable diagnosis is. (Q859565)

A. Ventricular dysfunction

B. Cardiac tamponade

C. CHF

D. Excessive mediastinal effusion

See Answer in Part B → Q119

@Neet_pg_bot

Q120: A male patient in his youth comes to the clinic complaining of a persistent high fever over the past 5 days. During the examination of his hands, painless lesions are observed, and a new regurgitant murmur is detected. The echocardiogram reveals the existence of a mass on the mitral valve. Based on these findings, which of the following abdominal findings would be expected in this case? (Q859791)

A. Ascites

B. Splenomegaly

C. Hepatomegaly

D. Portal hypertension

See Answer in Part B → Q120

@Neet_pg_bot

Q121: Which of the following leads to a continuous murmur? (Q859800)

A. Peripheral Pulmonic stenosis

B. Severe Pulmonary artery hypertension

C. Type A aortic dissection

D. Rupture of cardiac chamber

See Answer in Part B → Q121

@Neet_pg_bot

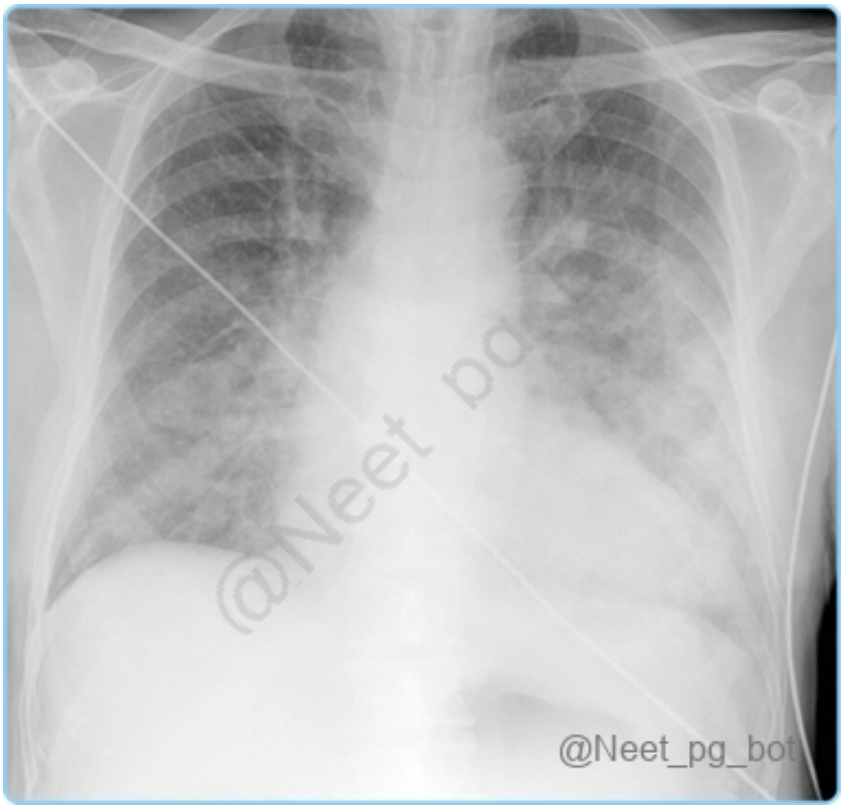
Q122: A hypertensive patient who is non-compliant with medication presents with sudden-onset breathlessness. A chest X-ray reveals findings consistent with pulmonary edema. How will you manage this patient? (Q855894)

A. Intravenous salbutamol

B. Intravenous nitroglycerin

C. Nebulization with salbutamol

D. Oxygen and antibiotics



See Answer in Part B → Q122

@Neet_pg_bot

Q123: A patient on antidepressants presents with hypotension. An ECG reveals wide QRS complexes and right axis deviation. How will you manage this patient? (Q855897)

A. Antiarrhythmics

B. Intravenous sodium bicarbonate

C. Propranolol

D. Phenytoin

See Answer in Part B → Q123

@Neet_pg_bot

Q124: A 25-year-old patient is undergoing tooth extraction for dental caries. Which of the following does not require prophylaxis against infective endocarditis? (Q855912)

A. Prior history of endocarditis

B. Atrial septal defect

C. Unrepaired cyanotic heart disease

D. Prosthetic heart valves

See Answer in Part B → Q124

@Neet_pg_bot

Q125: A patient presents to you with an irregularly irregular pulse of 120/minute and a pulse deficit of 20. Which of the following would be the jugular venous pressure (JVP) finding? (Q855932)

A. Absent p wave

B. Absent a wave

C. Cannon a wave

D. Raised JVP with normal waveform

See Answer in Part B → Q125

@Neet_pg_bot

Q126: An 11-year-old child with a history of streptococcal pharyngitis presents with fever and arthralgia. There is no past history of rheumatic heart disease or carditis. How often is 600,000 IU of benzathine penicillin recommended for prophylaxis of

rheumatic heart disease? (Q856007)

A. Immediately

B. Thrice weekly lifelong

C. Once in three weeks for 5 years or till the age of 18, whichever is longer

D. Once in three weeks for 10 years or till the age of 25, whichever is longer

See Answer in Part B → Q126

@Neet_pg_bot

Q127: A man on diuretics presents with weakness. An ECG shows flat T waves and prominent U waves. What is the most likely diagnosis? (Q856009)

A. Hypocalcemia

B. Hypomagnesemia

C. Hyperkalemia

D. Hypokalemia

See Answer in Part B → Q127

@Neet_pg_bot

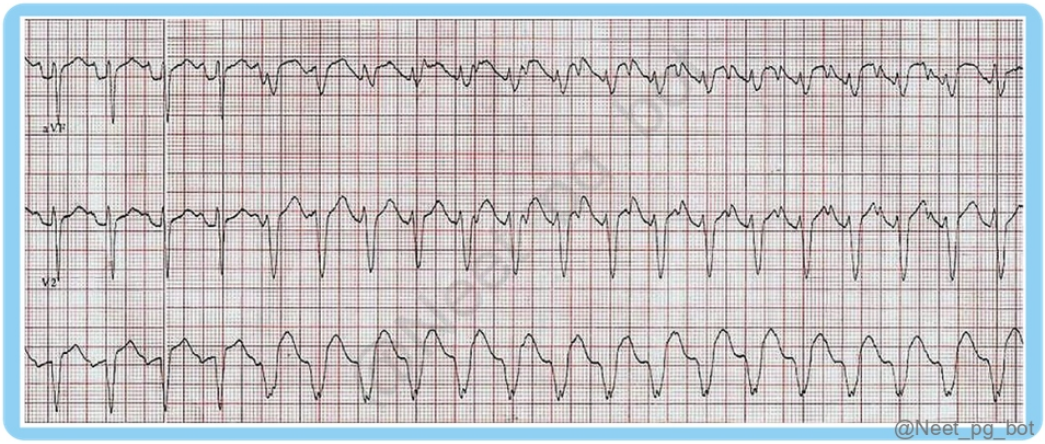
Q128: A patient with coronary artery disease presents to you with chest pain and palpitations. The ECG is shown below. Which of the following can be used in the management? (Q856017)

A. Oral metoprolol

B. Oral amiodarone

C. Intravenous amiodarone

D. Intravenous metoprolol



See Answer in Part B → Q128

@Neet_pg_bot

Q129: A 20-year-old female presents with septic shock, blood pressure 58/30 mmHg, and MAP 58 mmHg. She has received 30 mL/kg of crystalloid fluid, but her MAP remains <65 mmHg. What is the next best step in management? (Q865315)

A. Start dopamine

B. Start noradrenaline

C. Repeat crystalloid fluid

D. Start vasopressin

See Answer in Part B → Q129

@Neet_pg_bot

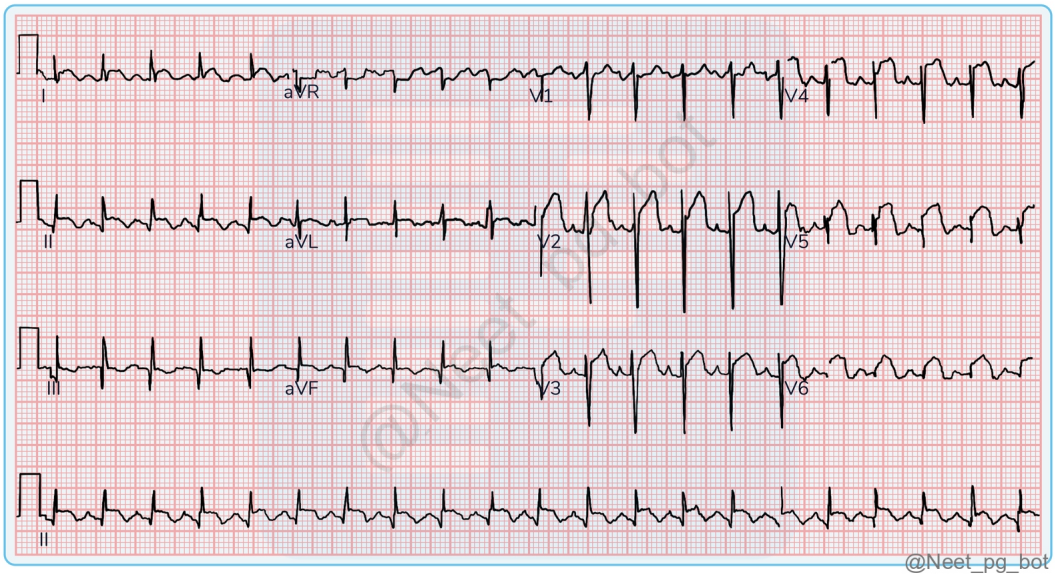
Q130: A patient presents to the ER with central chest pain. He has a past medical history of heart disease. ECG is shown below. What is the diagnosis? (Q866785)

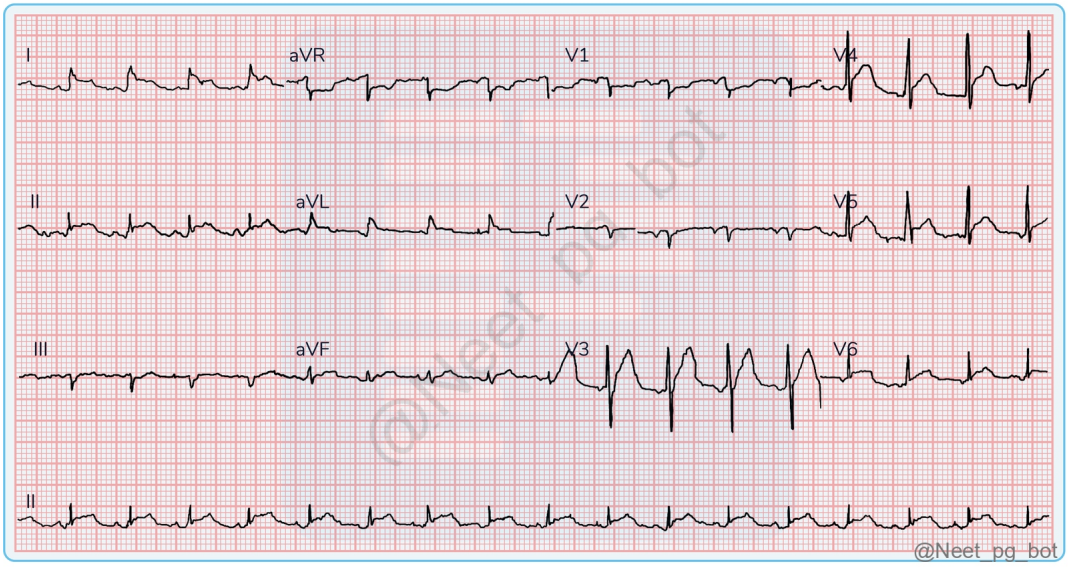
A. Anterolateral MI

B. Inferolateral MI

C. Acute pericarditis

D. Constrictive pericarditis





See Answer in Part B → Q130

@Neet_pg_bot

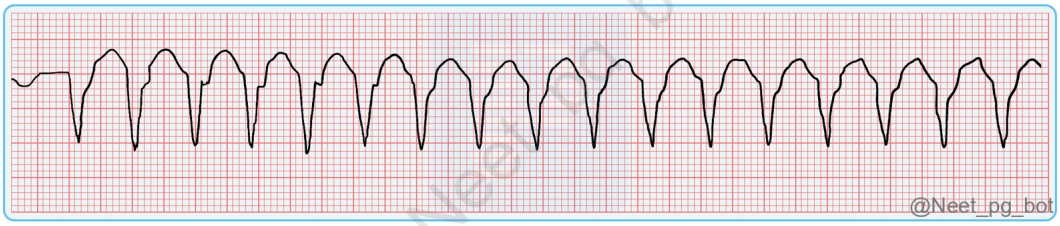
Q131: A patient after MI develops a broad QRS complex tachycardia. His BP is 120/85 mm Hg. ECG is given below. Best management? (Q866787)

A. Amiodarone iv

B. Labetalol iv

C. Metoprolol iv

D. Nitroglycerin iv



See Answer in Part B → Q131

@Neet_pg_bot

Q132: A man presents to the emergency department unconscious and hypotensive. His ECG reveals narrow complex tachycardia. What is the next best step in management? (Q840106)

A. Synchronized DC cardioversion

B. Carotid massage

C. IV adenosine 6 mg

D. IV amiodarone

See Answer in Part B → Q132

@Neet_pg_bot

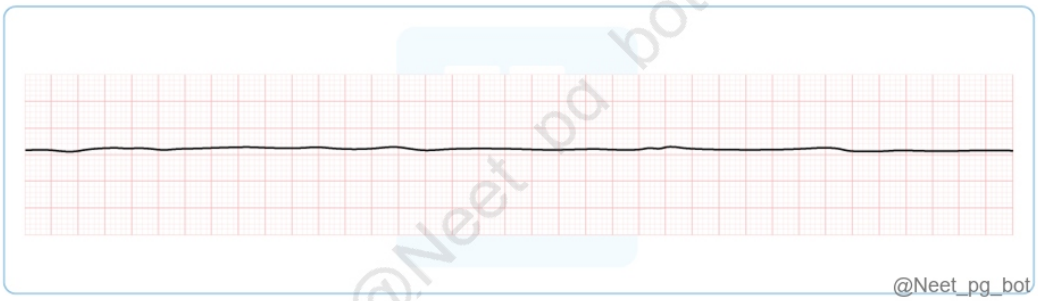
Q133: A 70-year-old man collapsed in his house and was rushed to the hospital. On arrival, his ECG tracing was as shown below. Which of the following is the best intervention for this patient? (Q859568)

A. Use of automated external defibrillator

B. Injection of vasopressin 40 IU

C. Injection of Adrenaline 1mg IV

D. Injection of Atropine 0.5mg IV



See Answer in Part B → Q133

@Neet_pg_bot

Q134: Which of these conditions will cause a large ‘P’ wave in ECG? (Q879158)

A. Mitral stenosis

B. Aortic stenosi

C. Aortic regurgitation

D. Tricuspid stenosis

See Answer in Part B → Q134

@Neet_pg_bot

Q135: Which of the following conditions does NOT share the same initial mechanism leading to heart failure as the others? (Q879211)

A. High salt intake

B. Anemia

C. Fever

D. Thyrotoxicosis

See Answer in Part B → Q135

@Neet_pg_bot

Q136: A 20-year-old athlete died during a practice session, and the attending doctor declared him dead on arrival and sent for an autopsy. The gross specimen of his heart is shown below. What is the plausible cause and advice to the family? (Q879215)

A. Cardiac arrest, check cholesterol in family members

B. Cardiac arrest due to hypertrophic cardiomyopathy, screen family members

C. Sudden cardiac death due to valvular pathology caused by rheumatic etiology

D. Cardiac arrest due to arrhythmias and heart blockwith no significant lesion on cardiac autopsy

See Answer in Part B → Q136

@Neet_pg_bot

Q137: A patient presents with exertional dyspnea and pedal oedema. His echocardiogram shows a dilated left ventricle with reduced systolic function. Which of the following statements regarding this condition is false? (Q879444)

A. Pulmonary hypertension may develop in this patient

B. Ejection fraction will be reduced in this condition

C. Long-term anticoagulation is not needed for this patient

D. Beta blockers are indicated in chronic management

See Answer in Part B → Q137

@Neet_pg_bot

Q138: Which of the following conditions is characterized by the absence of P waves? (Q793825)

A. Ventricular tachycardia

B. Focal atrial tachycardia

C. Ventricular fibrillation

D. Atrial fibrillation

See Answer in Part B → Q138

@Neet_pg_bot

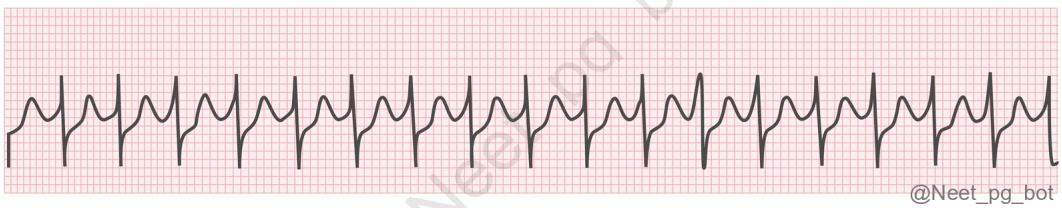
Q139: Interpret the ECG given below. (Q793832)

A. Ventricular fibrillation

B. Atrial fibrillation

C. Supra ventricular tachycardia

D. Ventricular tachycardia



See Answer in Part B → Q139

@Neet_pg_bot

Q140: J-wave is seen in? (Q793859)

A. Hypothermia

B. Heat stroke

C. High-altitude pulmonary edema

D. Drowning

See Answer in Part B → Q140

@Neet_pg_bot

Q141: A 26-year-old male patient, an accident victim started developing difficulty in breathing . On examination, his BP as 80/40 mmHg and pulses were feeble, JVP was found to be elevated with an absent Y descent, and heart sounds were muffled . What is the most likely diagnosis? (Q793863)

A. Constrictive pericarditis

B. Cardiac tamponade

C. Acute pericarditis

D. Cardiac failure

See Answer in Part B → Q141

@Neet_pg_bot

Q142: A known hypertensive patient is brought to the ER with palpitations and breathlessness. On examination, his BP was 220/140 with signs of encephalopathy. All of the following can be used to treat this condition except? (Q793876)

A. IV Nicardipine

B. IV Mannitol

C. IV Esmolol

D. IV Sodium Nitroprusside

See Answer in Part B → Q142

@Neet_pg_bot

Q143: A patient with chronic stable angina is having signs of heart failure. The use of which of the following drugs can decrease mortality? (Q793889)

A. Nifedipine

B. Digoxin

C. Lisinopril

D. Torsemide

See Answer in Part B → Q143

@Neet_pg_bot

Q144: A person collapses following a road traffic accident, and you begin performing CPR. The rescue team arrives with an automated external defibrillator (AED). Which of the following is the most appropriate next step? (Q793901)

A. Continue 5 rounds of CPR @ 30:2 followed by application of AED

B. Continue CPR while the team applies the AED paddles

C. Stop CPR and let them apply paddles

D. Handover the patient and leave

See Answer in Part B → Q144

@Neet_pg_bot

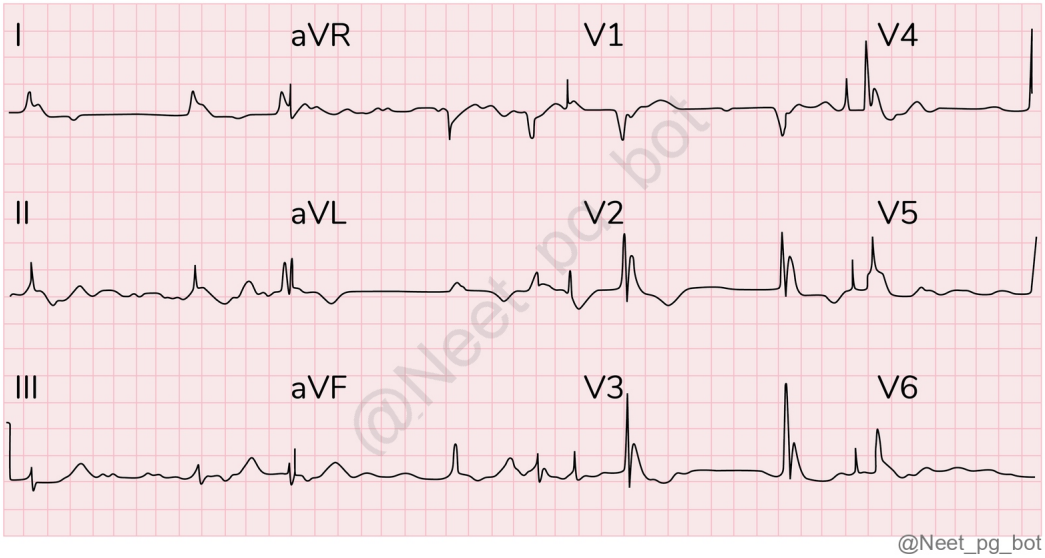
Q145: What is the probable diagnosis based on the ECG given below? (Q793909)

A. Hypokalemia

B. Hyperkalemia

C. Hypothermia

D. Hypocalcemia



See Answer in Part B → Q145

@Neet_pg_bot

Q146: A 19-year-old woman with no comorbidities presented with numbness and paraesthesia of the fingers along with the characteristic finding shown in the image below. She has no other illnesses, and she says these episodes occur when she is under excess stress or during cold temperatures . What is the most likely diagnosis ? (Q793945)

A. Primary Raynaud’s phenomenon

B. Secondary Raynaud’s phenomenon

C. Cold sores

D. Scleredema

See Answer in Part B → Q146

@Neet_pg_bot

Q147: Identify the false statement regarding management of NSTEMI (Q793962)

A. Aspirin loading dose should be initated immediately

B. ACC/AHA guidelines call for either a P2Y12 inhibitor (clopidogrel, prasugrel or ticagrelor) as a class I recommendation

C. Glycoprotein IIB/IIIA inhibitors are useful adjuncts

D. Fibrinolytic therapy is useful in acute coronary syndrome without ST-segment elevation

See Answer in Part B → Q147

@Neet_pg_bot

Q148: A 16-year-old female presents with recent episodes of palpitations and shortness of breath. On examination, she has a systolic murmur at the cardiac apex.

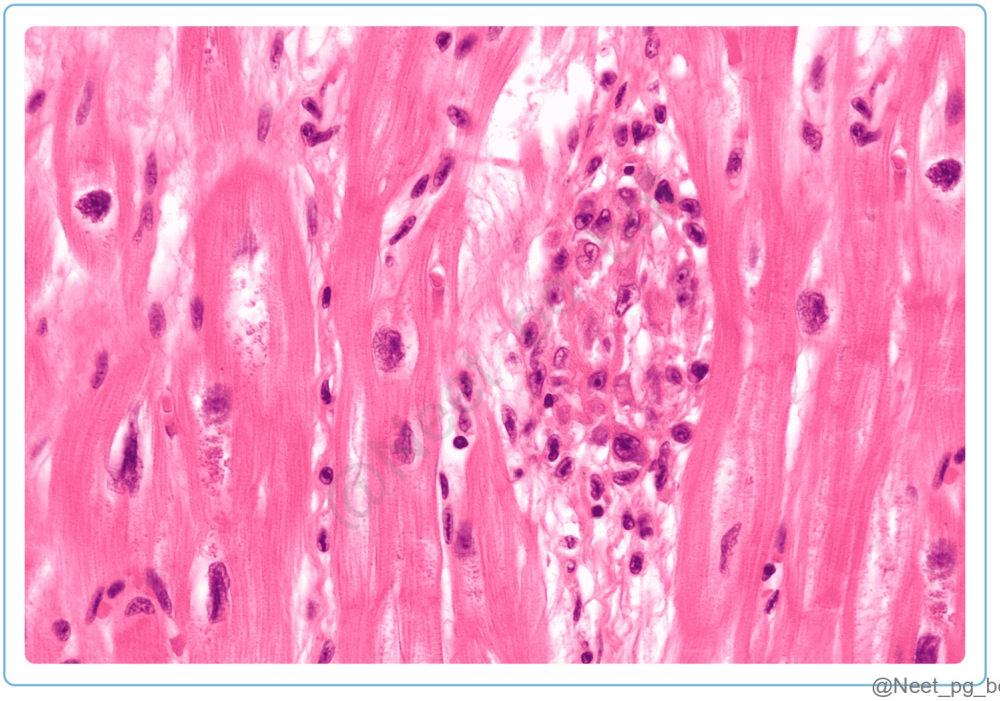
Laboratory evaluation shows elevated anti-streptolysin O titers and erythrocyte sedimentation rate. An echocardiogram reveals moderate regurgitation in the mitral valve. A biopsy of her heart tissue is performed, and a pathology image is provided below. Which of the following statements about this pathology is not true? (Q828964)

A. Present in myocardium and endocardium only

B. Fibrinoid necrosis in the center

C. Uncommon in chronic stages

D. Anitschkow cells



See Answer in Part B → Q148

Q13 (p. 201)

Q1: You are walking in a park when you notice an elderly person collapse in front of you. Which of the following is the first step in managment of this patient? (Q850935)

A. Initiate chest compressions

B. Check for scene safety

C. Call for help

D. Check carotid pulse

See Answer in Part B → Q1

@Neet_pg_bot

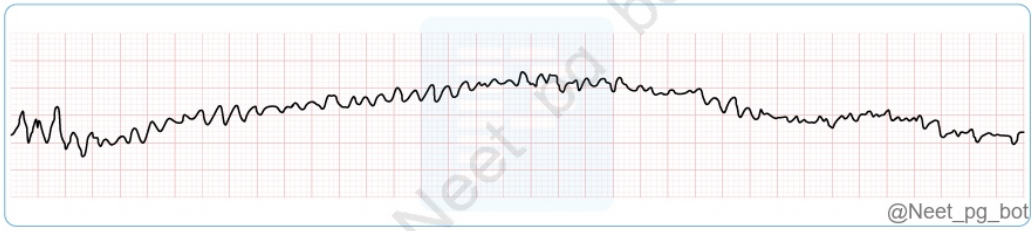
Q2: You are intern posted in ICU. Nurse calls you to assist for a sepsis patient whose ECG monitor is showing the following display and she has started chest compressions. Which of the following is the first step in managment of this patient? (Q850936)

A. Intubate the patient

B. Defibrillation

C. Cardioversion

D. Amiodarone



See Answer in Part B → Q2

@Neet_pg_bot

Q3: 65 year old patient with anterior wall MI develops asystole. Which of the following is the first step in management of this patient? (Q850937)

A. Asses for reversible causes

B. Check pulse

C. Chest compressions @30:2

D. 10 ml of 1:10,000 Epinephrine

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Assertion: Cardioversion is the preferred treatment for hemodynamic compromise caused by supraventricular tachycardia Reason: Synchronized direct current (DC) shock is administered at the peak of the R wave to avoid R on T phenomenon (Q850938)

A. Both assertion and reason are true, and the reason is a correct explanation of the assertion.

B. Both assertion and reason are true, but the reason is not a correct explanation of the assertion.

C. The assertion is true, but the reason is false.

D. The assertion is false, but the reason is true.

See Answer in Part B → Q4

@Neet_pg_bot

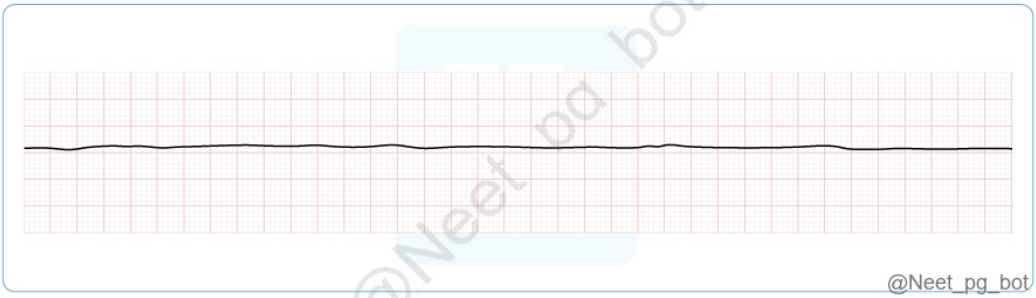
Q5: You are resuscitating a patient with following ECG tracing in ER. CPR is given @30:2 and 10 ml of 1: 10,000 adrenaline is given twice at interval of 3 minutes but the tracing is still the same. What is next best step in management of this patient? (Q850939)

A. Repeat 10 ml of 1: 10,000 adrenaline iv

B. Repeat 1 ml of 1: 10,000 adrenaline iv

C. Give DC shock 200J biphasic

D. Give DC shock 360J monophasic



See Answer in Part B → Q5

@Neet_pg_bot

Q6: Blood pressure of a 65-year-old male in the ICU crashes. ECG tracing shows Ventricular fibrillation. 200 J biphasic shock is given to patient. Which of the following is next best step for management of this patient? (Q850940)

A. Amiodarone

B. Start CPR

C. Secure advanced airway

D. Epinephrine

See Answer in Part B → Q6

@Neet_pg_bot

Q7: An alcoholic is admitted with diagnosis acute pancreatitis. On day 2 evening, he is shifted to ICU for Ventilator assistance for ARDS. Which of the following statements is not correct regarding the management of this patient? (Q850941)

A. Set tidal volume of 12 mL/kg lean body weight

B. Prone positioning

C. Set FiO2 at 1.0 and then titrate down to maintain pO2 55- 80 mm Hg

D. Adjust Respiratory rate to keep pH > 7.3

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 58-year-old male patient with chronic obstructive pulmonary disease (COPD) is admitted to the hospital and placed on mechanical ventilation. His arterial blood gas analysis shows the following values: PaO2: 86 mmHg, PaCO2: 50 mmHg and pH: 7.32. Which of the following management strategies should be prioritized for this patient? (Q850942)

A. Decrease the tidal volume to improve ventilation.

B. Increase the FiO2 immediately to avoid oxygen toxicity.

C. Increase PEEP to improve oxygenation and maintain lung recruitment.

D. Increase the expiratory time to promote CO2 washout

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 35-year-old male with Guillain-Barré Syndrome develops progressive respiratory muscle weakness and is placed on mechanical ventilation. Which of the following ventilator modes is most appropriate in this setting? (Q850943)

A. Pressure Support Ventilation

B. Synchronized Intermittent Mandatory Ventilation

C. Assist-Control Mechanical Ventilation

D. Continuous Positive Airway Pressure

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 60-year-old male is on mechanical ventilation for acute hypoxemic respiratory failure (Type 1). His latest ABG shows: pH: 7.43, PaCO■: 38 mmHg, PaO■: 54 mmHg, HCO■■: 24 mEq/L. Which of the following changes should be made to improve his oxygenation? (Q850944)

A. Increase tidal volume

B. Increase FiO■

C. Decrease respiratory rate

D. Increase minute ventilation

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 28-year-old male is admitted to the ICU after sustaining blunt chest trauma in a motor vehicle accident. Chest imaging reveals pulmonary contusions. After 48 hours, he develops severe hypoxemia with PaO■/FiO■ ratio of 110, bilateral infiltrates on chest X-ray, and no signs of left heart failure. What is the most appropriate next step in management? (Q850945)

A. Insert a wide-bore needle in the fifth intercostal space

B. Start intravenous furosemide to reduce pulmonary edema

C. Begin low tidal volume mechanical ventilation

D. Initiate high-flow nasal cannula oxygen therapy

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old male presents with acute shortness of breath, orthopnea, and bilateral pulmonary crackles. Work up shows elevated Pro-NT- BNP levels and ABG shows type 1 respiratory failure with pO2=60 mm Hg. Which of the following is best to improve his oxygenation status? (Q850946)

A. High-flow nasal cannula

B. Urgent intubation

C. Non-rebreather mask

D. NIV using Bi-PAP

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 68-year-old male with a history of COPD presents with increasing dyspnea, productive cough, and confusion. Arterial blood gas (ABG) shows pH 7.30, pCO■ 58 mmHg, and pO■ 55 mmHg. He is hemodynamically stable. What is the next best step in management? (Q850947)

A. Immediate endotracheal intubation

B. Noninvasive positive-pressure ventilation

C. Intravenous antibiotics only

D. High-flow nasal cannula oxygen therapy

See Answer in Part B → Q13

@Neet_pg_bot

Q1: A 60-year-old man collapses at a shopping mall. Bystanders start CPR and activate EMS. On arrival, paramedics find the patient unresponsive, pulseless, and in ventricular fibrillation on the monitor. What is the next best step for his managment? (Q850671)

A. Begin chest compressions and administer 1 mg epinephrine immediately, then attempt defibrillation

B. Deliver one shock with a biphasic defibrillator followed by immediate chest compressions, then secure airway

C. Deliver three stacked shocks followed by pulse check and atropine administration

D. Perform synchronized cardioversion followed by amiodarone if rhythm persists

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 35-year-old male mountaineer plans a rapid ascent to an altitude of 4500 meters for a climbing expedition. He has a history of experiencing symptoms like fatigue, non-productive cough, and difficulty breathing during previous high-altitude trips. Based on the scenario, which of the following strategies should the mountaineer implement to effectively prevent symptoms, and what is the main treatment he should consider if symptoms develop? (Q850690)

A. Maintain an average altitude gain exceeding 300 m per day, and begin immediate treatment with acetazolamide

B. Ascend rapidly without acclimatization, and use supplemental oxygen if symptoms develop

C. Ascend slowly with a maximum altitude gain of 300 m per day, and prioritize descent of 1000 meters if symptoms occur

D. Use alcohol to relax during the ascent, and rely solely on portable hyperbaric chambers if symptoms arise

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 28-year-old male skier is found unresponsive in the snow with a core body temperature of 27°C (81°F). Which of the following is NOT a treatment approach for managing his hypothermia? (Q850682)

A. Administer warm intravenous fluids at 40-42°C

B. Utilize extracorporeal membrane oxygenation to provide rewarming and circulatory support

C. Use passive external rewarming by layering him with wet clothing

D. Perform active internal rewarming using warm saline lavage of body cavities

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 40-year-old male fisherman is rescued after being exposed to cold water for several hours. Upon examination, his core body temperature is 29°C (84°F). He shows signs of lethargy, dilated pupils, and a slow heart rate. Which of the following statements about his condition is false? (Q850680)

A. Mild hypothermia typically presents with symptoms like shivering and increased muscle tone.

B. In moderate hypothermia shivering generally stops as the body temperature approaches 30°C.

C. Severe hypothermia can lead to unresponsiveness and increased risk of cardiac dysrhythmias.

D. Osborn waves are typically absent in hypothermic patients with temperatures below 28°C.

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 30-year-old male hiker ascends rapidly from sea level to an altitude of 4500 meters over 24 hours. Two days after his arrival, he begins to experience increasing fatigue, a non-productive cough, and difficulty breathing during physical activity. His oxygen saturation is 60% on examination, and he exhibits tachypnea and cyanosis. Based on the scenario, which factors do not contribute to the patient's clinical features? (Q850677)

A. Low hypoxic ventilatory response (HVR)

B. Use of sleep medications during ascent

C. Recent heavy physical exertion prior to ascent

D. Extended acclimatization period before ascent

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 34-year-old woman, 36 weeks pregnant, is brought to the emergency department after collapsing at home. Upon arrival, she is unresponsive and in cardiac arrest. CPR is initiated immediately. The team begins advanced cardiac life support for pregnancy. Which of the following is the correct to optimize maternal and fetal outcomes? (Q850676)

A. Delay chest compressions to position the patient for cesarean section.

B. Perform left uterine displacement.

C. Administer 2 mg epinephrine IV every 5 minutes.

D. Delay defibrillation to avoid harm to the fetus.

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 58-year-old man suffers a witnessed cardiac arrest in the emergency room. After 3 cycles of CPR , iv epinephrine, 2 defibrillation shocks, he achieves return of spontaneous circulation (ROSC). He is now unresponsive, with a blood pressure of 88/50 mmHg and SpO■ of 92% on 10 L/min oxygen by face mask. Which of the following is the most appropriate next step in management? (Q850674)

A. Administer 1 mg epinephrine IV every 3–5 minutes and continue chest compressions

B. Perform immediate coronary angiography and stenting regardless of ECG findings

C. Optimize oxygenation and ventilation, and assess for need of vasopressors and targeted temperature management

D. Discontinue resuscitation efforts and observe, as ROSC has been achieved

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old man experiences a sudden cardiac arrest while jogging in a park. A bystander witnesses the collapse. According to the Adult OHCA Chain of Survival, what is the correct sequence of actions performed by the emergency responders in this scenario? (Q850673)

A. Early recognition and Prevention → Activation of Emergency Response → Defibrillation → High-Quality CPR → Recovery→ Post-Cardiac Arrest Care

B. Activation of Emergency Response → High-Quality CPR → Defibrillation → Advanced Resuscitation → Post-Cardiac Arrest Care → Recovery

C. High-Quality CPR → Activation of Emergency Response → Advanced Resuscitation → Defibrillation → Post-Cardiac Arrest Care → Recovery

D. High-Quality CPR → Activation of Emergency Response → Defibrillation → Advanced Resuscitation → Post-Cardiac Arrest Care → Recovery

See Answer in Part B → Q8

@Neet_pg_bot

Q9: 4-year-old child is found unresponsive at home. The parents initiate CPR, and the child is transported to the emergency department. Upon arrival, the medical team begins CPR and attaches a defibrillator. The rhythm check shows asystole. What is the next step in managing this child according to the Pediatric cardiac arrest Algorithm? (Q850672)

A. Deliver a shock immediately

B. Administer Amiodarone IV/IO

C. Administer Epinephrine and continue CPR

D. Administer Lidocaine IV/IO

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following statements about massive transfusion is not correct? (Q850645)

A. PRBC should be administered first to address hypoxia and acidosis in bleeding patient

B. 1:1:0.25 ratio of PRBC: FFP: SDP

C. Blood products should be warmed before infusion to prevent coaguloapthy

D. ABO grouping is not required for platelet transfusion

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 35-year-old farmer is brought to ER 2 hours after being bitten by a snake on his left ankle. He has severe swelling of the left leg, gingival bleeding, and incoagulable blood on the 20-minute whole blood clotting time test. You decide to administer ASV . Twenty minutes after starting the ASV infusion, the patient develops urticaria, cough, and abdominal pain. His blood pressure drops to 85/50 mmHg. Which of the following is the most appropriate next step in management? (Q850669)

A. Discontinue ASV infusion permanently

B. Continue ASV infusion and administer corticosteroids

C. Stop ASV infusion temporarily and treat with epinephrine

D. Administer heparin to counteract coagulopathy

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 28-year-old farmer is brought to the ER 30 minutes after being bitten by a snake on his right leg. He presents with severe pain and swelling at the bite site, and examination reveals two puncture wounds. His blood pressure is 90/60 mmHg and he has gingival bleeding. The 20-minute whole blood clotting time test shows that the blood is incoagulable. Which of the following is the most appropriate next step in management? (Q850666)

A. Administer crypoprecipitate

B. Administer 150-200 ml of polyvalent antivenom

C. Apply a tight tourniquet above the bite site

D. Administer heparin to manage coagulopathy

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 32-year-old farmer is brought to the emergency department after being bitten by a snake while working in his field in rural India. He presents with severe local pain, swelling, and gum bleeding. Within 2 hours, he develops diplopia, dysphagia, and progressive weakness in his limbs. Laboratory tests show prolonged prothrombin time and decreased fibrinogen levels. Which of the following snakes is most likely responsible for this envenomation? (Q850661)

A. Cobra

B. Russell's viper

C. Saw-scaled viper

D. Krait

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 60-year-old woman is admitted to the ICU with sepsis secondary to a urinary tract infection. After 48 hours, she develops acute hypoxemic respiratory failure. Her chest X-ray shows bilateral infiltrates, and her PaO2/FiO2 ratio is 180 mmHg on PEEP of 8 cm H2O. An echocardiogram shows normal cardiac function. Which of the following is the most appropriate next step in management? (Q850660)

A. Initiate high-frequency oscillatory ventilation

B. Start inhaled nitric oxide therapy

C. Begin low tidal volume ventilation with 6 mL/kg lean body weight

D. Administer high-dose corticosteroids

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 45-year-old man is admitted to the ICU with severe pneumonia. He develops worsening respiratory symptoms and bilateral infiltrates on chest X-ray within 5 days. Which of the following best describes the pathophysiological mechanism occurring in the alveoli during the early phase of this patient's condition? (Q850655)

A. Increased surfactant production

B. Thickening of the alveolar basement membrane

C. Accumulation of protein-rich edema fluid

D. Fibrosis of the alveolar walls

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 55 year-old male presents to the emergency department with fever, tachypnea, and altered mental status. BP is 100/60 mm Hg Laboratory results show: WBC: 14,000/μL Serum lactate: 1.8 mmol/L Creatinine: 1.8 mg/dL (baseline 0.9 mg/dL) Chest X-ray reveals a right lower lobe infiltrate. The patient requires 6 L/min of oxygen to maintain pO2 of 90 mm Hg. Which of the following is the most accurate diagnosis for this patient? (Q850652)

A. Systemic Inflammatory Response Syndrome

B. Sepsis

C. Acute Tubular necrosis

D. Septic shock

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 30-year-old trauma patient underwent massive transfusion protocol after a road traffic accident. Six hours later, he develops acute onset dyspnea, hypoxia, and bilateral pulmonary infiltrates on chest X-ray. He is afebrile, Pulse 100/min with BP 124/ 80 mm Hg. JVP is normal and pro NT BNP levels are normal. What is the most likely diagnosis? (Q850648)

A. Transfusion-associated circulatory overload

B. Transfusion-related acute lung injury

C. Mismatched blood transfusion

D. Laryngospasm due to citrate induced hypocalcemia

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 28-year-old male is brought to the trauma center following a motorcycle accident. He is unconscious BP 70/40 mmHg and shows signs of active bleeding. Massive transfusion protocol is initiated. After receiving 4 units of PRBCs rapidly, he develops muscle twitching. ABG shows metabolic alkalosis. ECG shows normal sinus rythm with QT prolongation. What is the most appropriate immediate next step in his management? (Q850646)

A. Administer intravenous calcium gluconate to correct citrate-induced hypocalcemia, which is causing neuromuscular irritability and QT prolongation.

B. Start platelet transfusion immediately to correct dilutional thrombocytopenia, as prolonged transfusion leads to bleeding due to thrombocytopenia.

C. Give sodium bicarbonate to treat the developing metabolic alkalosis resulting from massive transfusion.

D. Transfuse cryoprecipitate to correct fibrinogen deficiency and prevent DIC-like picture often seen after >10 units of PRBC.

See Answer in Part B → Q18

Q1: An RTA patient has received 4 packed RBC within a few hours. Which of the following will be seen? (Q866789)

A. Hypernatremia

B. Hyponatremia

C. Hypocalcemia

D. Hyperkalemia

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which is the best confirmatory method to ensure the central line is in the jugular vein? (Q866816)

A. Chest x-ray

B. Blood pH

C. Blood color

D. ETCO2

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Young male has sustained Femur shaft fracture after RTA and internal fixation was done. 2 days later he develops shortness of breath with confusion and petechial rash. Diagnosis is? (Q866513)

A. FES

B. ARDS

C. Pulmonary embolism

D. Pleural effusion

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is not part of the clinical criteria for anaphylaxis? Urticaria, lip/tongue edema Wheeze and respiratory distress Abdominal cramps and vomiting Hypertension (Q840144)

A. 1, 2, and 3

B. 1 and 2

C. 2 and 3

D. 4

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 65-year-old patient with type 2 diabetes mellitus experiences hypoglycemia and falls, resulting in incoherent speech. CT scan reveals a large acute subdural hematoma (SDH) >30 cc. What is the most appropriate immediate management? (Q860237)

A. Administer intravenous mannitol and observe

B. Start dual antiplatelet therapy (aspirin + clopidogrel)

C. Emergent surgical evacuation (craniotomy or burr hole)

D. Stabilize the patient and schedule routine neurosurgical consultation

See Answer in Part B → Q5

@Neet_pg_bot

Q6: What medication can be administered to a patient who experiences altered consciousness, sweating, rapid heartbeat, persistent erection, and increased saliva production, with a blood pressure reading of 150/90 mm Hg after visiting a temple with their grandmother? (Q854658)

A. ASV

B. Adrenaline

C. Steroid

D. Prazosin

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A patient was being treated in ICU for sepsis. The initial ABG shows pH= 6.9, pO 2 = 80 mm Hg. pCO 2 = 55 mmHg, HCO 3 = 10 meq/L. A repeat ABG after 2 hours shows pH=7.1, pCO 2 = 20 mmHg, pO 2 = 140 mm Hg, and HCO 3 = 10 meq/L. Which is most plausible to explain the change seen in the ABG report? (Q854662)

A. Excessive air and less heparin in the ABG sample

B. Excess air and more heparin in the ABG sample

C. Less air and more heparin in the ABG sample

D. Less air and less heparin in the ABG sample

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements regarding the management of frostbite is incorrect? (Q855609)

A. Amputation in severe cases

B. Rewarming is done

C. Antibiotics and analgesics not used

D. The area is dried and cleaned

See Answer in Part B → Q8

@Neet_pg_bot

Q9: During a scorching summer afternoon, a man, who had been toiling in a field, unexpectedly collapsed. Upon examination, there were no apparent physical indications of dehydration, although his radial pulse was detectable. The doctor determined that the man's serum electrolyte levels were within the normal range. Shockingly, the man's body temperature measured 106 degrees Fahrenheit. Considering these circumstances, which of the following should be administered as an initial form of immediate assistance? (Q857001)

A. Inject epinephrine immediately

B. Cover with hot damp sheets

C. Cover with cool damp sheets

D. Start CPR

See Answer in Part B → Q9

@Neet_pg_bot

Q10: According to the ABCD2 scoring, which factors indicate a greater likelihood of a patient with TIA experiencing a future stroke? (Q856931)

A. Age <60 years

B. SBP>140 mm Hg and DBP <90 mmHg

C. Duration of TIA >5 mins

D. Diabetes

See Answer in Part B → Q10

@Neet_pg_bot

Q11: The recommended temperature of a water bath for a patient with frostbite is (Q858462)

A. 37 degree C

B. 42 degree C

C. 32 degree C

D. 30 degree C

See Answer in Part B → Q11

@Neet_pg_bot

Q12: All of the following is used in the management of breathless patients at a high altitude of 3000 mts except. (Q858463)

A. Intravenous digoxin

B. Oxygen supplementation

C. Immediate descent

D. Acetazolamide

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 47-year-old woman was brought to the casualty in an unconscious state after having suddenly collapsed. As there was no pulse, cardiopulmonary resuscitation was started and the monitor showed the following rhythm. What is the next step? (Q859792)

A. Defibrillation

B. Synchronized cardioversion

C. 1mg epinephrine

D. 0.5mg atropine

See Answer in Part B → Q13

Q1: You are a doctor in armed forces and are tasked with doing medical examination of new recruits. Your next candidate has a blood report that mentions a FBS of 116 mg/dl. Which of the following terms will you use to describe this blood report? (Q850583)

A. Impaired fasting glucose

B. Impaired glucose tolerance

C. Diabetes mellitus

D. Secondary diabetes

See Answer in Part B → Q1

@Neet_pg_bot

Q2: In type 1 DM, stage III of beta cell destruction presents as which of the following? (Q850609)

A. Autoimmune - , Symptomatic, Dysglycemia

B. ■■■■Autoimmune +, Symptomatic, Hyperglycemia

C. Autoimmune - , Asymptomatic, Normoglycemia

D. Autoimmune + , Asymptomatic, Normoglycemia

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following insulin preparations need to given once a week? (Q850608)

A. Icodec

B. Glargine

C. Degludec

D. Determir

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following dermatological diseases is most specific to a patient of diabetes mellitus with RBS of 220 mg/dl and RIA showing low fasting insulin levels? (Q850604)

A. Necrobiosis lipoidica diabeticorum

B. Acanthosis nigricans

C. Diabetic dermopathy

D. Intertriginous candidiasis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 17-year-old male with thalassemia major presents with fatigue, hyperpigmented skin, and recently diagnosed diabetes mellitus. He has been receiving regular blood transfusions since early childhood. On examination, he has discoloration of the skin shown below, mild hepatomegaly, and lab reports show elevated serum ferritin and fasting blood glucose of 180 mg/dL.Which of the following should not be done in the initial management of this patient? (Q850597)

A. Start basal bolus insulin

B. Start iron chelation therapy

C. Phlebotomy

D. Monitor for cardiac iron overload with MRI T2

@Neet_pg_bot

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following genetic factors is most strongly associated with an increased risk of developing Type 1 Diabetes Mellitus? (Q850595)

A. HLA-B27

B. HLA-DR3 DR4

C. HLA DR2

D. HLA DR 5

See Answer in Part B → Q6

@Neet_pg_bot

Q7: 25-year-old thin asymptomatic male is found to have fasting hyperglycemia during a routine checkup. His father and grandmother were diabetics.Genetic testing confirms a glucokinase mutation, consistent with MODY type 2. Which is correct management? (Q850593)

A. Start insulin

B. Start Metformin

C. Start semaglutide

D. No treatment required

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is most important intervention to reduce the progression of macrovascular complications of diabetes mellitus (Q850591)

A. Tight glycaemic control with HbA1c < 7%

B. Tight BP control and statins

C. Cessation of smoking

D. Limitation of sedentary activities

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is not a microvascular complication of diabetes mellitus? (Q850587)

A. Diabetic retinopathy

B. Diabetic neuropathy

C. Diabetic foot

D. Diabetic nephropathy

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is most important intervention for a newly diagnosed type 2 diabetes mellitus patient with HbA1c of 7%? (Q850586)

A. Hypocaloric diet

B. Carbohydrate counting

C. Light aerobic activity

D. Start cereals with low glycemic index

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 12-year-old girl presents with abdominal pain, vomitting and prostration for past one day. O/E: pulse:100/min, BP: 100/60 mm Hg and RR=20/min with a fruity-smelling breath. Work up shows plasma glucose level of 350 mg/dL and a positive urine ketone test. Which of the following is next step for managment of this patient? (Q850540)

A. Start regular insulin drip at 0.05–0.1 U/kg/hr

B. Give normal saline bolus

C. Perform ABG

D. Check serum electrolytes

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 50-year-old woman presents for a routine check-up. She has no family history of diabetes or hypertension. According to the American Diabetes Association (ADA) guidelines, what is the most appropriate screening recommendation for her? (Q850568)

A. No screening is necessary until age 60

B. Screen now and re-screen every 3 years if normal

C. Screen every year regardless of results

D. Screen only if symptoms of diabetes appear

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is best for monitoring of diabetes mellitus? (Q850566)

A. Continous glucose monitoring

B. HbA1c

C. Post prandial blood glucose

D. Self monitoring of blood glucose

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following tests is the most appropriate for short-term monitoring of glycemic control in a diabetic patient ? (Q850563)

A. HbA1c

B. Fructosamine

C. Fasting Blood Glucose

D. Oral Glucose Tolerance Test (OGTT)

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Glycosylated Hemoglobin is not reliable in diagnosis of which of the following types of diabetes mellitus? (Q850560)

A. Bronze diabetes

B. Type 1 Diabetes mellitus

C. Type 1.5 Diabetes mellitus

D. Type 2 Diabetes mellitus

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following values is not used for diagnosis of diabetes mellitus? (Q850556)

A. Random Blood sugar of 250 mg/dl with classic symptoms

B. Post prandial value of 200 mg/dl

C. Fasting blood sugar of 140 mg/dl in an asymptomatic patient

D. HbA1c value of 7.8% in asymptomatic patient

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following drugs is most likely to cause drug-induced diabetes by impairing insulin secretion from the pancreas? (Q850550)

A. Glucocorticoids

B. Thiazide diuretics

C. Phenytoin

D. β-lactam antibiotics

See Answer in Part B → Q17

@Neet_pg_bot

Q18: An 8-year-old boy is brought to ER with a 2-day history of vomiting, abdominal pain and prostration. On examination, he is drowsy, with sunken eyes, dry tongue, cold extremities, a thready pulse of 140/min, BP of 80/50 mmHg and RR =30/min. His RBS : 460 mg/dL, urine shows 4+ ketones and ABG shows pH= 7.2 , pC02 =20 mm Hg and HCO3 = 5 meq/L. What is the most appropriate next step in management? (Q850548)

A. Start IV insulin infusion at 0.1 U/kg/hr

B. Start normal saline with insulin drip

C. Give bolus of normal saline

D. Normal saline with insulin bolus followed insulin drip

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following statements about Type 1.5 Diabetes Mellitus is incorrect? (Q850545)

A. Characterized by autoimmune destruction of beta cells

B. Start basal bolus insulin if C- peptide > 0.8 ng/ml

C. It is often misdiagnosed as Type 2 DM

D. Avoid use of sulfonlyureas

See Answer in Part B → Q19

Q19 (p. 233)					

Q1: A 22-year-old female with newly diagnosed Type 1 Diabetes Mellitus is struggling to maintain postprandial glucose levels despite basal-bolus insulin therapy. Her endocrinologist decides to add an adjunctive medication approved for both type 1 and type 2 diabetes mellitus. Which of the following drugs fits this indication? (Q850634)

A. Empagliflozin

B. Linagliptin

C. Pramlintide

D. Semaglutide

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 65-year-old woman with poorly controlled diabetes mellitus presents to the emergency department with fever, facial pain, and a black necrotic eschar on her nasal turbinates. A CT scan shows sinus involvement and extension to the brain. What is the most appropriate initial management for this patient? (Q850781)

A. Fluconazole

B. Immediate surgical debridement and intravenous amphotericin B

C. Doxycyline and Azithromycin

D. Piperacillin Tazobactum

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55-year-old woman with a 10-year history of type 2 diabetes presents for a routine eye examination with compliants of visual loss. On examination, she is found to have microaneurysms, retinal haemorrhages, cotton wool spots and macular edema. What is the most effective management option for her symptomatic foveal oedema? (Q850780)

A. Pan-retinal laser photocoagulation

B. Intravitreal anti-VEGF injections

C. Corticosteroid injections

D. Routine observation and follow-up

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Best screening test for evaluation of diabetic nephropathy is (Q850779)

A. HbA1c

B. BUN: Creatinine ratio

C. Creatinine clearance

D. Urinary protein to creatinine ratio

See Answer in Part B → Q4

@Neet_pg_bot

Q5: All of the following are correct about diabetic neuropathy except? (Q850778)

A. Affects unmyelinated type C fibers

B. Third nerve palsy presents with pupillary involvement

C. Orthostatic hypotension occurs due to involvement of type B fibers

D. Clonidine is used for management of diabetic diarrhea

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is not correct about Type 2 diabetes mellitus? (Q850776)

A. Polygenic inheritance

B. Increased insulin levels

C. Beta cell exhaustion

D. Increased PPAR-γ activity

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is correct about mechanism of action of Acarbose? (Q850774)

A. Increases insulin secretion from pancreatic beta cells

B. Inhibits α-glucosidase in intestinal brush border

C. Increases glucose uptake in peripheral tissues

D. Enhances insulin sensitivity in peripheral tissues

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is not correct about complications seen in Diabetes mellitus? (Q850640)

A. Blindness incidence is increased by 25 times

B. Foot gangrene and amputation risk is increased by 100 times

C. Most common site of diabetic foot ulcer is heel

D. Diabetic nephropathy is leading cause of Chronic kidney disease

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is not correct about SGLT2i (Q850638)

A. Lowering of SBP

B. Used in HFreEF in non diabetic population

C. Cause afferent arteriolar dilatation

D. Increased risk of mycotic genital infections

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is the earliest renal abnormality in diabetic nephropathy? (Q850636)

A. Microalbuminuria

B. Nodular glomerulosclerosis

C. Increased glomerular filtration rate

D. Proteinuria (>300 mg/day)

See Answer in Part B → Q10

@Neet_pg_bot

Q11: 50-year-old man with T2DM presents with consistently elevated early morning blood glucose levels. His continous glucose monitoring does not show any noctural hypoglycemia. His current insulin regimen includes twice-daily intermediate-acting insulin. Which of the following is the most likely explanation for his fasting hyperglycaemia? (Q850615)

A. Excess dose of insulin given the day before

B. Increased insulin sensitivity between 4 am to 8 am

C. Inreased insulin resistance between 4 am to 8 am

D. Beta cell exhausation

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following drugs slows the progression of diabetic nephropathy and is an aldosterone antagonist? (Q850632)

A. Finrenone

B. Empagliflozin

C. Linagliptin

D. ACEi

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 52-year-old obese male with poorly controlled Type 2 Diabetes Mellitus is started on semaglutide. Which of the following statements is not true regarding this drug? (Q850629)

A. It acts via GLP-1 receptor agonism, enhancing glucose-dependent insulin secretion

B. It may cause abdominal pain and elevated serum amylase levels suggestive of pancreatitis

C. It can cause transient worsening of diabetic retinopathy, especially in patients with rapid glycemic improvement

D. It commonly causes fluid retention and weight gain due to PPAR-γ activation

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 50-year-old woman with Type 2 diabetes mellitus presents with extreme fatigue and thirst. She is non-compliant with her medications. Her blood pressure is 170/100 mmHg, and labs show: Random plasma glucose: 286 mg/dL HbA1c: 11.2% Urine glucose: +++ Serum creatinine: 2 mg/dL eGFR: 25 mL/min Serum potassium: 6.5 mEq/L Which of the following is NOT appropriate for managing this patient? (Q850628)

A. Monitor urine albumin creatinine ratio

B. Start Metformin with Sitagliptin

C. Start Amlodipine

D. Start Empagliflozin

See Answer in Part B → Q14

@Neet_pg_bot

Q15: You are educating a mother of 8-year-old girl with type 1 Diabetes Mellitus about insulin administration techniques. Which of the following statements is incorrect regarding insulin delivery? (Q850626)

A. The preferred site for subcutaneous insulin injection is the anterior abdominal wall.

B. Insulin pens should be held at a 90° angle to the skin for optimal delivery

C. Repeated insulin injections at the same site can cause lipohypertrophy

D. Repeat the insulin injection spot after 5-7 days

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 60-year-old diabetic patient collapsed in the bathroom in the morning and died. She was on metformin and glipizide for the last 10 years. Her latest HbA1c was 11%. What can be a possible cause of this event? (Q850623)

A. Autonomic neuropathy

B. Congestive chronic heart failure

C. Pericardial tamponade

D. Catastrophic CNS hemorrhage

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 55-year-old man with T2DM is brought to ER in unconcious state. Work up shows ABG pH=7.38, pCO2 40 mm Hg HCO3 = 26 meq/L, Sodium 140 meq/L , K =5.5 meq/L urine ketostix is negative, RBS : 150 mg/dl and serum lactate is normal. Which of the following is correct about next step in managment of this patient? (Q850621)

A. NCCT head

B. Normal saline followed by insulin drip

C. Administer 50% dextrose

D. Draw blood culture and start empirical antimicrobials

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following drug will worsen cardiovascular mortality in a diabetic patient who underwent a CABG? (Q850618)

A. Semaglutide

B. Empagliflozin

C. Rosiglitazone

D. Tirzepatide

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which form of insulin is used for basal delivery in basal bolus regimen? (Q850617)

A. Lispro

B. N.P.H

C. Glargine

D. Glulisine

See Answer in Part B → Q19

Q1: A 45-year-old man comes with recurrent episodes of loss of consciousness, tremors, excessive sweating, and confusion. A tumour of the pancreas is suspected, and the serum proinsulin level (on a 72-hour fasting test) is raised. Which of the following investigations would be most preferred? (Q850664)

A. Computed tomography

B. MRI

C. Manual Palpation and Intraoperative Ultrasound

D. Endoscopic Ultrasound (EUS)

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 48-year-old woman presents with a 6-month history of recurrent diarrhoea, weight loss, and intermittent abdominal pain. She also reports flushing and has recently developed diabetes without prior risk factors. Examination shows steatorrhea and a mild erythematous rash. Blood tests reveal elevated fasting plasma glucose. A pancreatic somatostatinoma is suspected.Which of the following investigations is NOT routinely used in the initial diagnosis of this condition? (Q850691)

A. Measurement of fasting somatostatin levels

B. CT/MRI imaging

C. Somatostatin receptor imaging

D. Biopsy with immunohistochemistry

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Assertion : In diabetic ketoacidosis (DKA), potassium levels can appear normal or even elevated initially despite a total body potassium deficiency. Reason : Potassium shifts from the intracellular to the extracellular space due to insulin deficiency and acidosis, temporarily raising serum potassium levels. (Q850688)

A. Both assertion and reason are correct, and the reason correctly explains the assertion.

B. Both assertion and reason are correct, but the reason does not correctly explain the assertion.

C. The assertion is correct, but the reason is incorrect.

D. The assertion is incorrect, but the reason is correct.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old male with type 1 diabetes presents with increased thirst, frequent urination, nausea, vomiting, and abdominal pain. On examination, he has dry mucous membranes, tachypnea, and a fruity odour to his breath. His blood pressure is 90/60 mmHg. Labs show blood glucose of 450 mg/dL, bicarbonate of 18 mEq/L, and pH of 7.28. Which of the following statements is FALSE? (Q850686)

A. Kussmaul breathing is deep, laboured, and rapid.

B. Fruity odour on the breath is caused by acetone.

C. Dehydration in DKA is associated with dry mucous membranes and poor capillary refill.

D. Fever is always present in DKA and indicates infection.

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 23-year-old male with Type 1 Diabetes Mellitus presents to the emergency department with nausea, vomiting, and abdominal pain. He reports that he has not taken his insulin for the past two days. On examination, he appears dehydrated, with deep and rapid breathing. Laboratory tests reveal high blood glucose, ketonemia, and metabolic acidosis. Which of the following statements about the pathophysiology of the patient's condition is TRUE? (Q850684)

A. Insulin deficiency leads to increased glucose utilization by the cells.

B. Elevated counterregulatory hormones increase glycogen synthesis, reducing blood glucose levels.

C. Lipolysis increases free fatty acids (FFA) in the liver, leading to ketogenesis.

D. Increased glucose utilization prevents hyperglycemia and osmotic diuresis.

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 35-year-old patient presents to the clinic with persistent diarrhoea, which has led to significant dehydration. After evaluation, it is determined that the diarrhoea is secretory. The patient has a history of diabetes, which is uncontrolled. Which of the following statements best describes the management and mechanisms associated with secretory diarrhoea in this patient? (Q850683)

A. Secretory diarrhoea primarily results from the malabsorption of nutrients

B. The main goal of management is reducing intestinal secretion

C. Antisecretory agents like Racecadotril and Crofelemer may help reduce fluid loss

D. Secretory diarrhoea shows a high osmotic gap that is not related to food intake

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following toxin-producing bacteria does a VIPoma mimic? (Q850679)

A. Shigella dysenteriae

B. Vibrio cholerae

C. Corynebacterium diphtheriae

D. Bordetella pertussis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Identify the true statement about the condition where the patient presents with high plasma somatostatin levels, steatorrhea, hypochlorhydria, and diabetes mellitus due to a tumour. (Q850675)

A. The tumour primarily occurs in the stomach

B. This is usually a small tumour that often goes unnoticed

C. This is rarely associated with MEN 1 syndrome

D. Metastasis is rare and is treated using chemotherapy for localized disease

See Answer in Part B → Q8

@Neet_pg_bot

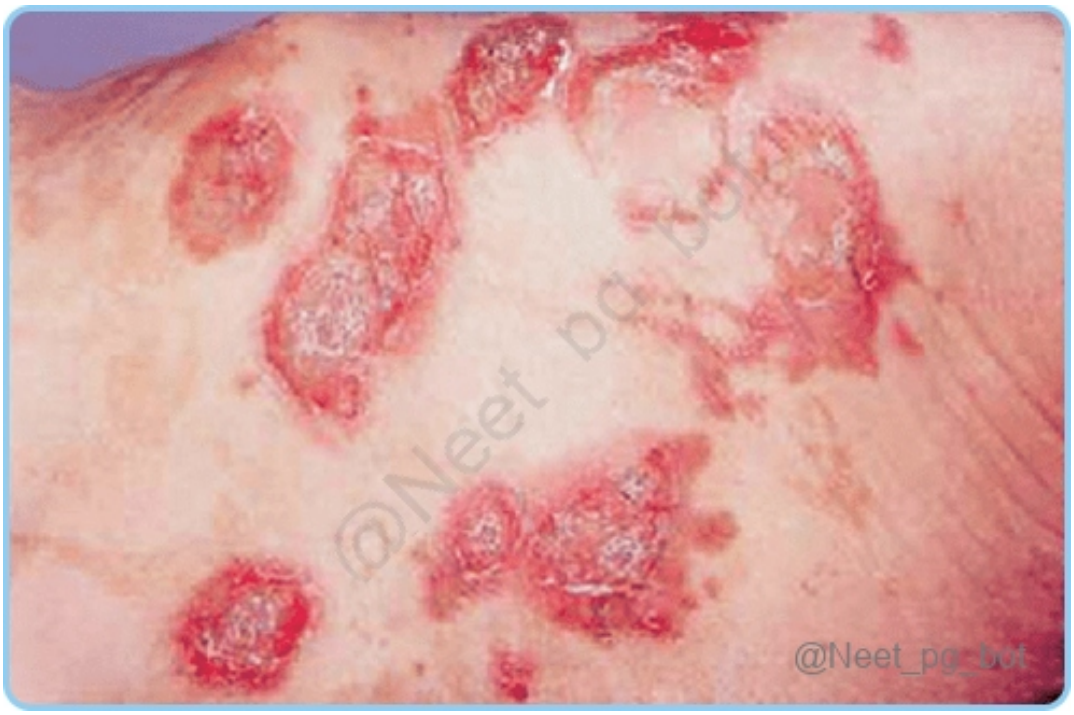
Q9: A 54-year-old female presents with significant weight loss and a characteristic rash as in the image. Blood tests reveal elevated plasma glucagon levels exceeding 1000 pg/mL. A CT scan shows a large mass in the tail of the pancreas. Which of the following statements regarding her condition is correct? (Q850667)

A. The mass is commonly found in the head of the pancreas

B. The initial treatment includes antibiotics and steroids

C. The rash seen is necrolytic migratory erythema

D. Surgical resection is the treatment option for this condition



See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 65-year-old female with type 2 diabetes on SGLT2 inhibitors is brought to the emergency department unconscious. Lab results show pH 7.2, $HCO3^{-}$ 15 mEq/L, RBS 210 mg/dl, and plasma beta-hydroxybutyrate 2.8 mmol/L with normal lactate. Urine analysis reveals the presence of ketones. What condition is most consistent with these findings? (Q850639)

A. Lactic Acidosis

B. Diabetic Ketoacidosis

C. Euglycemic Diabetic Ketoacidosis

D. Hyperglycemic Hyperosmolar State

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 40-year-old male comes to the clinic with recurrent episodes of hypoglycemia and loss of consciousness. On further evaluation, he is found to have a tumour on the pancreas. Which of the following is not a component of Whipple's triad to suspect insulinoma? (Q850662)

A. Symptoms of hypoglycemia

B. Low plasma glucose concentration

C. Subsequent improvement of symptoms with the use of glucose treatment

D. Elevated fasting insulin levels

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old woman with diabetes presents to the emergency department with confusion, fatigue, dizziness, palpitations, sweating, and tremors. Her blood glucose is 48 mg/dL. Which of the following is least likely to cause hypoglycemia in this patient? (Q850658)

A. Insulin

B. Sulfonylureas

C. Metformin

D. Meglitinides

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 55-year-old man presents with persistent abdominal pain and unintentional weight loss over the past 3 months. He reports no significant past medical history and denies any changes in bowel habits. A CT scan of the abdomen reveals a well-circumscribed mass in the pancreas. Laboratory tests show elevated serum glucose levels but normal levels of other pancreatic hormones. Which of the following is the most likely diagnosis for this patient? (Q850654)

A. Insulinoma

B. Gastrinoma

C. Non-functioning pancreatic NET

D. Glucagonoma

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 75-year-old man with poorly controlled type 2 diabetes presents to the emergency department with confusion and increased thirst over the past week. On examination, he has dry mucous membranes, a weak pulse, and a blood pressure of 85/50 mmHg. Laboratory tests show: (Plasma glucose: 1000 mg/dL, Serum osmolality: 360 mOsm/kg, Serum sodium: 130 mEq/L, Arterial blood gas: pH 7.38, bicarbonate 18 mEq/L). Which of the following is the most appropriate initial treatment for this patient? (Q850653)

A. Administer IV Ringer Lactate

B. Administer IV 0.9% normal saline

C. Start IV insulin bolus of 1 unit/kg with IV Potassium

D. Administer oral hypoglycemic agents

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 70-year-old woman with type 2 diabetes is admitted for confusion and severe dehydration. Her blood glucose is 900 mg/dL, and serum osmolality is elevated. Arterial blood gas reveals a normal pH and bicarbonate. Which of the following clinical signs would NOT be expected in this patient? (Q850650)

A. Hypotension

B. Tachycardia

C. Kussmaul breathing

D. Fever

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 28-year-old female with type 1 diabetes presents to the emergency department with increased thirst, frequent urination, nausea, abdominal pain, and signs of dehydration, including dry mucous membranes, tachycardia, and hypotension (BP: 98/60 mmHg). On examination, her vital signs include a heart rate of 110 bpm, respiratory rate of 22 breaths/min, and a blood pressure of 98/60 mmHg. Laboratory results show a blood glucose level of 350 mg/dL, serum bicarbonate of 18 mEq/L, and a pH of 7.30. What is the next step in management based on the ISPAD 2022 guidelines? (Q850647)

A. Start intravenous fluids and initiate insulin therapy

B. Administer subcutaneous insulin and monitor glucose

C. Provide oral hydration and adjust the diet accordingly

D. Ensure airway patency and consider nasogastric tube insertion

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 28-year-old male presents with tachycardia, hypotension, and drowsiness. He has a sweet smell of acetone on his breath. Laboratory results show a random blood sugar of 400 mg/dL, serum bicarbonate level of 12 mEq/L, arterial pH of 7.1, and serum β-hydroxybutyrate level of 6 mmol/L. What diagnosis is most consistent with this patient's condition? (Q850644)

A. Mild Diabetic Ketoacidosis

B. Moderate Diabetic Ketoacidosis

C. Severe Diabetic Ketoacidosis

D. Hyperglycemic Hyperosmolar State

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 40-year-old male with poorly controlled type 1 diabetes presents with vomiting and shortness of breath. He appears dehydrated and tachycardic, with a fruity odour on his breath. His lab results show elevated blood glucose and ketones. Which of the following is not a risk factor for his condition? (Q850642)

A. Infection

B. Pancreatitis

C. Hypothyroidism

D. Inadequate insulin administration

See Answer in Part B → Q18

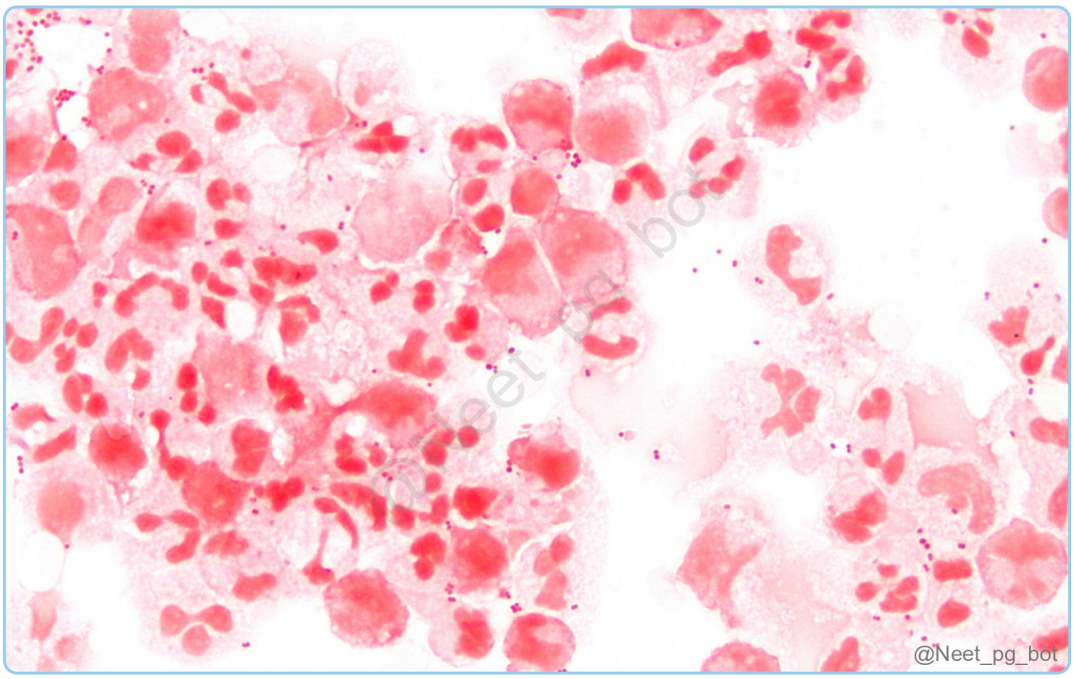
Q1: 16-year-old boy is brought to the ER due to fever, vomiting, and irritability for 2 days. Vitals are thready pulse 120/min, BP is 80/60 mm Hg with cold clammy extremities. General physical examination shows petechiae on extremities, CNS examination shows nuchal rigidity and kernig sign. CBC show TLC of 25000 cells/ cu.mm and platelet count of 15,000/cu.mm Gram stain of CSF is shown and rest of the lab report is awaited. Which of the following is not correct about managment of this patient? {{caption_text}} (Q850558)

A. Normal saline bolus

B. Hydrocortisone

C. Ceftriaxone and Vancomycin

D. Fludrocortisone



See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 30-year-old male presents to the clinic with complaints of hyperpigmented skin, lethargy, and abdominal pain occasionally. His vitals are blood pressure of 158/90mmHg, heart rate of 102/min, and a temperature of 98 ° F (37 ° C). Keeping in view the suspicion of primary hyperaldosteronism, which of the following set of metabolic findings correlates with this diagnosis? (Q876269)

A. Hyperkalaemia, hyponatremia, and normal renin

B. Hyponatremia only

C. Hypernatremia, hypokalaemia, and low renin

D. Hypercalcemia only

See Answer in Part B → Q2

@Neet_pg_bot

Q3: 40-year-old woman diagnosed with cushing syndrome presents with headaches and increased skin pigmentation over the past few months. She underwent a bilateral adrenalectomy six months ago. Which of the following is false about her condition? (Q850612)

A. Rapid expansion of pituitary tumor

B. Low ACTH level

C. Prevented by prophylactic radiation therapy before adrenalectomy

D. Occurs due to lack of negative feedback

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is first investigation to be performed in patient with ACTH dependant cushing syndrome? (Q850606)

A. MRI Pituitary

B. High dose dexamethasone suppression test

C. Low dose dexamethasone suppression test

D. Inferior petrosal sinus sampling

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is not a clinical feature of Cushing syndrome? (Q850600)

A. Hypokalemia

B. Increased susceptibility to infections

C. Menorrhagia

D. Wasting of gluteal musculature

See Answer in Part B → Q5

@Neet_pg_bot

Q6: 50-year-old man presents with severe cough for 3 months and hemoptysis episodes for past 3 days. Physical examination shows hypertension, purple abdominal wall striae, changes in hands as shown. Endobronchial lung biopsy is shown below. Which of the following is the most likely cause in this patient? (Q850594)

A. Carcinoid tumor

B. Oat cell cancer of lung

C. Squamous cell cancer of lung

D. Large cell cancer of lung

See Answer in Part B → Q6

@Neet_pg_bot

Q7: 35 year old bollywood actor develops flushing episodes, asthma like symptoms and frequent episodes of watery diarrhea . 24 hour urinary 5 HIAA levels are elevated. Which of the following drugs will be suitable for managment of GI complaints of this patient? (Q850588)

A. Loperamide

B. Telotristat ethyl

C. Somatostatin analogues

D. Racecadotril

See Answer in Part B → Q7

@Neet_pg_bot

Q8: 30 year old patient with pheochromocytoma is undergoing surgery for tumor resection. Which drug should be prepared by anaesthesiologist as a standy infusion and will not cause post operative hypotension? (Q850585)

A. Labetalol

B. Phenoxybenzamine

C. Nitroprusside

D. Phentolamine

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is the most sensitive and specific diagnostic test for detecting pheochromocytoma? (Q850581)

A. Plasma free metanephrine

B. Plasma-fractionated metanephrine

C. 24 hr urinary total metanephrine

D. 24 hr urinary catecholamines

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following drugs is used for managment of pre-operative hypertension in pheochromocytoma (Q850575)

A. Selective beta-blocker alone before surgery

B. Phenoxybenzamine + Phentolamine

C. Phenoxybenzamine + Propranolol

D. Propranolol and Phentolamine

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is imaging modality of choice for pheochromocytoma? (Q850567)

A. MRI abdomen

B. Gallium 68 dotatate PET/CT

C. MIBG scan

D. Somatostatin receptor Scinitgraphy

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old woman presents with persistent hypertension, weight gain, and muscle weakness. Lab results reveal elevated cortisol levels and suppressed ACTH. Which of the following is the next best investigation for work up of this patient? (Q850525)

A. High dose dexamethasone suppresion test

B. Low dose dexamethasone suppression test

C. CT abdomen

D. MRI pituitary

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements is incorrect regarding a patient with mineralocorticoid excess? (Q850552)

A. Excess aldosterone causes hypokalemic metabolic alkalosis

B. Serum sodium may remain normal despite total body sodium overload

C. Long-standing hypokalemia can lead to proximal muscle weakness

D. ACE inhibitors can falsely elevate aldosterone levels

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following is not correct about primary addison disease? (Q850546)

A. Increased Serum creatinine

B. Orthostatic hypotension

C. Skin color changes to pale alabaster

D. Hyperkalemia

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following is not a clinical feature of glucocorticoid deficiency (Q850543)

A. Hypoglycemia

B. Eosinopenia

C. Orthostatic hypotension

D. Hyponatremia

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which part of the nephron is affected in Gordon syndrome? (Q850541)

A. Distal convoluted tubule

B. Proximal nephron

C. Ascending limb of the loop of Henle

D. Descending limb of the loop of Henle

See Answer in Part B → Q16

@Neet_pg_bot

Q17: All of the following are clinical manifestations of Liddle’s syndrome except? (Q850537)

A. Hypokalemia

B. Hyporeninemia

C. Hypertension

D. Hyperaldosteronism

See Answer in Part B → Q17

@Neet_pg_bot

Q18: 45-year-old woman presents to the clinic with complaints of persistent high blood pressure despite medication and muscle weakness. On examination BP is

170/100 mmHg. Work up shows results pH= 7.46, serum potassium: 3.2 mEq/L, serum sodium: 142 mEq/L and increased aldosterone levels. CT abdomen shows adrenal mass size of 2cm. Which of the following test is used to confirm the diagnosis? (Q850535)

A. Plasma renin activity

B. Saline infusion test

C. ACTH stimulation test

D. Petrosal sinus sampling

See Answer in Part B → Q18

@Neet_pg_bot

Q19: 50-year-old hypertensive male presents with muscle weakness and frequent headaches. Work up shows hypokalemic metabolic alkalosis with low plasma aldosterone and low renin. Which of the following is the most likely diagnosis? (Q850531)

A. Liddle syndrome

B. Conn syndrome

C. Addison disease

D. Bilateral adrenal hyperplasia

See Answer in Part B → Q19

@Neet_pg_bot

Q20: 30 year old patient presents with hypertension and hypokalemic metabolic alkalosis. CT scan shows mass over the kidney of size 1.5 cm with elevated ARR. What is the next best step for management of this patient? (Q850528)

A. Spironolactone on life-long basis

B. Adrenalectomy

C. Adrenal venous sampling

D. Dexamethasone suppression test

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 35-year-old man presents with episodic headaches, palpitations, and excessive sweating. He is found to have labile hypertension and an adrenal mass on testing. Genetic testing confirms a ret proto-oncogene mutation, and ultrasound shows bilateral thyroid nodules. Which of the following is the major catecholamine produced by this tumor? (Q850527)

A. Epinephrine

B. Nor epinephrine

C. Dopamine

D. Metanephrine

See Answer in Part B → Q21

@Neet_pg_bot

Q1: An elderly woman is brought to the emergency department with altered behavior after a week of poor oral intake. She has a known history of hypothyroidism and has been irregular with her medications. On examination, she is bradycardic and hypotensive. Arterial blood gas analysis reveals respiratory acidosis, and serum sodium levels are low. Which of the following findings is least likely to be present in this patient? (Q884031)

A. Hypoglycemia

B. Hyperthermia

C. Rhabdomyolysis

D. Hypercapnia

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 64-year-old woman from an iodine-deficient region has had a slowly progressive multinodular thyroid enlargement for 18 years. She was asymptomatic and euthyroid until recently. She now presents with palpitations, weight loss, and tremors. Investigations show: TSH - Suppressed Free T4 - Normal T3 - Disproportionately elevated Thyroid scintigraphy - Heterogeneous uptake with multiple hot and cold areas FNAC from different nodules shows mixed polyclonal and

monoclonal populations Which of the following represents the most important pathophysiological change responsible for her current disease state? (Q884023)

A. Development of autoimmune TSH-receptor antibodies

B. Emergence of nodules with functional autonomy

C. Progressive iodine deficiency causing diffuse hyperplasia

D. Malignant transformation of polyclonal nodules

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 32-year-old woman presents with a painless thyroid nodule. Ultrasound shows a hypoechoic solid lesion with microcalcifications and irregular margins. FNAC reveals nuclear grooves and intranuclear cytoplasmic inclusions. Which thyroid malignancy is most likely to account for the majority of thyroid cancers worldwide? (Q884024)

A. Follicular carcinoma

B. Papillary carcinoma

C. Medullary thyroid carcinoma

D. Anaplastic carcinoma

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is/ are recognised risk factors for thyroid carcinoma in a patient presenting with a thyroid nodule? History of head and neck irradiation during childhood Male gender Slowly enlarging, mobile thyroid nodule in a middle-aged woman Hoarseness of voice or vocal cord paralysis PET-avid thyroid nodule on 18-FDG imaging (Q884025)

A. 1, 2, 4 and 5

B. 1 and 4 only

C. 1, 3 and 4

D. Only 1

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 19-year-old woman is evaluated for persistent biochemical thyrotoxicosis detected during routine screening. She has mild tachycardia but no weight loss, tremor, or ophthalmopathy. Her mother and maternal uncle are known to have "high thyroid hormone levels" but have never required treatment. Investigations show: Free T4 - High Free T3 - High TSH - Normal Which of the following best explains this patient's condition? (Q884026)

A. Activating mutation of the TSH receptor

B. Impaired feedback due to thyroid hormone receptor-β mutation

C. Autonomous hyperfunctioning thyroid nodules

D. TSH-secreting pituitary adenoma

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 27-year-old woman presents with weight loss, tremors and palpitations for 2 months. She has no neck pain or fever. Examination shows no goiter or thyroid tenderness. Laboratory evaluation shows: TSH - Suppressed Free T4 - Elevated ESR - Normal Thyroid radionuclide uptake - Very low Serum thyroglobulin - Normal Which of the following is the most likely diagnosis? (Q884027)

A. Subacute granulomatous thyroiditis

B. Graves' disease

C. Thyrotoxicosis factitia

D. Toxic multinodular goitre

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 38-year-old woman presents with weight gain, constipation, and cold intolerance. Laboratory evaluation shows low free T4 with elevated TSH. Which of the following conditions is least likely to produce this biochemical pattern? (Q884028)

A. Postpartum autoimmune thyroiditis

B. Lithium-induced thyroid dysfunction

C. Sheehan syndrome

D. Chronic autoimmune thyroiditis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 2-month-old infant presents with persistent constipation, poor feeding, prolonged jaundice and hypotonia. Examination reveals macroglossia and no palpable thyroid gland in the neck. Laboratory evaluation shows: TSH - markedly elevated Free T4 - very low Which of the following statements regarding this condition is true? (Q884029)

A. Most cases are caused by defects in thyroid hormone synthesis

B. High circulating T4 levels are required to normalize TSH in early life

C. The disorder is more common in males

D. Thyroid hormone replacement can be delayed until 1 year of age

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A patient with autoimmune thyroid disease is suspected to have autoimmune polyendocrine syndrome type 2 (APS-2). Which of the following pairs of additional diseases, when present together with autoimmune thyroid disease, would confirm the diagnosis of APS-2? (Q884030)

A. Hypoparathyroidism + Chronic mucocutaneous candidiasis

B. Addison's disease + Type 1 diabetes mellitus

C. Pernicious anemia + Vitiligo

D. Celiac disease + Sjögren syndrome

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 61-year-old woman from an iodine-deficient region presents with a gradually enlarging neck mass for 16 years. She is clinically euthyroid. On raising both arms above her head, she develops facial flushing and venous congestion. Her CT scan shows substernal extension with mild tracheal narrowing. Thyroid ultrasound reveals multiple nodules of varying size. Which of the following statements regarding her condition is correct? (Q884022)

A. Most nodules represent monoclonal neoplastic transformation

B. Sudden onset of neck pain most commonly indicates malignant change

C. Radioiodine can reduce goitre volume by nearly half and ablate autonomous nodules

D. Thyroxine suppression therapy is the preferred long-term treatment

See Answer in Part B → Q10

@Neet_pg_bot

Q11: An elderly woman is brought to the emergency department in winter with progressive drowsiness for 2 days. On examination, she is hypothermic, bradycardic, hypotensive, and has non-pitting facial puffiness. She is hypoventilating. Laboratory evaluation reveals hyponatremia, hypoglycemia, and hypercapnia. What is the most

likely diagnosis? (Q884032)

A. Septic shock

B. Cardiogenic shock

C. Myxedema coma

D. Acute adrenal crisis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 64-year-old man is admitted with severe community-acquired pneumonia requiring ICU care. He has no prior thyroid disease. Thyroid profile shows: Total T3 - Low Free T4 - Normal TSH - Normal Reverse T3 - Elevated What is the most appropriate interpretation of this thyroid profile? (Q884033)

A. Primary hypothyroidism

B. Secondary hypothyroidism

C. Sick euthyroid syndrome

D. Thyroid hormone resistance

See Answer in Part B → Q12

@Neet_pg_bot

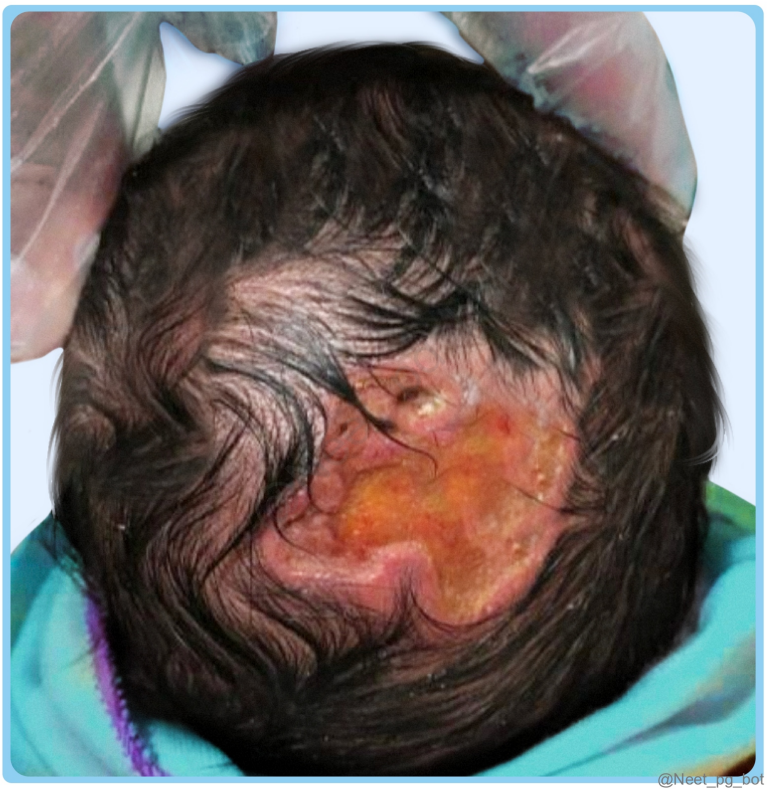
Q13: A neonate is born with a large scalp defect as shown. The mother had been treated for hyperthyroidism during early pregnancy. Which of the following drugs is most likely responsible for this congenital anomaly? (Q884034)

A. Propylthiouracil

B. Methimazole

C. Radioactive iodine

D. Levothyroxine



See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 32-year-old woman with Graves' disease has persistent hyperthyroidism despite 12 months of carbimazole therapy. She is a smoker and has mild exophthalmos. She is not pregnant and is not breastfeeding. She wishes to conceive in the future. Which of the following is the most appropriate next step? (Q884035)

A. Radioiodine therapy without any additional medication

B. Radioiodine therapy with concurrent oral prednisone

C. Radioiodine therapy after immediate conception

D. Total thyroidectomy without further evaluation

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 25-year-old primigravida at 9 weeks of gestation presents with palpitations, tremors and excessive sweating. Thyroid function tests confirm hyperthyroidism. Which is the most appropriate initial drug of choice? (Q884036)

A. Methimazole

B. Carbimazole

C. Propylthiouracil

D. Propranolol

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 42-year-old woman presents with a slowly progressive anterior neck swelling for 4 years. She has no palpitations, tremor, weight loss, or menstrual irregularities. Examination reveals a soft, symmetrically enlarged, non-tender thyroid gland with no palpable nodules. Thyroid function tests are normal. Which of the following best explains the pathogenesis of her condition? (Q884037)

A. Activating mutation of the TSH receptor

B. Chronic iodine deficiency causing diffuse follicular hyperplasia

C. Autoimmune destruction of thyroid follicles

D. Somatic mutations causing monoclonal nodular proliferation

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 29-year-old woman with no prior thyroid illness presents with intermittent tremors and heat intolerance for 10 days. She delivered her second child 5 months ago. There is no neck pain, fever, or sore throat. Examination shows a small, soft, non-tender thyroid gland. Investigations reveal: TSH - Suppressed Free T4 - Elevated ESR - Normal Anti-TPO antibodies - Positive 99mTc-pertechnetate uptake - Suppressed Which of the following best describes the expected course of this illness?

(Q884038)

A. Progression to permanent thyrotoxicosis requiring radioiodine

B. Spontaneous resolution after a transient hypothyroid phase

C. Requirement of prolonged glucocorticoid therapy

D. Lifelong antithyroid drug therapy due to high relapse rate

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 29-year-old woman with known primary hypothyroidism is 11 weeks pregnant and is on regular levothyroxine therapy. She is clinically well. Which of the following is the recommended upper limit of serum TSH that should be maintained in her at this gestational age? (Q884039)

A. < 1.5 mIU/L

B. < 2.5 mIU/L

C. < 3.0 mIU/L

D. < 4.0 mIU/L

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following is not a feature of hypothyroidism? (Q850927)

A. Pericardial efffusion

B. Pleural efffusion

C. Carpal tunnel syndrome

D. Diarrhea

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following is the most appropriate preoperative management to prevent thyroid storm in a pateint of grave's disease who is scheduled for total thyroidectomy? (Q850785)

A. Start propranolol 7 days before and perform surgery once heart rate normalizes

B. Start methimazole and wait till acheiving euthyroid status

C. Start methimazole, potassium iodide, propranolol and wait till achieving euthyroid status

D. Take consent for high risk emergency surgery with careful intraoperative monitoing

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 45-year-old woman with a history of multinodular goitre undergoes a CT angiogram with iodinated contrast for suspected pulmonary embolism. Two weeks later, she presents with palpitations, heat intolerance, and weight loss. Her thyroid function tests show suppressed TSH and elevated T3 and T4. Which of the following best explains this patient's current condition? (Q850786)

A. Wolff-Chaikoff effect

B. Jod-Basedow effect

C. Thyroid storm

D. Hashitoxicosis

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 52-year-old woman presents with a 2-week history of palpitations, anxiety, and weight loss. On examination, her heart rate is 110 bpm and regular, and she has a painful goitre. Thyroid function tests show decreased TSH level and elevated free T3

& T4 levels. A thyroid scan shows very low uptake. Which of the following is the most likely diagnosis? (Q850787)

A. Graves' disease

B. Toxic multinodular goiter

C. Subacute thyroiditis

D. TSH-secreting pituitary adenoma

See Answer in Part B → Q22

@Neet_pg_bot

Q23: 35-year-old woman presents with a history of weight loss, palpitations and heat intolerance. On examination, she has a diffuse goitre, ophthalmopathy and fine tremors in her outstretched hands. Her thyroid function tests show: TSH: < 0.01 mIU/L (normal range: 0.4-4.0 mIU/L) Free T4: 35 pmol/L (normal range: 10-20 pmol/L) Free T3: 12 pmol/L (normal range: 3.5-6.5 pmol/L) Which of the following is the most likely cause of her hyperthyroidism? (Q850790)

A. Toxic multinodular goiter

B. Graves' disease

C. TSH-secreting pituitary adenoma

D. Jod Basedow effect

See Answer in Part B → Q23

@Neet_pg_bot

Q24: 50 year old patient was diagnosed with atrial fibrillation. Diagnostic work up showed high T4, high T3 and high TSH. Which of the following is next best investigation for this patient? (Q850795)

A. MRI Head

B. USG neck

C. TSH receptor antibody titer

D. Radioactive thyroid scan

See Answer in Part B → Q24

@Neet_pg_bot

Q25: On the Thyroid function test, TSH is suppressed, Free T4 level is normal, and Free T3 is increased. Which of the following is the most likely diagnosis? (Q850796)

A. Subclinical hyperthyroidism

B. Euthyroid sick syndrome

C. Primary Hyperthyroidism

D. T3 thyrotoxicosis

See Answer in Part B → Q25

@Neet_pg_bot

Q26: RAIU scan was performed for a 35 year old lady with hypertension and palpitations. Diagnosis is? (Q850925)

A. Toxic multinodular goiter

B. Graves' disease

C. Thyroiditis

D. Thyroid adenoma

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 32-year-old woman presents with palpitations, weight loss, and heat intolerance for the past 3 months. On examination, she has a diffuse goitre and mild proptosis. Thyroid function tests show suppressed TSH and elevated free T4 and T3. Which of the following is the most appropriate next step in management? (Q850926)

A. Radioiodine ablation

B. Total thyroidectomy

C. Start propranolol and carbimazole

D. MRI Brain

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 45-year-old woman presents with palpitations, vomiting, diarrhea and marked agitation following an abrupt discontinuation of her antithyroid medication following a UTI. On examination, she is diaphoretic with proptosis and diffuse neck swelling with prominent jugular pulsations . Vitals are pulse: 120/min, BP 160/100 mm Hg, RR 24/min Temp: 39 C. Which of the following is best drug for managment of this patient? (Q850784)

A. Saturated solution of potassium iodide

B. Propylthiouracil

C. Liothyronine

D. Propranolol

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Which of the following is correct description of myxedema seen in patients with hypothyroidism? (Q850928)

A. Increased dermal collagen deposition

B. Accumulation of dermal glycosaminoglycans

C. Dermal saponification of fat

D. Dermal fibrosis

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 45-year-old woman comes with complaints of extensive hair loss, menorrhagia and weight gain. Work up shows elevated TSH , low T3, low T4 levels and anti TPO antibody present status. She has no known cardiovascular disease. Which of the following is the most appropriate next step regarding this patient? (Q850929)

A. Start levothyroxine 25 µg daily

B. Start levothyroxine 100 µg daily

C. Start liothyronine (T3) 5 µg three times daily

D. Observe and repeat thyroid function tests in 3 months

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A known case of autoimmune thyroiditis presents with confusion and seizures. EEG shows generalized slowing without epileptiform discharges. Vitals are pulse 60/min. BP 120/100 mm Hg and temp 37.2 C. Work up shows High TSH, low T4, low T3, blood counts and CRP is normal. Which of the following is correct about diagnosis and management? (Q851050)

A. Hashimoto's encephalopathy and Hydrocortisone

B. Myxedema coma and iv Liothyronine

C. Myxedema coma and iv Levothyroxine

D. Thyroid storm and NG tube Propylthiouracil

See Answer in Part B → Q31

@Neet_pg_bot

Q32: Most common cardiovascular finding in case of young female with Grave's disease is? (Q851051)

A. Sinus Tachycardia

B. Atrial fibrillation

C. Ejection systolic murmur

D. Widened pulse pressure

See Answer in Part B → Q32

@Neet_pg_bot

Q33: Which of the following is not correct about Grave's associated ophthalmopathy? (Q851052)

A. Occurs in the absence of hyperthyroidism in 10% of patients

B. Earliest manifestation is proptosis and diplopia

C. Can cause loss of vision and papilledema

D. Lid lag can occur in causes other than grave' disease

See Answer in Part B → Q33

@Neet_pg_bot

Q34: In a patient with suspected hyperthyroidism, what is the initial screening test to be considered? (Q851053)

A. TSH and free T4

B. TSH and unbound T3

C. TSH and ultrasound neck

D. TSH and RAIU

See Answer in Part B → Q34

@Neet_pg_bot

Q35: A 68-year-old man with ischemic cardiomyopathy has been on amiodarone for 1 year. Routine screening reveals: TSH: 9.4 mIU/L (↑) Free T4: Low-normal Free T3: Normal He has no neck pain or thyroid tenderness. Which of the following thyroid disorders is least likely to be related to amiodarone therapy? (Q884019)

A. Failure to escape from the Wolff-Chaikoff effect

B. Iodine-induced hyperthyroidism due to autonomous nodules

C. Destructive thyroiditis-like thyrotoxicosis

D. Painless autoimmune thyroiditis (silent/postpartum)

See Answer in Part B → Q35

@Neet_pg_bot

Q36: A 61-year-old man with long-standing multinodular goitre has been on amiodarone for ventricular arrhythmia for the past 9 months. He presents with palpitations, weight loss and tremors. Thyroid function tests show suppressed TSH with elevated free T4 and T3. Colour Doppler ultrasound of the thyroid shows markedly increased vascularity. Which of the following statements is correct regarding his condition? (Q884020)

A. Thyrotoxicosis is due to drug-induced lysosomal destruction of thyroid follicles

B. Radioiodine uptake is typically very low due to follicular cell destruction

C. It results from iodine-induced autonomous hormone synthesis

D. First-line therapy is systemic glucocorticoids

See Answer in Part B → Q36

Q31 (p. 285)	*Q32 (p. 286)*				

Q1: A 64 y/o man presents with 1 week of confusion, lethargy, constipation, and polydipsia. He also has unintentional weight loss. Examination shows cachexia. Laboratory investigations: Serum calcium: 16.8 mg/dL, Serum albumin: 3.8 g/dL, Serum phosphorus: 2.1 mg/dL If this patient had metabolic alkalosis and a history of consuming large quantities of over-the-counter heartburn relief tablets, which of the following would be the most likely diagnosis? (Q890423)

A. Primary hyperparathyroidism

B. Familial hypocalciuric hypercalcemia

C. Milk-alkali syndrome

D. Vitamin D intoxication

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following interventions is the initial therapy for a patient with severe, acute symptomatic hypocalcemia with tetany, laryngeal spasm, and seizures? (Q890445)

A. Oral calcium carbonate

B. Intravenous calcium infusion

C. Subcutaneous teriparatide

D. Intravenous bisphosphonates

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A physician taps the patient's face just anterior to the ear lobe, below the zygomatic arch. This produces the following characteristic finding. This physical sign is associated with which of the following electrolyte abnormalities? (Q890444)

A. Hypercalcemia

B. Hypocalcemia

C. Hypermagnesemia

D. Hypokalemia

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following ECG changes is characteristically associated with significant hypocalcemia? (Q890443)

A. Shortened QT interval

B. Prolonged QT interval

C. Prominent U waves

D. Peaked T waves

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is characteristic of a patient diagnosed with pseudopseudohypoparathyroidism (PPHP)? (Q890442)

A. Hypocalcemia, hyperphosphatemia, elevated PTH

B. Hypocalcemia, hypophosphatemia, elevated PTH

C. Hypercalcemia, hypophosphatemia, suppressed PTH

D. Normal calcium, normal phosphate, normal PTH

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following disorders is characterised by hypocalcemia with hyperphosphatemia in the absence of renal failure? (Q890440)

A. Vitamin D deficiency

B. Pseudohypoparathyroidism

C. Hungry bone syndrome

D. Malabsorption syndrome

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 68 y/o woman with chronic kidney disease presents with progressive confusion, lethargy, polyuria, and polydipsia. Examination shows severe dehydration. Laboratory results reveal: Serum calcium: 16.2 mg/dL, BUN: 52 mg/dL, Creatinine: 2.4 mg/dL. Which of the following is the most appropriate initial step in management? (Q890439)

A. Intravenous zoledronic acid

B. Intravenous hydration with normal saline

C. Intravenous furosemide

D. Subcutaneous calcitonin

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is the treatment of hypercalcemia caused by vitamin D intoxication, often leading to normalisation of serum calcium over several days? (Q890437)

A. Thiazide diuretics

B. Glucocorticoids

C. Lithium

D. Calcimimetics

See Answer in Part B → Q8

@Neet_pg_bot

Q9: The hand X-ray shown is most characteristic of which condition? (Q890435)

A. Rheumatoid arthritis

B. Acromegaly

C. Hyperparathyroidism

D. Osteoarthritis

See Answer in Part B → Q9

@Neet_pg_bot

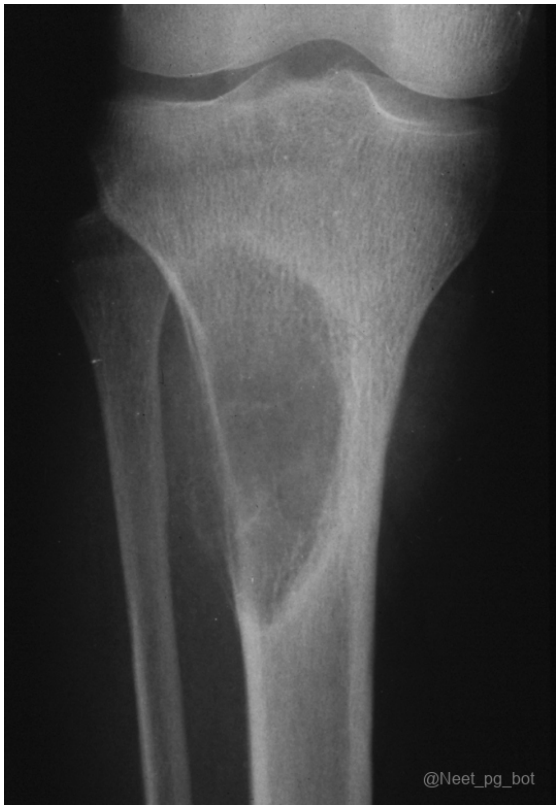
Q10: A 65 y/o man with untreated primary hyperparathyroidism presents with severe pain in his right thigh. An X-ray is as follows. Based on the described condition, which of the following histologic findings is most characteristic of this lesion? (Q890432)

A. Mosaic pattern of lamellar bone with cement lines

B. Replacement of marrow elements by fibrous tissue and giant multinucleated osteoclasts

C. Accumulation of unmineralized osteoid matrix

D. Malignant proliferation of plasma cells



See Answer in Part B → Q10

@Neet_pg_bot

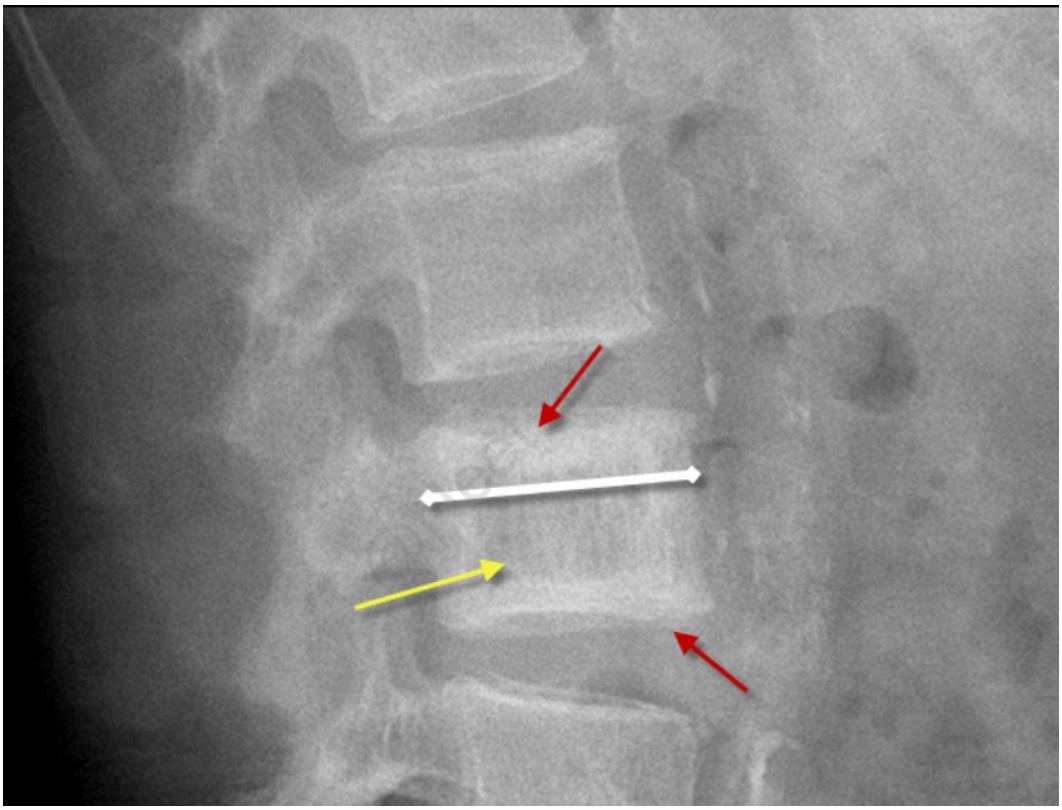
Q11: A patient presents with bone pain and an elevated alkaline phosphatase. A radiograph of the lumbar spine shows enlargement of a vertebral body with marked cortical thickening of the superior and inferior end plates, producing a "picture-frame" appearance. Which of the following is the most likely diagnosis? (Q890431)

A. Primary hyperparathyroidism

B. Paget's disease of bone

C. Fibrous dysplasia

D. Osteomalacia



See Answer in Part B → Q11

@Neet_pg_bot

Q12: In differentiating Familial Hypocalciuric Hypercalcemia (FHH) from primary hyperparathyroidism, which of the following urinary biochemical findings most strongly supports a diagnosis of FHH? (Q890430)

A. 24-hour urinary calcium >300 mg

B. Calcium-to-creatinine clearance ratio (CCCR) >0.02

C. Calcium-to-creatinine clearance ratio (CCCR) <0.01

D. Frank hematuria

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following biochemical patterns is most characteristic of primary hyperparathyroidism? (Q890429)

A. Low calcium, high phosphate, high PTH

B. High calcium, low phosphate, high PTH

C. High calcium, high phosphate, low PTH

D. Low calcium, low phosphate, low PTH

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following findings represents the most common underlying cause of primary hyperparathyroidism? (Q890428)

A. Parathyroid carcinoma

B. Diffuse hyperplasia of all four parathyroid glands

C. Solitary parathyroid adenoma

D. Multiple parathyroid adenomas

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following conditions causes hypercalcemia primarily due to increased bone turnover, in which bone resorption exceeds bone formation? (Q890426)

A. Milk-alkali syndrome

B. Vitamin D intoxication

C. Hyperthyroidism

D. Sarcoidosis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following gastrointestinal symptoms is most commonly associated with hypercalcemia? (Q890424)

A. Diarrhoea

B. Hyperactive bowel sounds

C. Constipation

D. Hematochezia

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 65-year-old patient presents with constipation, abdominal pain, nausea, vomiting, confusion, and bone pain. Laboratory tests reveal elevated calcium levels. Considering the role of the calcium-sensing receptor (CaSR) in calcium homeostasis, which of the following is regulated by CaSR? (Q850696)

A. PTH

B. FGF-23

C. Vitamin D3

D. Calcitonin

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 28-year-old woman presents with complaints of irregular menstrual cycles and infertility & reports increased headaches and visual changes over the past few months. An MRI reveals a large pituitary tumor. Family history is significant for several

relatives with breast and thyroid cancers. Which syndrome is most likely associated with her condition? (Q850741)

A. McCune-Albright Syndrome

B. Von Hippel-Lindau (VHL) Disease

C. Cowden Syndrome

D. Carney Complex

See Answer in Part B → Q18

@Neet_pg_bot

Q19: 40-year-old man presents with salt wasting, salt craving and postural hypotension. He has a family history of autoimmune disorders. Laboratory tests reveal elevated blood glucose levels and positive autoantibodies. Autoimmune Polyendocrine Syndrome is suspected. Which of the following statements regarding the diagnosis is not true? (Q850736)

A. Associated with Addison disease

B. Associated with Autoimmune thyroiditis

C. Associated with Celiac disease

D. Associated with Hypoparathyroidism

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 35-year-old man presents with recurrent kidney stones, abdominal pain, and peptic ulcers. His blood pressure is elevated, and he has a family history of thyroid carcinoma. Laboratory tests reveal high serum calcium and parathyroid hormone levels. What is the most likely diagnosis? (Q850735)

A. MEN Type 1

B. MEN Type 4

C. MEN Type 2B

D. MEN Type 2A

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 3-year-old boy with growth delays and leg bowing has not improved after six months of vitamin D treatment. Labs show low calcium, low phosphate, and elevated alkaline phosphatase. Genetic testing indicates a Vitamin D gene mutation. What is the best management option? (Q850733)

A. Increase in vitamin D dosage

B. Initiate phosphate supplementation

C. Administer Calcium

D. Administer Calcitriol

See Answer in Part B → Q21

@Neet_pg_bot

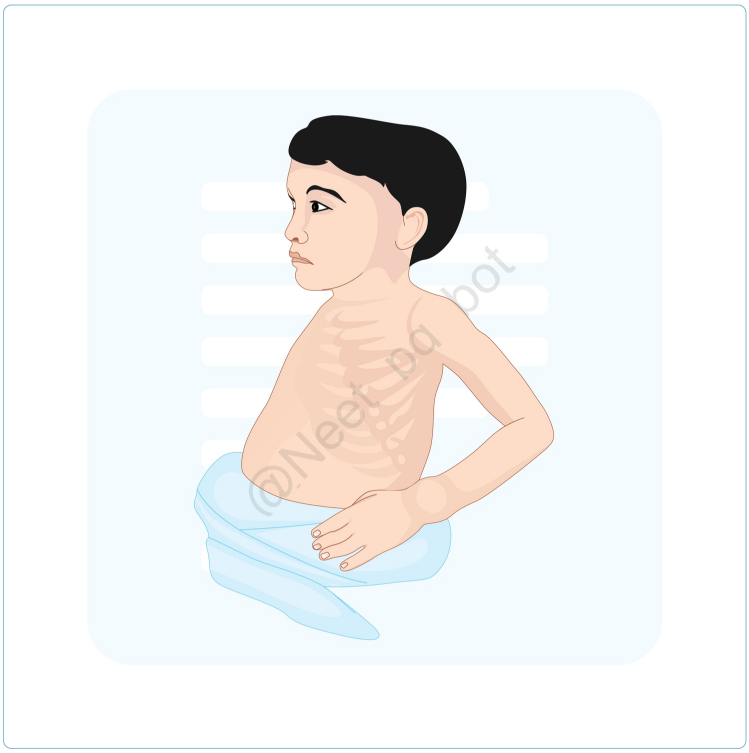
Q22: A 6-year-old boy presents with a history of recurrent fractures and pain in his lower limbs.He has a history of poor dietary intake, particularly low dairy consumption. Clinical examination leads to the findings similar to the images given below. Based on these observations, which of the following lab findings would be most consistent with his condition? (Q850731)

A. Low Parathyroid hormone, High Calcium

B. Low Calcium, High Phosphate

C. High Calcium, Low Phosphate

D. High Parathyroid hormone, Low Calcium



@Neet_pg_bot

@Neet_pg_bot

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 65-year-old woman with a history of chronic kidney disease secondary to hypertension presents with symptoms of nausea, vomiting, and confusion. On Investigating her Lab values are Serum calcium: 12.0 mg/dL (normal range: 8.5-10.5 mg/dL) Serum phosphate: 4.9 mg/dL (normal range: 2.5-4.5 mg/dL) Serum PTH: 200 pg/mL (normal range: 10-65 pg/mL) Which of the following is the most likely diagnosis of this patient? (Q850729)

A. Primary Hyperparathyroidism

B. Secondary Hyperparathyroidism

C. Pseudohypoparathyroidism

D. Tertiary Hyperparathyroidism

See Answer in Part B → Q23

@Neet_pg_bot

Q24: An 8-year-old boy presents with characteristic skeletal and developmental defects, such as short stature and shortened 4th and 5th metacarpals. Laboratory findings show elevated PTH levels, hypocalcemia, and hyperphosphatemia. Genetic testing reveals a deficiency in the Gsα subunit. Based on these findings, what is the most likely diagnosis? (Q850727)

A. Pseudopseudohypoparathyroidism (PPHP)

B. Pseudohypoparathyroidism type 1a (PHP1A)

C. Pseudohypoparathyroidism type 1b (PHP1B)

D. Hypoparathyroidism

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 45-year-old adult patient presents with symptoms of chronic hypocalcemia. Which of the following features is associated with this condition? (Q850723)

A. Extrapyramidal symptoms like dystonia

B. Tissue deposition of calcium due to hyperphosphatemia

C. Skin infections such as candidiasis

D. All of the above

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 65-year-old woman with primary hyperparathyroidism presents with nausea, vomiting, confusion, and dehydration. She shows signs of hypovolemia and altered mental status. Labs reveal high serum calcium, low phosphate, and elevated PTH. What is the first line of treatment? (Q850720)

A. Intravenous Bisphosphonates

B. Aggressive hydration with normal saline

C. Peritoneal dialysis

D. Calcitonin nasal spray

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 52-year-old man diagnosed with hypoparathyroidism six months ago after neck surgery presents with tingling in his hands and feet, muscle cramps, and fatigue. His lab results indicate low serum calcium, elevated phosphate, and severely low parathyroid hormone (PTH) levels. What is the most appropriate treatment for his condition? (Q850717)

A. Initiate intravenous calcium gluconate therapy

B. Administration of Alendronate

C. Administration of Teriparatide

D. Start oral calcium and Vitamin D supplement

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 45-year-old woman undergoes total thyroidectomy for a large goiter. Two days post-surgery, investigations reveal low serum calcium and low parathyroid hormone (PTH) levels. During clinical examination, the following observation is made. What is this sign known as ? (Q850712)

A. Trousseau sign

B. Chvostek sign

C. Hoffman's sign

D. Brudzinski's sign

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 45-year-old woman presents to the emergency department with muscle cramps, tingling in her fingers, and a tight sensation around her mouth. She has a history of thyroid surgery for papillary carcinoma. Examination revealed increased neuromuscular excitability. Lab results show low PTH, low calcium, and elevated phosphate levels. Which syndrome is most likely associated with this presentation? (Q850707)

A. Cushing's syndrome

B. McCune-Albright Syndrome

C. Turner syndrome

D. DiGeorge syndrome

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 58-year-old man with chronic kidney disease (CKD) returns for a follow-up, reporting fatigue, bone pain, and muscle weakness. Examination reveals bone tenderness, and lab tests show elevated parathyroid hormone (PTH) levels. Which of the following findings is not typically associated with this condition? (Q850704)

A. Elevated serum calcium levels

B. Raised serum alkaline phosphatase levels

C. Elevated serum phosphate levels

D. Raised urinary albumin creatinine ratio

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A 39-year-old woman presents with persistent constipation, abdominal pain, and intermittent lower back pain. She has a history of recurrent kidney stones and reports fatigue. Lab tests reveal elevated calcium and decreased phosphate levels. She has been advised to undergo a sestamibi Tc-99 scan. Which of the following is not an indication for surgery in this condition? (Q850700)

A. Nephrolithiasis

B. Renal impairment

C. Age >50 years

D. Osteoporosis

See Answer in Part B → Q31

@Neet_pg_bot

Q32: A 60-year-old female presents with complaints of abdominal pain, constipation, and recent episodes of confusion and depression. Laboratory tests reveal elevated serum calcium and alkaline phosphatase (SAP) levels and decreased phosphate levels. Which of the following clinical features is not typically associated with this condition? (Q850698)

A. Recurrent nephrolithiasis

B. Osteitis fibrosa cystica

C. Tetany

D. Urinary tract infection

See Answer in Part B → Q32

Q1: Which of the following is the sequence of hormonal supplementation in a patient of Panhypopituitarism (Q850924)

A. Glucocorticoids → Thyroid hormones → Growth hormone → Sex hormones

B. Glucocorticoid → thyroid hormone → Sex hormones → Growth hormone

C. Thyroid hormones → Sex hormones → Glucocorticoids → Growth hormone

D. Sex hormones → Growth hormone → Glucocorticoids → Thyroid hormones

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 38-year-old woman with a known pituitary adenoma presents with a sudden onset of severe headache, vomiting and rapidly progressive visual loss. MRI brain suggests an acute haemorrhage within the pituitary gland. Which of the following conditions is not associated with increased risk of developing this emergency? (Q890236)

A. Acute hypovolemic shock

B. Sickle cell anaemia

C. Poorly controlled diabetes mellitus

D. Graves’ disease

See Answer in Part B → Q2

@Neet_pg_bot

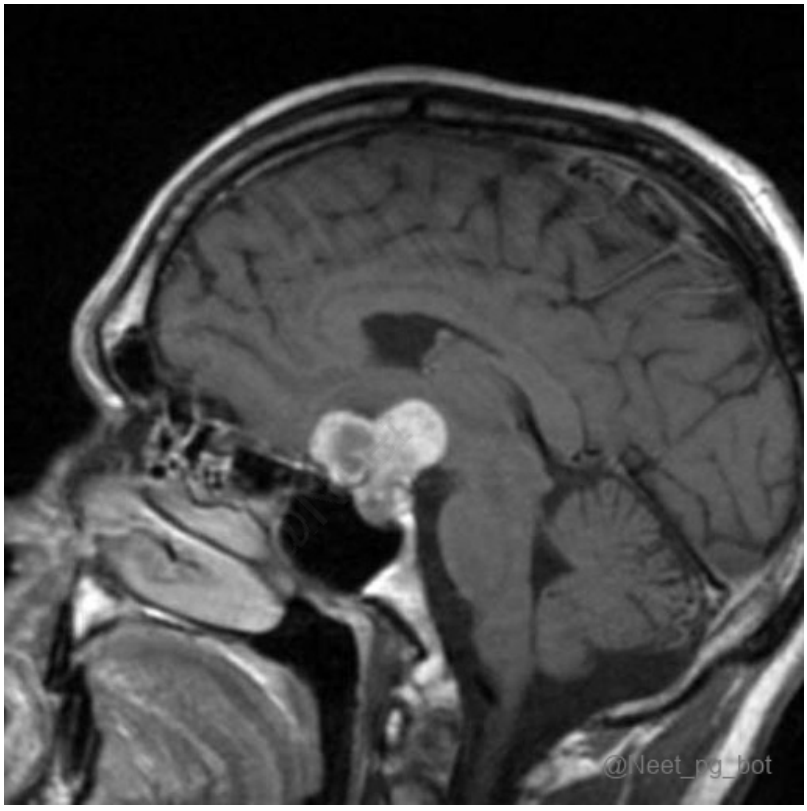
Q3: A 14-year-old boy presents with progressive headache, vomiting, declining school performance and polyuria. MRI brain reveals the following finding. Which of the following statements about this lesion is most accurate? (Q890235)

A. In the papillary variant, calcifications are commonly seen

B. In the adamantinomatous variant, calcifications are rare

C. Complete surgical excision is usually curative

D. Biopsy shows cholesterol crystals within the cyst



See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 49-year-old man presents with gradually progressive lethargy, loss of appetite and intermittent vomiting for several months. He also reports excessive thirst and passing large volumes of urine. MRI brain shows a suprasellar mass with mixed cystic-solid components and areas of calcification. Which of the following is the most common initial clinical presentation of this condition? (Q890234)

A. Bitemporal hemianopia

B. Hypogonadotropic hypogonadism

C. Persistent headache

D. Central diabetes insipidus

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 28-year-old man is diagnosed with a hereditary endocrine tumour syndrome and is being planned for surveillance imaging. In which of the following conditions is routine pituitary tumour screening not required? (Q890233)

A. MEN 1

B. MEN 4

C. Carney complex

D. MEN 2

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 34-year-old woman presents with secondary amenorrhea and spontaneous galactorrhea for 6 months. She also complains of gradually worsening peripheral vision. MRI brain reveals a 16-mm pituitary lesion. Which of the following visual field defects is most likely in this patient? (Q890232)

A. Bitemporal superior quadrantanopia

B. Homonymous superior quadrantanopia

C. Central scotoma

D. Monocular temporal hemianopia

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 55-year-old man presents with progressive fatigue and recent visual field defects. MRI shows a large sellar mass compressing the pituitary gland. Which of the following findings would be least likely to be present in this patient? (Q890231)

A. Increased adiponectin levels

B. Hypogonadotropic hypogonadism

C. Secondary hypothyroidism

D. Diffuse mucocutaneous hyperpigmentation

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 28-year-old woman presents with oligomenorrhea and spontaneous galactorrhea. Serum prolactin is 78 ng/mL. MRI of the sellar region is planned. Which of the following lesion sizes would classify the pituitary tumour as a microadenoma? (Q890230)

A. < 5 mm

B. < 8 mm

C. < 10 mm

D. < 15 mm

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 46-year-old man presents with progressively worsening headache and difficulty seeing objects in the peripheral field of vision. MRI reveals a large sellar mass compressing the optic chiasm. Hormonal evaluation shows mildly elevated serum prolactin with low cortisol and low TSH levels. Which of the following cell types is the most likely origin of this tumour? (Q890229)

A. Lactotroph cells

B. Corticotroph cells

C. Gonadotroph cells

D. Thyrotroph cells

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 27-year-old woman presents with 6 months of amenorrhea, spontaneous galactorrhea and infertility. Serum prolactin is 120 ng/mL. Which of the following is the most appropriate next step in evaluation? (Q884050)

A. MRI of pituitary fossa

B. Serum free T4 and TSH levels

C. Serum LH and FSH levels

D. Start cabergoline therapy

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 29-year-old woman presents with secondary amenorrhea and milky nipple discharge for 6 months. She also reports an inability to conceive despite regular unprotected intercourse. Which of the following clinical features would be least likely to be part of her underlying disorder? (Q884049)

A. Galactorrhea

B. Infertility

C. Diminished libido

D. Visual field defect

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 40-year-old man presents with progressive increase in ring and shoe size, coarse facial features, excessive sweating, arthralgia and new-onset diabetes mellitus. Serum IGF-1 is elevated, and growth hormone fails to suppress following an oral glucose tolerance test. MRI sella reveals a pituitary mass. What is the most common underlying aetiology of his condition? (Q884048)

A. Ectopic GHRH secretion from bronchial carcinoid

B. Pure somatotroph pituitary adenoma

C. Lactotroph adenoma with stalk effect

D. Hypothalamic hamartoma

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 23-year-old woman undergoes dynamic pituitary testing. Following TRH administration, her serum growth hormone (GH) levels show a paradoxical rise. Which of the following clinical conditions is most likely to show this response? (Q884047)

A. Acromegaly

B. Simple protein-energy malnutrition

C. Cushing syndrome

D. Chronic kidney disease

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 15-year-old boy receiving recombinant growth hormone therapy for constitutional short stature presents with progressive weight gain, facial puffiness and new-onset impaired fasting glucose. Which of the following adverse effects is he least likely to develop due to growth hormone therapy? (Q884046)

A. Slipped capital femoral epiphysis

B. Tinnitus

C. Pseudotumor cerebri

D. Hypotension

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 4-year-old boy is brought in with proportionate short stature, frontal bossing and recurrent episodes of fasting hypoglycemia. His serum growth hormone levels are markedly elevated, but IGF-1 levels are very low. Which of the following is the most likely underlying abnormality? (Q884045)

A. Congenital GHRH deficiency

B. Inactivating mutation of the growth hormone receptor

C. Isolated pituitary somatotroph hypoplasia

D. Congenital absence of IGF-1 production

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A patient with acromegaly presents with large spade-like hands and impaired glucose tolerance. The pituitary MRI shows a somatotrope adenoma. Which of the following is the preferred medical therapy to shrink the tumor preoperatively? (Q850805)

A. Cabergoline

B. Lanreotide

C. Bromocriptine

D. Pegvisomant

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following diseases is mismatched with its hormonal profile and management (Q850922)

A. Lymphocytic hypophysitis - variable deficiency in pituitary hormone Sheehan syndrome - treated with hormone replacement therapy Langerhans cell histiocytosis of pituitary - ADH deficiency present

B. Lymphocytic hypophysitis - Glucocorticoid to reduce inflammation Sheehan syndrome - Panhypopituitarism Langerhans cell histiocytosis of pituitary - surgical excision of the lesion

C. Lymphocytic hypophysitis - Glucocorticoid to reduce inflammation Sheehan syndrome - ADH deficiency present Langerhans cell histiocytosis of pituitary-thyroid hormone replacement is essential.

D. Lymphocytic hypophysitis - Surgical excision if vision is affected Sheehan syndrome - Thyroid hormone replacement after Corticosteroids are stabilized Langerhans cell histiocytosis of pituitary - Chemotherapy is systemic involvement present

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 60-year-old male with a history of pituitary adenoma presents with sudden-onset severe headache, palpitations, excessive sweating, and hypotension. Lab results show severe hypoglycemia, and imaging reveals hemorrhage within the pituitary and deviation of the pituitary stalk. What is the initial management for this

patient? (Q850921)

A. Urgent surgical decompression

B. High dose IV glucocorticoid

C. IV dextrose administration

D. Oral hydrocortisone

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Match the following pituitary gland disorders with their respective serum hormone levels. Pituitary gland disorder Serum hormone levels 1. Hypopituitarism a) Severe ↓ ACTH and GH, other hormones maybe ↓ or normal 2. Sheehan syndrome b) GH, ACTH, TSH, LH, FSH, prolactin, ADH ↓ 3. Pituitary apoplexy c) GH, ACTH, TSH, LH, FSH normal or ↓; prolactin ↑ 4. Stalk effect d) GH, ACTH, TSH, LH, FSH, prolactin ↓ and ADH normal (Q850920)

A. 1-c, 2-b, 3-d, 4-a

B. 1-b, 2-d, 3-a , 4-c

C. 1-d, 2-a, 3-c, 4-b

D. 1-a, 2-c, 3-b, 4-d

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following is not true regarding the stalk effect of the pituitary? (Q850918)

A. Hyperprolactinemia occurs due to a hypersecreting macroadenoma

B. There is reduced secretion of dopamine in the pituitary stalk

C. Significant deficiencies in other pituitary hormones are not present

D. Prolactin level is usually less than 200 ng/ml

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 32 year old nulliparous woman comes to the OB-GYN department for investigation of infertility. She also complains of occasional headaches and galactorrhoea. Lab tests and imaging lead to a diagnosis of prolactinoma. If we want to restore fertility in this patient, which of the following is the treatment of choice in this patient? (Q850917)

A. Cabergoline therapy till pregnancy is confirmed

B. Bromocriptine therapy till pregnancy is confirmed

C. Radiotherapy for mass reduction of tumor

D. Transsphenoidal resection of the mass

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 40-year-old man presents with erectile dysfunction and galactorrhea. Blood tests confirm elevated prolactin levels and an MRI reveals a macroadenoma. Which of the following management strategies is most appropriate for this patient? (Q850916)

A. Trans sphenoidal surgery

B. Start cabergoline

C. Observation & regular follow-up with MRI

D. Start Lanreotide

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 28-year-old woman presents to her primary care physician with complaints of irregular menstrual cycles, galactorrhea, and difficulty conceiving. Laboratory tests reveal elevated serum prolactin levels. MRI of the patient is given below. Which of the following statements about the given condition is not true? (Q850915)

A. Female-to-Male ratio is approximately 20:1 for microadenomas

B. Men generally present with symptoms earlier than women

C. Macroadenoma may cause bitemporal hemianopia

D. Prolactin levels correlate with the size of the tumor

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following is the most appropriate initial management for a patient with Sheehan syndrome? (Q850914)

A. Immediate thyroid hormone replacement

B. Hydrocortisone administration

C. Fludrocortisone administration

D. GH administration

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 32-year-old woman experiences severe postpartum hemorrhage during delivery, requiring a blood transfusion. Two weeks later, she reports fatigue, weight loss and failure of lactation. Which of the following hormone replacement will not be required in this case? (Q850913)

A. Hydrocortisone

B. Melatonin

C. Thyroxine

D. Somatotropin

See Answer in Part B → Q25

@Neet_pg_bot

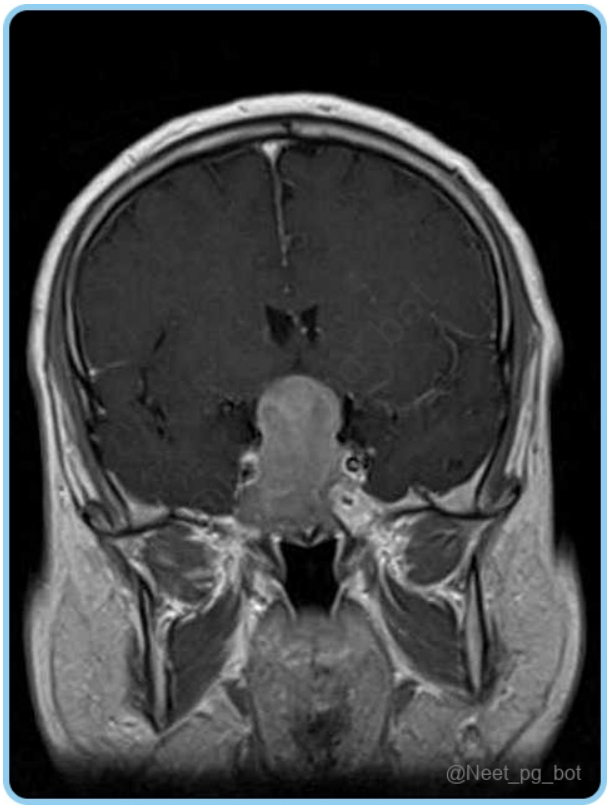
Q26: 45-year-old man presents with headaches, frequent change in shoe size and visual field defects. MRI head is shown below. IGF-1 is elevated and GH levels remain elevated on glucose challenge. Which of the following is the most appropriate management for this patient? (Q850912)

A. Initiate treatment with oral cabergoline

B. Start long-acting Octreotide

C. Perform transsphenoidal surgical resection

D. Initiate external beam radiation therapy



See Answer in Part B → Q26

@Neet_pg_bot

Q27: 50-year-old woman presents with increase in size of hand and feet with voice changes and carpal tunnel syndrome. IGF -1 levels are increased. Which of the following findings will likely not be seen in this case? (Q850911)

A. Hypoglycemic attacks

B. Galactorrhea

C. Bitemporal Hemianopia

D. Colonic polyps

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 45-year-old man presents with spade like hands, coarse facies and increased spacing between his lower teeth. Which of the following is screening test for this case? (Q850910)

A. IGF-1 levels

B. IGF-2 levels

C. GH Levels

D. GH levels after 2 hour of glucose challenge test

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Prolactin levels can be increased in all of the following conditions except? (Q850909)

A. Acromegaly

B. Primary hypothyroidism

C. Secondary hypothyroidism

D. Prolactinoma

See Answer in Part B → Q29

@Neet_pg_bot

Q30: Best test to confirm the diagnosis of acromegaly is? (Q850806)

A. IGF-1

B. IGF-2

C. Oral Glucose Tolerance Test

D. MRI pituitary

See Answer in Part B → Q30

Q103 (p. 344)					

Q1: A patient presents with weight gain, thinning of hair, and dry skin. Diagnosis is Hashimoto’s thyroiditis. Which antibody is seen in this case? (Q866788)

A. Anti-TPO antibody

B. Anti TSH

C. Anti TBG

D. Long-acting thyroid-stimulating antibody

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A patient has developed a cough and weight loss for the last 3 months. Biopsy of lung mass shows expression of chromogranin and synaptophysin. Which paraneoplastic syndrome will most likely occur in this patient? (Q866793)

A. Hypercalcemia

B. Cushing syndrome

C. Gynaecomastia

D. SIADH

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A patient presents with palpitations, headache, and sweating. His BP is 180/100 mmHg. 24-hour urinary metanephrine values are elevated. What is the diagnosis? (Q866794)

A. Carcinoid tumor

B. Pheochromocytoma

C. Carcinoid crisis

D. Neuroblastoma

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A known case of hyperthyroidism, who is not on medication, is scheduled for total thyroidectomy. The PAC check was not done properly. What is the leading complication that can occur during surgery? (Q866801)

A. Hyperthermia

B. Hypothermia

C. Arrhythmia

D. Hypothyroidism

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Patient presents with hypertension and hypokalemic metabolic alkalosis. CT scan shows a mass over the kidney with elevated ARR. What is the next best step for the management of this patient? (Q866803)

A. Spironolactone on a lifelong basis

B. Adrenalectomy

C. ACTH stimulation test

D. Dexamethasone suppression test

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A female presents with amenorrhea and galactorrhea. Serum prolactin is elevated. MRI shows pituitary adenoma. Best management for this patient? (Q866806)

A. Bromocriptine

B. Letrozole

C. Tamoxifen

D. Goserelin

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Hyperpigmentation in Addison’s disease is due to increased secretion of: (Q866480)

A. Cortisol

B. ACTH

C. Aldosterone

D. Renin

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A patient presents with palpitations, headache and diaphoresis + elevated 24 hour urine metanephrine levels. Which of the following drugs can be used both preoperatively and intraoperatively for control of BP? (Q866494)

A. Phenoxybenzamine

B. Esmolol

C. Clonidine

D. Labetalol

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 56-year-old diabetic patient is currently on Metformin and Insulin Glargine. His HbA1c is 8.2%, indicating suboptimal glycemic control. Echocardiography reveals a reduced ejection fraction (EF) of 35%. Which of the following is the most appropriate agent to add to his current regimen? (Q866500)

A. Pioglitazone

B. Glimepiride

C. Sitagliptin

D. Empagliflozin

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A patient presents with salt wasting, craving, hyperkalemia, metabolic acidosis, and skin pigmentation. What is the most likely diagnosis? (Q866509)

A. Addison’s disease

B. Cushing’s syndrome

C. Conn’s syndrome

D. Pheochromocytoma

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A known type 1 diabetic presents with glucose 799 mg/dL, Na■ 128 mEq/L, Cl■ 88 mEq/L, and signs of dehydration. Which of the following is NOT used in the initial management? (Q866515)

A. 0.9% Normal saline

B. 3% Saline

C. IV infusion insulin

D. Potassium monitoring

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A female patient with type 1 DM and hypothyroidism presented with chronic oral mucocutaneous candidiasis for 5 years. She is diagnosed with autoimmune polyendocrinopathy syndrome type 1. Which of the following is incorrect about this condition? (Q853349)

A. DM type-1 association is high

B. Starts in infancy

C. Hypoparathyroidism

D. High association with candidiasis

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A patient presents with hypotension, hyponatremia and blackening of the knuckles and perioral area. Which of the following conditions is most likely associated with these symptoms? (Q844204)

A. Conn syndrome

B. Cushing's syndrome

C. Primary ACTH deficiency

D. Addison’s disease

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A patient with a history of Wilson's disease presents with neurological manifestations. Which of the following is the best diagnostic modality? (Q844223)

A. Serum ceruloplasmin

B. Urinary copper excretion

C. Hepatic parenchymal demonstration of copper

D. Anti-tissue transglutaminase (Anti-tTG) antibody

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A patient presents with large sweaty hands, macroglossia, and frontal bossing. Select the best test for confirmation of the diagnosis: (Q844227)

A. GHRH levels

B. IGF- 1

C. IGF- 2

D. GH levels after glucose suppression

See Answer in Part B → Q15

@Neet_pg_bot

Q16: In a patient with type 1 diabetes at the 3rd stage of beta cell damage, which of the following conditions is most likely to be observed? (Q844327)

A. Autoimmune positive + normoglycemia

B. Autoimmune negative + normoglycemia

C. Autoimmune positive + dysglycemia

D. Autoimmune negative + dysglycemia

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A patient presents with features of hyperthyroidism, characterized by decreased TSH levels and elevated free T3 and T4. Which of the following statements about this condition is NOT true? (Q844328)

A. The condition will improve simultaneously with improvement in the thyrotoxic state.

B. In 10% of cases, the condition is present without hyperthyroidism.

C. Severe disease can cause vision loss.

D. No specs criteria is used for this condition.

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A young woman presents with weight loss, tachycardia, heat intolerance, and tremors. On examination, she has exophthalmos. What is the most likely diagnosis? (Q844329)

A. Parkinson's disease

B. Graves' disease

C. Addison's disease

D. Alzheimer's disease

See Answer in Part B → Q18

@Neet_pg_bot

Q19: In Type 1 Diabetes Mellitus, what characterizes stage 3 of beta-cell destruction? (Q844286)

A. Symptomatic hyperglycemia

B. Dysglycemic symptomatic

C. Normoglycemic symptomatic

D. Dysglycemic asymptomatic

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following antidiabetic drugs can cause glucosuria? (Q860437)

A. Glimepiride

B. Exenatide

C. Acarbose

D. Empagliflozin

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A diabetic patient came to the outpatient department with complaints of fatigue and frequent urination. On examination vitals are stable and an HbA1c is done. What is the cut-off percentage used for determining controlled diabetes? (Q860444)

A. 6.0

B. 6.5

C. 7.0

D. 7.5

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following is associated with MEN-1 syndrome? (Q860448)

A. Parathyroid adenoma

B. Parotid tumor

C. Renal cell carcinoma

D. Pheochromocytoma

See Answer in Part B → Q22

@Neet_pg_bot

Q23: All of the below are features of Conn's syndrome except? (Q860462)

A. Metabolic alkalosis

B. Metabolic acidosis

C. Hypertension

D. Muscle cramps

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 45-year-old man presents to the outpatient department with symptoms of headache, renal stones, and abdominal pain. Serum calcium is low and PTH is high. Which of the following hormone and associated disease might be causing these symptoms? (Q840096)

A. Parathyroid and Primary hyperparathyroidism

B. Catecholamines and Pheochromocytoma

C. Thyroxine and Hypothyroidism

D. Mineral and bone disorders

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 45-year-old man presents to the outpatient department with proximal muscle weakness, purple stretch marks, obesity, and easy bruising. What is the underlying condition? (Q840099)

A. Hyperthyroidism

B. Hypercortisolism

C. Hyperparathyroidism

D. Hyperaldosteronism

See Answer in Part B → Q25

@Neet_pg_bot

Q26: All of the following are criteria for diagnosis of diabetes ketoacidosis, except? (Q840103)

A. Serum glucose of more than 250 mg

B. Anion gap of more than 10-12

C. Serum bicarbonate less than 15 mmol

D. Serum potassium less than 3.5 mEq

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Which of the following is the diagnostic test for carcinoid tumors? (Q860132)

A. 24-hour urinary catecholamines

B. Serum calcitonin levels

C. Serum chromogranin A

D. Urinary 5-hydroxyindoleacetic acid

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which of the following tests is the best for assessing long-term control of diabetes mellitus? (Q860233)

A. Glycosylated Hemoglobin

B. Glycated Albumin

C. Serum Fructosamine

D. Urine Sugar

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Which of the following anti-diabetic drug is recently approved to be used in patients with heart failure with low ejection fraction and reduced urine output? (Q857286)

A. Linagliptin

B. Empagliflozin

C. Pioglitazone

D. Degludec

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A child is brought to the ER in an unconscious state after severe vomiting and abdominal pain episodes. HR = 100/min and BP=100/60 mm Hg. Work up shows: pH=7.2 Blood glucose 300 mg/dl Ketone 3+. What should be the best management? (Q857287)

A. Infusion of 0.05 – 0.1 U/kg dose insulin after 1 hour of IVF

B. 0.1 Unit/kg insulin stat followed infusion of 0.5 U- 0.1 U/kg dose insulin and IVF

C. 0.1 U/kg insulin subcutaneous stat followed by IVF

D. IVF followed by subcutaneous 0.1 U/kg insulin

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A 26-year-old female presents with palpitations, weight loss, tremors, sweating and diarrhoea. What is the next test that will help establish the diagnosis for this patient? (Q857288)

A. TSH and free T4

B. Anti Thyroid Peroxidase antibodies

C. Total T3

D. USG Neck

See Answer in Part B → Q31

@Neet_pg_bot

Q32: A patient with a history of rheumatoid arthritis (RA) presented to the ER with hypotension. She was on medication for RA but abruptly stopped them. On examination, her HR = 110 bpm, BP is 80/40 mm Hg, blood sugar = 50 mg/dl, Na = 130 meq/L and K = 6.0 meq/L. What should be the most appropriate management? (Q854674)

A. Fast IV fluids

B. Hydrocortisone

C. Dopamine infusion

D. Soda bicarbonate

See Answer in Part B → Q32

@Neet_pg_bot

Q33: Which of the following is not a component of metabolic syndrome? (Q854734)

A. LDL

B. Fasting glucose

C. Abdominal circumference

D. Blood pressure

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A female patient presents with severe restlessness, palpitations, and tremors to the emergency department. She is a known case of bronchial asthma. On examination, the neck looks swollen. Blood pressure is elevated, and tachycardia is noted. ECG shows atrial fibrillation. Which of the following drugs is used for immediate management in this patient? (Q855431)

A. Diltiazem

B. Propranolol

C. Esmolol

D. Propylthiouracil

See Answer in Part B → Q34

@Neet_pg_bot

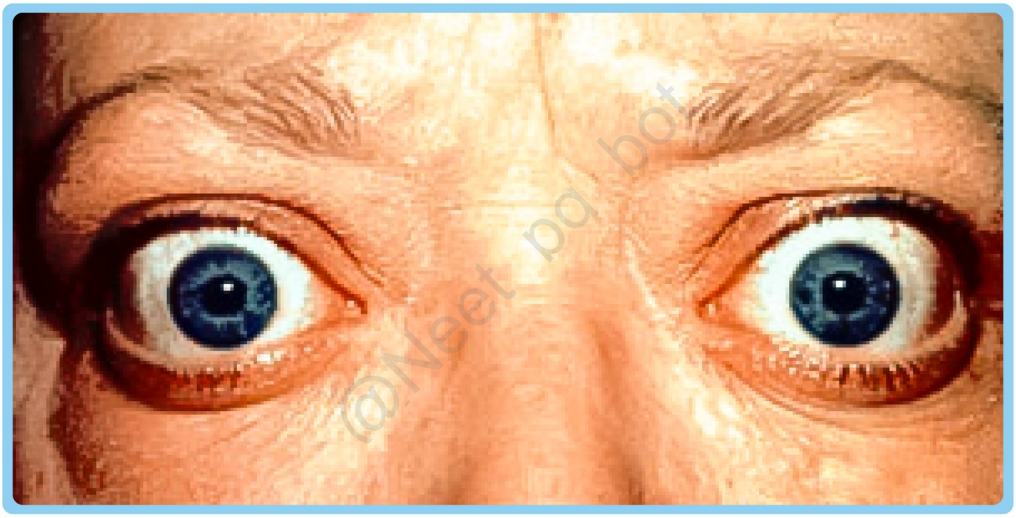
Q35: A 25-year-old male patient came with complaints of palpitations, sweating, and restlessness. He has a complaint of sweaty palms. Clinical findings are depicted in the image given below. What is the diagnostic finding seen in this patient? (Q855441)

A. Anti-thyroglobulin antibody

B. Anti-thyroid peroxidase antibody

C. Thyroid receptor antibody

D. Elevated ultrasensitive thyrotropin levels



@Neet_pg_bot

See Answer in Part B → Q35

@Neet_pg_bot

Q36: A patient came to medical OPD with complaints of polyuria. He has a history of undergoing total hypophysectomy. His Na + levels were found to be 155 mEq/L, and his urine osmolarity was 200 mOsm/L. What is the definitive management in this patient? (Q855498)

A. DDAVP for 2 weeks and then discontinue

B. DDAVP supplementation for lifelong

C. Upsetting of receptors, so no treatment required

D. Thiazides for 2 weeks

See Answer in Part B → Q36

@Neet_pg_bot

Q37: A 29-year-old male patient presents with coarse facial features and gradual enlargement of the hands and feet for the past decade. He has been diagnosed with acromegaly based on elevated levels of IGF-1 and growth hormone that did not suppress after a 75 g glucose challenge test. What drug is recommended for treatment? (Q858019)

A. Lanreotide depot formulation

B. Terlipressin

C. Ketoconazole

D. Leuprolide

See Answer in Part B → Q37

@Neet_pg_bot

Q38: A patient presents with complaints of sudden onset headache, palpitation, and profuse sweating. The patient has had multiple similar episodes in the past. During these episodes, the patient's blood pressure is elevated. A 24-hour urine metanephrine is elevated. What is the most likely diagnosis? (Q858021)

A. Addison's disease

B. Renal artery stenosis

C. Pheochromocytoma

D. Hyperthyroidism

See Answer in Part B → Q38

@Neet_pg_bot

Q39: In a 60-year-old male, what is the primary etiology typically associated with Cushing's disease? (Q858034)

A. Small-cell lung cancer

B. Adrenal tumor

C. Ectopic ACTH syndrome

D. Pituitary microadenoma

See Answer in Part B → Q39

@Neet_pg_bot

Q40: A 30-year-old female patient presented with bone pain and recurrent episodes of renal colic. Her family reported a history of abnormal behavior. Work up shows elevated serum calcium, low phosphate and elevated SAP. Which of the following is best for further work up of this patient? (Q858035)

A. MRI neck

B. Tc-99m MIBI stress test

C. Sestamibi SPECT /CT

D. CT scan of abdomen

See Answer in Part B → Q40

@Neet_pg_bot

Q41: Which medication is recommended as the primary treatment for high blood sugar in a 19-year-old woman with a medical history of type 1 diabetes mellitus, who has been brought to the emergency room due to symptoms of confusion, vomiting, and abdominal pain, and subsequently diagnosed with diabetic ketoacidosis? (Q793941)

A. Regular insulin

B. Lente insulin

C. Glyburide

D. 70/30 insulin

See Answer in Part B → Q41

@Neet_pg_bot

Q42: Which of the following is seen in MEN 2B syndrome? (Q855719)

A. Café au lait spot

B. Medullary thyroid carcinoma

C. Parathyroid adenoma

D. Optic nerve glioma

See Answer in Part B → Q42

@Neet_pg_bot

Q43: Which of the following is a characteristic feature of Kallmann syndrome? (Q855313)

A. Anosmia

B. Syndactyly in males

C. Precocious puberty in females

D. White forelock

See Answer in Part B → Q43

@Neet_pg_bot

Q44: What would be the most suitable course of action for managing a 65-year-old male who presented with symptoms of weakness, lethargy, excessive cold intolerance,

and slow ankle jerk? His thyroid function test (TFT) revealed a TSH level of 16 Mu/L (normal range: 0.4 - 4.0 mu / l), T4 level of 0.3 ng/dl (normal range: 0.6 - 1.6 ng / dl), and T3 level of 70 pg /dl. (Q857050)

A. Start levothyroxine at 100 micrograms and decrease the dose gradually

B. Start levothyroxine at 25 micrograms and increase the dose gradually

C. Start levothyroxine at 25 micrograms and decrease the dose gradually

D. Give T3 and T4 drugs simultaneously

See Answer in Part B → Q44

@Neet_pg_bot

Q45: Fulminant diabetes mellitus is seen in? (Q857056)

A. Diabetic ketoacidosis

B. Coxsackie B virus

C. Non ketonic hyperosmolar coma

D. Autoimmune pancreatitis

See Answer in Part B → Q45

@Neet_pg_bot

Q46: A comatose elderly patient with a weight of approximately 70 kilograms is presented to the emergency department. During examination, it was determined that the patient's serum glucose levels were 500mg/dL, arterial pH is 7.30, and there is an elevation in plasma ketones levels. However, the serum potassium levels are within the normal range. In order to treat this patient, which of the following should be added to the saline solution? (Q857668)

A. Insulin

B. Bicarbonate

C. Potassium

D. 14 units of regular insulin intravenously

See Answer in Part B → Q46

@Neet_pg_bot

Q47: Addison's disease is characterized by all of the following symptoms except? (Q857672)

A. Hyperglycemia

B. Hyponatremia

C. Hyperkalemia

D. Hypotension

See Answer in Part B → Q47

@Neet_pg_bot

Q48: What is the preferred medication for treating Hyperthyroidism during the second trimester of pregnancy? (Q857684)

A. Propyl Thiouracil

B. Carbimazole

C. Sodium iodide

D. Radioactive iodine

See Answer in Part B → Q48

@Neet_pg_bot

Q49: A 30-year-old female patient came to the outpatient department with complaints of neck swelling. She gives a history of weight loss and palpitations. On examination, she has exophthalmos and a diffusely enlarged thyroid gland. What are the essential

investigations that should be done for the patient? Thyroid scan Fine needle aspiration cytology (FNAC) Thyroid function tests Ultrasound of neck Anti-thyroid antibody (Q855715)

A. 1,2,3,4 and 5

B. 1,3,5 only

C. 3,4,5 only

D. 1,3,4 and 5 only

See Answer in Part B → Q49

@Neet_pg_bot

Q50: In a PHC, which of the following initial screening tests are used to diagnose diabetes? HbA1c >6.5 Fasting blood sugar >126mg/dl Random blood sugar >200mg/dl 2-hour post glucose load blood sugar (Q855721)

A. 1 and 2

B. 2 and 3

C. 2 and 4

D. 1,2 and 3

See Answer in Part B → Q50

@Neet_pg_bot

Q51: During her pregnancy, a woman who had Grave's disease was consistently taking. Consequently, the newborn suffered from aplasia cutis congenita. Which specific medication could be attributed to the occurrence of this condition? (Q856948)

A. Carbimazole

B. Levothyroxine

C. Methylthiouracil

D. Hydrouracil

See Answer in Part B → Q51

@Neet_pg_bot

Q52: Which of the following conditions are most commonly associated with elevated TSH levels and decreased T4 levels? (Q856970)

A. Hypoparathyroidism

B. Pituitary Adenoma

C. Grave's disease

D. Hashimoto's thyroiditis

See Answer in Part B → Q52

@Neet_pg_bot

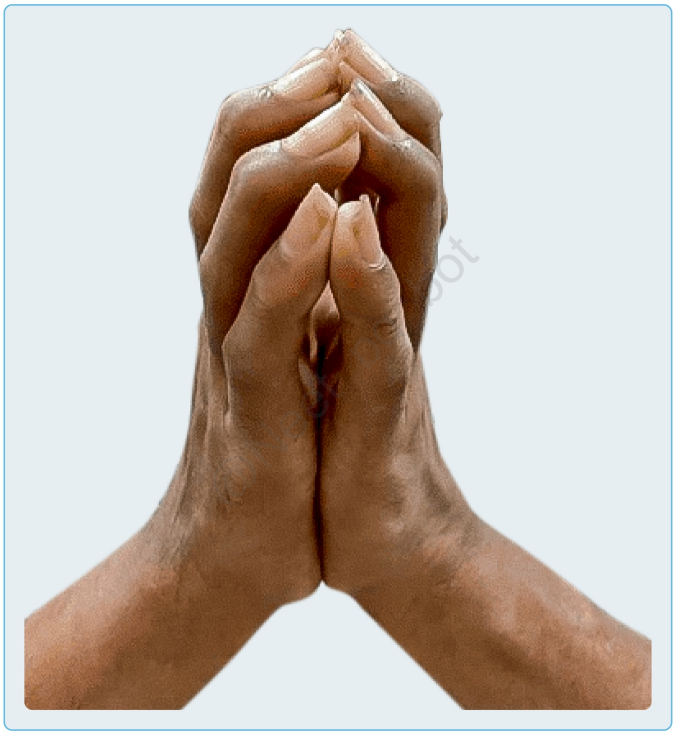
Q53: A diabetic patient walks into your clinic and does “namaste”. The image is given below. What could be the probable cause? (Q856286)

A. Flexor tenosynovitis

B. Cheiroarthropathy

C. Dupuytrens contracture

D. Ankyloses



@Neet_pg_bot

See Answer in Part B → Q53

@Neet_pg_bot

Q54: A 12-year-old child who is known to have type 1 diabetes mellitus presents with confusion and drowsiness. Her mother says that she seems to be breathing very fast. On examination, mucous membranes are dry, and blood pressure is 70/50 mmHg. Random blood glucose is 415 mg/d,l and urine ketones are 4+. What is the next best step in management? (Q855056)

A. 2-3 L of normal saline over 1-3 hours

B. Insulin infusion at 0.1 units/kg/hour

C. Arterial blood gas

D. Insulin bolus of 0.1 units/kg given

See Answer in Part B → Q54

@Neet_pg_bot

Q55: A patient came to the hospital with complaints of lethargy, increased sleep, and weight gain. Investigations revealed low plasma TSH concentration. However, on the administration of TRH, the TSH levels increased. Which of the conditions is likely in this patient? (Q858428)

A. Hyperthyroidism due to disease in the pituitary

B. Hypothyroidism due to disease in the pituitary

C. Hypothyroidism due to disease in the hypothalamus

D. Hyperthyroidism due to disease in the hypothalamus

See Answer in Part B → Q55

@Neet_pg_bot

Q56: A 55-year-old man with a known pituitary adenoma presents with sudden, severe headache, vomiting, and rapidly decreasing responsiveness. On examination, his blood pressure is 80/50 mmHg. Which of the following findings is most characteristic of pituitary apoplexy? (Q858432)

A. Hypertension

B. Shock

C. Unconsciousness

D. Fatigue

See Answer in Part B → Q56

@Neet_pg_bot

Q57: What is a macrovascular complication that develops in the advanced stages of diabetes? (Q859745)

A. Coronary artery disease

B. Foot ulcer

C. Nephropathy

D. Retinopathy

See Answer in Part B → Q57

@Neet_pg_bot

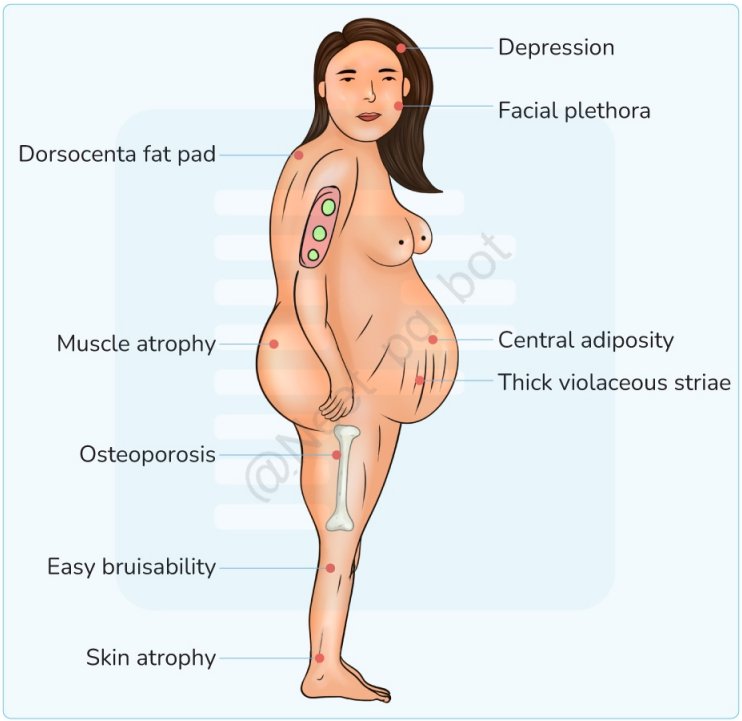
Q58: What is the disease depicted in the image below? (Q859778)

A. Acromegaly

B. PCOS

C. Cushing’s syndrome

D. Advanced obesity



See Answer in Part B → Q58

@Neet_pg_bot

Q59: A 30-year-old man presents with sudden onset of a headache, palpitation, and profuse sweating. He had several such episodes in the past. During these episodes, his BP is found to be high. A 24-hour urinary metanephrine is elevated. What is the most likely aetiology? (Q859793)

A. Fibromuscular dysplasia

B. Renal artery stenosis

C. Pheochromocytoma

D. Hyperthyroidism

See Answer in Part B → Q59

@Neet_pg_bot

Q60: A patient with diabetes mellitus for the past 5 years presents with vomiting and abdominal pain. She is non-compliant with medication and appears dehydrated. Investigations revealed a blood sugar value of 500 mg/dL and the presence of ketone bodies. What is the next best step in management? (Q855846)

A. Intravenous fluids with long-acting insulin

B. Intravenous fluids

C. Intravenous insulin

D. Intravenous fluids with regular insulin

See Answer in Part B → Q60

@Neet_pg_bot

Q61: A female patient with a negative urine pregnancy test presents to you with galactorrhea. An MRI was done, which revealed a large pituitary tumor. If the patient is not willing to undergo surgery, which of the following is the best drug for treatment? (Q855929)

A. Bromocriptine

B. Promethazine

C. Octreotide

D. Clozapine

See Answer in Part B → Q61

@Neet_pg_bot

Q62: Which of the following is not seen in MEN 2B syndrome? (Q856016)

A. Megacolon

B. Parathyroid adenoma

C. Mucosal neuroma

D. Marfanoid habitus

See Answer in Part B → Q62

@Neet_pg_bot

Q63: A lung cancer patient has hyperpigmentation of palmar and sole creases. Which of the following is responsible for this presentation? (Q860465)

A. Melanocyte Stimulating Hormone (MSH)

B. C-peptide

C. Neuropeptide Y

D. Melanin

See Answer in Part B → Q63

@Neet_pg_bot

Q64: Which of the following mutations is associated with the Philadelphia chromosome? (Q860473)

A. Inversion

B. Insertion

C. Reciprocal translocation

D. Deletion

See Answer in Part B → Q64

@Neet_pg_bot

Q65: Most common cause of hypercalcemia in a hospitalized patient is: (Q857290)

A. Malignancy

B. Parathyroid Adenoma

C. Parathyroid hyperplasia

D. Follicular thyroid CA

See Answer in Part B → Q65

@Neet_pg_bot

Q72: 24-year-old female presents with dysphagia, weight loss and bronchiectasis. Which investigation should be done to confirm the diagnosis. Barium swallow was shown? (Q866504)

A. Esophageal manometry

B. Upper GI endoscopy

C. CT chest

D. CECT chest

See Answer in Part B → Q72

@Neet_pg_bot

Q73: Which of the following is not associated with celiac disease? (Q853345)

A. IgA transglutaminase positive

B. IgG antigliadin positive

C. Modified Marsh classification

D. HLA DQ6 and HLA DQ11

See Answer in Part B → Q73

@Neet_pg_bot

Q74: A known case of ulcerative colitis is not responding to an anti-TNF alpha agent. Which JAK inhibitor is preferred for moderate to severe ulcerative colitis? (Q853355)

A. Vedolizumab

B. Tofacitinib

C. Ozanimod

D. Leflunomide

See Answer in Part B → Q74

@Neet_pg_bot

Q75: A 70-year-old male patient presents with a complaint of dysphagia, particularly for solids, which has been progressively worsening over the past few months. Additionally, he has experienced significant weight loss and cachexia over the same period. Which of the following diagnostic choices is best for this patient? (Q860394)

A. UGIE

B. Manometry

C. Barium swallow

D. Barium meal follow through

See Answer in Part B → Q75

@Neet_pg_bot

Q76: Which of the following symptoms suggests the use of steroids in IgA vasculitis? (Q840121)

A. Joint inflammation

B. Gastrointestinal hemorrhage

C. Abdominal discomfort

D. Dermatological eruption

See Answer in Part B → Q76

@Neet_pg_bot

Q77: In which of the following conditions is pneumomediastinum commonly found? (Q860160)

A. Pulsion diverticulum

B. Boerhaave syndrome

C. Mallory-Weiss syndrome

D. Pericarditis

See Answer in Part B → Q77

@Neet_pg_bot

Q78: A 42-year-old female presents with complaints of recurrent episodes of abdominal pain and cramps. An endoscopy is done and she is diagnosed with ulcerative colitis. She currently has 3-4 episodes of bloody stools per day. What is the appropriate initial treatment? (Q854665)

A. Budesonide

B. Sulfasalazine

C. Azathioprine

D. Bezlotoxumab

See Answer in Part B → Q78

@Neet_pg_bot

Q79: A patient was taking ampicillin for an upper respiratory tract infection. Then he started having watery diarrhoea for the past 3 days. Which is the drug of choice to

manage this condition? (Q854689)

A. Metronidazole

B. Fidaxomicin

C. Ciprofloxacin

D. Bezlotoxumab

See Answer in Part B → Q79

@Neet_pg_bot

Q80: A 49-year-old male is experiencing recurring episodes of watery diarrhea, dehydration, hypokalemia, and achlorhydria. Which type of neuroendocrine tumor could potentially cause these symptoms? (Q858363)

A. Insulinoma

B. Somatostatinoma

C. VIPoma

D. Glucagonoma

See Answer in Part B → Q80

@Neet_pg_bot

Q81: Mark the correct statement regarding inflammatory bowel disease. (Q855605)

A. Skip lesions are present in Crohn’s disease

B. Mucosal layers are involved in Crohn’s while transmural involvement seen in ulcerative colitis

C. Inflammatory bowel disease doesn’t have a genetic predisposition

D. Crohn’s is curable through surgical resection of the affected segment

See Answer in Part B → Q81

@Neet_pg_bot

Q82: Which of the following are not included in the components of the MELD (2016) score? (Q856338)

A. Bilirubin

B. INR

C. Albumin

D. Creatinine

See Answer in Part B → Q82

@Neet_pg_bot

Q83: What is the probable diagnosis of a patient who has significant abdominal swelling and laboratory analysis of the fluid obtained through paracentesis reveals SAAG <1.1? (Q856355)

A. Congestive heart failure

B. Myxoedema

C. Budd Chiari syndrome

D. Tuberculosis

See Answer in Part B → Q83

@Neet_pg_bot

Q84: What is not a characteristic feature of Wilson's disease? (Q856381)

A. Autosomal recessive disease

B. No free radical injury

C. ATP7B gene involved

D. Presents before age 40 with liver disease

See Answer in Part B → Q84

@Neet_pg_bot

Q85: A 15-year-old girl presented with fatigue, chronic diarrhoea, weight loss, bone pain and abdominal distension. Investigations revealed iron deficiency anemia and osteoporosis. Which of the following is the single best test to be done for her evaluation? (Q858444)

A. TSH levels

B. C-peptide levels

C. Urine sugar and ketone

D. IgA tissue transglutaminase antibody

See Answer in Part B → Q85

@Neet_pg_bot

Q86: A patient with inflammatory bowel disease presents with the following lesion. What is the most likely diagnosis? (Q859643)

A. Erythema nodosum

B. Pyoderma gangrenosum

C. Diabetic ulcer

D. Venous ulcer

See Answer in Part B → Q86

@Neet_pg_bot

Q87: Match the following? a. Trisomy 13 1. Huntington's disease b. Trisomy 18 2. Patau syndrome c. Trinucleotide repeat sequence 3. Sickle disease d. Hb point mutation of glutamate to valine 4. Edward syndrome (Q857256)

A. a-2, b-4, c-1, d-3

B. b-1, a-3, d-2, c-4

C. a-2, b-1, c-4, d-3

D. a-4, b-1, c-3, d-2

See Answer in Part B → Q87

@Neet_pg_bot

Q88: How much sodium deficit needs to be corrected in a 40 kg female with a serum sodium level of 120 mEq/L to achieve a desired sodium concentration of 140 mEq/L? (Q830815)

A. 400 mEq

B. 300 mEq

C. 200 mEq

D. 100 mEq

See Answer in Part B → Q88

@Neet_pg_bot

Q89: During the medication review of an elderly male patient with a history of COPD, hypertension, and diabetes, what criteria should the physician consider? (Q830826)

A. Duke’s criteria

B. Light criteria

C. Beer’s criteria

D. Jones criteria

See Answer in Part B → Q89

@Neet_pg_bot

Q90: What vitamin deficiency is responsible for the following symptoms in a patient: tingling sensation in the hands and feet, generalized weakness, easy fatigability, pallor, and ataxia? (Q793810)

A. Vitamin B1

B. Vitamin B12

C. Vitamin B2

D. Vitamin B3

See Answer in Part B → Q90

@Neet_pg_bot

Q91: Cat scratch disease is caused by? (Q793845)

A. Bartonella henselae

B. Bartonella quintana

C. Bartonella bacilliformis

D. Borrelia burgdorferi

See Answer in Part B → Q91

@Neet_pg_bot

Q92: A man brings his father who became unconscious while working in a field in the host sun at 42 degrees Celsius in May. One examination, there were no physical signs of dehydration. His serum electrolyte values were normal. The physician found that the body temperature was 106 F. Which of the following symptoms is least likely to be seen in this patient? (Q793895)

A. Nausea

B. Hypotension

C. Sweating

D. Headache

See Answer in Part B → Q92

@Neet_pg_bot

Q93: What is the most likely diagnosis for a tall male with a lack of pubic and axillary hair, underdeveloped genitalia, elevated levels of LH and FSH, and a karyotype of XXY? (Q793914)

A. Vanishing testis syndrome

B. Klinefelter’s syndrome

C. Noonan syndrome

D. Adrenal hyperplasia

See Answer in Part B → Q93

@Neet_pg_bot

Q94: A 25-year-old female with systemic lupus erythematosus presents with weight gain, moon facies, buffalo hump, and hirsutism. Which of the following is the most appropriate next investigation? (Q879210)

A. Serum ACTH and Serum cortisol levels

B. Serum ACTH and low-dose dexamethasone suppression test

C. Low-dose followed by high-dose dexamethasone suppression test

D. Serum ACTH and High-dose dexamethasone suppression test

See Answer in Part B → Q94

@Neet_pg_bot

Q95: A 10-year-old child is on long-term oral corticosteroid therapy for nephrotic syndrome. On examination, he has moon facies, truncal obesity, and a buffalo hump. There is no history of weight loss or hyperpigmentation. Most likely diagnosis is: (Q879213)

A. Addison’s disease

B. Cushing’s syndrome

C. Congenital adrenal hyperplasia

D. Hypothyroidism

See Answer in Part B → Q95

@Neet_pg_bot

Q96: PTH is increased in (Q879216)

A. Immobility

B. Familial hypocalciuric hypercalcemia

C. Vitamin D toxicity

D. Thiazide diuretics

See Answer in Part B → Q96

@Neet_pg_bot

Q97: A patient presents with complaints of sudden onset headache, palpitation, and profuse sweating . The patient has had multiple similar episodes in the past. During these episodes, the patient's blood pressure is elevated . A 24-hour urine metanephrine is elevated . What is the most likely diagnosis? (Q794485)

A. Addison's disease

B. Renal artery stenosis

C. Pheochromocytoma

D. Hyperthyroidism

See Answer in Part B → Q97

@Neet_pg_bot

Q98: 70 year old man presents with low back ache and progressive pallor. On work up, KFT is deranged. LFT is normal with normal level of Albumin, but gamma globulins are disproportionately increased. X ray spine shows multiple lytic lesions. Which of the following is the cell of origin of the diagnosis of this patient? (Q820435)

A. Lymphocyte

B. Plasma cell

C. Histiocytes

D. Monocytes

See Answer in Part B → Q98

@Neet_pg_bot

Q99: Calcitonin is a marker of which malignancy? (Q820447)

A. Papillary thyroid cancer

B. Follicular thyroid cancer

C. Medullary thyroid cancer

D. Anaplastic thyroid cancer

See Answer in Part B → Q99

@Neet_pg_bot

Q100: What should be done next in the management of a patient who is diabetic and presents with symptoms of vomiting and abdominal pain? Upon examination, the patient displays hyperventilation, sweet breath, and low blood pressure. The blood glucose level is 320 mg/dL, and urine ketones are detected. (Q793814)

A. IV insulin drip

B. IV soda-bicarbonate

C. Check blood ketone levels

D. IVF and check K+

See Answer in Part B → Q100

@Neet_pg_bot

Q101: A 25-year-old P1L1 woman is planning for her second child. She has been recently diagnosed with Grave's disease. Which of the following is the antithyroid drug to be used in early gestation? (Q793948)

A. Propylthiouracil

B. Methimazole

C. Carbimazole

D. All the above

See Answer in Part B → Q101

@Neet_pg_bot

Q102: Patient is identified as having a tumor in the ileum leading to urinary 5 HIAA being elevated. What is the diagnosis? (Q793830)

A. Carcinoid tumor

B. Neuroblastoma

C. Leiomyoma

D. Chromaffinoma

See Answer in Part B → Q102

@Neet_pg_bot

Q103: What is the probable diagnosis for a 50-year-old woman with a skin lesion visible in the provided image, which initially appeared small but has now spread to her entire limb and abdomen? Despite being on anticoagulation therapy, she has a longstanding history of diabetes and recurring deep vein thrombosis episodes. (Q793836)

A. Insulinoma

B. Gastrinoma

C. Glucagonoma

D. VIPoma

See Answer in Part B → Q103

Q13 (p. 351) *Q14 (p. 351)* *Q15 (p. 352)*

Q1: A 32-year-old woman with a history of Sjögren syndrome presents with excessive thirst and passage of large volumes of urine. Labs are show below: Serum sodium: 154 mEq/L Plasma osmolality: 310 mOsm/kg Urine osmolality: 120 mOsm/kg Serum chloride: 104 mEq/L Serum potassium: 4.1 mEq/L Serum magnesium: 1.9 mg/dL (normal) Serum calcium: 9.2 mg/dL ABG: pH = 7.35, pCO 2 = 38 mm Hg, HCO 3 =24 mEq/L Which of the following is the most likely diagnosis? (Q850514)

A. Bartter syndrome

B. Gitelman syndrome

C. Distal renal tubular acidification defect/ Type 1 RTA

D. Impaired tubular response to ADH

See Answer in Part B → Q1

@Neet_pg_bot

Q2: 25-year-old man presents with complaints of polyuria, polydipsia and dizziness on change of posture. He has a recent history of head trauma. Work up shows RBS: 100 mg/dl, serum sodium: 152 mEq/L, plasma osmolality: 308 mOsm/kg, Urine osmolality: 90 mOsm/kg. Serum copeptin levels are low and fail to rise with hypertonic saline stimulation. Which of the following is the most likely diagnosis? (Q850517)

A. Central diabetes insipidus

B. Nephrogenic diabetes insipidus

C. Primary polydipsia

D. Syndrome of inappropriate ADH secretion

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following scenario will not lead to nephrogenic diabetes insipidus? (Q850518)

A. Patient of bipolar disorder on lithium

B. HIV patient with cerebral toxoplasmosis

C. Laxative abuse

D. Sickle cell anaemia

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following causes will lead to nephrogenic diabetes insipidus? a. Hypercalcemia b. Toxoplasmosis c. Laxative abuse d. Sickle cell anaemia (Q850519)

A. a,b

B. a,b,c

C. b,c,d

D. a,c,d

See Answer in Part B → Q4

@Neet_pg_bot

Q5: 58-year-old male smoker, recently diagnosed with small-cell lung carcinoma, presents with cough and shortness of breath. On examination, he is alert and oriented (GCS 15/15), vitals are stable, and he appears euvolemic. Laboratory tests show:

Serum sodium: 120 mEq/L Serum osmolality: 255 mOsm/kg Urine osmolality: 650 mOsm/kg Which of the following is the most appropriate initial management for this patient? (Q850521)

A. 3% hypertonic saline bolus

B. 3% hypertonic saline infusion

C. Oral salt tablets with loop diuretics

D. Tolvaptan

See Answer in Part B → Q5

@Neet_pg_bot

Q6: 22-year-old female presents with recurrent episodes of muscle cramps, weakness, and fatigue. Blood pressure is 110/70 mmHg. ECG shows a QT interval of 500 msec. Labs show serum potassium: 2.8 mEq/L, serum magnesium: 1.1 mg/dL, serum calcium: normal, 24 hour urinary calcium: low, plasma renin activity: high, aldosterone: high. Diagnosis is? (Q850561)

A. Barter syndrome

B. Gitelman syndrome

C. Liddle syndrome

D. Gordon syndrome

See Answer in Part B → Q6

@Neet_pg_bot

Q7: 10-year-old boy presents with growth retardation and recurrent episodes of muscle weakness. BP is 100/60 mmHg. Labs reveal: serum potassium: 2.6 mEq/L, serum magnesium: normal, serum calcium: normal, 24-hour urinary calcium: high, plasma renin activity: high, aldosterone: high. What is the most likely diagnosis? (Q850565)

A. Bartter syndrome

B. Gitelman syndrome

C. Liddle syndrome

D. Gordon syndrome

See Answer in Part B → Q7

@Neet_pg_bot

Q8: 25-year-old HIV-positive male presents with a GTCS episode and headache. MRI brain shows calcification in basal ganglia. On admission, serum sodium is 120 mEq/L, serum osmolality is 260 mOsm/kg, urine osmolality is 620 mOsm/kg, and urine sodium is 48 mEq/L. There is no edema, normal JVP and normal BP with no significant change on positional variation. Diagnosis? (Q850569)

A. Cerebral salt wasting

B. SIADH

C. Adrenal insufficiency

D. Psychogenic polydipsia

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A patient is found to have hypotonic euvolemic hyponatremia with inappropriately concentrated urine. Which of the following respiratory conditions is least likely to cause this disorder? (Q890249)

A. Small cell carcinoma of the lung

B. Asthma

C. Respiratory failure requiring positive-pressure ventilation

D. Primary pulmonary emphysema

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45-year-old man presents with headache, nausea and confusion 5 days after starting a new medication. He is clinically euvolemic. His investigations reveal: Serum sodium - 116 mEq/L Plasma osmolality - Low Urine osmolality - Inappropriately high Which of the following drugs is least likely to be responsible for this condition? (Q890250)

A. Carbamazepine

B. Demeclocycline

C. Desmopressin

D. Selective serotonin reuptake inhibitors (SSRIs)

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 60-year-old man presents with progressive headache, nausea, lethargy and confusion. Examination shows no signs of dehydration or oedema. Investigations reveal: Serum sodium: 122 mEq/L Plasma osmolality: Low Urine osmolality: Inappropriately high Urine sodium: >40 mmol/L Which of the following tumours is least likely to be associated with this condition? (Q890251)

A. Small cell carcinoma of the lung

B. Thymoma

C. Ewing’s sarcoma

D. Chromophobe pituitary adenoma

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 38-year-old man is admitted following a subarachnoid haemorrhage. On day 4 of hospitalisation, he develops dizziness and postural hypotension. He is passing large volumes of urine. Laboratory evaluation shows: Serum sodium: 118 mEq/L Urine sodium: 140 mmol/L Urine output: High Central venous pressure: Low Which of the following is the most likely diagnosis? (Q890252)

A. Syndrome of inappropriate ADH secretion

B. Cerebral salt wasting

C. Central diabetes insipidus

D. Primary polydipsia

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 58-year-old man is brought to the emergency department with a sudden onset of confusion, repeated vomiting and headache. Examination shows no signs of dehydration or oedema. His laboratory investigations reveal: Serum sodium - 114 mEq/L Plasma osmolality - Low Urine osmolality - Inappropriately high Urine sodium - 52 mmol/L Which of the following is the most appropriate initial management? (Q890253)

A. Infusion of hypertonic (3%) saline

B. Infusion of hypotonic (0.45%) saline

C. Infusion of normal (0.9%) saline

D. Administration of DDAVP

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 62-year-old man with small-cell carcinoma of the lung has persistent asymptomatic hyponatremia (Na■ 124-128 mEq/L) for 3 weeks. He is clinically euvolemic and has been poorly compliant with fluid restriction. Which of the following

is the drug of choice for long-term management? (Q890254)

A. Furosemide

B. Tolvaptan

C. Demeclocycline

D. Fludrocortisone

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 56-year-old man with a history of chronic alcoholism is admitted with altered sensorium. His serum sodium is 110 mEq/L. He is treated in a local hospital and discharged after 3 days. Two days later, he presents again with progressive quadriparesis, slurred speech, difficulty in swallowing, and preserved consciousness. His Brain MRI shows a symmetric lesion in the central pons. What is the most likely diagnosis? (Q890255)

A. Wernicke encephalopathy

B. Central pontine myelinolysis

C. Acute disseminated encephalomyelitis

D. Brainstem infarction

See Answer in Part B → Q15

Q1: Which of the following conditions is least likely to be associated with hyperphosphatemia? (Q850713)

A. Hypoparathyroidism

B. Pseudohypoparathyroidism

C. Pseudo-pseudo-hypoparathyroidism

D. Chronic kidney disease

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following causes non anion gap acidosis? (Q850747)

A. Diarrhea

B. Ethylene glycol poisoning

C. Starvation

D. Glue sniffing

See Answer in Part B → Q2

@Neet_pg_bot

Q3: First line management of life-threatening hypercalcemia? (Q850744)

A. Normal saline

B. Lasix infusion

C. Hemodialysis

D. Zolendronate

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Hypomagenesemia is seen in all except? (Q850743)

A. Renal failure

B. Alcoholism

C. Gitelman syndrome

D. Amphotericin B

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 25 year old lady with eclampsia was given magnesium sulfate by the Pritchard regimen. She developed areflexia of bilateral ankle jerks and knee jerks with a respiratory rate of 8/min. Which of the following will be used? (Q850742)

A. Calcium gluconate

B. Calcium carbonate

C. Sevelamer

D. Lanthanum carbonate

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 5 year old child with jaw swelling is diagnosed with Burkitt lymphoma based on histopathology reports. You have started chemotherapy. Which of the following electrolyte imbalance will not be seen in this case? (Q850740)

A. Hyperphosphatemia

B. Hyperkalemia

C. Hypocalcemia

D. Hypernatremia

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Euvolemic hyponatremia is seen with? (Q850738)

A. Secondary Addison disease

B. Primary Addison disease

C. Cushing syndrome

D. Congestive heart failure

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Tolvaptan can be used in management of all except? (Q850737)

A. Hypervolemic hyponatremia

B. Hypovolemic hyponatremia

C. Euvolemic hyponatremia

D. SIADH

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 62-year-old man is brought to the emergency department with sudden onset confusion, vomiting, and a generalized tonic-clonic seizure. He has a history of small cell lung carcinoma and was recently started on chemotherapy. On examination, he is drowsy and disoriented. Laboratory investigations reveal a serum sodium level of 112 mEq/L.What is the most appropriate immediate management for this patient? (Q850734)

A. Bolus of 3% saline

B. Slow correction with 3% saline over 24 hours

C. Slow correction with 3% saline over 46 hours

D. Water restriction with oral salt capsules

See Answer in Part B → Q9

@Neet_pg_bot

Q10: While drawing blood for estimation of ionized calcium, all of the following pre-analytical factors can alter the test result except? (Q850732)

A. Prolonged tourniquet application

B. Isometric hand exercise during sampling

C. Exposure of sample to air before analysis

D. Haemolysis of sample

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following causes a steroid-responsive hypercalcemia? (Q850730)

A. Vitamin D intoxication

B. Multiple myeloma

C. Lung cancer

D. Parathyroid carcinoma

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is correct about Chvostek sign? (Q850724)

A. Twitching of the ipsilateral perioral levator and zygomaticus muscles

B. Twitching of the ipsilateral corrugator cili and zygomaticus muscles

C. Twitching of the contralateral perioral levator and zygomaticus muscles

D. Twitching of the contralateral corrugator cili and zygomaticus muscles

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Post thyroid surgery patient has developed muscle cramps followed by breathing difficulty due to bronchospasm. ECG shows QTc prolongation. Which of the following would be used for management? (Q850721)

A. KCL infusion 40meq/L

B. KCL infusion 40 meq/L with salbutamol nebulization

C. 10 ml of 10% calcium gluconate diluted in 50 ml of 5% dextrose over 10 min

D. 10 ml of 10% calcium gluconate over 1 min

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following conditions classically presents with elevated serum calcium, normal phosphate, and normal serum alkaline phosphatase (SAP)? (Q850718)

A. Osteoporosis

B. Paget disease

C. Multiple myeloma

D. Primary Hyperparathyroidism

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following is the leading cause of hypoparathyroidism? (Q850716)

A. Autoimmunity

B. Hemochromatosis

C. Wilson disease

D. Riedel Struma

See Answer in Part B → Q15

@Neet_pg_bot

Q16: 30-year-old patient came in with a severe headache and seizure episode. Serum sodium on admission was 98 meq/L. You have started correction with 3% saline and now after 24 hours of infusion sodium is 110 meq/L. The patient develops quadriparesis and altered sensorium. Which investigation will you perform now? (Q850574)

A. MRI Head

B. LP for CSF

C. Brainstem evoked potentials

D. EEG

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Leading cause of hypercalcemia in hospitalized patients? (Q850709)

A. Sarcoidosis

B. Oat cell cancer of lung

C. Non small cell cancer of lung

D. Inferior parathyroid adenoma

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following will have no role in immediate management of acute onset hyperkalemia? (Q850670)

A. Albuterol nebulization

B. Soda bicarbonate

C. Sodium polystyrene sulfonate

D. 50 ml of 50% dextrose with 10 units of regular insulin

See Answer in Part B → Q18

@Neet_pg_bot

Q19: All of the following cause hyperkalemia except? (Q850665)

A. Yellow oleander

B. Prolonged immobilization

C. Autoimmune polyglandular syndrome

D. Cushing syndrome

See Answer in Part B → Q19

@Neet_pg_bot

Q20: All of the following cause hypokalemia except? (Q850663)

A. Thyrotoxicosis

B. Salbutamol

C. Lupus nephritis

D. Conn syndrome

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following causes hypokalemia? (Q850659)

A. Tumor lysis syndrome

B. Crush injury

C. Hemolysis

D. Massive transfusion

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following is a cause of chloride-resistant metabolic alkalosis? (Q850657)

A. Chronic vomiting

B. Bartter syndrome

C. Infantile hypertrophic pyloric stenosis

D. Gastric outlet obstruction

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following is not a cause of chloride responsive metabolic alkalosis? (Q850651)

A. Gastric adenocarcinoma

B. IHPS

C. Ascites

D. Chronic vomiting

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following is fluid of choice for metabolic alkalosis? (Q850643)

A. Normal saline

B. Ringer lactate

C. 5% dextrose

D. Isolyte-P

See Answer in Part B → Q24

@Neet_pg_bot

Q25: For a patient of acute onset hypernatremia Na= 158 meq/L with confusion and seizures, which of the following fluids is not to be used? (Q850641)

A. 5% Dextrose

B. N/2 saline

C. N/4 saline

D. Normal saline

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Which of the following is correct about the rate of correction for chronic hyponatremia? (Q850630)

A. 4-6 meq/ d

B. 6-8 meq/d

C. 8-10 meq/d

D. 10-12 meq/d

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 60-kg male runner develops cramps, disorientation, and seizures after completing a marathon. On admission, serum sodium is 120 mEq/L and serum potassium is 3.2 meq/L. What is the approximate sodium deficit in this patient? (Q850627)

A. 180 meq

B. 360 meq

C. 420 meq

D. 720 meq

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which of the following is not a cause of hypervolemic hyponatremia? (Q850599)

A. HFrEF

B. CLD

C. Nephrotic syndrome

D. Atypical pneumonia

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Which of the following is not seen in patients with hypokalemia? (Q850577)

A. Ileus

B. Polyuria

C. Atrial arrhythmias

D. Metabolic acidosis

See Answer in Part B → Q29

@Neet_pg_bot

Q30: Sudden shrinkage of brain cells in acute hypernatremia encountered in neonate on day 2 of life can lead to development of: (Q850576)

A. Intra- parenchymal bleeding

B. Osmotic demyelination syndrome

C. Paralytic ileus

D. Tachyarrhythmias

See Answer in Part B → Q30

Q1: Which of the following is not correct about thrombotic thrombocytopenic purpura? (Q850750)

A. Deficiency of ultra large multimers of vWF

B. Microangiopathic haemolytic anaemia

C. Deficiency of ADAMTS13

D. Treated with plasma exchanges

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 32-year-old woman presents with fever, confusion, and generalized weakness for 3 days. On examination, she has pallor, multiple petechiae, and a right-sided facial droop. Laboratory investigations reveal: Hemoglobin: 7.8 g/dL Platelet count: 25,000/mm³ Peripheral smear shows numerous schistocytes LDH: markedly elevated Creatinine: 1.2 mg/dL Which of the following is the most likely diagnosis? (Q850758)

A. Thrombotic Thrombocytopenic Purpura

B. Henoch–Schönlein Purpura

C. Haemolytic Uremic Syndrome

D. Tubulointerstitial Kidney Disease

See Answer in Part B → Q2

@Neet_pg_bot

Q3: 30-year-old man presents with dull aching bilateral flank pain. BP is 160/100 mmHg. Family history reveals that his father died of brain haemorrhage at age 60. What is the first investigation that should be done in this case? (Q850759)

A. NCCT: KUB

B. CECT: KUB

C. Ultrasound abdomen

D. DTPA scan

See Answer in Part B → Q3

@Neet_pg_bot

Q4: What is the leading cause of death in ADPKD? (Q850760)

A. Renal failure

B. Rupture of berry aneurysm

C. Renal cell cancer

D. CV mortality

See Answer in Part B → Q4

@Neet_pg_bot

Q5: In a follow-up visit of a 40-year-old man diagnosed with ADPKD based on Ravine criteria, which investigation should be done to screen for intracranial aneurysm and risk of subarachnoid bleeding? (Q850761)

A. Lumbar puncture

B. MRA

C. NCCT head

D. Transcranial doppler

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which is the most common cardiac valvular lesion seen in patients of ADPKD? (Q850762)

A. Mitral valve prolapse

B. Tricuspid valve prolapse

C. Pulmonic insufficiency

D. Tricuspid insufficiency

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which is the most common cardiac valvular lesion seen in patients of carcinoid syndrome? (Q850763)

A. Tricuspid insufficiency and pulmonic stenosis

B. Tricuspid stenosis and pulmonic insufficiency

C. Mitral insufficiency and pulmonic stenosis

D. Mitral stenosis and pulmonic insufficiency

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is not correct about autosomal dominant tubulointerstitial kidney disease? (Q850764)

A. Enlarged kidneys

B. Medullary cysts

C. UMOD gene defect

D. Increased incidence of gout

See Answer in Part B → Q8

@Neet_pg_bot

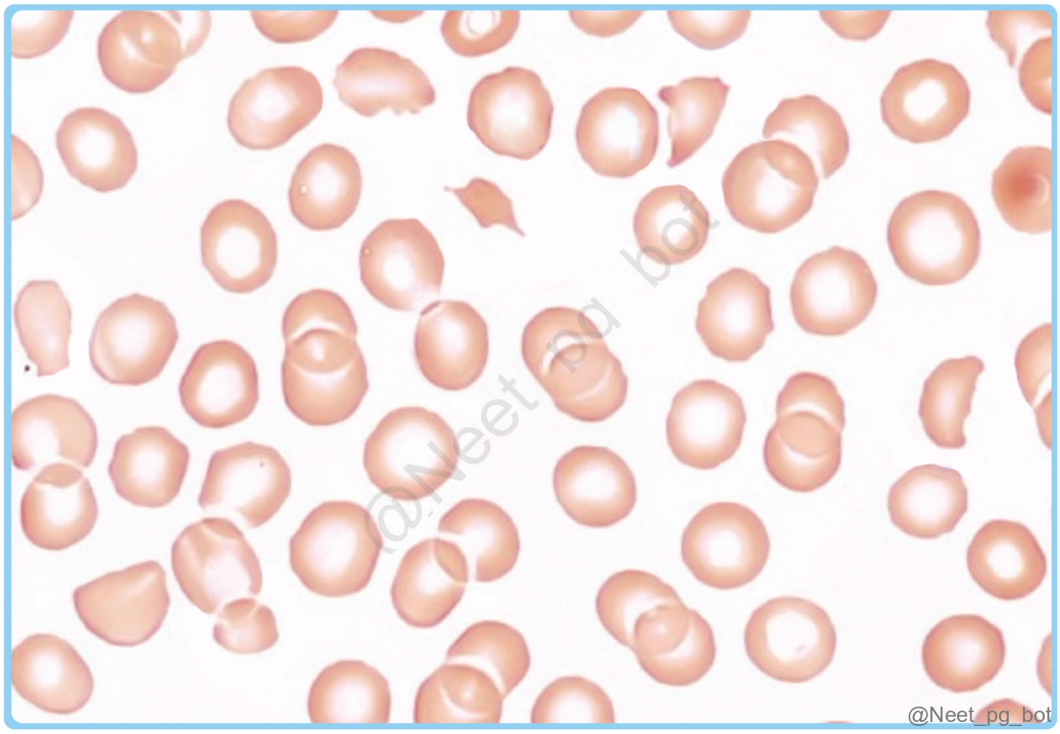
Q9: 5-year-old child developed vomiting, cramping and bloody diarrhea that was managed with ORS and antibiotics. After 1 week the patient is admitted due to anuria for the last 24 hours and encephalopathy. Work up shows Hb 7gm%, TLC 15000 / cu.mm, platelet count 50,000 /cu.mm, LDH is elevated and peripheral smear is shown below. What is the diagnosis? (Q850765)

A. Hemolytic uremic syndrome (HUS)

B. Thrombotic thrombocytopenic purpura (TTP)

C. Acute tubular necrosis (ATN)

D. Henoch–Schönlein purpura (HSP)



See Answer in Part B → Q9

@Neet_pg_bot

Q10: The leading extra-renal manifestation of autosomal recessive polycystic kidney disease is? (Q850766)

A. Hepatic cysts

B. Hepatic fibrosis

C. Berry aneurysm

D. Arachnoid cysts

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is correct about genetic aspects of Autosomal recessive polycystic kidney disease? (Q850767)

A. PKHD1 gene, chromosome 6

B. PKD1 gene, chromosome 16

C. PKD2 gene, chromosome 4

D. UMOD gene, chromosome 16

See Answer in Part B → Q11

@Neet_pg_bot

Q12: 35-year-old man is treated with amoxicillin + clavulanic acid for lobar pneumonia. After 10 days of therapy, he develops fever, maculopapular rash, and decreased urine output. Labs show serum creatinine of 3.2 mg/dL. Urinalysis reveals mild proteinuria, microscopic hematuria, and numerous WBCs. Wright's stain of the urine demonstrates eosinophiluria. Which of the following is the most likely diagnosis? (Q850768)

A. Acute tubular necrosis

B. Acute interstitial nephritis

C. Rapidly progressive glomerulonephritis

D. Nephrolithiasis

See Answer in Part B → Q12

@Neet_pg_bot

Q13: All of the following are correct about Renal vein thrombosis except? (Q850769)

A. Seen with membranous glomerulopathy

B. Associated with ADAMTS 13 deficiency

C. CT angiography is 100% sensitive

D. Oral anticoagulation is first line treatment

See Answer in Part B → Q13

Q1: A known Type II DM, 70 year old patient was under medication. He aslo takes Telmisartan. Patients current lab values: HbA1c- 8.5, eGFR- 50 mL/min/1.73 m. Normal potassium levels. What is the next appropriate step to decrease the risk of further eGFR decrement? (Q882282)

A. Shift to Ramipril

B. Increase the dose of antidiabetic meds

C. Start Carvedilol

D. Increase Telmisartan dose

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Oval fat bodies in urine are seen in all of the following conditions except? (Q851037)

A. Minimal change disease

B. Focal segmental glomerulosclerosis

C. Membranous nephropathy

D. Fat embolism syndrome

See Answer in Part B → Q2

@Neet_pg_bot

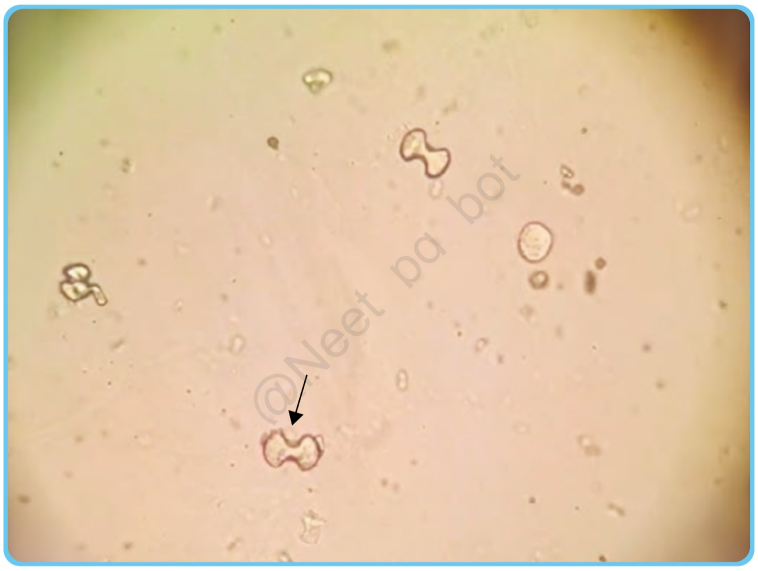
Q3: 28-year-old man presents to the emergency department after ingesting a large quantity of over-the-counter cough syrup in a suicide attempt. He complains of severe abdominal pain and confusion. ABG shows high anion gap metabolic acidosis. Urinalysis microscopy is shown below. Which of the following is the most appropriate initial treatment? (Q851038)

A. Sodium bicarbonate infusion

B. Hemodialysis

C. Fomepizole

D. N-acetylcysteine



@Neet_pg_bot

See Answer in Part B → Q3

@Neet_pg_bot

Q4: 25-year-old patient is having recurrent kidney stones. Urine microscopy is shown below. Which of the following drugs will prevent recurrence of these kidney stones.

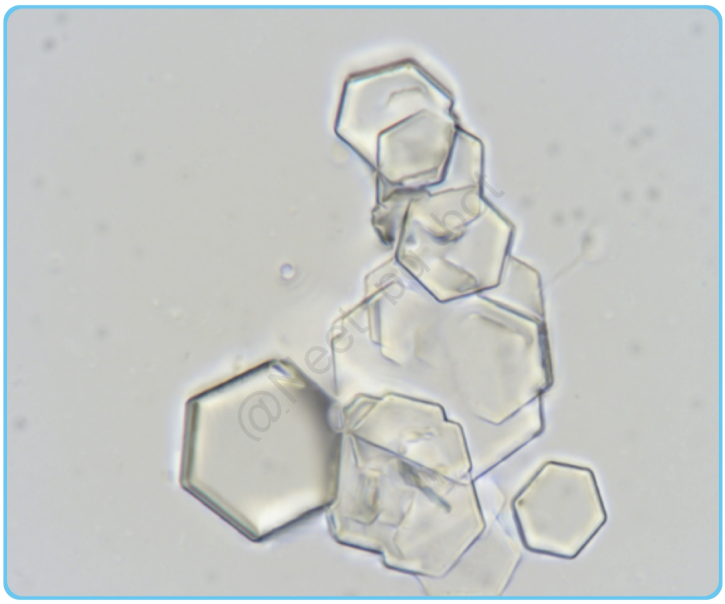
(Q851039)

A. Thiazides

B. Furosemide

C. Tiopronin

D. Mercaptopurine



@Neet_pg_bot

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Eosinophiluria is typically seen in all of the following conditions except: (Q851040)

A. Allergic interstitial nephritis

B. Atheroembolic kidney disease

C. Pyelonephritis

D. Tubulointerstitial nephritis

See Answer in Part B → Q5

@Neet_pg_bot

Q6: The presence of broad casts on urine microscopy is most suggestive of which condition? (Q851041)

A. Acute tubular necrosis

B. Acute interstitial nephritis

C. Chronic kidney disease

D. Thrombotic thrombocytopenic purpura

See Answer in Part B → Q6

@Neet_pg_bot

Q7: What is the diagnostic cutoff used to define hematuria on urine microscopy? (Q851042)

A. > 1 RBC/ HPF in centrifuged sediment X 3 reports

B. > 5 RBC/ HPF in centrifuged urine sediment X 3 reports

C. > 50 RBC/ HPF in centrifuged urine sediment X 3 reports

D. > 500 RBC/ HPF in centrifuged urine sediment X 3 reports

See Answer in Part B → Q7

@Neet_pg_bot

Q8: What is the hallmark feature of glomerular hematuria? (Q851043)

A. RBC casts

B. Dysmorphic RBC

C. Low C3

D. Cola color urine

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Muddy brown granular casts are seen in? (Q851044)

A. ATN

B. CGN

C. AIN

D. AGN

See Answer in Part B → Q9

@Neet_pg_bot

Q10: What is the recommended screening test for diabetic nephropathy? (Q851045)

A. 24-hour urine protein estimation

B. Serum creatinine

C. Spot urine albumin-to-creatinine ratio

D. Urine dipstick for protein

See Answer in Part B → Q10

@Neet_pg_bot

Q11: 24-year-old man presents with red-colored urine after trauma due to being repeatedly punched in the abdomen during a street fight. On keeping the urine sample standing, the color clears in the next few hours. Which of the following is the most likely cause? (Q851046)

A. Hematuria

B. Hemoglobinuria

C. Myoglobinuria

D. Porphyria

See Answer in Part B → Q11

@Neet_pg_bot

Q12: 9-year-old boy presents with his urine turned dark red after playing football. On examination, he has no hepatosplenomegaly. Laboratory studies reveal normal blood lactate after forearm exercise testing but elevated creatine kinase. Which of the following is the cause? (Q851047)

A. Orthostatic haematuria

B. Muscle glycogen phosphorylase deficiency

C. Trauma

D. Acid maltase deficiency

See Answer in Part B → Q12

@Neet_pg_bot

Q13: 35-year-old woman diagnosed with rheumatoid arthritis presents with swelling of the face and legs for 2 weeks. Urine is frothy. On urine microscopy, the following are observed: 3 RBC per HPF Oval fat bodies Maltese crosses under polarized light 4+ proteinuria Which of the following is the most likely diagnosis? (Q851048)

A. Acute glomerulonephritis

B. Minimal change disease

C. Membranous glomerulopathy

D. Membranoproliferative glomerulopathy

See Answer in Part B → Q13

Q1: 65-year-old man with hypertension and diabetes undergoes a coronary angiography. Two days later, his serum creatinine rises from 1.2 mg/dL to 2.0 mg/dL. Urine output is normal. Urinalysis shows muddy brown casts.Which of the following is the most likely diagnosis? (Q851006)

A. Contrast-associated AKI

B. Athero-embolic kidney disease

C. Pre-renal Azotemia

D. Acute glomerulonephritis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: 5-year-old child with chronic kidney disease presents with bow legs. He has low sunlight exposure. Laboratory investigations reveal: Serum calcium: 7 mg/dL (low) Serum phosphate: 6.3 mg/dL (elevated) Alkaline phosphatase: Elevated Vitamin D3 levels: Low What is the most appropriate next step in management? (Q851016)

A. Phosphate binder

B. Calcium acetate + Vitamin D3

C. Only vitamin D3

D. Haemodialysis

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Nephrologist has started empirical hemodialysis in a patient with sepsis whose BUN is 150 mg/dl and progressive decline in renal function. Which of the following is the leading side effect anticipated in this case? (Q851015)

A. Infection

B. Hypotension

C. Cerebral oedema

D. Hyponatremia

See Answer in Part B → Q3

@Neet_pg_bot

Q4: All of the following drugs are useful in reducing progression of Diabetic Nephropathy except? (Q851014)

A. ACEi

B. Finrenone

C. Sitagliptin

D. Empagliflozin

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following are common complications of acute kidney injury ? a. Bleeding b. Anemia c. Pericardial effusion d. Hypomagnesemia (Q851013)

A. a,b

B. b,c

C. a,b,c

D. a,b,c,d

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Kidney injury molecule -1 is a transmembrane protein expressed in (Q851012)

A. PCT

B. DCT

C. Collecting duct

D. Pyramids

See Answer in Part B → Q6

@Neet_pg_bot

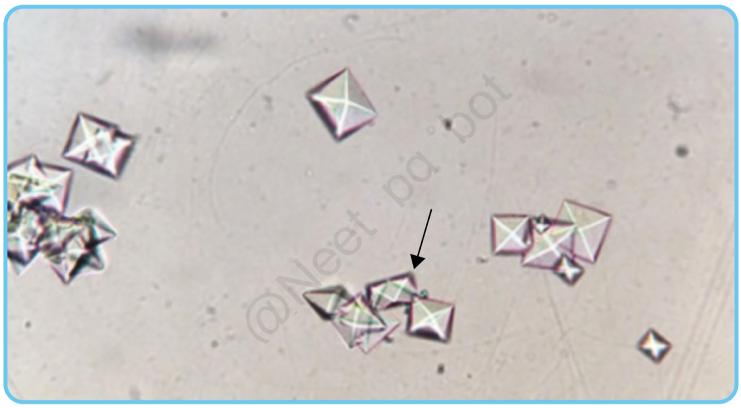
Q7: 25-year-old patient is having recurrent kidney stones. Urine microscopy is shown below. Which of the following drugs will prevent recurrence of these kidney stones. (Q851011)

A. Thiazides

B. Furosemide

C. Tiopronin

D. Mercaptopurine



@Neet_pg_bot

See Answer in Part B → Q7

@Neet_pg_bot

Q8: RBC casts are seen in all except? (Q851010)

A. Acute glomerulonephritis

B. Malignant hypertension

C. Thrombotic microangiopathy

D. Mismatched blood transfusion

See Answer in Part B → Q8

@Neet_pg_bot

Q9: The patient is having recurrent kidney stones. Work up shows 24-hour urinary calcium excretion is three times normal and envelope shaped crystals are found in

urine. The current stone in the renal pelvis was 1.5 cm and was successfully managed with ESWL. Which of the following dietary advice is best suited for this patient? (Q851009)

A. Restriction of calcium in diet

B. Restriction of sodium in diet

C. Restriction of calories and vitamin D3 in diet

D. Restriction of carbonated energy drinks

See Answer in Part B → Q9

@Neet_pg_bot

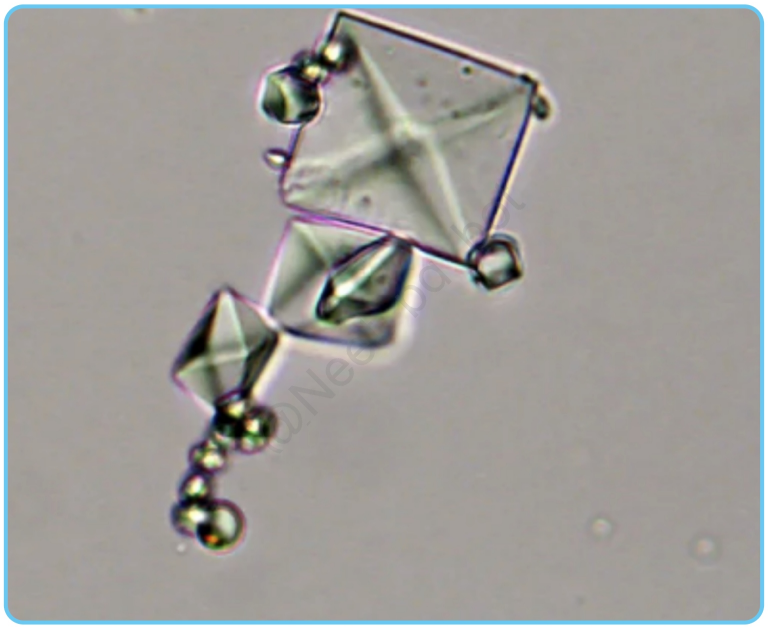
Q10: Which of the following is the leading cause of kidney stones whose crystals are shown below? (Q851008)

A. Proteus mirabilis infection

B. Idiopathic hypercalciuria

C. Idiopathic hyperoxaluria

D. Defective transport of basic amino acids



@Neet_pg_bot

See Answer in Part B → Q10

@Neet_pg_bot

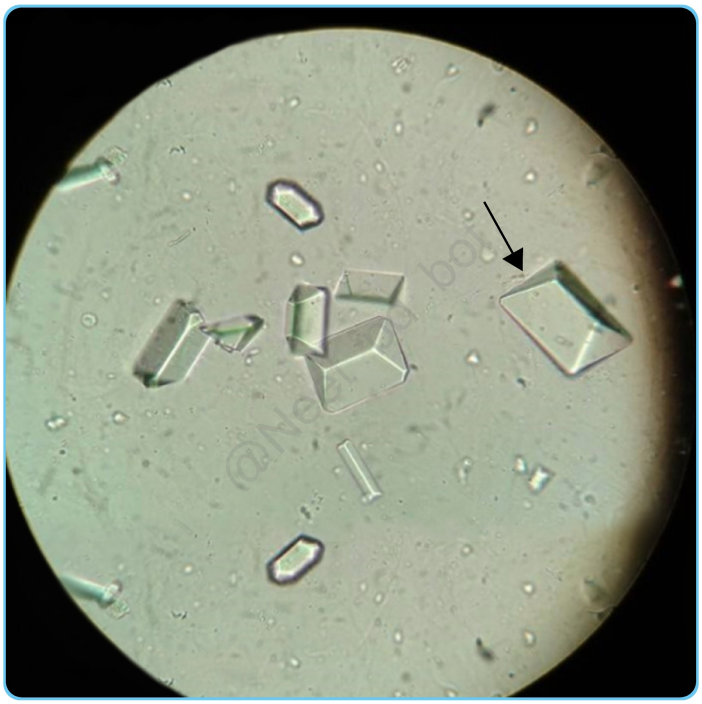
Q11: Which of the following is the leading cause of kidney stones whose crystals are shown below? (Q851007)

A. Proteus mirabilis infection

B. Idiopathic hypercalciuria

C. Idiopathic hyperoxaluria

D. Defective transport of basic amino acids



@Neet_pg_bot

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 65-year-old man is admitted with a CURB score of 3 for pneumonia for the past 2 days. His urine output in the last 24 hours is 100 ml and BP is 90/60 mm Hg on Norepinephrine infusion. p02/FiO2 is 350. Labs are: Serum creatinine: 3.5 mg/dL Urine output: 300 mL/24 hr Urine sodium: 45 mEq/L Urine osmolality: 320 mOsm/kg pH= 7.2, pCO2= 30 mm Hg, HCO3 = 10 meq/ L Which of the following is the correct diagnosis of this patient? (Q850995)

A. Acute interstitial nephritis

B. Acute tubular necrosis

C. Acute respiratory distress syndrome

D. Systemic inflammatory response syndrome

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 4-year-old child weighing 12 kg presents for routine evaluation. His height is 100 cm, and laboratory testing shows a serum creatinine level of 1 mg/dL. Using the updated bedside Schwartz formula (eGFR = 0.41 × height in cm / serum creatinine), what is the estimated GFR of this child? (Q851005)

A. 20 mL/min/1.73 m²

B. 32 mL/min/1.73 m²

C. 41 mL/min/1.73 m²

D. 55 mL/min/1.73 m²

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Non oliguric acute kidney injury is seen with (Q851004)

A. Kanamycin

B. Captopril

C. Telmisartan

D. Cyclosporine

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 35 year old man got electrocuted from a high tension cable while flying kites and presents with extensive burns. 12 hours after admission urine output is 100 ml, urine heme is positive with few RBC and CK is elevated. Diagnosis is? (Q851003)

A. Rhabdomyolysis

B. Pre- renal AKI due to hypoperfusion of kidneys

C. Post renal AKI due to debris occluding ureters

D. Hematuria due to renal injury by electrocution

See Answer in Part B → Q15

@Neet_pg_bot

Q16: All of the following are causes of pre renal AKI except? (Q851002)

A. NSAIDS

B. ACEI

C. Amphotericin B

D. Cyclosporine

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Neutrophil Gelatinase-Associated Lipocalin is used as a biomarker for? (Q851001)

A. Immunodeficiency

B. Kidney injury

C. Pancreatic injury

D. Sepsis

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following electrolyte abnormalities is not correct about patient in acute kidney injury due to acute glomerulonephritis? (Q851000)

A. Hyponatremia

B. Normal anion gap metabolic acidosis

C. Hyperkalemia

D. Hyperphosphatemia

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Sodium nitroprusside test on urine is positive in which of the following kidney stones? (Q850999)

A. Calcium oxalate stones

B. Uric acid stones

C. Cystinuria

D. Struvite stones

See Answer in Part B → Q19

@Neet_pg_bot

Q20: 72-year-old man with a history of coronary artery disease underwent coronary angiography 2 weeks ago. He now presents with progressive renal dysfunction, livedo reticularis over the lower limbs, and blue-toe lesions. Laboratory investigations show: Serum creatinine: 3.2 mg/dL (baseline 1.1 mg/dL) Eosinophilia: 12% Urinalysis: mild proteinuria, bland sediment Which of the following is the most likely diagnosis? (Q850998)

A. Acute tubular necrosis

B. Athero-embolic kidney disease

C. Rapidly progressive glomerulonephritis

D. Post-renal obstruction

See Answer in Part B → Q20

@Neet_pg_bot

Q21: 20-year-old patient with T1DM comes for a follow up visit. Which of the following is the earliest finding in diabetic nephropathy? (Q850997)

A. Hyperfiltration

B. Diffuse glomerulosclerosis

C. Kimmel stein Wilson changes

D. Armani ebstein changes

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 60-year-old diabetic patient underwent coronary angiography for suspected triple vessel disease. After the procedure he develops oliguria and rising serum creatinine. Labs are Baseline serum creatinine: 1.5 mg/dL Current serum creatinine: 3.0 mg/dL Urine output: 0.35 mL/kg/hr for 18 hours According to KDIGO criteria, what is the stage of acute kidney injury in this patient? (Q850996)

A. Stage 1

B. Stage 2

C. Stage 3

D. Stage 4

See Answer in Part B → Q22

Q1: A 60-year-old type 2 Diabetic patient with eGFR of 30 ml/min came with a headache and shortness of breath on climbing stairs fast. BP is 160/100 mmHg. Which of the following combination would not be suitable for this case profile? (Q850988)

A. ACEi with Furosemide

B. ACEi with Amiloride

C. ACEi with Metazolone

D. ACEi with Patiromer

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 46-year-old man, 6 months after kidney transplantation, presents with malaise, rising creatinine, oliguria, and edema. Urine cytology shows renal tubular epithelial cells with large basophilic intranuclear inclusions. Which organism is the most likely cause? (Q869059)

A. Cytomegalovirus

B. Epstein–Barr virus

C. BK polyomavirus

D. Adenovirus

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is used for the management of dialysis disequilibrium? (Q869058)

A. Mannitol

B. Dexamethasone

C. 5% dextrose

D. N/2 in 5% dextrose

See Answer in Part B → Q3

@Neet_pg_bot

Q4: What is the most common complication of recurrent haemodialysis? (Q850994)

A. Dialysis dysequilibrium

B. Dialysis dementia

C. Peripheral neuropathy

D. Accelerated atherosclerosis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: What is the most common acute complication of haemodialysis? (Q850993)

A. Bleeding

B. Infection

C. Hypotension

D. Myocardial infarction

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 72-year-old patient undergoing hemodialysis suddenly develops symptoms of dizziness, significant leg cramps, and chest pain during the treatment session. Which of the following is the most common acute complication occurring in patients undergoing dialysis? (Q850992)

A. Cardiac arrhythmias

B. Hypotension

C. Anaphylactoid reactions

D. Muscle cramps

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following will help in differentiating acute kidney injury from chronic kidney disease? (Q850991)

A. Urine albumin

B. Size of kidney

C. Serum creatinine

D. Urine output

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 60-year-old man with chronic kidney disease eGFR of 45 ml/min presents with complaints of increasing fatigue and dyspnoea on exertion. On evaluation, he is found to have Hb=7 gm/dl with normocytic normochromic anaemia. What is the next step in management? (Q850990)

A. Oral iron therapy

B. Intravenous iron infusion

C. Blood transfusion

D. Darbepoetin alfa

See Answer in Part B → Q8

@Neet_pg_bot

Q9: CKD patient with G5A3 status presents with chest pain for 6 hours. Auscultation shows a friction rub. ECG shows PR segment depression with global ST elevation. Which of the following should be done for management of this patient? (Q850989)

A. Call nephrologist for urgent hemodialysis

B. Start IVF with Colchicine/ NSAIDS

C. Arrange for pericardial drainage procedure

D. Start Morphine, oxygen 6L /min and chewable aspirin

See Answer in Part B → Q9

@Neet_pg_bot

Q10: In annual medical check up of type 2 DM patient with HbA1c of 10% which of the following tests will identify primary kidney disease? (Q850964)

A. UACR >2.5 mg/mmol on two occasions

B. Urine dipstick for protein 2+ on two occasions

C. Serum creatinine rise by 1.5-1.9 times over 48 hours

D. Urine output < 0.5 ml/kg/ hour for 24 hours

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A CKD patient is determined to have adynamic bone disease. Which of the following is the best explanation for this presentation? (Q850987)

A. Excessive use of vitamin D preparations and phosphate binders

B. Less use of vitamin D preparations and phosphate binders

C. High levels of FGF-23

D. Low levels of FGF-23

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Cardiovascular disease is the leading cause of morbidity and mortality in patients at every stage of CKD. Which of the following correlates best with this morbidity and mortality pattern? (Q850986)

A. Elevated Phosphate levels

B. Elevated Calcium levels

C. Elevated H+ levels

D. Increased Total body water

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is calcimimetic agent that enhances the sensitivity of parathyroid cells to the suppressive effect of calcium? (Q850985)

A. Etelcalcetide

B. Teriparatide

C. Sodium Zirconate cyclosilicate

D. Lanthanum

See Answer in Part B → Q13

@Neet_pg_bot

Q14: CKD patient presents with sudden onset chest pain and sweating. Which of the following is best practice for further management of this patient? (Q850984)

A. Troponin I

B. Serial Troponin I

C. Serial Troponin I + ECG

D. Troponin I + ECG

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 45-year-old patient with chronic kidney disease is being evaluated for kidney transplantation. Doppler shows iliac artery calcification. Laboratory investigations reveal: Serum calcium: 8 mg/dL Serum phosphate: 6.5 mg/dL Alkaline phosphatase: Elevated Vitamin D3: Low What is the most appropriate next step in management? (Q850968)

A. Sevelamer

B. Sevelamer + Calcitriol

C. Calcium supplementation + Calcitriol

D. Haemodialysis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 45-year-old diabetic patient with an HbA 1 c of 12% is calculated by MDRD formula to have e-GFR of 50 ml/min/m 2 . Which is not correct about this patient? (Q850967)

A. Less ammonium ion production

B. Increased urinary chloride

C. Associated with severe protein catabolism

D. Start oral bicarbonate supplementation in grade 3 CKD

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following is the leading cause of chronic kidney disease? (Q850966)

A. Chronic Glomerulonephritis

B. Autosomal dominant polycystic kidney disease

C. Diabetes insipidus

D. Hypertension

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 38-year-old man with type 2 diabetes mellitus for the last 3 years undergoes an annual renal evaluation. His serum creatinine is 0.9mg/dL. Urine albumin excretion is 2 mg/mmol on multiple occasions. Which of the following represents the earliest renal abnormality in diabetic nephropathy? (Q850965)

A. Microalbuminuria (30–300 mg/day)

B. Decline in GFR <60 mL/min/1.73 m²

C. Glomerular hyperfiltration

D. Armani Ebstein changes in proximal convoluted tubule

See Answer in Part B → Q18

@Neet_pg_bot

Q1: Which of the following is most likely based on the lab values given? Blood pH: 7.32 Na + : 130mEq/L K + : 2.8 mEq/L Cl - : 110 mEq/L HCO 3 : 12 mEq/L Urea: 25 mg/dL Creatinine: 0.6 mg/dL Urinary pH: 9.4 (Q850782)

A. RTA 1

B. RTA 2

C. RTA 3

D. RTA 4

See Answer in Part B → Q1

@Neet_pg_bot

Q2: 60-year-old smoker presents with difficult to control hypertension and is on Ramipril, amlodipine and thiazides. Duplex imaging shows increased flow velocity in bilateral renal artery. Which of the following is the leading cause of this presentation? (Q850789)

A. Fibromuscular dysplasia

B. Atherosclerosis

C. Takayasu arteritis

D. TTP

See Answer in Part B → Q2

@Neet_pg_bot

Q3: 65-year-old man with hypertension presents with sudden onset breathlessness. He is found to have bilateral crackles, pink frothy sputum, and hypoxemia requiring non-invasive ventilation. His BP is persistently high despite ramipril, amlodipine and hydrochlorothiazide for past 6 months. Echo shows preserved LV ejection fraction. Duplex Doppler of renal arteries demonstrates markedly increased flow velocity bilaterally. Likely cause of this presentation is? (Q850792)

A. Thrombo-embolic disease of kidney

B. Atherosclerosis

C. Athero-embolic kidney disease

D. Fibromuscular dysplasia

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Renal tubular acidosis that presents with hyperkalemia is? (Q850794)

A. RTA 1

B. RTA 2

C. RTA 3

D. RTA 4

See Answer in Part B → Q4

@Neet_pg_bot

Q5: 25-year-old young female is diagnosed with hypertension. Work up shows renal artery stenosis and renal angiogram image is shown. Diagnosis is: (Q850812)

A. Polyarteritis nodosa

B. Microscopic polyangiitis

C. Fibromuscular dysplasia

D. Takayasu arteritis

@Neet_pg_bot

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which is not correct about RTA 1? (Q850813)

A. Hypokalemia

B. Hypercalciuria

C. Positive Urinary anion gap

D. High urinary NH 4 +

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which type of Renal tubular acidosis is related to Fanconi syndrome? (Q850814)

A. RTA 1

B. RTA 2

C. RTA 3

D. RTA 4

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following drugs most commonly causes Type 2 (proximal) renal tubular acidosis? (Q850816)

A. Acetazolamide

B. Furosemide

C. Amiloride

D. Spironolactone

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 28-year-old woman presents with recurrent renal stones and bone pain. Investigations reveal: Serum potassium: 3.1 mEq/L Serum bicarbonate: 16 mEq/L Urine pH: 6.5 (not decreasing below 5.5 even after acid load) Positive urinary anion gap Which of the following is the most likely diagnosis? (Q850817)

A. Proximal RTA (Type 2)

B. Distal RTA (Type 1)

C. Hyperkalemic RTA (Type 4)

D. Carbonic anhydrase inhibitor–induced RTA

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 35-year-old woman with recurrent episodes of weakness and bone pain has xerostomia and Schirmer test of filter paper wetting of < 5 mm at 5 minutes. Laboratory results show: Serum potassium: 2.8 mEq/L Serum bicarbonate: 15 mEq/L Urine pH: 6.7 (does not fall below 5.5 on ammonium chloride loading) Positive urinary anion gap ANA and anti-SSA antibodies: positive Which of the following best explains her presentation? (Q850818)

A. Distal RTA due to autoimmune interstitial nephritis in Sjögren syndrome

B. Distal RTA due to autoimmune interstitial nephritis in Scleroderma

C. Distal RTA due to autoimmune interstitial nephritis in lupus nephritis

D. Distal RTA due to autoimmune interstitial nephritis in mixed connective tissue disorder

See Answer in Part B → Q10

@Neet_pg_bot

Q11: 10-year-old boy is evaluated for growth retardation and polyuria. Investigations reveal: Serum bicarbonate: 14 mEq/L Serum potassium: 3.2 mEq/L Urine pH: 4.8 after ammonium chloride loading Fractional excretion of bicarbonate: 20% No nephrolithiasis or nephrocalcinosis Aminoaciduria and glucosuria are also present Which of the following is the most likely diagnosis? (Q850820)

A. Distal RTA (Type 1)

B. Proximal RTA (Type 2) due to Fanconi syndrome

C. Hyperkalemic RTA (Type 4)

D. Distal RTA associated with Sjögren syndrome

See Answer in Part B → Q11

@Neet_pg_bot

Q12: 55-year-old man with long-standing diabetes mellitus presents with weakness. His medications include lisinopril and spironolactone. Investigations show: Serum bicarbonate: 18 mEq/L Serum potassium: 5.9 mEq/L Serum sodium: 132 mEq/L Urine pH: 5.2 Transtubular potassium gradient (TTKG): 3 (low) Which of the following best explains his presentation? (Q850821)

A. Distal RTA due to impaired H■ secretion in α-intercalated cells

B. Proximal RTA due to defective bicarbonate reabsorption

C. Hyperkalemic RTA due to hypoaldosteronism/aldosterone resistance

D. Distal RTA due to excess glycogen deposition in distal tubule

See Answer in Part B → Q12

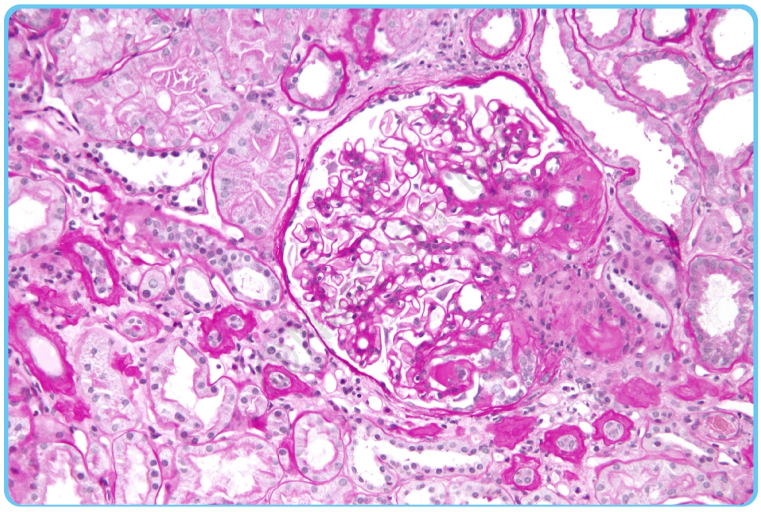
Q1: A 32-year-old man presents with generalized edema and frothy urine. Laboratory evaluation reveals 24-hour urine protein of 8 g/day, serum albumin of 2.2 g/dL, serum cholesterol of 310 mg/dL, and serum creatinine of 1.3 mg/dL. A kidney biopsy is performed and light microscopy is shown below. Which of the following is the most likely diagnosis? (Q850823)

A. Minimal change disease

B. Focal segmental glomerulosclerosis

C. Membranous nephropathy

D. Amyloidosis



@Neet_pg_bot

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 4-year-old child presents with swelling all over the body. Workup shows proteinuria >40 mg /m 2 BSA with hypoalbuminemia. KFT is normal. C3 levels are normal. USG shows normal-sized kidneys. What is the best treatment for this case? (Q850824)

A. Steroids plus spironolactone

B. Steroids plus hydrochlorothiazide

C. Steroids plus ACEI

D. Steroids plus cyclophosphamide

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 5-year-old girl presents with fever, abdominal pain, and dysuria. The consultant performs the imaging study shown. Which investigation has been performed? (Q850827)

A. Intravenous pyelography

B. Retrograde pyelography

C. Voiding cystourethrography

D. DTPA scan

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Patient presents with pitting pedal oedema for the past 2 weeks. Labs: LFT = normal, serum albumin= 2 gm/dl, KFT= deranged with massive proteinuria, Hb A1c 10% and Echo report is normal. USG abdomen shows bilaterally enlarged kidneys. Kidney biopsy was done. Which of the following histopathological reports is most likely to be seen? (Q850831)

A. Diffuse glomerulosclerosis

B. Nodular glomerulosclerosis

C. A-beta 2 microglobulin deposits

D. Apple green birefringence for Congo red deposits

See Answer in Part B → Q4

@Neet_pg_bot

Q5: 30-year-old man presents with periorbital oedema. Urine examination shows massive proteinuria and hypoalbuminemia. He undergoes a kidney biopsy and Congo red staining shows apple-green birefringence under polarized light. What is the most likely diagnosis? (Q850834)

A. Amyloidosis

B. Minimal change disease

C. Diabetic nephropathy

D. Membranous nephropathy

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 40-year-old man presents with leg swelling and frothy urine. Labs show nephrotic-range proteinuria and low serum albumin. Kidney biopsy shows diffuse GBM thickening with subepithelial deposits, and immunofluorescence reveals granular IgG and C3 along the capillary wall. Which marker is most specific for primary membranous nephropathy? (Q850835)

A. Anti-dsDNA antibody

B. Anti-PLA2 receptor antibody

C. Anti-GBM antibody

D. ANCA antibody

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Renal vein thrombosis is most commonly associated with which of the following conditions? (Q850838)

A. Membranous glomerulonephropathy (MGN)

B. Membranoproliferative glomerulonephritis (MPGN)

C. Minimal change disease

D. Focal segmental glomerulosclerosis (FSGS)

See Answer in Part B → Q7

@Neet_pg_bot

Q8: 40-year-old man with nephrotic syndrome due to membranous glomerulonephropathy in on steroids with cyclophosphamide. He presents with sudden onset flank pain and hematuria. On examination, the left kidney is enlarged and tender. Which of the following is the most likely diagnosis? (Q850839)

A. Acute pyelonephritis

B. Hydronephrosis with pyelonephritis

C. Renal Abscess

D. Renal vein thrombosis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: 2-year-old child with a history of severe watery diarrhea and dehydration is brought to the emergency. He develops sudden onset hematuria and flank mass.

Examination reveals unilateral enlarged tender kidney. Which of the following is the most likely diagnosis? (Q850841)

A. Haemolytic uremic syndrome

B. Pre-renal acute kidney injury

C. Renal vein thrombosis

D. Hydronephrosis due to ureteric stone

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Most common cause of Primary glomerulonephritis is? (Q850842)

A. Post-streptococcal glomerulonephritis (PSGN)

B. Rapidly progressive glomerulonephritis (RPGN)

C. Henoch–Schönlein purpura (HSP)

D. Berger disease (IgA nephropathy)

See Answer in Part B → Q10

@Neet_pg_bot

Q11: 10-year-old boy presents with cola-colored urine, periorbital puffiness, and mild hypertension. He had a sore throat 2 weeks ago. Urine examination shows red blood cell casts and mild proteinuria. Serum C3 is decreased while C4 remains normal. Which of the following is the most likely diagnosis? (Q850844)

A. IgA nephropathy

B. Post-streptococcal glomerulonephritis

C. Membranous glomerulopathy

D. Rapidly progressive glomerulonephritis

See Answer in Part B → Q11

@Neet_pg_bot

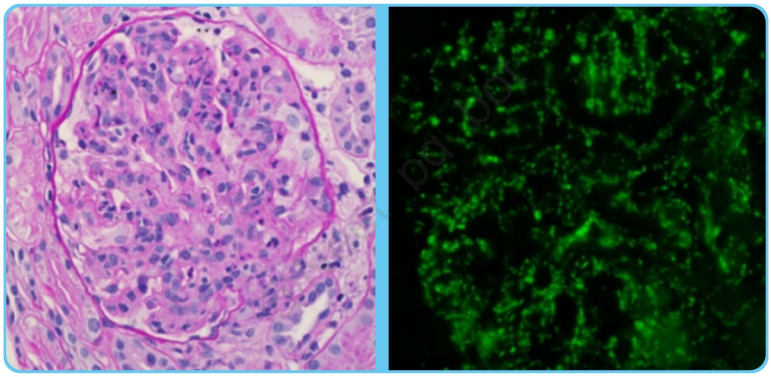
Q12: A 15-year-old boy presents with periorbital edema, dyspnea, and dark-colored urine for 2 days. His BP is 160/100 mmHg, and urine microscopy shows 100 dysmorphic RBCs/HPF with S. creatinine 1.5 mg/dL. Kidney biopsy was done and H&E and IF findings are shown below. Which of the following correctly describes the pathogenesis of this condition? (Q850850)

A. Type III hypersensitivity with subepithelial humps

B. Type III hypersensitivitywith subendothelial deposits

C. Type IIhypersensitivity with anti-GBM deposition

D. Type III hypersensitivity with thickening of basement membrane



@Neet_pg_bot

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Kidney biopsy showing diffuse endocapillary hypercellularity with diffuse subendothelial immune deposits is most consistent with which of the following conditions? (Q850853)

A. Post-streptococcal glomerulonephritis (PSGN)

B. Lupus nephritis

C. Rapidly progressive glomerulonephritis (RPGN)

D. Berger disease

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 20-year-old college student presents with recurrent episodes of cola-colored urine 1–2 days after upper respiratory infections. Urinalysis shows dysmorphic RBCs and mild proteinuria. Renal biopsy demonstrates mesangial proliferation with IgA deposits on immunofluorescence. Which of the following best explains the pathophysiology of his condition? (Q850857)

A. Immune complex formation against glucose-deficient IgA1

B. Immune complex formation against galactose-deficient IgA1

C. Antibody formation against glomerular basement membrane antigens

D. T-cell mediated podocyte injury leading to foot process effacement

See Answer in Part B → Q14

@Neet_pg_bot

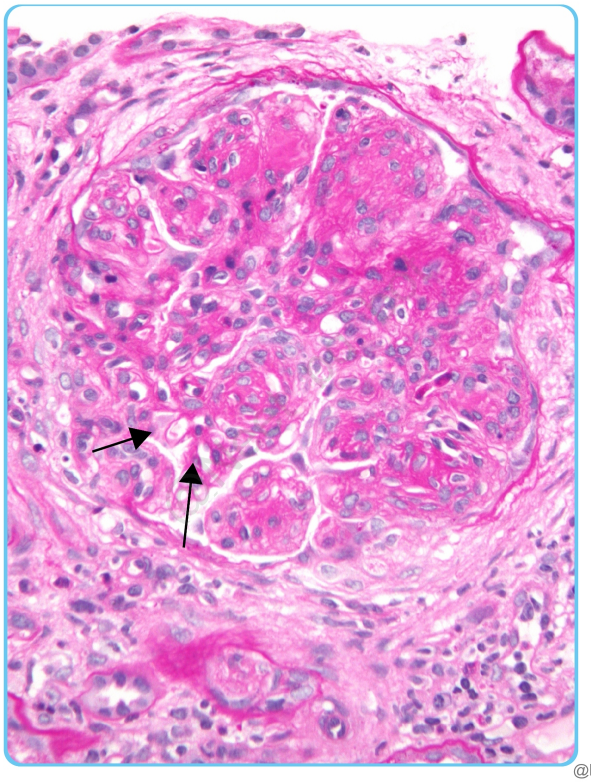
Q15: A 45-year-old man with a history of IV drug use and HCV positivity presents with edema and fatigue. Labs show 3.8 g/day proteinuria, microscopic hematuria, and low C3. Kidney biopsy specimen under light microscopy is shown below. What is the most likely diagnosis? (Q850860)

A. Focal segmental glomerulosclerosis

B. Membranous nephropathy

C. Membranoproliferative glomerulonephritis

D. Minimal change disease



See Answer in Part B → Q15

Q1: A 29-year-old male patient presents with multiple oral and genital ulcers. The patient claims these ulcers resolve spontaneously and that he experiences such episodes at least four times a year. Ocular examination reveals features of anterior uveitis. What is the likely diagnosis? (Q856261)

A. Rheumatoid arthritis

B. Psoriatic arthritis

C. SLE

D. Behcet’s disease

See Answer in Part B → Q1

@Neet_pg_bot

Q2: What is the most probable cause of the muteness, quadriplegia, and rigidity observed in an elderly female patient who had a previous medical history of severe vomiting and was aggressively treated for severe dehydration at a different hospital one week ago? (Q855368)

A. Malignant hyperthermia

B. Severe catatonia

C. Rapid sodium correction

D. Neuroleptic malignant syndrome

See Answer in Part B → Q2

@Neet_pg_bot

Q3: In methanol intoxication, which of the subsequent electrolyte abnormalities is observed? (Q855370)

A. Metabolic alkalosis with high anion gap

B. Metabolic acidosis with high anion gap

C. Metabolic acidosis with normal anion gap

D. Metabolic alkalosis with normal anion gap

See Answer in Part B → Q3

@Neet_pg_bot

Q4: AKIN and RIFLE criteria is used for classification of which of the folowing coditions? (Q857655)

A. Acute kidney injury

B. Chronic kidney failure

C. Acute glomerulonephritis

D. Nephrotic syndrome

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following conditions is associated with hypokalemic metabolic alkalosis with hypertension? (Q855709)

A. Barter syndrome

B. Liddle syndrome

C. Gitelman syndrome

D. Gordon syndrome

See Answer in Part B → Q5

@Neet_pg_bot

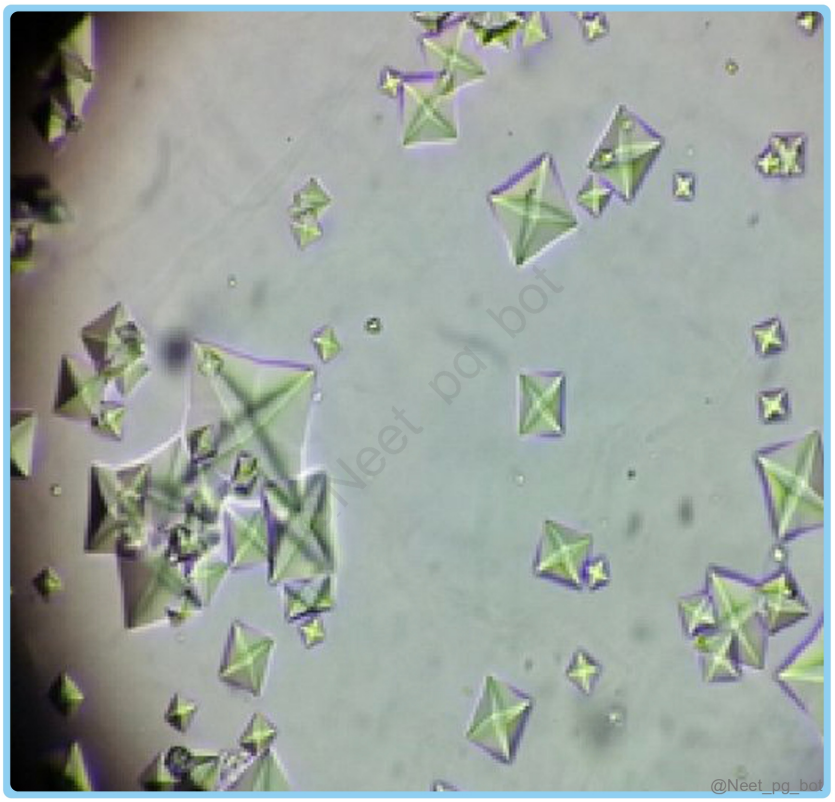
Q6: Identify the urinary crystal shown below: (Q855724)

A. Calcium oxalate

B. Calcium phosphate

C. Uric acid

D. Cysteine



See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is not true about syndrome of inappropriate antidiuretic hormone secretion (SIADH)? (Q856599)

A. Urinary sodium <20 mEq/L

B. Serum sodium <135 mEq/L

C. Urine osmolality >100 mOsm/kg

D. Patient can be clinically euvolemic to hypervolemic

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 40-year-old male presents with complaints of episodes of palpitations, headache, and profuse sweating for the past few days. MIBG scan shows a deep-seated tumour in the adrenal medulla. Which of the following statements is incorrect regarding the condition described? (Q856115)

A. Diagnosed by urine VMA & catecholamines

B. Surgical excision is the definitive treatment

C. Propranolol is given initially to manage hypertension

D. Can present as hypertension alone and sometimes with vomiting and pain abdomen

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A patient presents with a seizure. On evaluation, urine osmolality is 1000 mOsm/kg, and serum osmolality is 270 mOsm/kg. Which electrolyte abnormality can be expected in this patient? (Q856120)

A. Hypernatremia

B. Hyponatremia

C. Hyperkalaemia

D. Hypokalaemia

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Hemodialysis is an indication for all the below conditions except? (Q856921)

A. Uremic encephalopathy

B. Peripheral neuropathy

C. Metabolic acidosis

D. Uremic pericarditis

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following options represents the most severe manifestation of Chronic Kidney Disease (CKD)? (Q856933)

A. Decreased GFR

B. Increased creatinine

C. Hyperkalaemia

D. Proteinuria

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 56-year-old man presents to the casualty with severe shortness of breath and fatigue for the past 3 hours. He reports a history of vomiting and epigastric pain 2 days back, for which he took an anti-emetic. His past medical history is significant for hypertension and diabetes mellitus type 1. As the CBG valve of this patient showed 356mg/dL, the physician advises immediate ABG analysis, which reveals a pH=7.32, pCO 2 =38mEq/L, and HCO 3 -=15mEq/L. This report showed a type of acidosis with an increased anion gap. Which of the following conditions does not belong to the same classification of metabolic acidosis as in this patient? (Q856972)

A. Renal failure

B. Lactic acidosis

C. Renal aciduria

D. Aspirin poisoning

See Answer in Part B → Q12

@Neet_pg_bot

Q13: An increased anion gap is seen in: (Q855362)

A. Respiratory acidosis

B. Respiratory alkalosis

C. Metabolic acidosis

D. Metabolic alkalosis

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 55-year-old man with long-standing diabetes mellitus and end-stage renal disease (eGFR <20 mL/min) is being evaluated for renal transplantation. Which of the following statements correctly describes an ideal candidate outcome or consideration for renal graft transplant in a patient with diabetic nephropathy? (Q856285)

A. The survival rate of graft is 95% in the first year

B. The transplantation is cost effective after the second transplant year

C. The life expectancy is doubled in a diabetic patient with renal transplant

D. The treatment of chronic rejection has improved over the last 10 years

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Calculate the sodium deficit in the male patient, who weighs 60 kg, using the provided serum electrolyte values: pH of 7.42, sodium (Na+) level of 120 mEq/L, and serum chloride (CI-) level of 90 mEq/L. (Q856302)

A. 20 mEq

B. 200 mEq

C. 400 mEq

D. 720 mEq

See Answer in Part B → Q15

@Neet_pg_bot

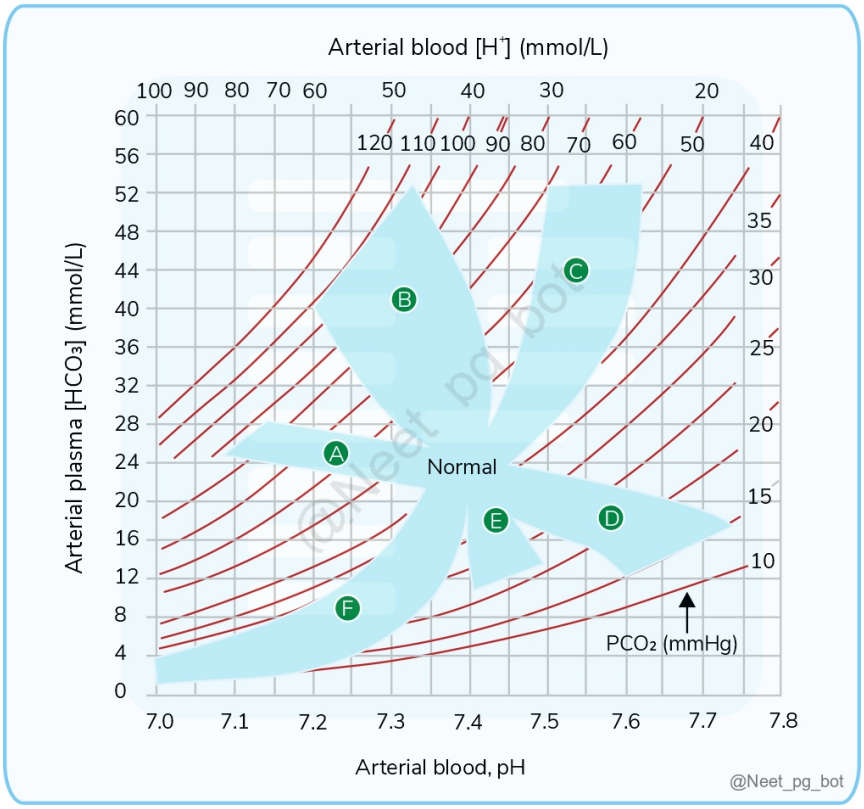
Q16: In the given acid-base nomogram diagram, areas marked A and D indicated which of the following conditions? (Q856341)

A. Chronic respiratory acidosis, acute metabolic alkalosis

B. Acute metabolic alkalosis, acute respiratory acidosis

C. Acute respiratory acidosis, acute respiratory alkalosis

D. Acute respiratory acidosis, acute metabolic alkalosis



See Answer in Part B → Q16

@Neet_pg_bot

Q17: A mutation in the gene for the aquaporin channel leads to which of the following conditions? (Q855043)

A. Liddle’s syndrome

B. Nephrogenic DI

C. Cystic fibrosis

D. Barter syndrome

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 30-year-old woman presents to the OPD with palpitation and weight loss. On examination of her legs the following lesion was found which on applying pressure, the indentation does not persist on release. ECG shows sinus rhythm. What is the probable cause of the oedema? (Q859558)

A. Myxedema

B. Nephrotic syndrome

C. Chronic lymphangitis

D. Dilated cardiomyopathy

See Answer in Part B → Q18

@Neet_pg_bot

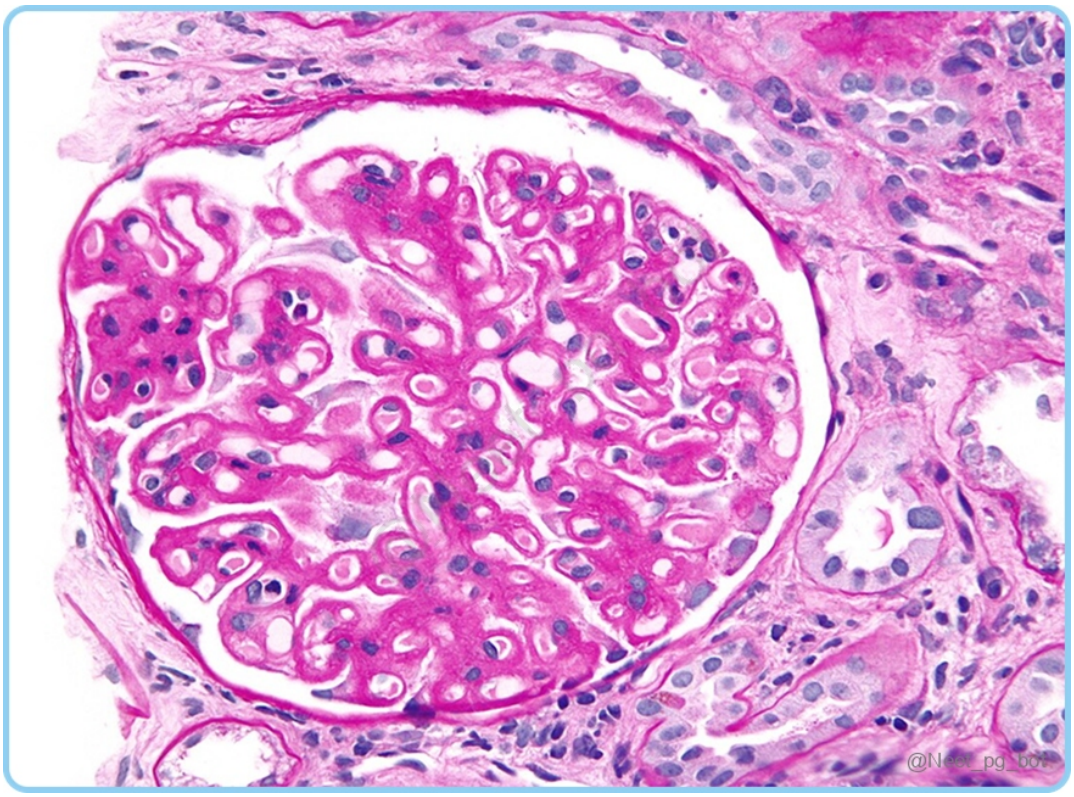
Q19: A hepatitis B-positive adult presents with massive proteinuria (>3.5 g/day). Renal biopsy was performed as shown below. What is the most likely diagnosis? (Q859566)

A. Focal segmental glomerulosclerosis

B. Membranous glomerulonephritis

C. Membranoproliferative glomerulonephritis

D. Minimal change disease



See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following agents is most likely causing the condition in a 60-year-old woman, who had a kidney transplant 2 months ago, and is now experiencing a high fever, severe difficulty in breathing, and a dry cough with a hacking sound? A chest x-ray shows widespread interstitial infiltrates in both lungs, and urine examination reveals the presence of cells with an 'owl-eye' appearance. (Q859782)

A. Adenovirus

B. Cytomegalovirus

C. Influenza virus

D. Respiratory syncytial

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A patient exhibits symptoms of increased urination, nighttime urination, and involuntary urination, along with a recorded 24-hour urine volume of 7 litres. He has a urine osmolarity of 260 mOsm/L. The ADH assay shows a recorded value of 0.8 pg/ml, and an MRI of the brain reveals the absence of a bright spot on T1-weighted imaging. What is the probable diagnosis? (Q859788)

A. Nephrogenic DI

B. Primary polydipsia

C. Pituitary DI

D. Mannitol infusion

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 10-year-old male child presents with headache and cola-colored urine. His parents report throat pain 2 weeks ago. Work up shows RBC casts in urine and his KFT is increased two fold. What is the likely light microscopy finding in this case? (Q859810)

A. Spike and dome appearance

B. Starry sky appearance

C. Enlarged hypercellular glomeruli with obliteration of bowman space

D. Electron dense deposits

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following clinical conditions are correctly matched with their anion gap status? Starvation – Increased anion gap Diabetic ketoacidosis – Increased anion

gap Severe vomiting – Increased anion gap (Q879184)

A. Only b is correct

B. a and b are correct

C. a and c are correct

D. Only a is correct

See Answer in Part B → Q23

@Neet_pg_bot

Q24: An 8-year-old child with a history of GTCS came with an episode of convulsions for more than 45 minutes. What will be the appropriate management for this patient? (Q860439)

A. Lorazepam followed by levetiracetam

B. Valproate followed by gabapentin

C. Carbamazepine followed by lorazepam

D. Levetiracetam followed by valproate

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A patient after RTA had a renal shut down. Work-up shows: FeNa: < 1%, Urine osmolality: 300 mOsm/kg, Urinary sodium: 40 mEq/L. Most likely diagnosis? (Q866812)

A. Acute Tubular Necrosis

B. Pre-renal AKI

C. Post-renal AKI

D. Renal AKI

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 58-year-old male presents with complaints of burning micturition. Prostatic examination was normal. Urinalysis shows >50 pus cells per high power field, but urine culture shows no growth. What is the most likely diagnosis? (Q865326)

A. Chronic bacterial prostatitis

B. Acute bacterial prostatitis

C. Granulomatous prostatitis

D. Sterile pyuria

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 56-year-old diabetic male presents with a complicated urinary tract infection and is found to be hypotensive. His blood pressure does not respond to intravenous fluids. Which of the following is the most appropriate antibiotic to manage his condition? (Q865371)

A. Amoxicillin-Clavulanate

B. Nitrofurantoin

C. Meropenem

D. Ciprofloxacin

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 60-year-old man with chronic kidney disease presents with complaints of increasing fatigue, dyspnea on exertion, and signs of congestive heart failure. On

evaluation, he is found to have anemia. Work up shows Hb=7 gm/dl and Peripheral Smear shows Normocytic normochromic anemia. What is the next step in management of this case? (Q866502)

A. Oral iron therapy

B. IV iron infusion

C. Blood transfusion

D. Darbepoetin alfa

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A patient has undergone an acute renal allograft transplantation. What would indicate its rejection? (Q853353)

A. Rise of creatinine by more than 10% is suggestive of acute rejection.

B. Rise of creatinine by more than 5% is suggestive of acute rejection.

C. Serum creatinine does not rise in acute renal allograft rejection.

D. Any rise in serum creatinine will be suggestive of acute renal allograft rejection.

See Answer in Part B → Q29

@Neet_pg_bot

Q30: As per KDIGO, which of the following falls under G3b? (Q853357)

A. 45-59

B. 60-89

C. 30-44

D. 15-29

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A 25-year-old male presents with hematuria. Which of the following are seen in glomerular hematuria? Statements: Brown-colored urine Dysuria absent Crystals present Edema rare (Q853360)

A. 1 only

B. 1, 2

C. 1, 2, 3

D. 1, 2, 4

See Answer in Part B → Q31

@Neet_pg_bot

Q32: What is the recommended treatment for nephrotic syndrome in children? (Q852685)

A. Steroids

B. Steroids and cyclophosphamide

C. Cyclophosphamide

D. ACE inhibitors

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A 55-year-old woman with a history of type 2 diabetes presents for a routine follow-up. Her serum creatinine and potassium levels are normal, but she has microalbuminuria and an HbA1c of 8%. Her blood pressure and pulse are within normal limits, and she is currently on metformin for diabetes management. What should be the next step in her management? (Q852754)

A. Begin a thiazide diuretic

B. Start insulin therapy

C. Stop Metformin and start a different OHA

D. Start an ACE inhibitor

See Answer in Part B → Q33

@Neet_pg_bot

Q34: Which of the following is most likely based on the lab values given? Blood pH: 7.3 (indicating mild acidosis) Sodium (Na+): 134 mEq/L (mildly decreased) Potassium (K+): 2.8 mEq/L (hypokalemia) Chloride (Cl-): 113 mEq/L (elevated) Bicarbonate (HCO■■): 12 mEq/L (low, indicating metabolic acidosis) Blood Urea Nitrogen (BUN): 3 mg/dL (low-normal) Creatinine: 0.6 mg/dL (normal) Urinary pH: 9.4 (alkaline) (Q844330)

A. Renal Tubular Acidosis (RTA) Type 1 (Distal RTA)

B. Renal Tubular Acidosis (RTA) Type 2 (Proximal RTA)

C. Renal Tubular Acidosis (RTA) Type 4

D. High Anion Gap Metabolic Acidosis (HAGMA)

See Answer in Part B → Q34

@Neet_pg_bot

Q35: A patient having hypertension is on thiazides and is complaining of fatigue and hypokalemia. Which of the following drugs can prevent potassium loss? (Q860435)

A. Furosemide

B. Amiloride

C. Acetazolamide

D. Indapamide

See Answer in Part B → Q35

@Neet_pg_bot

Q36: A patient with RTA is passing red color urine due to myoglobinuria. Which of the following will most likely be seen in this patient? (Q866811)

A. Hypernatremia

B. Hyperkalemia

C. Hyponatremia

D. Hypokalemia

See Answer in Part B → Q36

@Neet_pg_bot

Q37: A 30-year-old male is admitted to the medicine ward with complaints of vomiting and diarrhea. Lab investigations reveal a serum potassium level of 3.2 mEq/L. All of the following can be signs of underlying dyselectrolytemia except: (Q840102)

A. Ventricular tachycardia

B. Quadriplegia

C. Diabetes insipidus

D. Cerebral edema

See Answer in Part B → Q37

@Neet_pg_bot

Q38: Which of the following is the most likely condition responsible for a 35-year-old male experiencing nausea, diarrhea, and vomiting, with ABG results indicating pH of 7.55, PCO2 of 50 mmHg, and HCO3- of 44 mmol? (Q840111)

A. Respiratory Acidosis

B. Respiratory Alkalosis

C. Metabolic Acidosis

D. Metabolic Alkalosis

See Answer in Part B → Q38

@Neet_pg_bot

Q39: Which of the following best characterizes the acid-base status of a 45-year-old diabetic patient presenting to the emergency department with abdominal pain, tachypnea, and tachycardia, whose arterial blood gas analysis reveals the following: pH: 7.34 Sodium (Na): 135 Potassium (K): 5 Bicarbonate (HCO3): 12 Chloride (Cl): 92 RBS = 450 mg/dl (Q840113)

A. Non-Anion Gap Metabolic Acidosis (NAGMA)

B. High Anion Gap Metabolic Acidosis (HAGMA)

C. Compensated Metabolic Alkalosis

D. Respiratory Acidosis

See Answer in Part B → Q39

@Neet_pg_bot

Q40: Which of the following is not a cause of chronic bipedal edema? (Q840123)

A. Chronic liver disease

B. Nephrotic syndrome

C. Chronic venous insufficiency

D. Lupus nephritis

See Answer in Part B → Q40

@Neet_pg_bot

Q41: A patient presented with complaints of pain in the flank region with hematuria. On investigation, an X-ray shows multiple calcifications (stones) in both kidneys. What is the probable diagnosis? (Q857275)

A. Parathyroid Adenoma

B. Renal calculi

C. Polycystic kidney disease

D. CKD

See Answer in Part B → Q41

@Neet_pg_bot

Q42: A young patient developed hyperpigmentation of distal fingers after being hospitalized post-adrenalectomy. What could be the possible cause? (Q857289)

A. Addison’s disease

B. Conn's syndrome

C. Nelson syndrome

D. Cushing syndrome

See Answer in Part B → Q42

@Neet_pg_bot

Q43: A 5 year old male child was brought to the hospital with complaints of flank pain and fatigue with a history of red coloured urine. On investigation there were more than 20 RBC/ hpf and microscopy showed dysmorphic RBC. What is the most likely diagnosis? (Q820455)

A. Minimal change disease

B. PSGN

C. UTI

D. Bladder calculi

See Answer in Part B → Q43

@Neet_pg_bot

Q44: A patient with hyperkalemia and elevated urea levels underwent dialysis. Towards the end of the session, she became drowsy and had a sudden seizure episode. On examination, the patient was hypotensive. What is the treatment for this condition? (Q855427)

A. Bumetanide

B. Ethacrynic acid

C. Nesiritide

D. IV Mannitol

See Answer in Part B → Q44

@Neet_pg_bot

Q45: Which one of the following medications is not employed for the urgent (immediate) treatment of hyperkalemia? (Q855701)

A. 10% calcium gluconate over 10 min

B. Salbutamol nebulisation

C. Insulin-dextrose

D. Injection MgSO4

See Answer in Part B → Q45

@Neet_pg_bot

Q46: All of the following aid in the localization of the lesion to the spinal cord except? (Q855322)

A. Contralateral hemiplegia

B. Fasciculation at the level of lesion

C. Upper motor neuron lesion and lower motor neuron lesion

D. Bladder involvement

See Answer in Part B → Q46

Q8: IBD is usually associated with extraintestinal features. Which of the following hepatobiliary features is not seen in Patients with IBD? (Q850889)

A. Fatty liver

B. Cholelithiasis

C. Primary sclerosing cholangitis

D. Primary biliary cholangitis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is correct about joint involvement seen in patient with IBD? (Q850891)

A. Migratory peripheral arthritis, Sacroilitis and HLA B27 positive

B. Erosive small joint arthritis, Sacroilitis and HLA B27 positive

C. Migratory peripheral arthritis, tenosynovitis and HLA B27 positive

D. Erosive small joint arthritis, tenosynovitis and HLA B27 positive

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 28-year-old woman with a history of migraine presents with a 3-month history of bloody diarrhoea and tenesmus. Labs show Hb 10 gm%, CRP positive, and sigmoidoscopy showing erythema, mucosal friability starting from the rectum and extending proximally. Which of the following drugs will be started for the management of this patient? (Q850894)

A. Sulphasalazine

B. Mesalamine

C. Azathioprine

D. Methylprednisolone

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following small molecule is approved for treatment of ulcerative colitis? (Q850896)

A. Tofacitnib

B. Ustekinumab

C. Certolizumab

D. Azathioprine

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 35-year-old patient with ulcerative colitis presents with severe abdominal distension, pain, fever, and tachycardia. Abdominal X-ray shows colonic dilatation >6 cm. Ultrasound show no free fluid in peritoneal cavity. What is the first-line medical management for this condition? (Q850898)

A. Intravenous corticosteroids

B. Oral mesalamine

C. Azathioprine

D. Subtotal colectomy

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Leading cause of death in patients with Crohn’s disease? (Q850900)

A. Infection

B. Lymphoma of gut

C. Adenocarcinoma of gut

D. Malabsorption

Q1: Patients with Irritable Bowel Syndrome (IBS) have demonstrated preferential activation of which brain region in response to distal colonic stimulation, correlating with altered attention processes and response selection? (Q890588)

A. Mid-cingulate cortex

B. Cerebellum

C. Occipital lobe

D. Hippocampus

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 35 y/o man with constipation-predominant Irritable Bowel Syndrome (IBS-C) has persistent symptoms despite lifestyle modification and over-the-counter laxatives. He has started on a medication that inhibits the gastrointestinal sodium-hydrogen exchanger 3 (NHE3). Which medication has most likely been prescribed? (Q890596)

A. Tenapanor

B. Prucalopride

C. Eluxadoline

D. Rifaximin

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 42 y/o woman with irritable bowel syndrome (IBS) reports recurrent lower abdominal cramping and pain shortly after meals. To optimise symptom control for her postprandial pain pattern, what is the most appropriate change to her dosing schedule? (Q890595)

A. Take the medication 30 minutes before meals

B. Take the medication with the first bite of food

C. Take the medication 1 hour after meals

D. Take the medication only at bedtime

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 68 y/o woman with constipation-predominant Irritable Bowel Syndrome (IBS-C) and mild cognitive impairment presents with dry mouth, blurred vision, and difficulty initiating urination shortly after starting a new medication for abdominal cramping and pain. Which of the following agents is most likely responsible for her symptoms? (Q890594)

A. Linaclotide

B. Peppermint oil

C. Hyoscyamine

D. Lubiprostone

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Pharmacologic agents targeting serotonin receptors are used in the management of irritable bowel syndrome (IBS). While 5-HT■ agonists stimulate intestinal

peristalsis, drugs that act as serotonin antagonists (5-HT■ antagonists) fall under which therapeutic category for IBS? (Q890593)

A. Stool-bulking agents

B. Prescription antidiarrheals

C. Osmotic laxatives

D. Antiflatulence therapy

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A patient with irritable bowel syndrome (IBS) is being treated with paroxetine. On follow-up, the patient reports fatigue and jaundice. Paroxetine is most commonly associated with which pattern of hepatic injury? (Q890592)

A. Fatty liver (steatosis)

B. Granulomatous hepatitis

C. Hepatitis (hepatocellular injury)

D. Vascular injury

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following clinical features, if reported by a patient, most strongly suggests inflammatory bowel disease (IBD) or another organic pathology rather than irritable bowel syndrome (IBS)? (Q890591)

A. Relief of abdominal pain with defecation

B. Presence of visible mucus in the stool

C. Waking from sleep due to diarrhoea (nocturnal diarrhoea)

D. Sensation of incomplete evacuation

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following sets of diagnostic tests is recommended as part of the initial evaluation for a patient with diarrhoea-predominant irritable bowel syndrome who has no alarm features? (Q890590)

A. Complete blood count (CBC), faecal calprotectin, and serologic testing for celiac disease

B. Colonoscopy with random biopsies and stool examination for ova and parasites

C. Abdominal CT scan and erythrocyte sedimentation rate (ESR)

D. Hydrogen breath test and upper gastrointestinal endoscopy (EGD)

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which demographic profile is most strongly associated with an increased risk of developing post-infectious irritable bowel syndrome (IBS) following an episode of acute gastroenteritis? (Q890589)

A. Male patients over the age of 50

B. Female patients of younger age

C. Male patients of younger age

D. Female patients over the age of 60

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 30-year young female is diagnosed as having IBS. Which of the following is not a feature of irritable bowel syndrome? (Q850815)

A. Dyspepsia and bloating

B. Recurrent abdominal pain

C. Constipation alternating with diarrhoea

D. Nocturnal diarrhoea

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 34 y/o woman has a 2-year history of recurrent abdominal cramping and frequent loose, watery stools that worsen with stress and meals. She is diagnosed with diarrhoea-predominant irritable bowel syndrome (IBS-D). Which of the following cellular abnormalities is most likely to be identified in her colonic mucosa? (Q890587)

A. Decreased density of mast cells in the lamina propria

B. Increased number of serotonin-containing enterochromaffin cells

C. Atrophy of myenteric plexus ganglion cells

D. Reduced expression of cholecystokinin (CCK) receptors

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which pathophysiologic abnormality is most consistently observed in patients with IBS, particularly those with the diarrhoea-predominant subtype, during simulated visceral stimulation? (Q890586)

A. Decreased contractile activity in the rectosigmoid colon

B. Higher threshold for pain perception during rectal balloon inflation

C. Exaggerated sensory response to visceral stimulation (visceral hypersensitivity)

D. Generalised somatic hypersensitivity involving skin and muscle

See Answer in Part B → Q12

@Neet_pg_bot

Q13: According to the Rome IV criteria, which of the following symptoms is a mandatory prerequisite for establishing a diagnosis of irritable bowel syndrome (IBS)? (Q890585)

A. Abdominal bloating and distention

B. Recurrent abdominal pain

C. Chronic watery diarrhoea

D. Feeling of incomplete evacuation

See Answer in Part B → Q13

@Neet_pg_bot

Q14: 65-year-old man with obesity and hypertension develops haematochezia needing hospitalization. Which of the following is probable cause? (Q850828)

A. Diverticulitis

B. Colorectal cancer

C. Irritable bowel syndrome

D. Internal Haemorrhoids

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 30-year-old lady with GERD symptoms underwent a UGI endoscopy that shows loss of vascular pattern, multiple rings and trachealization appearance of oesophagus. Which of the following is correct diagnosis? (Q850826)

A. IBS-D

B. Barrett oesophagus

C. Eosinophilic esophagitis

D. Achalasia cardia

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 35-year-old female presents with chronic abdominal pain, bloating, and alternating diarrhea and constipation. Following a diagnosis of Irritable Bowel Syndrome (IBS), which dietary approach is considered the most effective for managing her symptoms? (Q850825)

A. Low gluten diet

B. Atkins diet

C. Ketogenic diet

D. Low FODMAP diet

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 28-year-old patient presents with months of recurrent abdominal pain and diarrhea, now alternating with constipation. He also reports weight loss, low-grade fever, and laboratory findings of normocytic anemia with elevated inflammatory markers. What is the most likely diagnosis? (Q850822)

A. IBS

B. IBD

C. Tropical sprue

D. Bacterial overgrowth syndrome

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following is correct about mechanism of action of Lubiprostone used in IBS-C? (Q850819)

A. Increase intestinal chloride secretion

B. 5HT4 receptor agonist

C. 5HT4 receptor antagonist

D. Guanylate cyclase -C agonist

See Answer in Part B → Q18

@Neet_pg_bot

Q13 (p. 458) *Q14 (p. 458)*

Q1: A 30-year-old alcoholic patient presents with vomiting episode and hematemesis. On examination pulse thready 120/min, BP is 80/60 mmHg with cold clammy hands and feet. Per abdomen shows splenomegaly. Which is next best step in management of this patient? (Q850830)

A. UGIE

B. Large-bore IV access and rapid blood transfusion

C. Octreotide infusion

D. Bolus terlipressin

See Answer in Part B → Q1

@Neet_pg_bot

Q2: An elderly man had undergone PCI with stenting 6 weeks ago. Today he passed fresh blood in stool and then collapses in the washroom. On admission pulse is 130 /min, low volume and BP is 80/60 mm Hg. His wife tells that yesterday he was complaining of melena. Medication history is of use of aspirin and clopidogrel for last 6 weeks. Which of the following investigations should be done to determine source of bleeding? (Q850832)

A. Upper GI Endoscopy

B. Colonoscopy

C. Stool for occult blood

D. USG abdomen

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Alcoholic patient with bleeding oesophageal varices is stabilized in ICU. Which of the following interventions will be done in this patient to prevent recurrence of such an event? (Q850833)

A. Endoscopic variceal ligation

B. Trans-jugular intrahepatic portosystemic shunting

C. Octreotide infusion with albumin

D. Terlipressin with midodrine

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Patient with upper GI bleeding and pedal oedema is found to have ‘cerebriform appearance of stomach mucosa’ on UGI endoscopy. Diagnosis is? (Q850836)

A. Gastric antral vascular ectasia

B. Menetrier disease

C. GIST

D. MALToma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is most common site of Mallory Weiss syndrome? (Q850837)

A. Lower 1/3 rd of Oesophagus

B. Middle 1/3 rd of Oesophagus

C. Lower Oesophageal sphincter

D. Pylorus of stomach

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Alcoholic went for a party and did binge drinking. He developed coffee ground vomitus episodes and developed cold clammy extremities. Post volume resuscitation UGI endoscopy was done revealed a ulcer in first part of duodenum. Which of the tests will be done to determine the aetiology of this presentation? (Q850840)

A. Ultrasound abdomen for liver echotexture

B. Urease test

C. Doppler to measure portal vein pressure

D. Oesophageal manometry

See Answer in Part B → Q6

@Neet_pg_bot

Q7: H. Pylori can lead to development of all of the following except? (Q850843)

A. MALToma

B. Duodenal ulcer

C. Gastric adenocarcinoma

D. Barrett oesophagus

See Answer in Part B → Q7

@Neet_pg_bot

Q8: You have given triple therapy to a patient with documented H. Pylori infection by urease test. Which is correct about follow up of this patient? (Q850845)

A. Call after 4 weeks of treatment completion and do urea breath test

B. Call after 4 weeks of treatment completion and do repeat endoscopy

C. Call after 4 weeks of treatment completion and do stool PCR for toxin A and toxin B

D. Call after 4 weeks of treatment completion and give reassurance

See Answer in Part B → Q8

@Neet_pg_bot

Q9: 60 year old obese man is having osteoarthritis and he is taking ibuprofen daily for the past 3 months. He developed epigastric pain and occult GI bleeding. Which of the following is correct about the cause? (Q850846)

A. PGE2 and prostacyclin production reduced with decreased mucosal barrier

B. Increased acid production due to ibuprofen

C. PGE1 and prostacyclin production reduced with decreased mucosal barrier

D. Mucosal injury due to inhibition of COX-2

See Answer in Part B → Q9

@Neet_pg_bot

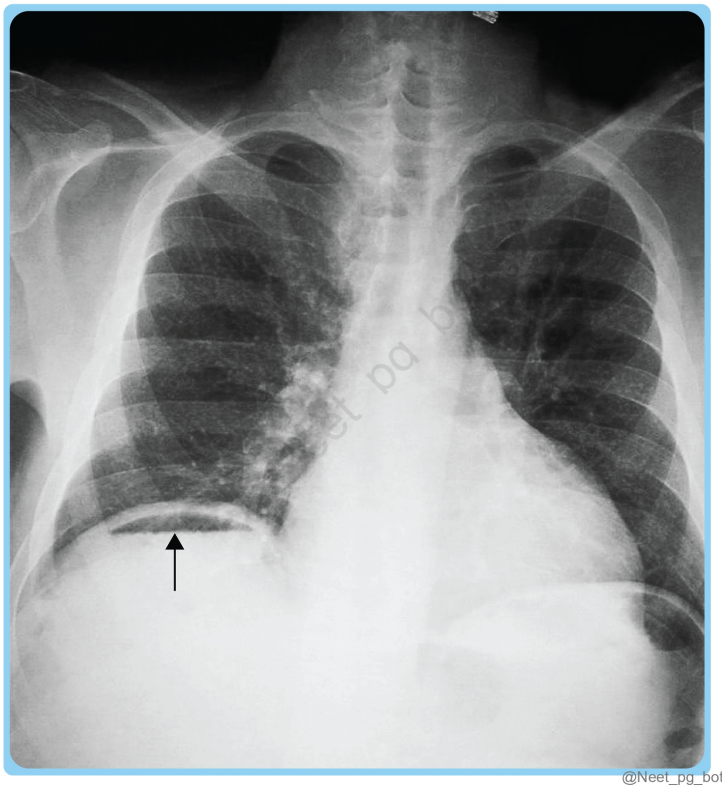
Q10: 30-year-old alcoholic male presents with diffuse abdominal pain and prostration. On examination guarding and rigidity of anterior abdominal wall is noted. Urgent X ray abdomen is done. Past medical records show multiple hospital visits for epigastric pain and positive “clo test’. Which of the following is the cause of this presentation? (Q850847)

A. Viscus perforation

B. Necrotising pancreatitis

C. Pseudo-pancreatic cyst

D. Acute mesenteric insufficiency



See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 65-year-old patient with a history of atrial fibrillation presents with vomiting and sudden onset severe diffuse abdominal pain that is disproportionate to physical examination findings. On examination, the abdomen is soft with minimal tenderness, but tachycardia is noted. Laboratory studies reveal elevated lactate levels. What is the most appropriate next step to confirm the diagnosis? (Q850848)

A. Abdominal X-ray

B. CT angiography

C. Colonoscopy

D. Upper gastrointestinal endoscopy

See Answer in Part B → Q11

@Neet_pg_bot

Q12: HIV positive truck driver presents with odynophagia. UGIE shows serpiginous ulcers in oesophagus. Biopsy from ulcer base shows basophilic intranuclear and intracytoplasmic bodies. Which is the likely cause of this presentation? (Q850849)

A. HSV

B. CMV

C. Candida

D. Varicella zoster

See Answer in Part B → Q12

@Neet_pg_bot

Q13: 40-year-old female patient presents with dysphagia for past one year to solid food items . On examination, she has pallor with cheilosis and koilonychia. The diagnosis is? (Q850851)

A. Plummer Vinson syndrome

B. Oesophageal cancer

C. Achalasia cardia

D. Tylosis palmaris

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following conditions will have "watermelon appearance of stomach mucosa" on upper GI endoscopy? (Q850852)

A. Gastric antral vascular ectasia

B. Menetrier disease

C. MALToma

D. Gastrointestinal stromal tumor

See Answer in Part B → Q14

Q1: Which of the following GI condition will have intestinal biopsy finding of normal villi with epithelial cells vacuolated with fat post prandially? (Q850870)

A. Abetalipoproteinemia

B. Agammaglobulinemia

C. Intestinal lymphangiectasia

D. Intestinal lymphoma

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following organisms is most classically associated with gastroenteritis due to ingestion of a preformed toxin? (Q890578)

A. Salmonella enterica

B. Staphylococcus aureus

C. Shigella dysenteriae

D. Campylobacter jejuni

See Answer in Part B → Q2

@Neet_pg_bot

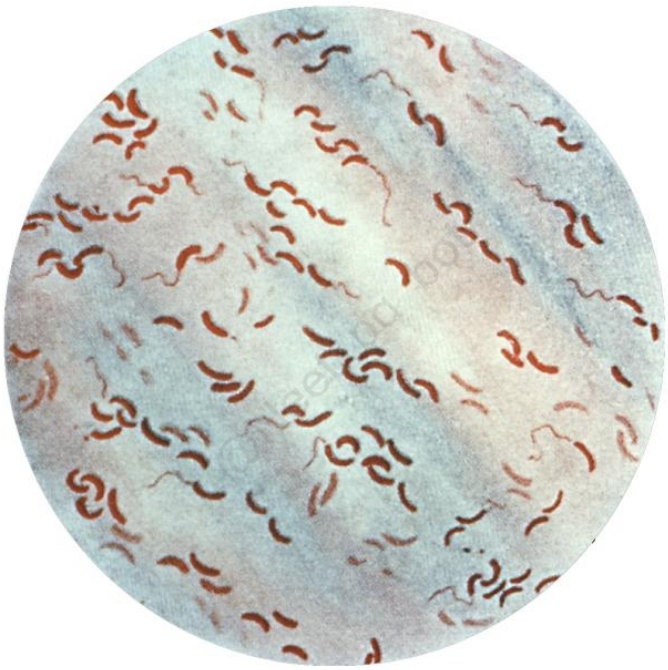
Q3: A 40 y/o woman presents with acute, profuse watery diarrhoea and severe dehydration after consuming contaminated water. Stool microscopy findings are shown below. She is hypotensive, with laboratory evidence of prerenal azotemia. Which of the following statements best distinguishes this presentation from osmotic diarrhoea in terms of fluid and electrolyte pathophysiology? (Q890577)

A. The diarrhoea would cease immediately upon stopping oral intake

B. The diarrhoea persists despite a 24-hour fast

C. The stool pH is acidic due to bacterial fermentation

D. The primary driver of fluid loss is nutrient malabsorption



@Neet_pg_bot

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A history of exposure to contaminated water in a patient presenting with diarrhoea most strongly raises concern for which of the following etiologic agents? (Q890576)

A. Staphylococcus aureus

B. Giardia lamblia

C. Clostridioides difficile

D. Cytomegalovirus

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 22 y/o man with 2 days of fever and right lower-quadrant abdominal pain with mild diarrhoea. O/E, he has tenderness at McBurney's point. Laparoscopy reveals the terminal ileum is thickened and inflamed with mesenteric lymphadenopathy. Which organism is the most likely etiologic agent responsible for this presentation? (Q890575)

A. Campylobacter jejuni

B. Yersinia enterocolitica

C. Shigella dysenteriae

D. Giardia lamblia

See Answer in Part B → Q5

@Neet_pg_bot

Q6: In the evaluation of diarrhoea in an immunocompromised adult, which of the following viral agents should be considered a potential aetiology? (Q890574)

A. Hepatitis A virus

B. Adenovirus

C. Hepatitis C virus

D. Epstein-Barr virus

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which pathophysiologic mechanism is primarily responsible for the diarrhoea observed in patients with bile acid malabsorption? (Q890572)

A. Osmotic retention of water by unabsorbed fatty acids

B. Stimulation of active colonic fluid and electrolyte secretion

C. Exudation of protein and fluid due to mucosal inflammation

D. Inhibition of pancreatic enzyme activity

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 30 y/o woman presents with chronic diarrhoea and hypokalemia. Stool analysis shows a low faecal osmotic gap (<50 mOsm/kg). Factitious diarrhoea due to laxative abuse is suspected. Which of the following is the most appropriate diagnostic test to confirm the diagnosis? (Q890571)

A. Urine D-xylose test

B. Stool laxative screen

C. 72-hour faecal fat collection

D. Serum chromogranin A

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following faecal osmotic gap values is most characteristic of secretory diarrhoea? (Q890570)

A. >125 mOsm/kg

B. >100 mOsm/kg

C. >50 mOsm/kg

D. <50 mOsm/kg

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following clinical features is most characteristic of diarrhoea originating from the small intestine? (Q890568)

A. Frequent passage of small-volume stools

B. Presence of tenesmus

C. Large-volume watery stools

D. Frank hematochezia (bright red blood)

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 27 y/o man develops abdominal bloating, crampy pain, and diarrhoea shortly after consuming milk. Stool analysis is performed while he is symptomatic. Which of the following stool profiles is most consistent with lactose intolerance? (Q890566)

A. High pH (>7.0) and a low stool osmotic gap (<50 mOsm/kg)

B. Low pH (<6.0) and a high stool osmotic gap (>100 mOsm/kg)

C. High pH (>7.0) and a high stool osmotic gap (>100 mOsm/kg)

D. Low pH (<6.0) and a low stool osmotic gap (<50 mOsm/kg)

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 34 y/o man with Crohn's disease undergoes surgical resection. Six months later, he presents with progressive weight loss and bulky, foul-smelling, floating stools despite a balanced diet.Which of the following pathophysiologic mechanisms best explains his steatorrhea? (Q890565)

A. Stimulation of colonic fluid secretion by unabsorbed bile acids

B. Hepatic bile acid synthesis compensating for faecal losses

C. Depletion of the circulating bile acid pool

D. Primary failure of pancreatic enzyme secretion

See Answer in Part B → Q12

@Neet_pg_bot

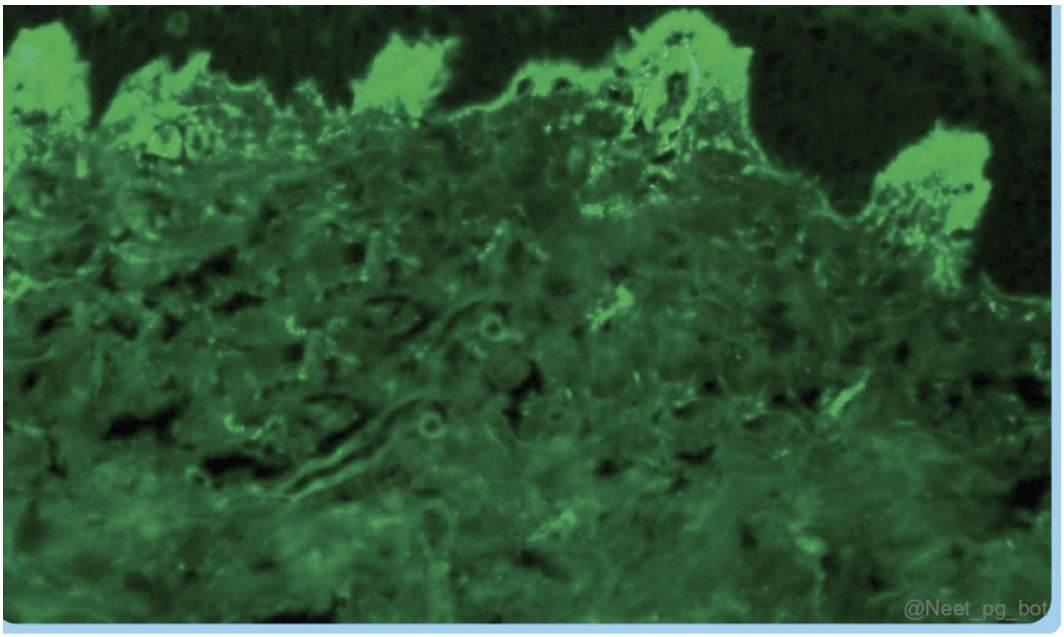
Q13: A 16-year-old boy presents with intensely itchy vesicular skin lesions on elbows and knees. Her mother says that she is giving him rice based diet only and he does not tolerate cereals. Skin biopsy was performed from the lesions and IF staining is shown below. Which of the following is the most likely diagnosis? (Q850854)

A. Bullous pemphigoid

B. Pemphigus vulgaris

C. Dermatitis herpetiformis

D. Psoriasis



See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following diseases is not a cause of protein losing enteropathy? (Q850868)

A. Ulcerative colitis

B. Menetrier's disease

C. Intestinal lymphangiectasia

D. Abetalipoproteinemia

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Gold standard investigation for steatorrhea is? (Q850866)

A. 72-hour faecal fat estimation

B. Breath triolein test

C. PIVKA test

D. Small intestinal mucosal biopsy

See Answer in Part B → Q15

@Neet_pg_bot

Q16: You are asked to evaluate lab reports of patient with peripheral oedema. Serum albumin is low and serum globulin is low. Which of the following is likely cause? (Q850865)

A. Cirrhosis

B. Minimal change disease

C. Protein losing enteropathy

D. SCID

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Stool alpha1 anti-trypsin levels are used for diagnosis of which of the following disease? (Q850864)

A. Alpha 1 antitrypsin deficiency

B. Protein losing enteropathy

C. Small bowel syndrome

D. Abetalipoproteinemia

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following is correct treatment of tropical sprue? (Q850863)

A. Tetracycline with folic acid

B. Ceftriaxone with TMP-SMX

C. Ofloxacin with Ornidazole

D. Budesonide ileal release preparation

See Answer in Part B → Q18

@Neet_pg_bot

Q19: 30-year-old woman with scleroderma was having steatorrhea and anaemia. She was found to have vitamin B12 deficiency and elevated serum folate levels. Which is next best investigation to be done in this patient? (Q850862)

A. Anti topoisomerase antibody

B. Duodenal aspirate for bacterial titers

C. Small intestinal mucosal biopsy

D. Breath urea test

See Answer in Part B → Q19

@Neet_pg_bot

Q20: 30-year-old woman with scleroderma was having steatorrhea and anaemia. She was found to have vitamin B12 deficiency and elevated serum folate levels. Which of the following is probable cause of her malabsorptive diarrhoea? (Q850861)

A. Chronic pancreatitis

B. Autoimmune gastritis

C. Small intestinal bacterial overgrowth

D. Whipple’s disease

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Severity of celiac sprue is determined by which classification? (Q850859)

A. Forrest

B. Marsh

C. Vienna and Montreal

D. Truelove and Witts

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Middle aged man presented with arthralgias, diarrhoea, weight loss and abdominal pain. Small intestinal mucosal biopsy shows PAS positive macrophages laden with intracellular bacteria. Which of the following is correct about management of this patient? (Q850858)

A. Oral TMP-SMX

B. Ceftriaxone

C. Ceftriaxone plus oral TMP-SMX

D. Tetracycline plus oral TMP-SMX

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following is not correct about celiac sprue? (Q850856)

A. Lactase deficiency

B. Steatorrhea

C. Secretory diarrhoea

D. Lipid laden intestinal epithelial cells that appears normal after 72 hours fasting

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following is correct about celiac sprue? (Q850855)

A. Demonstration of host genetic factors HLA DQ2 DQ8 is a must for diagnosis

B. BROW cereals intake is mainstay of managing the disease

C. Presents with iron deficiency anaemia

D. Leading cause is colonization of gut by Tropheryma whippelli

See Answer in Part B → Q24

Q1: What is not a characteristic feature of Wilson's disease? (Q856381)

A. Autosomal recessive disease

B. No free radical injury

C. ATP7B gene involved

D. Presents before age 40 with liver disease

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which classification is used for Barrett esophagus? (Q866826)

A. Prague classification

B. Savary-Miller classification

C. Johnson classification

D. Forrest classification

See Answer in Part B → Q2

@Neet_pg_bot

Q3: 30 year old male is found to have anemia (MCV 110 fl) with leukonychia and enlarged spleen. The clinical diagnosis is? (Q866825)

A. Portal Hypertension

B. Plummer-Vinson syndrome

C. Achalasia cardia

D. Tylosis palmaris

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A patient with osteoarthritis, for the last 3 months, has been taking ibuprofen and has developed occult GI bleeding. Which is correct about the cause? (Q866795)

A. PGE-2 and prostacyclin production were reduced

B. Increased acid production

C. PGE-1 and prostacyclin production were reduced

D. Mucosal injury due to inhibition of COX-2

See Answer in Part B → Q4

@Neet_pg_bot

Q5: 24-year-old female presents with dysphagia, weight loss and bronchiectasis. Which investigation should be done to confirm the diagnosis. Barium swallow was shown? (Q866504)

A. Esophageal manometry

B. Upper GI endoscopy

C. CT chest

D. CECT chest

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 70-year-old male patient presents with a complaint of dysphagia, particularly for solids, which has been progressively worsening over the past few months. Additionally, he has experienced significant weight loss and cachexia over the same period. Which of the following diagnostic choices is best for this patient? (Q860394)

A. UGIE

B. Manometry

C. Barium swallow

D. Barium meal follow through

See Answer in Part B → Q6

@Neet_pg_bot

Q7: In which of the following conditions is pneumomediastinum commonly found? (Q860160)

A. Pulsion diverticulum

B. Boerhaave syndrome

C. Mallory-Weiss syndrome

D. Pericarditis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A patient with inflammatory bowel disease presents with the following lesion. What is the most likely diagnosis? (Q859643)

A. Erythema nodosum

B. Pyoderma gangrenosum

C. Diabetic ulcer

D. Venous ulcer

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 15-year-old girl presented with fatigue, chronic diarrhoea, weight loss, bone pain and abdominal distension. Investigations revealed iron deficiency anemia and osteoporosis. Which of the following is the single best test to be done for her evaluation? (Q858444)

A. TSH levels

B. C-peptide levels

C. Urine sugar and ketone

D. IgA tissue transglutaminase antibody

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 49-year-old male is experiencing recurring episodes of watery diarrhea, dehydration, hypokalemia, and achlorhydria. Which type of neuroendocrine tumor could potentially cause these symptoms? (Q858363)

A. Insulinoma

B. Somatostatinoma

C. VIPoma

D. Glucagonoma

See Answer in Part B → Q10

@Neet_pg_bot

Q11: What is the probable diagnosis of a patient who has significant abdominal swelling and laboratory analysis of the fluid obtained through paracentesis reveals SAAG <1.1? (Q856355)

A. Congestive heart failure

B. Myxoedema

C. Budd Chiari syndrome

D. Tuberculosis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following are not included in the components of the MELD (2016) score? (Q856338)

A. Bilirubin

B. INR

C. Albumin

D. Creatinine

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Mark the correct statement regarding inflammatory bowel disease. (Q855605)

A. Skip lesions are present in Crohn's disease

B. Mucosal layers are involved in Crohn's while transmural involvement seen in ulcerative colitis

C. Inflammatory bowel disease doesn't have a genetic predisposition

D. Crohn's is curable through surgical resection of the affected segment

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A patient was taking ampicillin for an upper respiratory tract infection. Then he started having watery diarrhoea for the past 3 days. Which is the drug of choice to manage this condition? (Q854689)

A. Metronidazole

B. Fidaxomicin

C. Ciprofloxacin

D. Bezlotoxumab

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 42-year-old female presents with complaints of recurrent episodes of abdominal pain and cramps. An endoscopy is done and she is diagnosed with ulcerative colitis. She currently has 3-4 episodes of bloody stools per day. What is the appropriate initial treatment? (Q854665)

A. Budesonide

B. Sulfasalazine

C. Azathioprine

D. Bezlotoxumab

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A known case of ulcerative colitis is not responding to an anti-TNF alpha agent. Which JAK inhibitor is preferred for moderate to severe ulcerative colitis? (Q853355)

A. Vedolizumab

B. Tofacitinib

C. Ozanimod

D. Leflunomide

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following is not associated with celiac disease? (Q853345)

A. IgA transglutaminase positive

B. IgG antigliadin positive

C. Modified Marsh classification

D. HLA DQ6 and HLA DQ11

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following symptoms suggests the use of steroids in IgA vasculitis? (Q840121)

A. Joint inflammation

B. Gastrointestinal hemorrhage

C. Abdominal discomfort

D. Dermatological eruption

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Patient is identified as having a tumor in the ileum leading to urinary 5 HIAA being elevated. What is the diagnosis? (Q793830)

A. Carcinoid tumor

B. Neuroblastoma

C. Leiomyoma

D. Chromaffinoma

See Answer in Part B → Q19

@Neet_pg_bot

Q20: What is the probable diagnosis for a 50-year-old woman with a skin lesion visible in the provided image, which initially appeared small but has now spread to her entire limb and abdomen? Despite being on anticoagulation therapy, she has a longstanding history of diabetes and recurring deep vein thrombosis episodes. (Q793836)

A. Insulinoma

B. Gastrinoma

C. Glucagonoma

D. VIPoma

See Answer in Part B → Q20

Q13 (p. 485)

Q1: 70-year-old retired man presents with low grade fever, painless swelling in the neck and fatigue for the past 3 months. Examination reveals generalized lymphadenopathy and mild splenomegaly. CBC shows WBC 85,000/µL with absolute lymphocyte count 65,000/µL. Peripheral smear shows numerous small mature-appearing lymphocytes and smudge cells. Which of the following is the investigation of choice to confirm the diagnosis? (Q850873)

A. Peripheral blood flow cytometry

B. Bone marrow aspiration showing lymphoblasts > 20%

C. FISH analysis for 17p deletion

D. PCR for ZAP-70 expression

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 65-year-old man on an annual medical check-up is found to have lymphocytosis on routine CBC (total leukocyte count: 11,000/µL; absolute lymphocyte count: 4,200/µL). He is asymptomatic with no lymphadenopathy or organomegaly. Peripheral smear shows mature-appearing small lymphocytes. Flow cytometry reveals a monoclonal B-cell population with CLL immunophenotype. Which of the following features will help distinguish this condition from CLL? (Q850875)

A. Presence of B symptoms

B. Absolute B-cell count < 5 × 10y/L

C. Positive Coombs test

D. Expression of CD19, CD20, CD5

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Radiation exposure is associated with increased risk of several hematological malignancies. Which of the following is least likely to be related to radiation exposure (Q850877)

A. ALL

B. AML

C. CML

D. CLL

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following peripheral smear findings is not seen in CLL? (Q850879)

A. Spherocytes

B. Smudge cells

C. Prolymphocytes

D. Lymphoblasts

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following statements regarding Richter transformation is correct? (Q850881)

A. Transformation of CLL into diffuse large B-cell lymphoma

B. Transformation of follicular lymphoma into diffuse large B-cell lymphoma

C. Transformation of marginal zone lymphoma into diffuse large B-cell lymphoma

D. Transformation of mantle cell lymphoma into diffuse large B-cell lymphoma

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Leading cause of death in patients diagnosed with CLL? (Q850882)

A. Hypo-gammaglobulinemia

B. Heart disease

C. Kidney failure

D. Hyper viscosity syndrome

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Known case of CLL is admitted with shortness of breath on minimal activity. Work up shows Hb= 7 gm%, TLC 25000 cells/cu.mm, platelet count of 50K/cu.mm, reticulocyte count is 2% with low haptoglobin and elevated LDH. Which of the following test would help in further evaluation of this patient? (Q850884)

A. Direct coombs test

B. ZAP-70

C. FISH

D. Treadmill test

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is drug used in CLL acts is inhibitor of antiapoptotic protein BCL-2? (Q850886)

A. Venetoclax

B. Ibrutinib

C. Idelalisib

D. Duvelisib

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Evan syndrome is defined as? (Q850888)

A. Autoimmune hemolytic anemia + autoimmune thrombocytopenia

B. Autoimmune hemolytic anemia + autoimmune granulocytopenia

C. Pure red cell aplasia + autoimmune granulocytopenia

D. Pure red cell aplasia + autoimmune thrombocytopenia

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is not a component of Rai staging system used in CLL? (Q850890)

A. Lymphocytosis

B. Lymphadenopathy

C. Hepatosplenomegaly

D. Autoimmune hemolytic anemia

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is not a component of CLL prognostic index? (Q850893)

A. Age

B. Beta 2 microglobulin

C. Clinical staging

D. BCL-2

See Answer in Part B → Q11

@Neet_pg_bot

Q12: What secondary malignancy can be seen in patients with CLL? (Q850895)

A. Skin and prostate cancer

B. Oro-pharyngeal cancer

C. Ca- larynx

D. Hepatocellular cancer

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 62-year-old man presents with generalized lymphadenopathy and mild splenomegaly. Peripheral smear shows small-to-medium sized lymphoid cells with irregular nuclear contours. Lymph node biopsy reveals a diffuse proliferation of small lymphocytes with cleaved nuclei. Immunophenotyping shows CD19+, CD20+, CD5+, cyclin D1+, and negative for CD23. Which is the most likely diagnosis? (Q850897)

A. Chronic lymphocytic leukemia

B. Mantle cell lymphoma

C. Follicular lymphoma

D. Marginal zone lymphoma

See Answer in Part B → Q13

Q1: Which of the following is correct about the Philadelphia chromosome? (Q850439)

A. Balanced translocation between long arms of chromosome 9 and 22

B. Balanced translocation between short arms of chromosome 9 and 22

C. Unbalanced translocation between long arms of chromosome 9 and 22

D. Unbalanced translocation between short arms of chromosome 9 and 22

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is correct about CML? (Q850533)

A. Reciprocal exchange between breakpoint Cluster Region gene on chromosome 22, ABL1 gene on chromosome 9

B. Reciprocal exchange between breakpoint Cluster Region gene on chromosome 9, ABL1 gene on chromosome 22

C. Non-reciprocal exchange between breakpoint Cluster Region gene on chromosome 22, ABL1 gene on chromosome 9

D. Non-reciprocal exchange between breakpoint Cluster Region gene on chromosome 9, ABL1 gene on chromosome 22

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Best for management of gatekeeper mutation T315I that prevents binding and causes resistance to known TKI in Chronic myeloid leukemia is? (Q850538)

A. Dasatinib

B. Nilotinib

C. Bosutinib

D. Ponatinib

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Bcr-abl1 fusion gene is seen in which of the following blood cancers? (Q850559)

A. ALL

B. AML

C. CLL

D. Hairy cell leukemia

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following findings is not seen in patients with CML? (Q850582)

A. Basophilia

B. Low serum Vitamin B12 levels

C. Low NAP score

D. Reticulin fibrosis in bone marrow

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 48-year-old male presents with fatigue and early satiety. On examination massive splenomegaly is seen. Work up is shown below. What is next best investigation to be done in this case CBC Bone marrow aspiration report Hb: 10.5 g/dL TLC: 1.5 × 10■ /mm³ Platelets: 4.0 × 10■ /mm³ Myeloblasts: 2% , Promyelocytes: 15% , Myelocytes: 25% , Metamyelocytes: 20% Band forms & neutrophils: 18% , Basophils: 6%, Blasts + promyelocytes together: <10%, NAP score: low (Q850605)

A. Bone marrow biopsy

B. Peripheral blood FISH for BCR-ABL1

C. Peripheral blood RT-PCR for BCR-ABL1

D. G-banding cytogenetics

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 35-year-old male with CML in chronic phase is started on imatinib. At diagnosis, bone marrow cytogenetics showed t(9;22)(q34;q11) in all metaphases. The treating physician now wants to assess whether he has achieved deep molecular remission. Which is the most appropriate investigation at this stage? (Q850613)

A. Conventional karyotyping from bone marrow aspirate

B. FISH for BCR-ABL on peripheral blood

C. Quantitative RT-PCR for BCR-ABL transcript levels

D. Qualitative PCR for BCR-ABL transcript

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is the most common presenting feature of CML? (Q850649)

A. Lymphadenopathy

B. Splenomegaly

C. Petechiae

D. Bone pain

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following drugs is approved for CML in case of failure of >2 or more TKI (Q850656)

A. Omacetaxine

B. Dasatinib

C. Bosutinib

D. Nilotinib

See Answer in Part B → Q9

@Neet_pg_bot

Q10: 48-year-old man presents with fatigue, headache, and visual blurring. Examination reveals splenomegaly. CBC shows: Hb 9.8 g/dL, TLC 1.2 × 10■/µL, platelet count 650 × 10^3/µL. Peripheral smear shows marked myeloid proliferation with occasional myeloblasts. Fundoscopy reveals retinal vein engorgement. Which of the following is the most appropriate immediate next step in management? (Q850678)

A. Start imatinib therapy

B. Leukapheresis

C. Hydroxyurea + hydration

D. Allopurinol prophylaxis

See Answer in Part B → Q10

@Neet_pg_bot

Q11: 70-year-old male presents with fatigue, unintentional weight loss, and recurrent respiratory infections over the last 6 months. Examination reveals pallor and mild splenomegaly. CBC shows: Hb: 9.8 g/dL TLC: 28,000/µL (Monocytes: 5,500/µL) Platelets: 110,000/µL Peripheral smear shows monocytosis with occasional myelocytes and metamyelocytes. Bone marrow aspirate is hypercellular with increased monocytes, <20% blasts, and dysplastic features in granulocytic and megakaryocytic lineages. Cytogenetic analysis is negative for the Philadelphia chromosome Diagnosis is? (Q850681)

A. CML

B. AML

C. CMML

D. JMML

See Answer in Part B → Q11

Q1: Arsenic trioxide is used for treatment of which of the following malignancy? (Q850715)

A. Acute promyelocytic leukemia

B. Acute myelomonocytic leukemia

C. Acute monocytic leukemia

D. Acute megakaryocytic leukemia

See Answer in Part B → Q1

@Neet_pg_bot

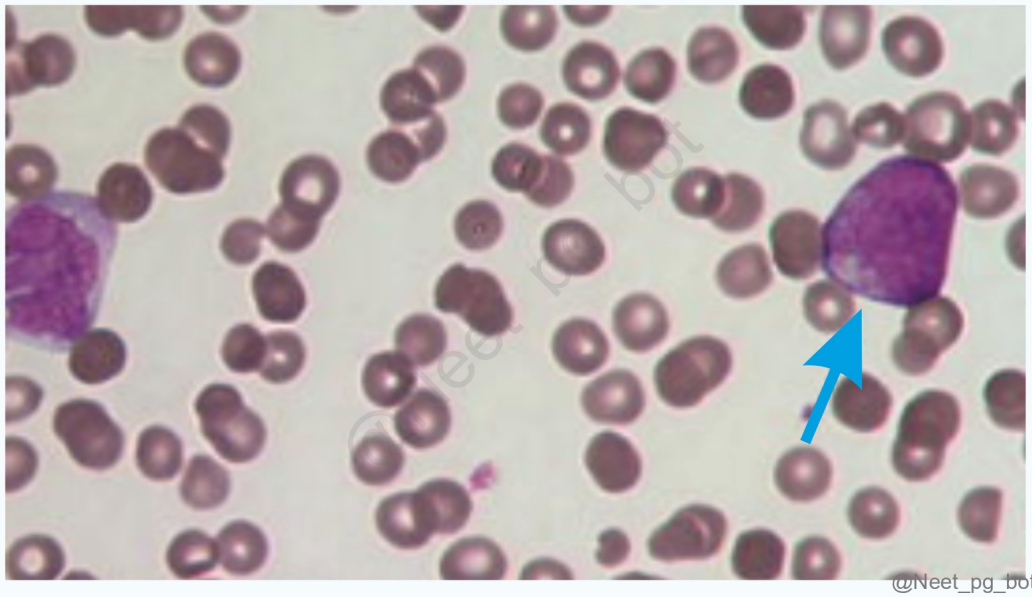
Q2: 34-year-old female presented with progressive pallor and organomegaly. Work up shows low Hb, platelet count of 25000/mm3. raised PT and aPTT. Peripheral smear is given. Which of the following fusion gene is affected? (Q850689)

A. PML RARA

B. RUNX1 RUNX1T1

C. IGH NSD2

D. BCR ABL



See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 60-year-old man presents with recurrent episodes of bleeding from nose and progressive pallor. Peripheral smear shows the presence of cells shown below. Which of the following is the most common chromosomal abnormality seen in this condition? (Q850693)

A. t (8:21)

B. t (15:17)

C. t (14:18)

D. Inv (16)

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old male presents with fatigue, progressive pallor and recurrent nasal bleeds. Bone marrow aspiration shows 10% myeloblasts with abnormal eosinophils. Cytogenetic analysis reveals inv(16) (p13;q22). Which of the following is the most appropriate diagnosis? (Q850695)

A. Myelodysplastic syndrome

B. Acute myeloid leukemia

C. Chronic myelomonocytic leukemia

D. Chronic myeloid leukemia

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 60-year-old man presented with early satiety and abdominal pain. On examination grossly enlarged spleen and liver is palpable Work up shows low Hb with WBC-50000/mm3 and platelet count of 6 lac/cu.mm. Which of the following will cause this presentation? (Q850702)

A. t (9:22)

B. Del 1q

C. t (15:17)

D. Del 3q

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following chromosomal aberrations occur in topoisomerase II inhibitor–associated acute myeloid leukemia? (Q850705)

A. t (15:17)

B. inv16

C. 11q23

D. t (8:21)

See Answer in Part B → Q6

Q1: Adult T cell leukemia is caused by which of the following viruses? (Q850770)

A. HTLV-1

B. EBV

C. HPV

D. Polyoma virus

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is not correct about CNS leukemia? (Q850771)

A. LP is restricted to patients with platelet count less than 20K /cu mm

B. Intrathecal methotrexate to be given after performing lumbar puncture

C. LP is routine diagnostic test during work up of patient of ALL

D. Cell count > 5 cells/uL or leukemic blast cells on morphology is diagnostic

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 10-year-old patient presents with fatigue and bleeding. Peripheral blood shows anaemia, thrombocytopenia and neutropenia. Bone marrow flow cytometry shows blasts positive for both CD19, CD79a , CD13, CD33, along with cytoplasmic

myeloperoxidase. Which of the following is the most likely diagnosis? (Q850772)

A. B cell ALL

B. T cell ALL

C. Biphenotypic ALL

D. AML

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is correct about complete molecular response in patients with ALL? (Q850773)

A. Patient in remission, MRD not detectable, < 1 leukemia cell in 1,000 BM cells

B. Patient in remission, MRD not detectable, < 1 leukemia cell in 10,000 BM cells

C. Patient in remission, MRD not detectable, < 1 leukemia cell in 100,000 BM cells

D. Patient in remission, MRD not detectable, < 1 leukemia cell in 100,0000 BM cells

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following types of ALL is associated with the Philadelphia chromosome? (Q850775)

A. Common ALL

B. Mature B cell ALL

C. T cell ALL

D. Pro B- ALL

See Answer in Part B → Q5

@Neet_pg_bot

Q6: What drugs are used in pre-phase therapy for a patient with Acute lymphoblastic leukemia? (Q850777)

A. Rasburicase

B. Allopurinol

C. Dexamethasone plus vincristine

D. Dexamethasone plus methotrexate

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 12-year-old boy with relapsed B-cell ALL is planned for therapy with CAR-T cells. In this context, CAR stands for which of the following? (Q850783)

A. Chimeric Antigen Receptor

B. Chimeric Antibody Receptor

C. Clustered Antigen Receptor

D. Chimeric Antigen Recognition

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is an anti CD-19 targeting antibody used in acute lymphoblastic leukemia? (Q850788)

A. Blinatumomab

B. Rituximab

C. Ruxolitinib

D. Dasatinib

See Answer in Part B → Q8

@Neet_pg_bot

Q9: The most common benign tumor in children is? (Q850791)

A. Hemangioma

B. Acute lymphoblastic lymphoma

C. Cerebellar astrocytoma

D. Medulloblastoma

Q1: Which of the following is not a biomarker of malignancy in patient with symptomatic multiple myeloma (Q850793)

A. M protein on urinary or serum electrophoresis

B. Involved: uninvolved free light chain ratio > 100

C. > 1 focal lesion on MRI studies

D. Clonal bone marrow plasma cell percentage > 60%

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 72-year-old man presents with 3 months of low back pain, fatigue, and weight loss. Examination shows pallor and mild splenomegaly. Investigations reveal: Hemoglobin: 8.5 g/dL Serum calcium: 12.2 mg/dL Creatinine: 2.3 mg/dL Serum protein electrophoresis: M-spike in γ-region MRI spine: Multiple lytic lesions Peripheral smear: 25% plasma cells What is the most likely diagnosis? (Q850797)

A. Multiple myeloma

B. Monoclonal gammopathy of undetermined significance (MGUS)

C. Smoldering multiple myeloma

D. Primary plasma cell leukemia

See Answer in Part B → Q2

@Neet_pg_bot

Q3: You calculated eGFR of multiple myeloma on a follow up visit as 20 ml/min. Which of the following is the leading cause of this presentation? (Q850800)

A. Amyloidosis

B. Hypercalcemia

C. Pyelonephritis

D. Tubular damage by bence jones proteins

See Answer in Part B → Q3

@Neet_pg_bot

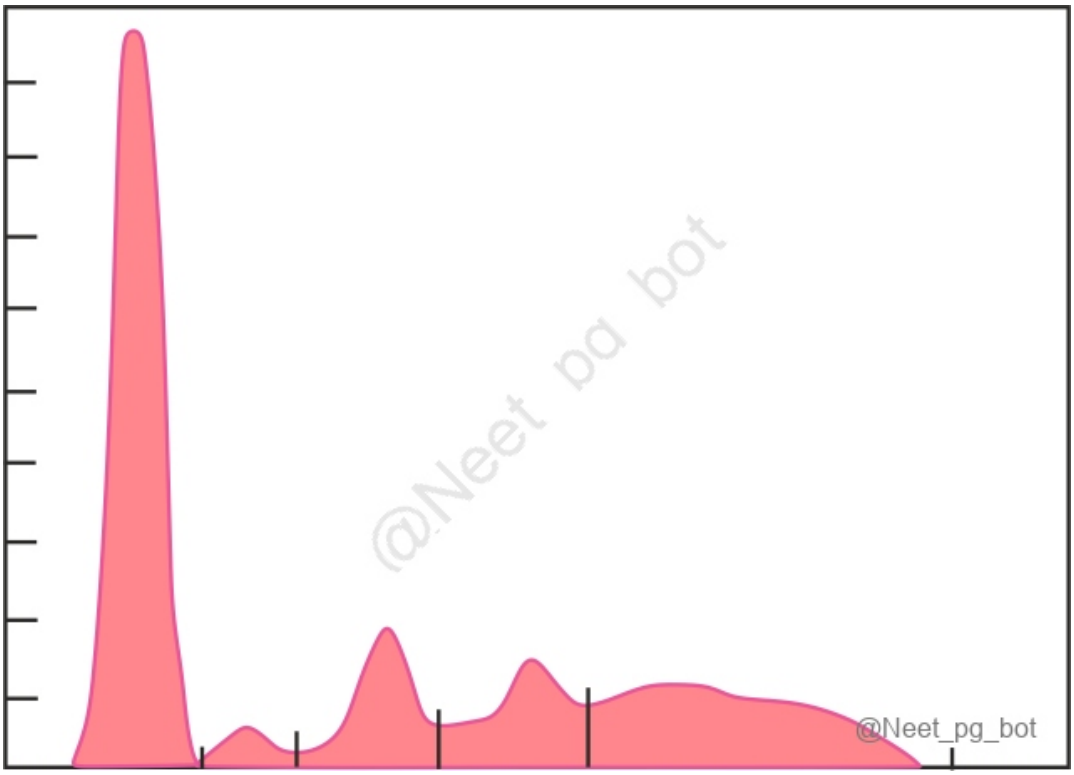
Q4: Comment on agarose gel electrophoresis and immunofixation reports? (Q850801)

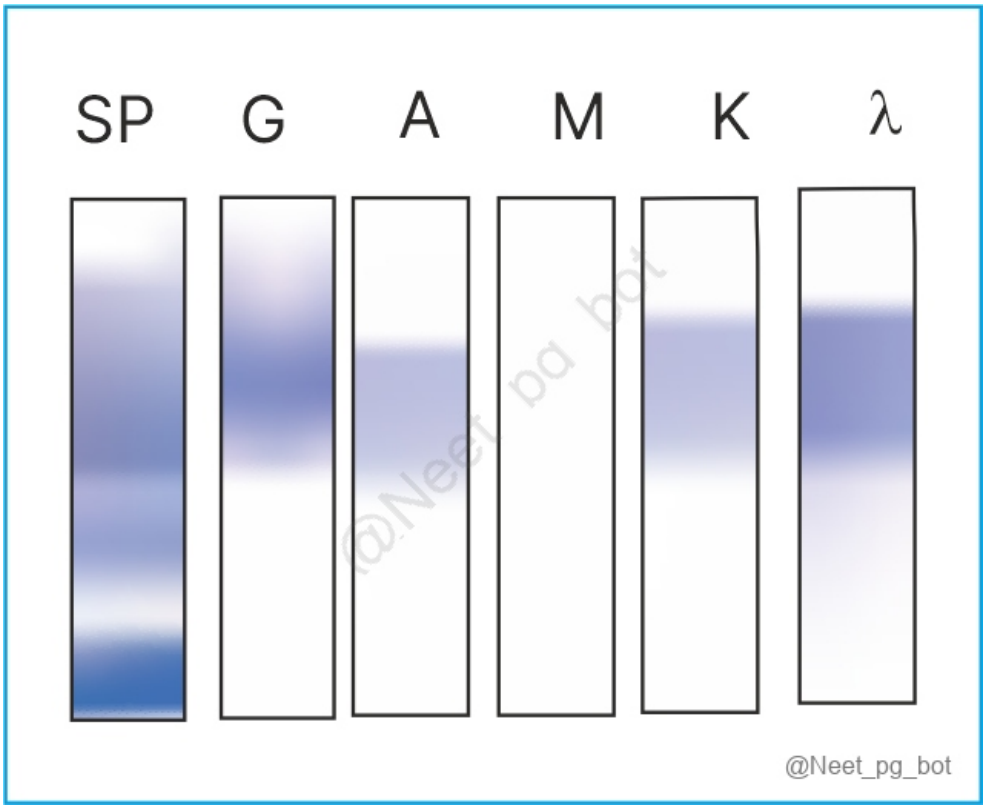
A. Monoclonal Ig A kappa

B. Monoclonal Ig G kappa

C. Monoclonal Ig G kappa lambda

D. Polyclonal





See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is incorrect about histopathological findings in multiple myeloma? (Q850802)

A. Clock face chromatin

B. Intracytoplasmic Dutcher bodies

C. Mott cells

D. Eccentric nucleus with basophilic cytoplasm

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Earliest manifestation of tubular damage in multiple myeloma due to bence jones proteins causes? (Q850803)

A. Glucosuria and aminoaciduria

B. Hematuria

C. Proteinuria

D. Metabolic alkalosis

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is not correct about multiple myeloma? (Q850804)

A. Increased anion gap

B. Pseudohyponatremia

C. Hyperviscosity

D. Reduced creatinine clearance

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 70-year-old male presents with progressive fatigue, recurrent headaches, blurred vision, and episodes of epistaxis for the past 2 months. On examination, there is pallor and mild hepatosplenomegaly. Labs are shown below. What is the most likely diagnosis? Hb: 8.5 g/dL Serum protein electrophoresis: M spike in the β–γ region Immunofixation: IgM monoclonal protein Bone marrow: infiltration with small lymphocytes and plasma cells (Q850807)

A. Multiple myeloma

B. Chronic lymphocytic leukemia

C. Waldenström macroglobulinemia

D. Monoclonal gammopathy of undetermined significance

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 70-year-old man presents with pallor and a low back ache. MRI spine shows lytic lesions in L5 and S1. In his past medical history, he had pneumonia last winter. Workup shows Hb 7 gm/dl, deranged RFT and serum calcium 11.2 mg/dl. Which of the following investigations is the next best test for the suspected diagnosis of this patient? (Q850808)

A. Serum electrophoresis

B. Peripheral blood flow cytometry

C. Serum free light chain assay

D. Bone marrow biopsy

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is correct about multiple myeloma? 1. Decreased anion gap 2. Glucosuria and aminoaciduria 3. Hypoviscosity 4. Increased creatinine clearance (Q850809)

A. 1,2

B. 1,4

C. 1,2,3

D. 1,2,4

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 70 year old man recently diagnosed with multiple myeloma has been declared non eligible for transplantation due to poor cardiovascular health. Which of the following drug combinations is used for management of this patient? (Q850810)

A. Lenalidomide + dexamethasone + Bortezomib + daratumumab

B. Rituximab + cyclophosphamide + Vincristine

C. Adriamycin + bleomycin+ Vinblastine

D. Fludarabine + cyclophosphamide+ Rituximab + daratumumab

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 60-year-old female presents with weakness, back pain and repeated infections. Work up shows M spike on serum electrophoresis. Bone marrow biopsy shows 15% plasma cells. The prognosis of this patient is best determined by which of the following? (Q850811)

A. Ig G and albumin

B. Hb and albumin

C. Albumin and LDH

D. Albumin and beta 2 Micro-globulin

See Answer in Part B → Q12

Q1: Which of the following neoplasms has the highest incidence of causing tumor lysis syndrome (Q851117)

A. Burkitt lymphoma

B. DLBCL

C. AML

D. ALL

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Lumbar puncture and CSF cytology is part of diagnostic workup of all except? (Q851127)

A. ALL

B. AML

C. NHL

D. HL

See Answer in Part B → Q2

@Neet_pg_bot

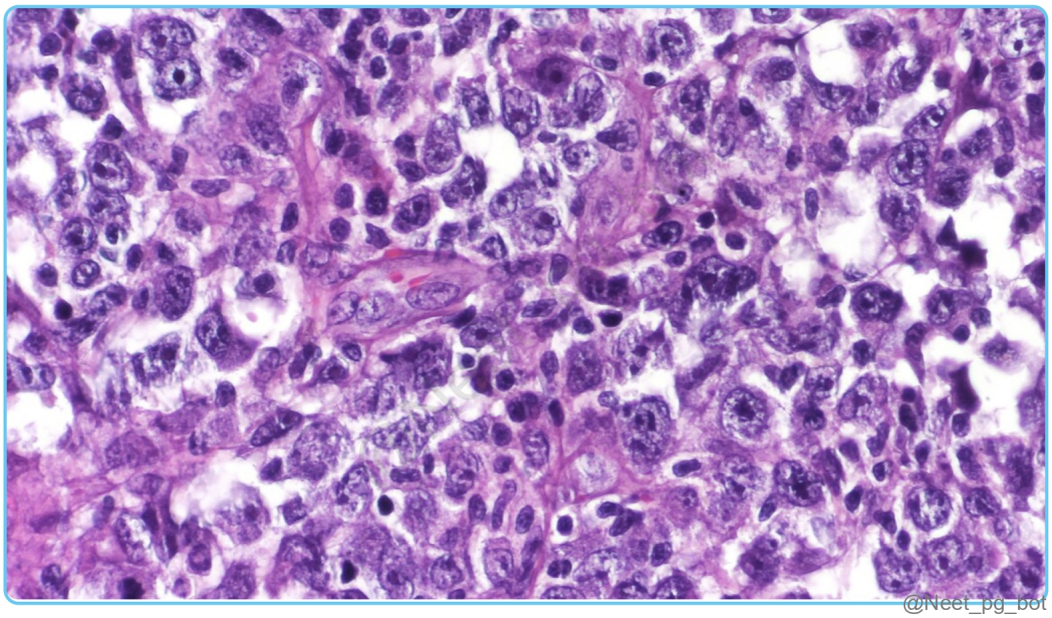
Q3: A 72-year-old man presents with progressive abdominal distension and early satiety for 3 months. USG shows multiple enlarged para-aortic lymph nodes. CT abdomen confirms bulky retroperitoneal lymphadenopathy. Excisional biopsy of a lymph node was done and is shown below. Immunohistochemistry is positive for CD10, CD19, CD20, and BCL6. Which of the following is the most likely diagnosis? (Q851124)

A. Burkitt lymphoma

B. DLBCL

C. Follicular lymphoma

D. Mycosis fungoides



See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is the most common type of Non-Hodgkin lymphoma (NHL)? (Q851123)

A. Nodular sclerosis

B. Mixed cellularity

C. Nodular lymphocytic predominant

D. Diffuse large B cell lymphoma

See Answer in Part B → Q4

@Neet_pg_bot

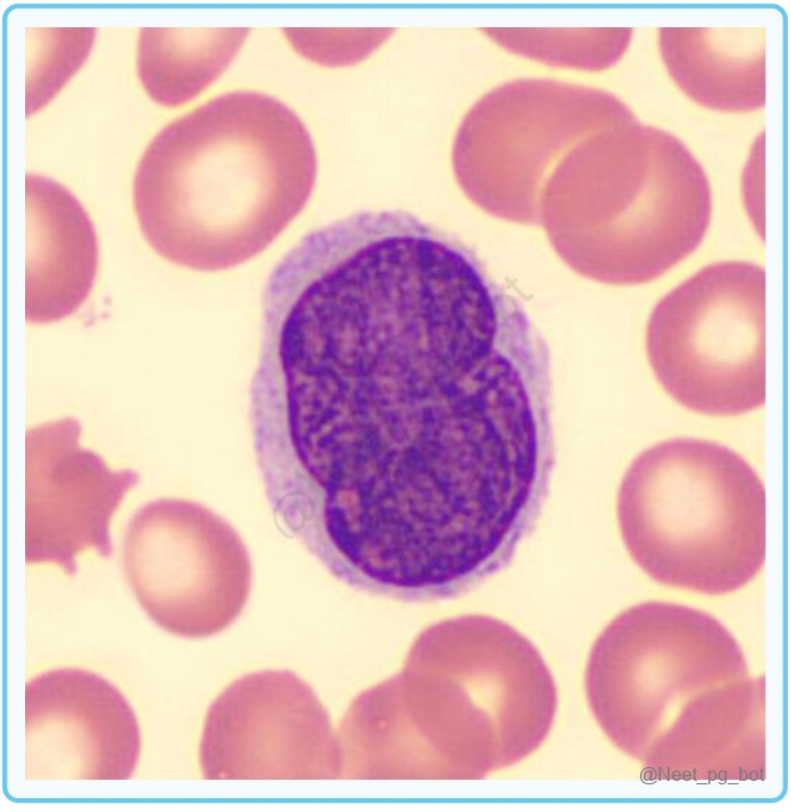
Q5: A 62-year-old man presents with generalized redness and scaling of the skin involving more than 80% of his body surface area, associated with intense itching. Examination reveals generalized lymphadenopathy and hepatosplenomegaly. Peripheral smear is shown below. Which of the following is the most likely diagnosis? (Q851122)

A. Mycosis fungoides

B. Sézary syndrome

C. Psoriasis vulgaris

D. Adult T-cell leukemia/lymphoma



See Answer in Part B → Q5

@Neet_pg_bot

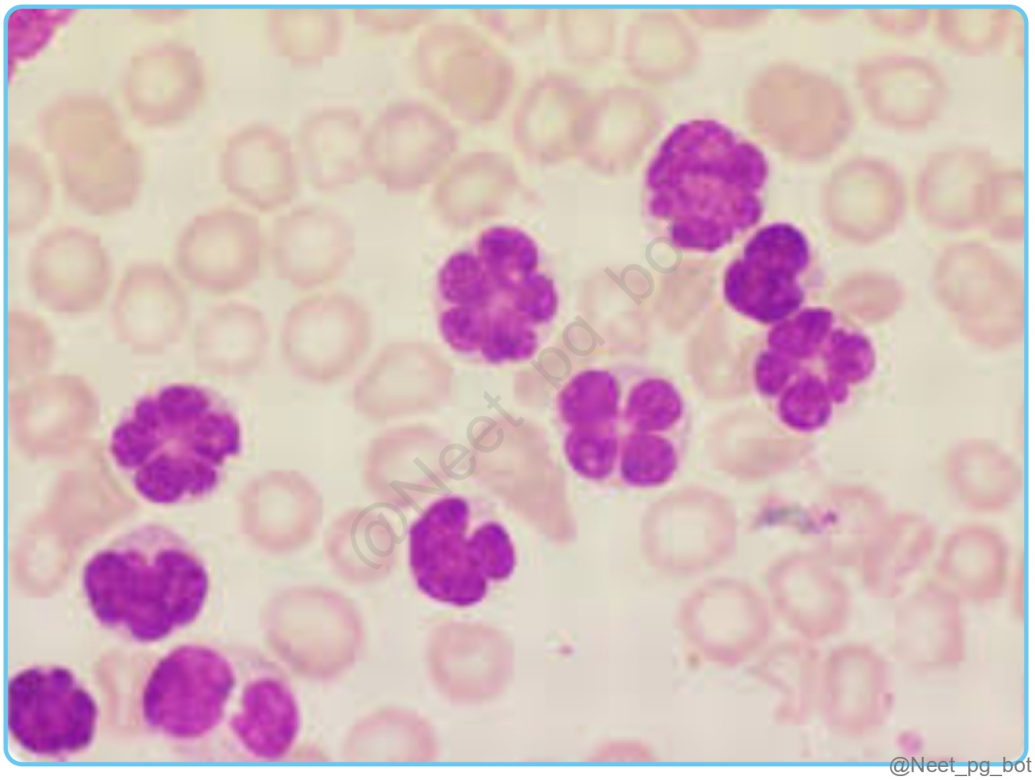
Q6: A 48-year-old man on medical tourism presents with generalized lymphadenopathy, skin rash, and hypercalcemia. Peripheral smear is shown below. Which of the following is the most likely diagnosis? (Q851121)

A. Sézary syndrome

B. Adult T-cell leukemia/lymphoma

C. Mycosis fungoides

D. Multiple myeloma



See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 54-year-old woman presents with painless, generalized lymphadenopathy. Lymph node biopsy shows a nodular growth pattern with centrocytes and

centroblasts. Immunohistochemistry is positive for CD10 and BCL2. Which chromosomal translocation is most commonly associated with this lymphoma? (Q851120)

A. t(2:5)

B. t(2:8)

C. t(14:18)

D. t(11:14)

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following lymphoma is seen in a 30 year old woman with SLE? (Q851119)

A. Extra nodal marginal zone B cell lymphoma

B. Diffuse large B cell lymphoma

C. Enteropathy associated T cell lymphoma

D. MALToma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is not correct about burkitt lymphoma? (Q851118)

A. Most common chromosomal translocation is t(8:22)

B. Non endemic form presents with ascites

C. Biopsy shows sheets of monotonous cells with basophilic cytoplasm with interspersed macrophages

D. CD10, CD19, CD20, and BCL-6 positive and BCL-2 negative

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is incorrect about Hodgkin’s lymphoma? (Q851094)

A. B-cell tumor

B. HIV and EBV are risk factor

C. CD19, CD20, CD23, PAX-5 positive cells

D. Genetic aberration on chromosome 9

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following chromosomal translocations is correct about anaplastic lymphoma? (Q851114)

A. t(2:5)

B. t(8:14)

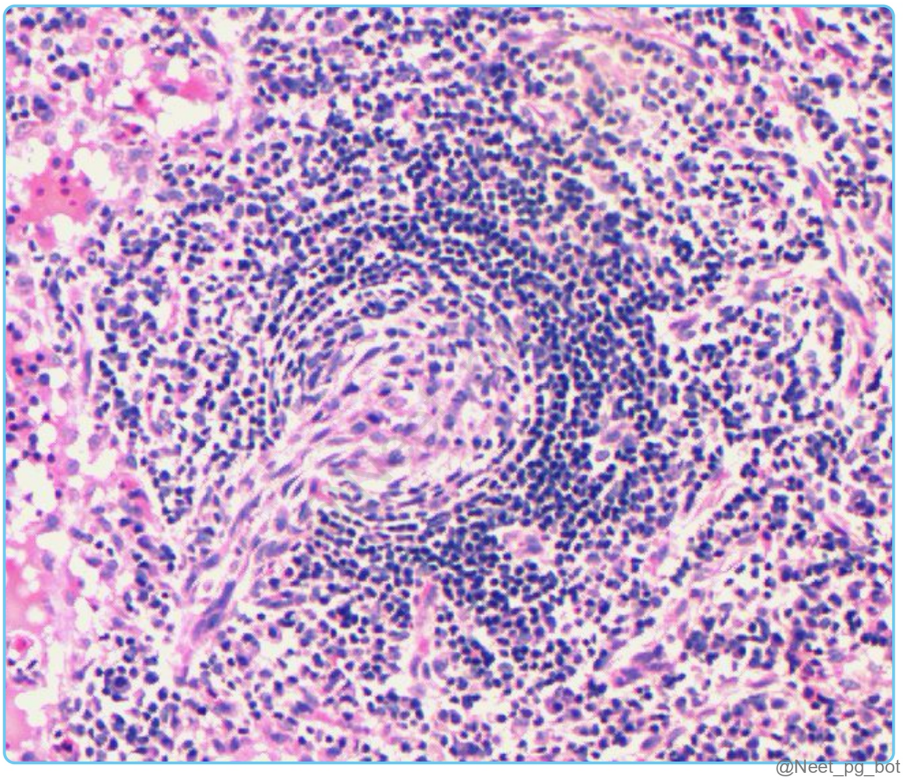
Q12: A 45-year-old male presents with fever, night sweats, fatigue, and unintentional weight loss for 2 months. On examination, he has generalized lymphadenopathy and mild hepatosplenomegaly. Laboratory tests reveal anemia, elevated ESR, and hypergammaglobulinemia. Excision lymph node biopsy is shown. Which of the following viruses is implicated in its pathology (Q851108)

A. HIV

B. EBV

C. HCV

D. HHV8



See Answer in Part B → Q12

@Neet_pg_bot

Q13: A patient is diagnosed with lymphoplasmacytic lymphoma (LPL). Which of the following viruses is most strongly associated with this condition? (Q851106)

A. EBV

B. HIV

C. HCV

D. HHV8

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which organism causes primary effusion lymphoma? (Q851104)

A. EBV

B. HIV

C. HCV

D. HHV8

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 28-year-old male presents with painless cervical lymphadenopathy for 3 months. He also reports intermittent fever, night sweats, and unintentional weight loss. Excisional lymph node biopsy shows classical Reed-Sternberg cells that are CD15+, CD30+, and weakly PAX-5+, with negative CD20. Staging scans reveal involvement of cervical and mediastinal lymph nodes without extranodal disease. What is the treatment of choice for this patient? (Q851103)

A. ABVD

B. R-CHOP

C. PCR

D. FCR

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following is not a category B symptom in ann arbor classification for HL? (Q851101)

A. Unexplained weight loss of > 10% during 6 months

B. Unexplained cough > 2weeks

C. Unexplained fever > 38 C in last month

D. Recurrent drenching night sweats

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 20 year old girl presents with breathing difficulty at rest. On examination enlarged cervical lymph are palpated with rubbery consistency. CXR shows hilar lymphadenopathy. Biopsy shows large cells with abundant cytoplasm and bilobed nuclei. Which of the following is/are correct about this condition 1. Stellate inclusions in cytoplasm 2. Langhans type of giant cells 3. Aberration in chromosome 9 4. CD15 and CD 30 positivity (Q851099)

A. only 1

B. 1,2

C. 2,3

D. 3,4

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 20 year old girl presents with breathing difficulty at rest. On examination enlarged cervical lymph are palpated with rubbery consistency. CXR shows hilar lymphadenopathy. Biopsy shows large cells with abundant cytoplasm and bilobed nuclei. What is the diagnosis? (Q851097)

A. Sarcoidosis

B. Pulmonary TB

C. Langhans cell histiocytosis

D. Lymphoma

See Answer in Part B → Q18

Q1: In a child with thalassemia major, which of the following drugs should be started to reduce transfusion dependency? (Q851128)

A. Luspatercept

B. Deferoxamine

C. Deferiprone

D. Deferasirox

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 4-year-old child with anemia, chipmunk facies and splenomegaly is found to have low Hb A and elevated HbF and HbA2. He has received multiple blood transfusions for which no records are available Which of the following is least likely to occur as a complication in this case? (Q851129)

A. Lung fibrosis

B. Cardiomyopathy

C. Diabetes

D. Infections with capsulated organisms

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Investigation of choice for diagnosis of beta thalassemia ? (Q851130)

A. NESTROFT

B. Gene sequencing

C. HPLC

D. Hemoglobin electrophoresis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Earliest radiological finding in patients with beta thalassemia is (Q851131)

A. Widening of diploic spaces of skull

B. Lytic lesion in vertebrae

C. Squaring of metacarpals

D. AVN of metacarpals

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 2 year old child is undergoing workup for severe anemia. Labs show Low MCV, Increased MCHC. USG abdomen shows enlarged spleen with acoustic shadows in gall bladder. Which of the following is not correct about this patient? (Q851133)

A. Peripheral smear shows RBC that lack central pallor

B. Black pigmented gall stones in gall bladder

C. Counsel about Elective splenectomy

D. Defective gene on chromosome 14

See Answer in Part B → Q5

@Neet_pg_bot

Q6: In a transfusion dependent thalassemia major child, deferoxamine should be started at serum ferritin values > _____ ug/L (Q851134)

A. 500

B. 1000

C. 1500

D. 2000

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 10 year old boy presents with pallor. Work up shows Hb= 8 gm%, Peripheral smear has anisocytosis with poikilocytosis, Hemoglobin electrophoresis report has Hb A = 60%, HbF = 34%, HbA2 = 6%. Diagnosis is? (Q851135)

A. Thalassemia minor

B. Thalassemia major

C. Thalassemia intermedia

D. Thalassemia trait

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is incorrect about Hb Barts? (Q851136)

A. Extremely low oxygen affinity

B. Causes functional tissue hypoxia

C. Unstable structure so precipitates in RBC

D. Presents as non immunogenic hydrops fetalis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: In a newly diagnosed beta thalassemia major patient which manifestation will not be seen? (Q851137)

A. Ectopic hematopoiesis

B. Reticulocyte count of 0.1%

C. Ineffective erythropoiesis

D. Elevated LDH and low Haptoglobin levels

See Answer in Part B → Q9

@Neet_pg_bot

Q10: You are counseling parents of a 3 year old severely anaemic child diagnosed with hereditary spherocytosis about surgical options. Which of the following will you inform them about? (Q851138)

A. Splenectomy

B. Gall bladder removal

C. Splenectomy plus gall bladder removal

D. Nephrectomy

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following tests is used in diagnosis of hereditary spherocytosis? (Q851139)

A. Acidified lysis test

B. Acid glycerol lysis test

C. Sucrose hemolysis test

D. Flow cytometry for CD55 and CD59

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 25-year-old man of Southeast Asian origin presents with anemia and fatigue. CBC shows : Hemoglobin: 9.2 g/dL, MCV: 68 fL, MCH: 22 pg/dl. Peripheral smear shows microcytosis, hypochromia, and numerous target cells. Supravital staining with brilliant cresyl blue reveals multiple small inclusions in RBCs giving a “golf ball” appearance. Which of the following is the most likely diagnosis? (Q851140)

A. β-thalassemia minor

B. HbH disease

C. Sideroblastic anemia

D. Hereditary spherocytosis

See Answer in Part B → Q12

@Neet_pg_bot

Q19 (p. 531)	*Q20 (p. 532)*	*Q21 (p. 532)*			

Q1: All of the following are complications of sickle cell disease except? (Q851153)

A. Stroke

B. Pulmonary hypertension

C. Vitreous hemorrhage

D. Neonatal jaundice

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 15-year-old male with sickle cell anemia presents with hematuria and flank pain. Urinalysis shows isosthenuria (urine specific gravity ~1.010). Which of the following is the most likely explanation? (Q851199)

A. Medullary infarction causing papillary necrosis

B. Glomerulonephritis due to immune complex deposition

C. Recurrent urinary tract infection causing tubular damage

D. Hyperfiltration injury from chronic anemia

See Answer in Part B → Q2

@Neet_pg_bot

Q3: For prenatal diagnosis of sickle cell anemia which is the best test? (Q851195)

A. NESTROFT

B. Sickling test

C. DNA analysis

D. Hb electrophoresis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Heinz bodies in G6PD deficiency is? (Q851193)

A. Denatured Hemoglobin

B. DNA remnants

C. RNA remnants

D. Iron granules

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is correctly matched? (Q851191)

A. Heinz bodies: Asplenia

B. Howell Jolly bodies: G6PD

C. Cabot rings : Dyserythropoiesis

D. Pappenheimer bodies: Lead poisoning

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is correct about Paroxysmal nocturnal hemoglobinuria (Q851188)

A. Extravascular hemolysis

B. Sucrose hemolysis test is gold standard

C. Thrombosis of hepatic veins

D. Hypocellular bone marrow that becomes hypercellular in late stages

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 6-year-old boy is brought to the clinic with multiple petechiae over his lower limbs and mild gum bleeding for 2 days. He had an upper respiratory infection about 3 weeks ago. Examination shows scattered ecchymoses and petechial rash but no hepatosplenomegaly or lymphadenopathy. CBC reveals: Hemoglobin: 12.4 g/dL, Total leukocyte count: 8,500/mm³ and Platelet count: 35,000/mm³ Peripheral smear confirms thrombocytopenia with normal RBC and WBC morphology. Coagulation profile is normal. What is the most likely diagnosis and next step in management? (Q851185)

A. Acute lymphoblastic leukemia; bone marrow biopsy

B. Acute immune thrombocytopenic purpura; observation

C. Hemophilia A; factor VIII assay

D. Thrombotic thrombocytopenic purpura; plasma exchange

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A patient with acute kidney injury is found to have hemolytic uremic syndrome. Which of the following is not correct about this patient? (Q851183)

A. Thrombocytopenia

B. Microangiopathic hemolytic anemia

C. Schistocytes

D. Antibodies to ADAMTS13

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old diabetic with an HbA1c of 10% has been detected with a low EGFR of 10, has come for a hemodialysis session. His Hb is 6gm% with normocytic normochromic anemia. Which of the following is the first-line treatment for this patient? (Q851179)

A. Oral iron

B. Darbepoeitin

C. Hemodialysis

D. Roxadustat

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is correct about anemia of chronic disease? (Q851155)

A. Low serum iron, elevated serum ferritin, low erythropoietin

B. Low serum iron, low serum ferritin, low erythropoietin

C. High serum iron, low serum ferritin, low erythropoietin

D. High serum iron, elevated serum ferritin, low erythropoietin

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 55-year-old woman presents with fatigue, glossitis, and paresthesias. Laboratory tests show macrocytic anemia and low vitamin B12 levels. Further testing reveals the presence of parietal cell antibodies. What is the most common underlying cause of her condition? (Q851154)

A. Alcoholism

B. Autoimmune gastritis

C. Malabsorption syndrome

D. Ileal resection

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is true about hand and foot syndrome seen in sickle cell anemia? (Q851141)

A. Usually seen after 5 year of age

B. Infection with capsulated organisms causing osteomyelitis of small bones of hands

C. Causes swan neck joint deformities

D. X-ray-shows periostitis and soft tissue swelling

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is correct about sickle cell anaemia? (Q851152)

A. Beta 7 valine residues cause polymerization of HbS on deoxygenation

B. Beta 7 valine residues cause polymerization of HbS on oxygenation

C. Beta 6 glutamate residues cause polymerization of HbS on oxygenation

D. Beta 6 glutamate residues cause polymerization of HbS on deoxygenation

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A patient is suspected of having sickle cell anemia. Which of the following hemoglobin electrophoresis patterns is most consistent with this diagnosis? (Q851151)

A. HbA absent , Hb S present, Hb F elevated, Hb A2 elevated

B. HbA present ,Hb S present, Hb F elevated, Hb A2 elevated

C. HbA present ,Hb S present , Hb F elevated, Hb A2 elevated

D. HbA absent , Hb S present, Hb F reduced , Hb A2 elevated

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following is the earliest embryonic hemoglobin to appear? (Q851150)

A. Gower 1

B. Gower 2

C. Portland

D. Fetal hemoglobin

See Answer in Part B → Q15

@Neet_pg_bot

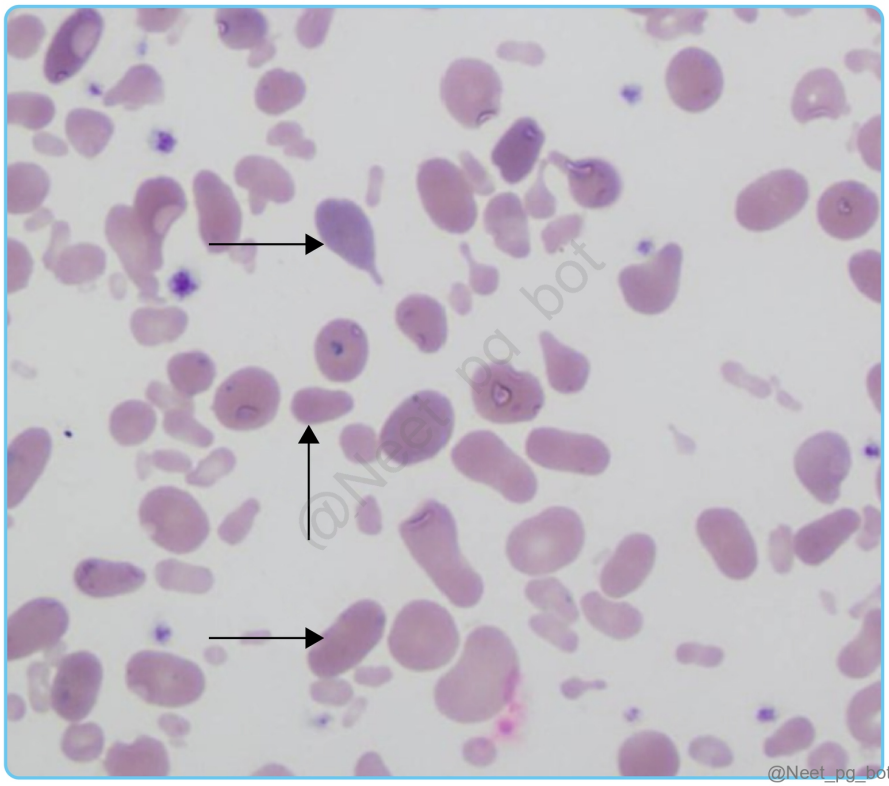
Q16: A 15 year old patient presents with anemia with splenomegaly. P. Smear is shown below. Comment on the Peripheral smear shown below (Q851149)

A. Hereditary spherocytosis

B. Hereditary elliptocytosis

C. Hemolytic uremic syndrome

D. Pyropokilocytosis



See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 5 year child born to consanguineous marriage is brought with complaints of pain in both hands over the metacarpals. Work up shows low Hb with increased reticulocyte count, increased LDH and low haptoglobin levels. Spleen is not palpable. Hb electrophoresis report is awaited. He has had previous hospitalizations for acute abdomen. Diagnosis is? (Q851148)

A. Sickle cell anemia

B. Beta Thalassemia

C. Hereditary spherocytosis

D. ITP

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following drugs can be used in patients with G6PD? (Q851147)

A. Primaquine

B. Artesunate

C. Dapsone

D. Rasburicase

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Peripheral smear of a neonate with jaundice shows normocytic normochromic anemia with anisocytosis and poikilocytosis with RBC showing unevenly distributed hemoglobin " hemighosts" or "blister cells". This is seen in which of the following? (Q851146)

A. Abetalipoproteinemia

B. Hemolytic uremic syndrome

C. G6PDdeficiency

D. Pyruvate kinase deficiency

See Answer in Part B → Q19

@Neet_pg_bot

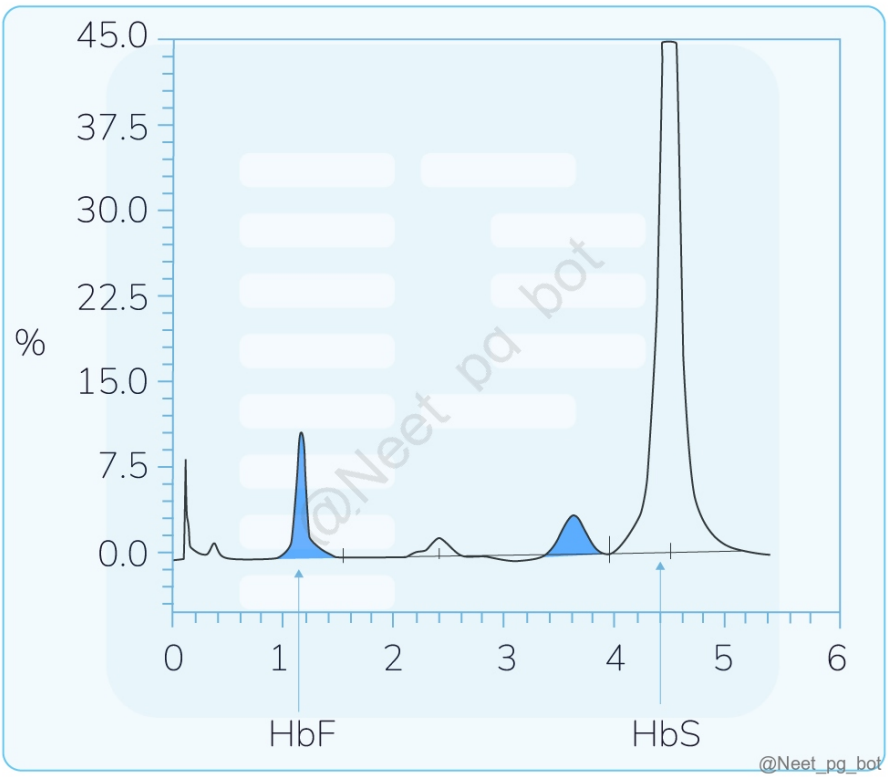
Q20: A 5 year old child is brought with complaints of pain in hands. On examination he has severe pallor, elevated LDH and low haptoglobin. The HPLC report is shown below. Which of the following is the drug of choice for this patient? (Q851144)

A. Hydroxy urea

B. Azacytidine

C. Voxeletor

D. Bortezomib



See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following treatments is curative in sickle cell anemia? (Q851142)

A. Hyroxyurea

B. Hematopoietic stem cell transplantation

C. Voxelotor

D. Packed RBC transfusions

See Answer in Part B → Q21

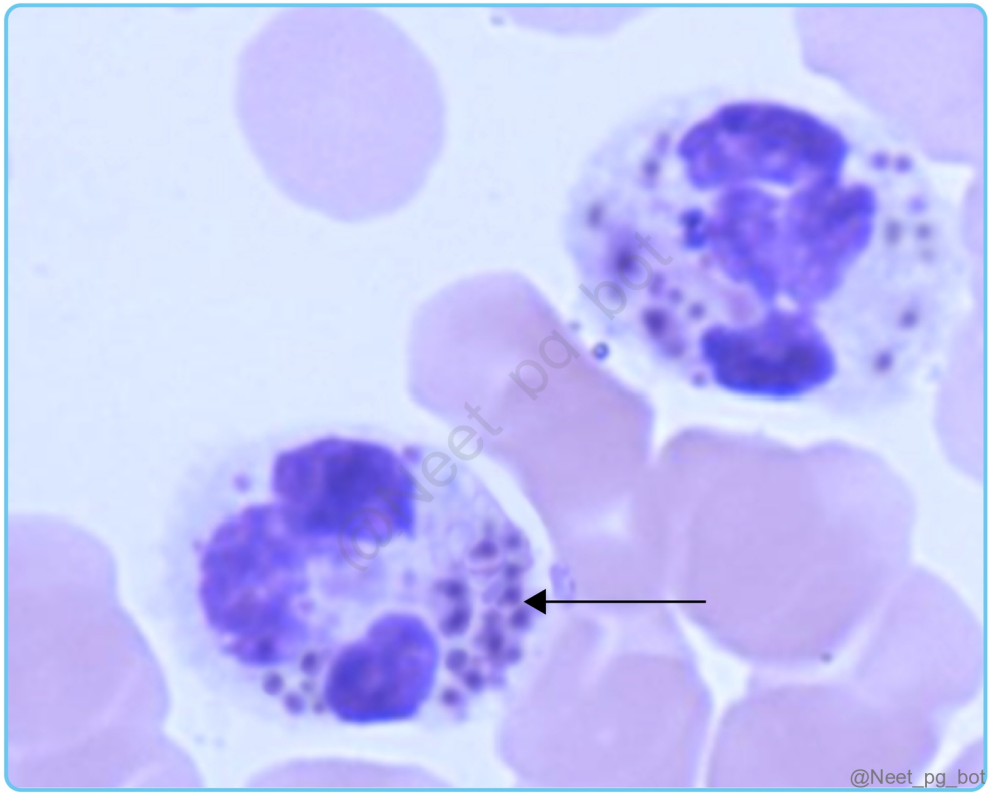
Q1: A 6-year-old boy presents with recurrent skin and respiratory infections since infancy. Examination reveals partial albinism and peripheral neuropathy. Peripheral smear is shown below. Which of the following is the most likely underlying defect? (Q851167)

A. Defective lysosomal trafficking

B. NADPH oxidase deficiency

C. Defective adhesion molecule

D. Myeloperoxidase deficiency



See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following statements regarding von Willebrand disease is not true? (Q866839)

A. Type 2 vWD is associated with a moderate bleeding tendency

B. Type 3 vWD is associated with a complete absence of factor VIII

C. Type 1 vWD presents with severe bleeding since childhood

D. Type 2 vWD includes subtypes with varying defects in the von Willebrand factor

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is the correct presentation of Bernard–Soulier syndrome? (Q851177)

A. Presence of large platelets with thrombocytopenia and defective platelet adhesion

B. Small platelets, eczema, recurrent infections, and thrombocytopenia due to an X-linked disorder

C. Umbilical stump bleeding on day 1 of life

D. Normal platelet count with defective platelet aggregation caused by absent GPIIb/IIIa receptors

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is correct about the mechanism of action of Ticagrelor? (Q851176)

A. Inhibiting P2Y12 , ADP receptor

B. Acetylation of COX-1

C. Blocking activated glycoprotein Gp IIb/IIIa

D. Inhibiting production of COX-1

See Answer in Part B → Q4

@Neet_pg_bot

Q5: What is the life span of a platelet in the body? (Q851175)

A. 3-5 days

B. 5-7 days

C. 7-10 days

D. 10-14 days

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 30 year old multigravida post-partum female developed multiple bruises and ecchymosis after delivery. coagulogram shows prolonged aPTT, normal TT and normal PT. and TT and a mixing study that does not correct with normal pooled plasma. The Bethesda assay using factor-specific deficient plasma is planned. What is the first differential diagnosis? (Q851174)

A. Von Willebrand disease

B. HELLP syndrome

C. Acquired Hemophilia A

D. DIC

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following cause/s lead to DIC? a. Fulminant hepatic failure b. Acute promyelocytic leukemia c. Carcinoma prostate d. Fungal sepsis (Q851173)

A. b,c,d

B. a,c,d

C. a,b,d

D. a,b,c,d

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 9-year old with acquired factor IX deficiency. However, the coagulation abnormality corrected after administration of Vitamin K. What is the most likely diagnosis? (Q851172)

A. Classic Hemophilia

B. Pernicious anemia

C. Hepatitis A

D. Bile duct obstruction

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following are used in non transfusion therapy for hemophilia A? a. Factor VIII concentrate b. Cryoprecipitate c. DDAVP d. Epsilon amino caproic acid (Q851171)

A. a,b

B. a,c

C. a,d

D. c,d

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which clotting factor has the longest half life? (Q851170)

A. 2

B. 7

C. 9

D. 13

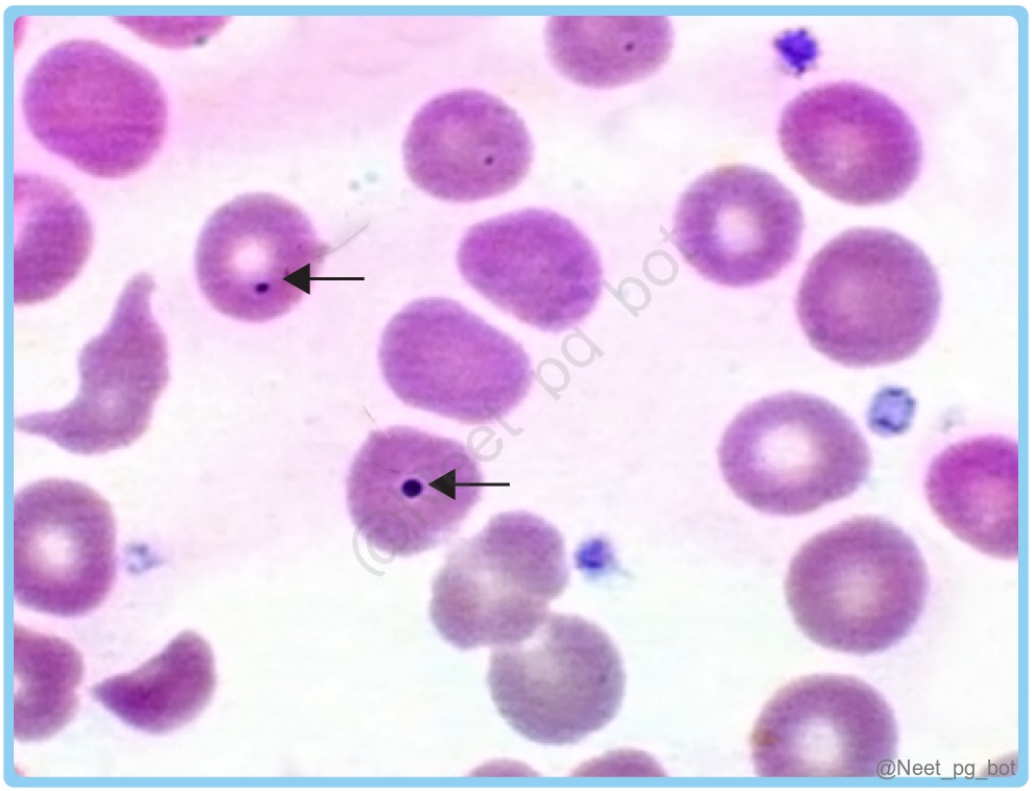
Q11: The following inclusions inside RBC are called _____ (Q851169)

A. Dohle bodies

B. Pappenheimer bodies

C. Howell Jolly bodies

D. Dutcher bodies



See Answer in Part B → Q11

@Neet_pg_bot

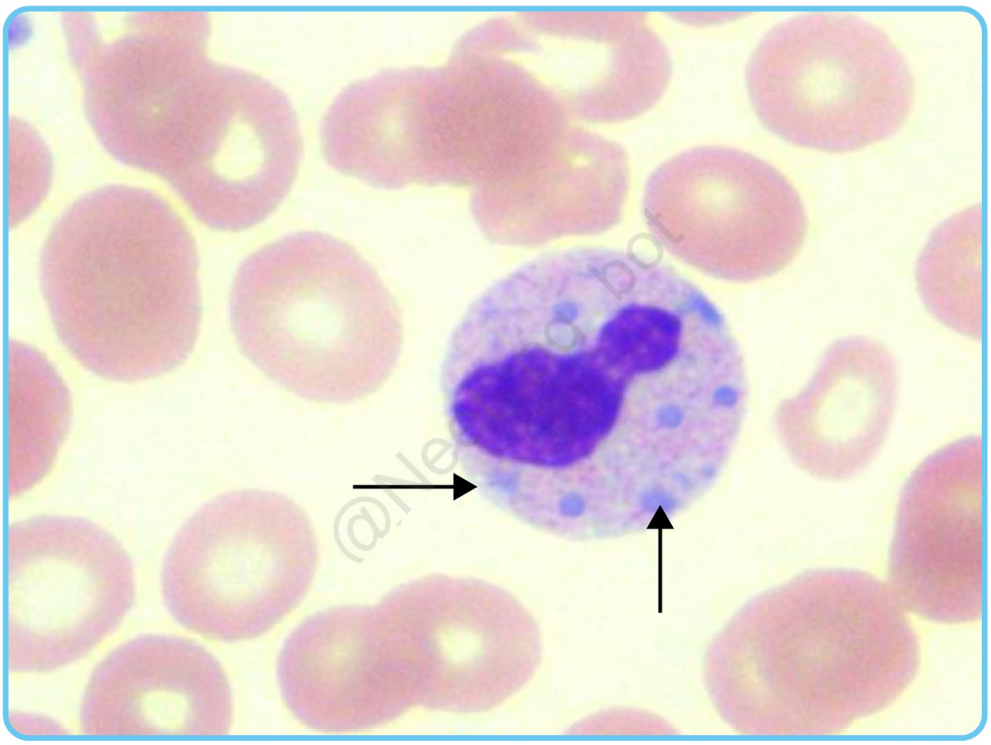
Q12: The following inclusions in neutrophils are seen in? (Q851168)

A. Burns

B. Chediak higashi granules

C. Celiac sprue

D. Whipple disease



See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is not correct about ITP? (Q851143)

A. Secondary ITP occurs due to autoimmune causes like SLE and infections like HIV , HCV

B. Wet purpura heralds life threatening bleed

C. Severe ITP needs emergency splenectomy

D. Eltrombopag is used in patients who relapse

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following is correct about the neutrophil shown in peripheral smear? (Q851166)

A. Chediak higashi Syndrome

B. Myelodysplastic syndrome

C. Perinicious anemia

D. Burns

See Answer in Part B → Q14

@Neet_pg_bot

Q15: The following feature is seen in which of the following conditions (Q851165)

A. Plasma cell dyscrasia

B. Multiple lineage dysplasia

C. Myelofibrosis

D. Leukemoid reaction

See Answer in Part B → Q15

@Neet_pg_bot

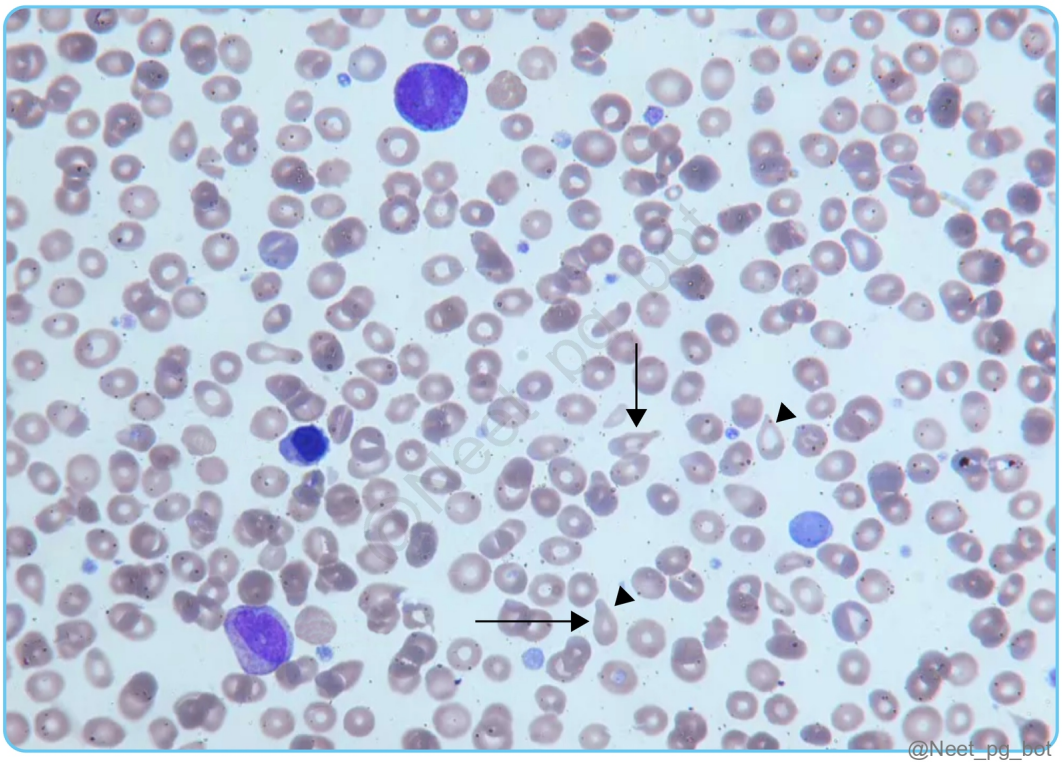
Q16: A 60-year-old man presents with progressive fatigue, early satiety, and weight loss over 3 months. Examination reveals massive splenomegaly. Laboratory findings: Hemoglobin: 8.5 g/dL, WBC: 3,000/µL, Platelets: 90,000/µL, Peripheral smear is shown below.. Which of the following is the most likely diagnosis? (Q851164)

A. Chronic myeloid leukemia

B. Myelofibrosis

C. Polycythemia vera

D. Aplastic anemia



See Answer in Part B → Q16

@Neet_pg_bot

Q17: A patient diagnosed with Acute promyelocytic leukemia develops bleeding from body orifices. Which of the following coagulogram report will be seen in this case? (Q851163)

A. PT increased, BT increased, aPTT increased

B. PT increased, BT normal, aPTT increased

C. PT normal, BT increased, aPTT increased

D. PT normal, BT normal , aPTT increased

See Answer in Part B → Q17

@Neet_pg_bot

Q18: All of the following are contraindications to use of the following instruments in hematology except? (Q851162)

A. Consumptive coagulopathy

B. Local site infection

C. Patient on warfarin

D. Low platelet count 40,000/uL

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 5-year-old boy presents with petechiae over his legs, pallor and decreased urine output. His mother reports that he had bloody diarrhea a week ago. The examination shows mild edema and hypertension. Laboratory results reveal: Hemoglobin: 7.8 g/dL, platelet count: 65,000/µL, Creatinine: 2.5 mg/dL, Peripheral smear: schistocytes present. Which of the following is the most likely diagnosis? (Q851161)

A. Immune thrombocytopenic purpura

B. Hemolytic uremic syndrome

C. Henoch Scholein Purpura

D. Post-infectious-glomerulonephritis

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following causes non thrombocytopenic purpura? (Q851160)

A. HUS

B. TTP

C. DIC

D. HSP

See Answer in Part B → Q20

@Neet_pg_bot

Q21: An 18-year-old boy with severe hemophilia A (factor VIII activity <1%) is scheduled for wisdom tooth extraction. His past history includes multiple episodes of hemarthrosis but no inhibitors to factor VIII. Which of the following is the best strategy to prevent perioperative bleeding? (Q851159)

A. Administer desmopressin (DDAVP) before the procedure

B. Transfuse fresh frozen plasma 1 hour before surgery

C. Give prophylactic factor VIII concentrate to raise levels to ≥50% before the procedure

D. Start oral tranexamic acid only after the extraction

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 16-year-old girl presents with a history of heavy menstrual bleeding since menarche and frequent gum bleeding after brushing her teeth. She reports prolonged bleeding after a tooth extraction last year. There is no history of joint swelling or muscle hematomas. Examination reveals pallor but no petechiae or ecchymoses. Laboratory results show: Hemoglobin: 9.5 g/dL, Platelet count: 250,000/µL, PT: Normal, aPTT: Mildly prolonged, Bleeding time: Prolonged, Ristocetin cofactor assay: Decreased. Which of the following is the most likely diagnosis? (Q851158)

A. Hemophilia A

B. Bernard–Soulier syndrome

C. Von Willebrand disease

D. Glanzmann thrombasthenia

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 4-year-old boy presents with a history of easy bruising and frequent nosebleeds since infancy. His parents report prolonged bleeding after minor cuts, but there is no history of deep muscle or joint bleeds. Examination reveals petechiae and multiple ecchymoses over the extremities. Laboratory findings show:Platelet count: 250,000/µL, PT: Normal, aPTT: Normal, Bleeding time: Prolonged, Platelet aggregation absent with ADP, collagen, and epinephrine; normal with ristocetin. Which of the following is the most likely diagnosis? (Q851157)

A. Bernard–Soulier syndrome

B. Hemophilia A

C. Glanzmann thrombasthenia

D. Von Willebrand disease

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Elective splenectomy is done in which of the following conditions? a. Beta thalassemia major with 50% increase in transfusion requirement over last one year b. Hereditary spherocytosis with severe anemia by 5 years of age c. Chronic ITP non responsive to steroids d. Myelopthisis (Q851156)

A. a,b

B. a,c

C. a,b,c

D. a,b,c,d

See Answer in Part B → Q24

Q19 (p. 555)	*Q20 (p. 555)*				

Q1: Which is the correct ratio for acute hypovolemic coagulopathy requiring massive transfusion? (Q851027)

A. 1 RBCC: 1 plasma: 0.25 platelet concentrate

B. 1 RBCC: 1 plasma: 0.5 platelet concentrate

C. 1 RBCC: 1 plasma: 1 platelet concentrate

D. 1 RBCC: 1 plasma: 4 platelets concentrate

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which transfusion reaction is most strongly associated with HLA antibodies in donor plasma? (Q851036)

A. TRALI

B. TACO

C. Acute hemolytic reaction

D. Sepsis

See Answer in Part B → Q2

@Neet_pg_bot

Q3: 30-year-old man receives a unit of O■ packed RBCs. Within 10 minutes, he develops fever, chills, hypotension, and flank pain. Which investigation will be most specific for confirming the diagnosis? (Q851035)

A. Indirect antiglobulin test

B. Direct antiglobulin Coombs test

C. Blood cultures from patient

D. Reticulocyte count

See Answer in Part B → Q3

@Neet_pg_bot

Q4: The patient is started on blood transfusion in a post operative room and within 5 minutes you notice that the patient develops a rash all over the body with cold clammy extremities. pulse is 120/min, BP is 80/60 mm Hg with inspiratory rhonchi in bilateral lungs The blood group of the patient is 0+ and the patient was given 0+ blood as verified by the blood bank. Which of the following is the first differential diagnosis? (Q851034)

A. Alloimmunization

B. Anaphylaxis

C. TACO

D. Mismatched blood transfusion

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following blood components has the highest chances of causing transfusion transmitted infection? (Q851033)

A. Platelet concentrate

B. Packed RBC

C. Plasma

D. Whole blood

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is not correct about usage and storage of blood components? (Q851032)

A. Packed RBC can be stored for up to 42 days at 4 °C

B. Platelets can be stored for 3–7 days at 20–24 °C

C. Granulocyte concentrate at room temperature and used within 24 hours of end of collection

D. Plasma is cryopreserved at –4 °C and should be used within 1 hour of thawing

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Deleucocytation is defined as ? (Q851031)

A. <1–5. 10 6 leukocytes per unit of blood components

B. <1–5. 10 7 leukocytes per unit of blood components

C. <1–5. 10 8 leukocytes per unit of blood components

D. <1–5. 10 9 leukocytes per unit of blood components

See Answer in Part B → Q7

@Neet_pg_bot

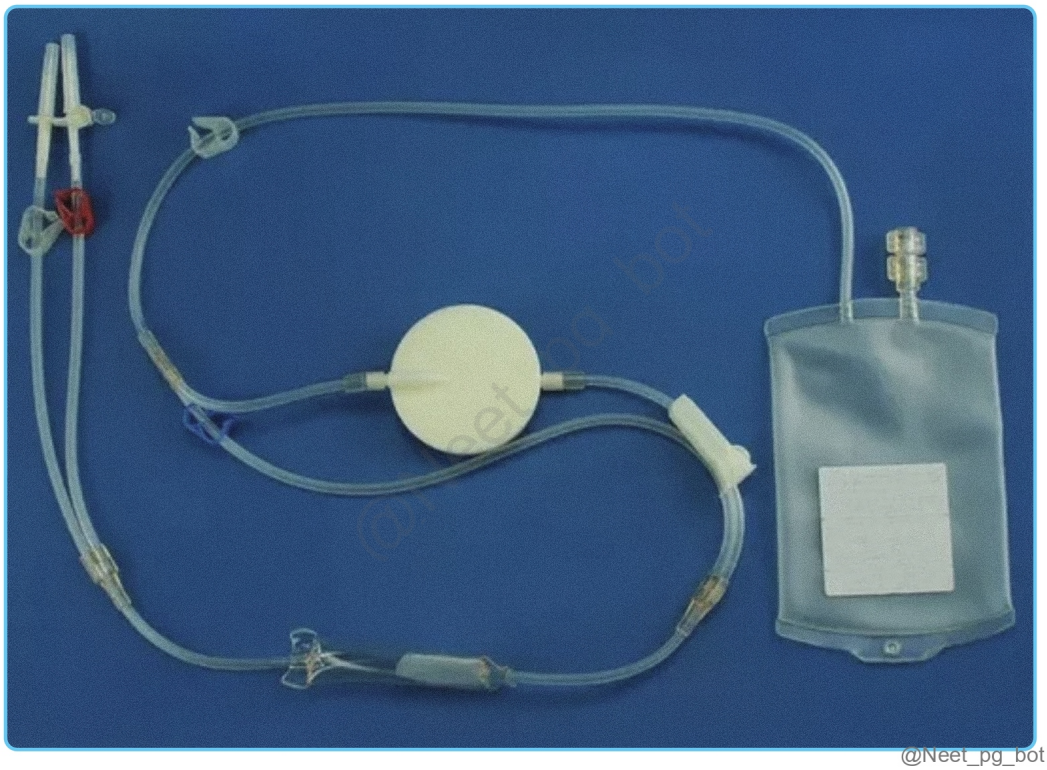
Q8: High efficiency deleucocytation is being done using the filter shown in the image. It will reduce all of the following complications of blood transfusion except? (Q851030)

A. Mismatched blood transfusion

B. Febrile non hemolytic transfusion reaction

C. Transmission of CMV

D. Alloimmunization



See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following is immunodominant sugar in patient with blood group A (Q851029)

A. N-acetyl- glucosamine

B. N- acetyl- galactosamine

C. Galactose

D. Fucose

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following blood groups is a universal plasma donor? (Q851028)

A. A

B. B

C. AB

D. O

See Answer in Part B → Q10

@Neet_pg_bot

Q11: An unbooked 30 year old multigravida in the 36 weeks of pregnancy is having severe anemia with Hb of 6.8 gm/dl. She was prescribed 2 units of PRBC . She develops high grade fever 40 C with chills and rigors, hypotension and bleeding from IV cannula site 1 hour after completion of transfusion. Diagnosis is? (Q851017)

A. Mismatched Blood transfusion

B. Febrile non hemolytic transfusion reaction

C. Transfusion transmitted bacterial infection

D. TRALI

See Answer in Part B → Q11

@Neet_pg_bot

Q12: “Lethal triad of death” includes (Q851026)

A. Acidosis, hypothermia and coagulopathy

B. Alkalosis, hypothermia and coagulopathy

C. Acidosis, hyperthermia and coagulopathy

D. Alkalosis, hyperthermia and coagulopathy

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following complications can occur after multiple blood transfusions? 1. Hypokalemia 2. Hyperkalemia 3. Hypocalcemia 4. Metabolic acidosis (Q851025)

A. 1,3

B. 2,3

C. 1,2,3

D. 1,3,4

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Cryoprecipitate can be used in all of the following cases except (Q851024)

A. Type II vWD

B. Type III vWD

C. Haemophilia A in absence of factor VIII concentrate

D. Hemophilia B in absence of factor IX concentrate

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A stable patient without fever or infection has severe thrombocytopenia. At what platelet count threshold is platelet transfusion generally indicated? (Q851023)

A. < 5,000 / uL

B. <10,000/ uL

C. <20,000/ uL

D. <50,000/ uL

See Answer in Part B → Q15

@Neet_pg_bot

Q16: The RTA victim was given 6 units of whole blood in the last 6 hours. Which of the following complications is most likely in this patient? (Q851022)

A. Hypokalemia

B. Hyponatremia

C. Hypocalcemia

D. Hypercalcemia

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 65-year-old man with chronic kidney disease on maintenance hemodialysis receives 2 units of PRBCs over 4 hours for severe anemia. Shortly after transfusion, he develops acute dyspnea, elevated JVP, hypertension, and bilateral basal crackles. Which of the following is the most likely diagnosis? (Q851021)

A. Transfusion-related acute lung injury

B. Transfusion-associated circulatory overload

C. Febrile non-hemolytic reaction

D. Acute hemolytic reaction

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 30 year old woman on steroids for SLE had received one unit of blood transfusion after her recent delivery of a healthy boy baby. 10 days later she developed fever, rashes and diarrhea. Which complication of blood transfusion would you suspect? (Q851020)

A. Mismatched blood transfusion

B. Graft versus host disease

C. Febrile non-hemolytic transfusion reaction

D. Transfusion transmitted infection

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following is not correct about TRALI (Q851019)

A. Donor antibodies bind to recipient neutrophils in pulmonary endothelium causing release or pro inflammatory cytokines

B. Usually occurs within 6 hours of transfusion

C. Bilateral interstitial infiltrates due to cardiogenic pulmonary edema

D. Reduced incidence by taking plasma from only male donor

See Answer in Part B → Q19

@Neet_pg_bot

Q20: The leading cause of death due to blood transfusion is? (Q851018)

A. TACO

B. TRALI

C. Mismatched blood transfusion

D. Dilutional coagulopathy

See Answer in Part B → Q20

@Neet_pg_bot

Q1: A 60-year-old female presents with weakness, back pain and repeated infections. Work up shows M spike on serum electrophoresis. Prognosis is determined by which of the following factors? (Q866809)

A. IgG and albumin

B. IgM and albumin

C. Albumin and LDH

D. Albumin and β■-microglobulin

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A girl experiences prolonged menstrual bleeding and has normal platelet count, PT, and aPTT, but an increased bleeding time, which was determined to be due to a deficiency of GpIIb-IIIa after further analysis. What is the diagnosis? (Q859787)

A. Bernard Soulier syndrome

B. Glanzmann thrombasthenia

C. Haemophilia A

D. Von Willebrand disease

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 30-year-old female with a history of recurrent headaches presented for further evaluation. On further workup, haemoglobin and total WBC count were normal, while an elevated platelet count was seen. Bone marrow aspiration showed increased megakaryocytes and a JAK2 mutation. Which is the most likely diagnosis? (Q859739)

A. Polycythemia vera

B. Essential thrombocytosis

C. Primary myelofibrosis

D. Chronic myelogenous leukaemia

See Answer in Part B → Q3

@Neet_pg_bot

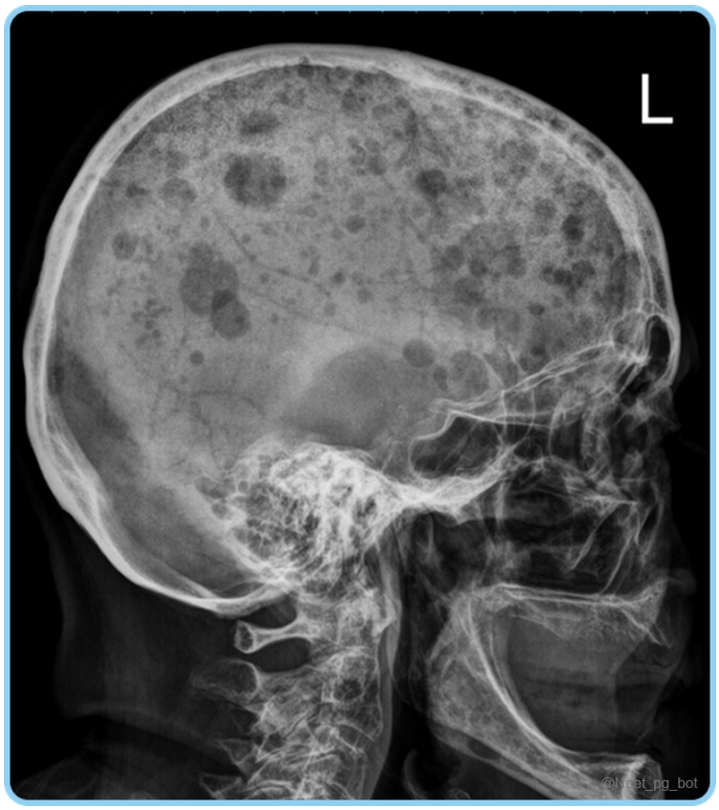
Q4: A 68-year-old male came to the physician with complaints of chronic back pain, easy fatigability and a history of multiple urinary tract infections in the last 3 months. His ESR is elevated, and an x-ray of his skull is shown below. Which of the following investigations is useful for diagnosis? (Q859531)

A. MRI brain

B. PET scan

C. Head CT scan with contrast

D. Serum electrophoresis



See Answer in Part B → Q4

@Neet_pg_bot

Q5: A ten-year-old boy was brought to the OPD with fever and swelling of his hands after playing football. He gives a history of previous episodes of swelling of his hands. On imaging, his spleen was found to be shrunken. Which of the following is a likely diagnosis? (Q855013)

A. Sickle cell anaemia

B. Malaria

C. Pancreatitis

D. Measles

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Thrombocytopenia, eczema and recurrent infections are seen in: (Q854999)

A. Wiskott-Aldrich syndrome

B. Chediak-Higashi syndrome

C. Thrombocytopenia - absent radius syndrome

D. Hermansky-Pudlak syndrome

See Answer in Part B → Q6

@Neet_pg_bot

Q7: For hairy cell leukemia, which drug is considered the preferred choice? (Q856268)

A. Rituximab

B. Vemurafenib

C. Cladribine

D. Interferon-alpha

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 65-year-old woman was brought to the emergency department with symptoms of breathlessness anemia and severe bone pain. On evaluation a hemoglobin level was found to be 5.4 g/dl, urea level of 86 mg/dl, creatinine level of 6 mg/dl, calcium level of 12, and potassium level of 4.4 and the bone marrow aspiration revealed over 60% of plasma cells. Which of the following could be the appropriate next course of action for the management of this patient? (Q856938)

A. Urgent consultation for dialysis

B. Dexamethasone + lenalidomide

C. Dexamethasone + fluids

D. Bone marrow transplantation

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 62-year-old male patient with heart failure is scheduled for a heart transplant. His renal function test is deranged, and haemoglobin is 6gm%. The physician ordered 2 units of whole blood. Four hours after transfusion, he developed severe respiratory distress. On examination, he is hypoxemic, has tachycardia and his mean arterial pressure is elevated. Which of the following are the best investigations for the above scenario? Chest X-ray Brain natriuretic peptide (BNP) level Absolute neutrophil count Leucocyte antibodies Platelets (Q856626)

A. 4 and 5

B. 3 and 5

C. 1 and 2

D. 2 only

See Answer in Part B → Q9

@Neet_pg_bot

Q10: An elderly woman presented with symptoms of confusion, thirst, and abdominal pain. On examination, she had pallor and thoracic spine tenderness. X-ray spine showed osteolytic lesions. Her lab investigations showed the following findings. What is the most likely diagnosis? Hb - 6.9g/dl WBC 4000/cm3 with normal differential count Serum calcium 13mg/dl Creatinine 2.3mg/dl Total protein 9g/dl Albumin 2.4g/dl (Q856590)

A. Metastatic breast cancer

B. Multiple myeloma

C. Primary hyperparathyroidism

D. Milk alkali syndrome

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following interfere with iron absorption? (Q857690)

A. Vitamin C

B. Phytates

C. Oxalate

D. Myoglobin

See Answer in Part B → Q11

@Neet_pg_bot

Q12: What is the interpretation of elevated serum Calcium levels in a patient with normal serum alkaline phosphatase, PTH, and Vitamin D3 levels? (Q857688)

A. Vitamin D intoxication

B. Hyperparathyroidism

C. Multiple myeloma

D. Nutritional rickets

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following investigations should be conducted in a 7-month-old child who has a hemoglobin level of 6.3, a history of recurrent blood transfusions, an MCV of 70 fl, normal MCH, normal MCHC, and a peripheral smear indicating a hypochromic microcytic image? (Q857031)

A. Serum iron

B. Direct coomb’s test

C. Osmotic fragility test

D. Hb electrophoresis

See Answer in Part B → Q13

@Neet_pg_bot

Q14: What is the diagnosis of a 50-year-old man who presents with symptoms of anemia, fever, and recurrent nosebleeds? The patient has hepatosplenomegaly and lab investigations indicate a hemoglobin level of 6g/dL, a total leukocyte count of 40,000/cu.mm with 10% blasts, and a platelet count of 12,000/cu.mm. Further investigation reveals the presence of t(8;21) in the blasts. (Q857007)

A. Acute lymphoblastic leukemia

B. Acute myeloblastic leukemia

C. Preleukemia

D. Aleukemic leukemia

See Answer in Part B → Q14

@Neet_pg_bot

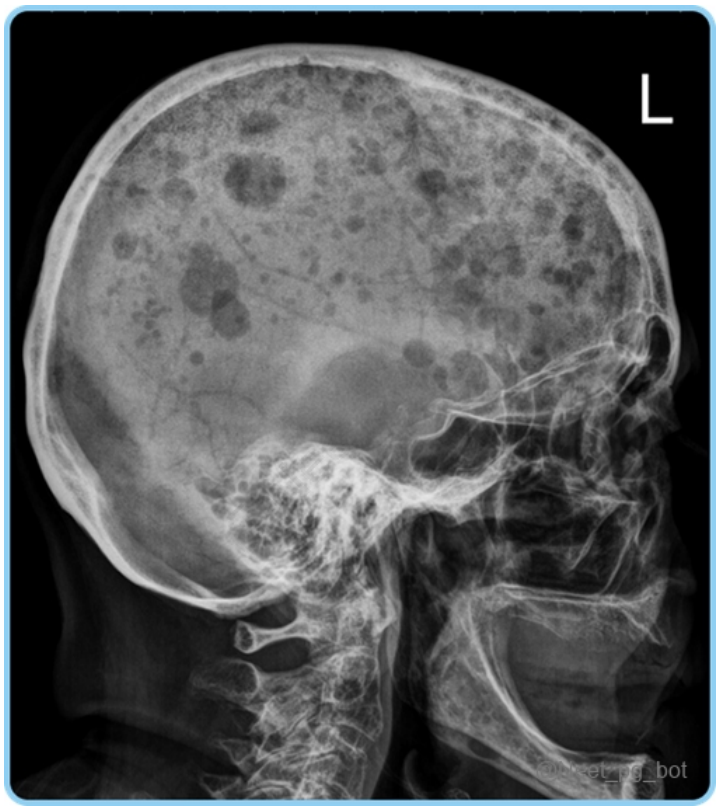
Q15: A 68-year-old male came to the physician with complaints of chronic back pain, easy fatigability, and a past history of multiple urinary tract infections in the last 3 months. His ESR is elevated, x-ray of his skull is shown below. Which of the following investigations is useful for diagnosis? (Q856997)

A. MRI brain

B. PET scan

C. Head CT scan with contrast

D. Serum electrophoresis



See Answer in Part B → Q15

@Neet_pg_bot

Q16: A female patient presents to the AIIMS emergency department with severe fatigue. She is a known case of chronic stable angina. While collecting a blood sample, you notice the blood has a brownish hue. What is the underlying diagnosis? (Q855354)

A. Carboxy-hemoglobinemia

B. Sideroblastic anaemia

C. Methemoglobinemia

D. Sulfhemoglobinemia

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A young woman presents with recurrent headaches, easy bruising, and episodes of visual blurring. Her platelet count is elevated, while her red blood cell (RBC) and white blood cell (WBC) counts are normal. What is the most likely diagnosis? (Q860145)

A. Essential Thrombocytosis

B. Polycythemia Vera

C. Chronic Myeloid Leukemia (CML)

D. Acute Myeloid Leukemia (AML)

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A child with progressive pallor and bone has an elevated HbS based on the HPLC report. Which is the best treatment to manage hemolysis in this patient? (Q866807)

A. Hydroxyurea

B. Azacytidine

C. Voxelator

D. Bortezomib

See Answer in Part B → Q18

@Neet_pg_bot

Q19: What defect is seen in Bernard Soulier syndrome? (Q866817)

A. Deficiency of GpIIb/IIIa receptor

B. Deficiency of GpIb receptors

C. Deficiency of von Willebrand factor

D. Deficiency of ADP receptors

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following is not a feature of thrombotic thrombocytopenic purpura? (Q853347)

A. Thrombocytopenia

B. Thrombosis

C. Microangiopathic hemolytic anemia

D. Renal failure

See Answer in Part B → Q20

@Neet_pg_bot

Q21: What is the mutation seen in Sickle cell anemia? (Q853348)

A. Glu → Val (6)

B. Lys → Arg

C. Glu → Lysine

D. Ala → Gly (9)

See Answer in Part B → Q21

@Neet_pg_bot

Q22: In hemolytic anemia, which of the following statements are true? Indirect Van den Bergh test is positive. Serum conjugated bilirubin is raised. Serum transaminases are raised. Urobilinogen is high. GGT is elevated. (Q853352)

A. 1, 3, 5

B. 1, 4

C. 2, 5

D. 1, 4, 5

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following statements regarding von Willebrand disease is incorrect? (Q844288)

A. Type 2 von Willebrand disease is associated with a moderate bleeding tendency

B. Type 3 von Willebrand disease causes almost complete absence of von Willebrand factor, resulting in very low factor VIII levels.Type 3 von Willebrand disease is associated with a complete absence of factor VIII

C. Type 1 von Willebrand disease presents with severe bleeding since childhood

D. Type 2 von Willebrand disease includes subtypes with varying defects in von Willebrand factor.

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following is incorrect regarding myelodysplastic syndrome? (Q840143)

A. More commonly seen in females

B. Treatment-induced MDS is not dependent on age

C. Median age of onset 70 years

D. It can be radiation-induced

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 46-year-old male presents to the outpatient department with a history of lower back pain and painful urination. Upon investigation, he is found to have normocytic normochromic anemia and hypercalcemia. Serum protein electrophoresis reveals an M-spike in the gamma region. Which of the following tests is most appropriate to confirm the diagnosis of multiple myeloma? (Q860141)

A. Liver function test

B. Bence Jones protein in urine

C. Urine albumin-to-creatinine ratio (UACR) test

D. Heat and acetic acid test

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A patient presents with fatigue, pallor, and weakness. Laboratory tests reveal low hemoglobin and a markedly low reticulocyte count, while white blood cell and platelet counts remain normal. Which of the following is the most likely diagnosis? (Q860244)

A. Aplastic Anemia

B. Pure Red Cell Aplasia

C. Iron Deficiency Anemia

D. Hemolytic Anemia

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 26-year-old female presents with menorrhagia and excessive bleeding after a minor surgery. She gave the history of her father and sister having the same bleeding issues and the pattern of inheritance was determined to be autosomal dominant. What is the most likely disorder? (Q857254)

A. Von Willebrand disease

B. Hemophilia A

C. Christmas disease

D. Factor 10 deficiency

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which of the following is NOT a complication of blood transfusion in a 25-year-old mother who developed acute postpartum haemorrhage, hypovolemic shock, and underwent major blood transfusion after delivering a baby boy? (Q857272)

A. Hypocalcemia

B. Hypokalemia

C. Hypothermia

D. Hyperkalemia

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Elective splenectomy is preferred in which of the following conditions? (Q858020)

A. G6PD deficiency-Glucose-6-phosphate dehydrogenase deficiency

B. Paroxysmal nocturnal hemoglobinuria

C. Hereditary spherocytosis

D. Hairy cell leukemia

See Answer in Part B → Q29

@Neet_pg_bot

Q30: Which of the following is not a feature of Gaisböck syndrome? (Q858031)

A. Hypotension

B. Erythrocytosis

C. Normal leukocyte counts

D. Obesity

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A 60-year-old man presents with fatigue, pallor, weight loss, and heaviness in the left hypochondrium, for the past 2 months. Abdominal palpation reveals splenomegaly. His hemogram and peripheral smear results are given below. What is the most likely diagnosis? Hemogram: Hb-10 gm/dl WBC count – 1,65,000/cu.mm (leukocytosis) Platelet count – 3 lakhs/mm 3 Peripheral smear: Metamyelocytes – 15% Promyeloblasts – 30% Myeloblasts – 45% (Q793841)

A. Chronic lymphocytic leukemia

B. Chronic myeloid leukemia

C. Acute lymphoblastic leukemia

D. Acute myeloid leukemia

See Answer in Part B → Q31

@Neet_pg_bot

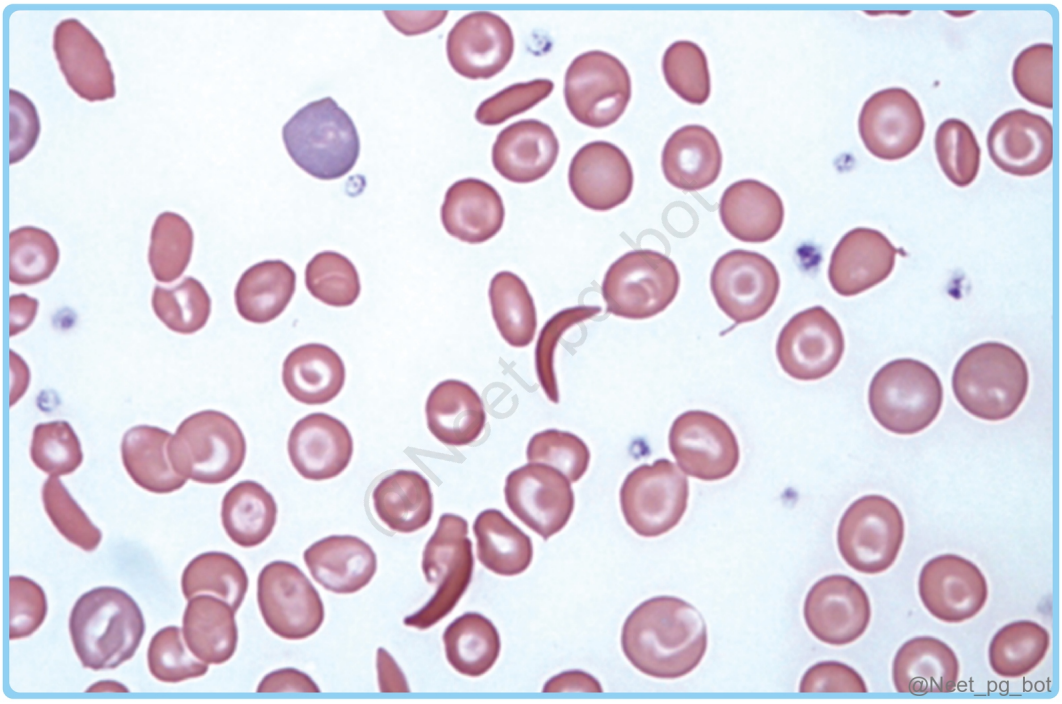
Q32: What would be the most appropriate course of action for managing a patient presenting with fatigue, a haemoglobin level below 9 g/dl, and sickle-shaped red blood cells on peripheral smear examination? (Q793796)

A. Administer IV antibiotics

B. Blood transfusion

C. Administer desferoxamine

D. Wait and watch



See Answer in Part B → Q32

@Neet_pg_bot

Q33: An elderly woman presented with symptoms of confusion, thirst, and abdominal pain. On examination, she had pallor and thoracic spine tenderness. Her lab investigations showed the following findings. An x-ray of her skull is shown below. What is the most likely diagnosis? Hb-6.9g/dl WBC 4000/cm3 with normal differential count Serum calcium 13mg/dl Creatinine 2.3mg/dl Albumin 2.4g/dl Urinalysis: positive for Bence-Jones proteins (Q793847)

A. Metastatic breast cancer

B. Multiple myeloma

C. Primary hyperparathyroidism

D. Milk alkali syndrome

See Answer in Part B → Q33

Q25 (p. 585)

Q1: Most common childhood epilepsy syndrome is? (Q851091)

A. Janz Syndrome

B. Lennox-Gastaut Syndrome

C. Rolandic epilepsy

D. Febrile seizures

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Match each drug with its preferred use for the corresponding type of seizure. 1. Focal seizures a. Lorazepam 2. Dravet syndrome b. Clobazam 3. Febrile seizures prophylaxis c. Cannabinoids 4. Status epilepticus d. Carbamazepine (Q851113)

A. 1-d, 2-c, 3-b, 4-a

B. 1-c, 2-d, 3-b, 4-a

C. 1-b, 2-d, 3-a, 4-c

D. 1-d, 2-b, 3-a, 4-c

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 27-year-old woman with a history of seizures and poor medication adherence presents to the ER after a 6-minute seizure followed by another, with impaired consciousness between episodes. She is unresponsive and has labored breathing. Which of the following is correct about managment this patient? (Q851112)

A. IV Lorazepam followed by phenytoin infusion

B. Rectal diazepam followed by midazolam drip

C. Intranasal midazolam

D. IV midazolam infusion

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 4 year girl presents to the clinic with a frequent seizure episodes. You notice she has port-wine stain on her forehead and upper eyelid. Neuroimaging reveals tram-track calcifications in the brain. Which type of seizures is seen in this condition ? (Q851111)

A. Focal seizures

B. Myoclonic jerks

C. Atonic seizures

D. Febrile seizures

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following manifestations is earliest to be seen in this neurocutaneous disorder (Q851110)

A. A

B. B

C. C

D. All of the above

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is not correct about SSPE? (Q851107)

A. Delayed neurological complication of measles vaccine

B. CSF IgG Measles antibody

C. Periodic generalized high-voltage slow-wave complexes

D. Isoprinosine improves survival

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 10 year boy unvaccinated child is brought to hospital with increased irritability, social withdrawal, and difficulty in school. On examination he has myoclonic jerks and motor difficulties. EEG shows periodic spikes of slow-wave discharges occurring every 4–10 seconds. Select the best investigation to be performed in this patient? (Q851105)

A. CSF electrophoresis showing oligoclonal bands

B. CSF showing albuminocytogical dissociation

C. CSF shows Anti measles antibody

D. CSF IgG index

See Answer in Part B → Q7

@Neet_pg_bot

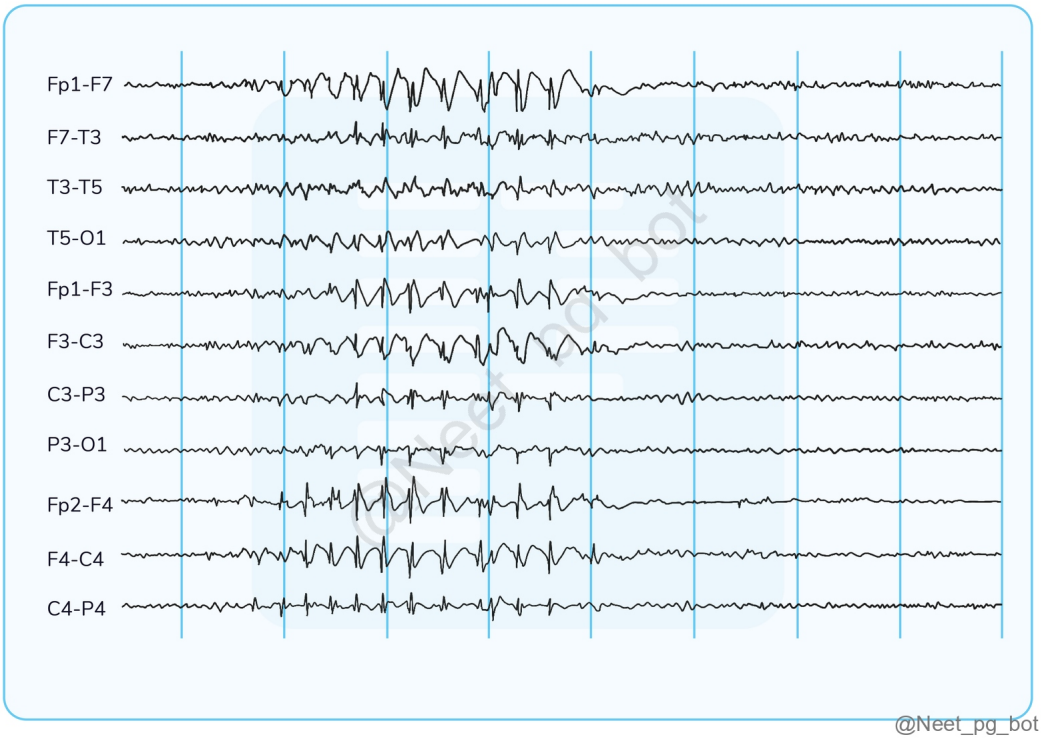
Q8: Match the following conditions with their respective EEGs. 1) Focal seizure a) 2) Absence seizure b) 3) Hypsarrythmia c) 4) Periodic sharp wave complexes d) (Q851102)

A. 1-c, 2-a, 3-d, 4-b

B. 1-b, 2-d, 3-c, 4-a

C. 1-d, 2-c, 3-b, 4-a

D. 1-d, 2-b, 3-c, 4-a



@Neet_pg_bot

Q9: A 62 y/o man presents with rapid cognitive decline, visual disturbances, and myoclonus. An EEG shows localized frontal intermittent rhythmical delta activity (FIRDA) that evolves to periodic sharp wave complexes (PSWC) after a few weeks. Based on this presentation and EEG findings, which of the following conditions is most likely associated with his symptoms? (Q851100)

A. Hepatic encephalopathy

B. Creutzfeldt-Jakob disease

C. Renal encephalopathy

D. Alzheimer's disease

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 2-day-old neonate born at 39 weeks gestation by venthouse is having jitteriness. Which of the following is correct about this presentation? (Q851098)

A. Benign Rolandic epilepsy

B. Subtle seizure

C. Febrile seizures

D. Myoclonic seizures

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 25 y/o woman with a history of catamenial epilepsy reports an increase in seizure frequency just before her menstrual period. She is currently taking carbamazepine and is newly started on OCPs by her GP for contraception. What is the most appropriate advice for her regarding her current situation? (Q851096)

A. Change to Levetiracetam due to high risk of neural tube defects

B. Switch to Valproate to reduce risk of neural tube defects

C. Consider alternative contraception methods due to carbamazepine's effect on oral contraceptives.

D. Stop all antiseizure medications while trying to conceive.

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following antiepileptic drugs can worsen generalized seizures, particularly absence or myoclonic types, and should be avoided in idiopathic generalized epilepsy? (Q851095)

A. Valproate

B. Lamotrigine

C. Carbamazepine

D. Topiramate

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which statement about Mesial Temporal Lobe Epilepsy Syndrome is false? (Q851092)

A. EEG may show unilateral or bilateral anterior temporal spikes.

B. MRI typically reveals an enlarged hippocampus with trilaminar architecture.

C. It is often refractory to anticonvulsants but may respond well to surgical intervention.

D. Auras, postictal disorientation and memory loss can occur.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 30 y/o man is brought to the neurology clinic for evaluation after a brief period of unconsciousness. He is awake and alert during the examination. An EEG is performed while his eyes are closed. What is the frequency range recorded in the patient's EEG? (Q851076)

A. 8-13 Hz

B. >13 Hz

C. <4 Hz

D. 4-8 Hz

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 7 y/o girl presents to the pediatric neurology clinic with a history of multiple seizure types. Her parents report that she has experienced GTCS, atonic seizures where she suddenly drops to the ground, and atypical absence seizures. The child has also shown signs of cognitive impairment. Which of the following statements is true regarding her condition? (Q851090)

A. Characterized by bilateral myoclonic jerks that are most frequent in the morning.

B. The EEG findings show diffuse, symmetric, bilateral 4 to 6 Hz polyspike and wave discharges.

C. Valproate and Topiramate are used in treatment.

D. The condition typically presents in early adolescence.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 25 y/o man is brought to the ED after experiencing a generalized tonic-clonic seizure. An EEG is performed after the seizure. Which of the following statements is true regarding the EEG findings associated with his seizure? (Q851089)

A. The interictal EEG shows electrodecremental response

B. During the tonic phase, the EEG typically shows a progressive increase in generalized low-voltage fast activity.

C. The postictal EEG usually reveals localized spikes corresponding to the seizure focus.

D. The EEG during the clonic phase shows low frequency polyspikes with variable amplitude

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 25-year-old patient with a recently diagnosed PNET experiences recurrent episodes of fainting, often preceded by sweating, tremors and confusion. What is the most likely cause? (Q851088)

A. Orthostatic Hypotension

B. Vasovagal Syncope

C. Metabolic cause

D. Electrolyte imbalance

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 6-month-old infant presents with brief episodes of sudden flexion of the trunk and limbs, lasting a few seconds. EEG shows hypsarrhythmia, and during the episodes, there's marked background suppression on the EEG. What is the most likely diagnosis? (Q851087)

A. Absence seizures

B. Atonic seizures

C. Epileptic spasms

D. Lennox-Gastaut syndrome

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 23 year patient presents with sudden, brief muscle jerks on loud auditory stimuli and dementia. T2/FLAIR MRI shows hyperintensity in the pulvinar nucleus of the thalamus. What is the first differential diagnosis? (Q851086)

A. Epileptic spasms

B. Juvenile Myoclonic Epilepsy

C. Variant Creutzfeldt-Jakob Disease (vCJD)

D. Anoxic brain injury

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 7 year child is brought to the clinic due to frequent episodes of "daydreaming" during school, which last for a few seconds and are accompanied by subtle eyelid blinking. Which of the following is correct about this condition? (Q851084)

A. Episodes can be stopped by hyperventilation

B. Episodes are triggered by photic stimulation

C. < 2.5 Hz spike and slow wave pattern

D. Occur due to defect of sodium channel closure in thalamocortical circuit

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 35 y/o woman experiences sudden unresponsiveness during conversations, followed by repetitive hand movements and lip-smacking. Afterwards, she seems confused and does not remember the event. Which of the following is the most likely diagnosis? (Q851083)

A. Absence Seizure

B. Panic Attack

C. Focal Seizure with Impaired Awareness

D. Focal Seizure with Intact Awareness

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 32 y/o woman experiences involuntary movements that begin in her right hand and progressively spread to her right arm and face. She remains fully aware throughout the episode. What is the most likely diagnosis? (Q851080)

A. Absence seizure

B. Todd’s paralysis

C. Epilepsia partialis continua

D. Jacksonian march

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 20-year-old student experiences episodes of sudden drop attacks with brief loss of consciousness and confusion after the episode. What is the likely diagnosis? (Q851079)

A. Orthostatic hypotension

B. Atonic seizures

C. GTCS

D. Myoclonic seizure

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 15-year-old boy is brought to the OPD with complaints of repeated episodes of blank staring, and lip-smacking movements lasting around 1–2 minutes. He is confused afterward and has no memory of the episode. Diagnosis is? (Q851078)

A. Focal seizure

B. Absence seizures

C. Pseudo seizures

D. Generalised tonic-clonic seizure

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 19-year-old medical student collapses in the anatomy dissection hall. His friends report a brief period of limb jerking lasting about 10–15 seconds during the episode. He regained consciousness in a minute, he appeared pale around the lips with sweating on forehead. Diagnosis is? (Q851077)

A. Vasovagal syncope

B. GTCS

C. Pseudoseizures

D. Focal seizures with secondary generalization

See Answer in Part B → Q25

Q1: A 50-year-old woman with T2DM is brought in by her family due to strange behaviour. Her daughter says that she noticed that her mother at her wedding was applying makeup only to the left side of her face and eating food from only the left half of her plate. When asked to copy simple shapes such as a triangle, square, and circle her drawings are incomplete and poorly organized. Which of the following brain regions is most likely affected? (Q851256)

A. Left parietal lobe

B. Right parietal lobe

C. Left temporal lobe

D. Right temporal lobe

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 60 -year-old retired banker and right-handed man is brought with complaints of speech difficulties. He speaks fluently and with normal grammar, and appears to understand both verbal and written commands. However, when asked to repeat phrases, he is unable to do so. His naming and reading comprehension are intact. Which of the following regions is most likely affected? (Q851269)

A. Broca’s area

B. Wernicke’s area

C. Arcuate fasciculus

D. Angular gyrus

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is not a feature of Weber syndrome? (Q851268)

A. Contralateral lower face weakness

B. Eye down and out (ipsilateral)

C. Vertical gaze palsy

D. Hemiplegia (contralateral)

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 65-year-old woman presents to ER with history of suddenly falling down with difficulty in swallowing. On examination patient can stick out her tongue without any deviation, and gag reflex is diminished. Ipsilateral nystagmus is noted with ataxia of limbs, ipsilateral face numbness with a contralateral pain and temperature loss. Diagnosis is? (Q851267)

A. Brown sequard syndrome

B. Wallenberg Syndrome

C. Locked in syndrome

D. Medial Medullary Syndrome

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 70-year-old diabetic man presents with sudden right-sided weakness. On examination, there is loss of proprioception and vibration on the right side of the body, and his tongue deviates to the left on protrusion. Facial sensation is intact. What is the most likely diagnosis? (Q851266)

A. Lateral medullary syndrome

B. Medial medullary syndrome

C. Central pontine myelinosis

D. Anterior cerebral artery stroke

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 38-year-old Formula 1 driver suffers a high-speed crash. At the hospital, he is unable to move his limbs, talk, or drink from a straw. Examination reveals quadriplegia with bilateral long tract signs, with absent gag reflex, but a nurse notices that he can move his eyes vertically on command. What is the most likely diagnosis? (Q851265)

A. Brain stem death

B. Locked in syndrome

C. Vegetative state

D. Decerebrate posturing

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 62-year-old patient presents with left-sided arm and leg weakness, right-sided facial paralysis with lateral rectus gaze palsy and nystagmus. Which of the following syndromes is consistent with these symptoms? (Q851264)

A. Foville Syndrome

B. Benedikt syndrome

C. Millard Gubler

D. Wallenberg syndrome

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 60-year-old male presents to neurology follow-up OPD four weeks after a stroke with persistent allodynia, especially while taking a bath with warm water. Which of the following is correct about this case? (Q851263)

A. Complex regional pain syndrome type I

B. Thalamic infarct

C. Internal capsule infarct

D. Complex regional pain syndrome type II

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 25-year-old woman presents with double vision. On examination, she has paralysis of vertical gaze and pupils that constrict during accommodation but not in response to light (light-near dissociation). CT head shows mass arising in pineal region. Diagnosis is? (Q851262)

A. M.Gravis

B. Neurosyphilis

C. Internuclear opthalmoplegia

D. Perinaud syndrome

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 60-year-old man presents with a sudden onset drooping of left eye and balance issues. On examination, he has left-sided ptosis, dilated left pupil, and the left eye is "down and out." He demonstrates significant right-sided ataxia. He is unable to move his eyes vertically . Diagnosis is? (Q851261)

A. Weber syndrome

B. Nonthangel syndrome

C. Benedikt syndrome

D. Millard gubler syndrome

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 35-year-old alcoholic patient presents with palpitations for the last 2 hours. On examination, he has an irregularly irregular pulse, BP 130/100 mm Hg, and a GCS of 15/15. Higher mental functions and cranial nerve examination are normal. There is no focal neurological deficit. What is the most appropriate next step in management? (Q851260)

A. Thrombolysis as patient is in window period

B. Control ventricular rate

C. Start anticoagulation with warfarin

D. Start anticoagulation with novel oral anticoagulants

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A patient presents with sudden onset aphasia and right sided arm weakness for the past 4 hours. On examination he has irregularly irregular pulse. Which of the

following investigations will be done to determine etiology of this case presentation? (Q851259)

A. Transthoracic echocardiography

B. Carotid doppler

C. Transesophageal echaocardiography

D. MRI Brain

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 54-year-old male presents with a sudden onset of double vision and left-sided weakness. On examination he has a right-sided ptosis, a dilated pupil that does not react to light, and an outward deviation of the right eye. The left side of his body shows spastic weakness with hyperreflexia. MRI reveals an ischemic lesion in the midbrain. Which of the following structures is most likely involved in this patient's condition? (Q851258)

A. Occulomotor motor and red nucleus

B. Oculomotor nerve and crus cerebri

C. Occulomotor nerve and superior cerebellar penduncle

D. Occulomotor nerve and substania nigra

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A patient with stroke cannot perform simple actions on command, such as waving goodbye or pretending to brush teeth, even though they understand what to do and have no muscle weakness. When spoken a phrase "Repeat after me: 'The sky is blue'", the patient struggles to repeat it but speaks fluently and understands spoken language. Which lobe is most likely affected? (Q851257)

A. Right Parietal

B. Right Temporal

C. Left Parietal

D. Left Temporal

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 60-year-old man presents with sudden onset of right-sided face and arm weakness at the breakfast table at 8 am. He arrives at the ER at 4 pm in the evening. His pulse is 100/min, BP 180/100 mm Hg, NIHSS is 6, and GCS is 13/15. NCCT head shows hypodensity in the left MCA territory and CTA reveals a M1 left MCA occlusion. . Which of the following is the best intervention for management of this patient? (Q851178)

A. Rapid lowering of BP with nicardipine to achieve target BP 140/100 mm Hg

B. Thrombectomy

C. Secure airway

D. Schedule for thrombolysis after lowering of BP

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 60-year-old hypertensive man presents with sudden onset slurred speech and difficulty comprehending language. NCCT head scan reveals an ischemic stroke. The stroke likely involves which of the following vessels? (Q851198)

A. Left anterior cerebral artery

B. Left middle cerebral artery

C. Right middle cerebral artery

D. Right anterior cerebral artery

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 40-year old lady complains of difficulty in kneading the dough for past 6 months. On examination she has atrophy of right hand muscles and fasiculations are noted in thenar muscles. Select the site of lesion? (Q851197)

A. Right anterior horn cells in spinal cord

B. Left anterior horn cells in spinal cord

C. Right Parietal Lobe

D. Left Parietal Lobe

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Gait apraxia and urinary incontinence are clinical features associated with damage to which lobe of the brain? (Q851196)

A. Temporal

B. Parietal

C. Occipital

D. Frontal

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 65 year man can recognise voices of family members while talking over mobile phone. But when he meets them in person he is not able to recognise them. Lesion is present in which part of brain? (Q851194)

A. Frontal lobe

B. Temporal Lobe

C. Parietal Lobe

D. Occipital Lobe

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 60-year-old right-handed woman is brought by her husband after he notices she has trouble doing dishes and confuses her left and right sides since last evening. On examination, she cannot perform simple calculations, but her speech is fluent. The lesion is most likely in which structure? (Q851192)

A. Right Temporal Lobe

B. Left Temporal Lobe

C. Left Parietal Lobe

D. Right Parietal Lobe

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A patient presents with sudden onset weakness affecting the face, arm, and leg on one side of the body without sensory loss or cortical signs. Which is the most likely site of lesion? (Q851190)

A. Anterior limb of internal capsule

B. Posterior limb of internal capsule

C. Genu of internal capsule

D. Thalamus

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 70-year-old male presents to ER with sudden-onset right-sided arm weakness and difficulty speaking which started 2 hours ago. His medical history includes hypertension, hyperlipidemia, and a prior TIA. His BP is 160/100 mm Hg. A CT scan of the head rules out hemorrhagic stroke. Which of the following is the most appropriate initial management for this patient? (Q851189)

A. Administer intravenous Alteplase immediately.

B. Start intravenous heparin for anticoagulation therapy.

C. Intubate the pateint

D. Control BP with Labetalol

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 65-year-old diabetic male presents to the emergency department with a sudden onset of right-sided weakness and slurred speech that resolved completely within 2 hours. His blood pressure is 160/90 mmHg. Based on his ABCD2 score of 6, what is the most appropriate immediate management? (Q851187)

A. Start oral aspirin 81 mg daily alone

B. Combination of ticagrelor plus aspirin

C. Warfarin with target INR 2-3

D. Tenecteplase

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following is not correct about ABCD2 score for diagnosis of Transient ischemic attack? (Q851186)

A. Age > 60 years

B. Elevated BP

C. Past history of stroke

D. Duration of symptoms

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 60-year-old man presents with sudden onset right arm weakness and slurred speech for 1 hour. His blood pressure is 170/100 mm Hg. He has a history of atrial fibrillation and is on warfarin; current INR is 2.0. NCCT head shows no intracranial hemorrhage. CT angiography reveals a left MCA occlusion. Which of the following is the most appropriate next step in management? (Q851184)

A. Intravenous Alteplase

B. Mechanical thrombectomy after confirming salvageable tissue with CT perfusion

C. Cardiology consult for chemical cardioversion

D. Mannitol and dual antiplatelet therapy

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 58-year-old right-handed man is brought to the ER for speaking fluently but producing nonsensical words and sentences. He has difficulty understanding spoken commands. Neurological exam shows no significant motor weakness. Which of the following vessels is most likely involved? (Q851182)

A. Superior division of left middle cerebral artery

B. Inferior division of left middle cerebral artery

C. Left anterior cerebral artery

D. Left posterior cerebral artery

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 65-year-old male presents with sudden onset of vertigo, dysphagia, hoarseness, and left-sided facial numbness. On examination, he has left-sided Horner's syndrome, right-sided loss of pain and temperature sensation in the body, and left-sided cerebellar signs. Which of the following is the most likely diagnosis? (Q851181)

A. Parinaud syndrome

B. Dejerine syndrome

C. Wallenberg syndrome

D. Weber syndrome

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 65-year-old hypertensive man presents with a sudden onset of right-sided weakness affecting his face, arm, and leg. The NCCT head shows an intraparenchymal bleed in left side basal ganglia. Which of the following vessels is most likely involved in this pathology? (Q851180)

A. Internal carotid artery

B. Posterior communicating artery

C. Penentrating branches of lenticulostriate arteries

D. Anterior communicating artery

See Answer in Part B → Q28

Q1: A 62-year-old woman presents with chronic burning pain, numbness, and tingling on the right side of her body not relieved with NSAIDs. The symptoms began 2 months after she suffered a stroke. On examination, she has hyperesthesia and allodynia on the right side. The clinician suspected it to be due to lacunar infarct. What could be the likely site of infarct causing her present symptoms? (Q851217)

A. Ventroposterolateral thalamus

B. Posterior limb of internal capsule

C. Genu of internal capsule

D. Cortical pontocerebellar tract

See Answer in Part B → Q1

@Neet_pg_bot

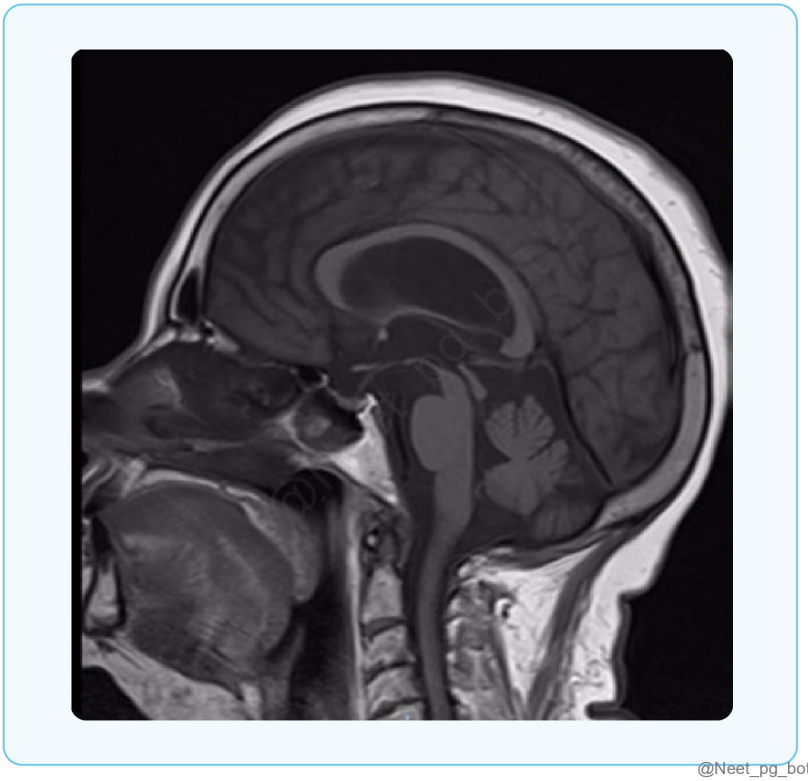
Q2: An elderly patient presented with a history of slowing of movements, frequent falls and forgetfulness. MRI done is as shown below. Which among the following is not a feature of this condition? (Q852414)

A. Defective downward gaze

B. Resting tremors

C. Poor response to levodopa

D. Gunslinger’s gait



See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following clinical signs of upper motor neuron lesion is described correctly ? (Q851230)

A. Babinski’s sign - Lateral stroke of the sole resulting in flexion of all toes

B. Gordon’s sign - A stroke beneath and in front of the lateral malleolus causing an extensor plantar response.

C. Oppenheim’s sign - Apply pressure along the medial aspect of tibia causing an extensor plantar response

D. Chaddock’s sign - Squeeze the calf muscles to produce extensor plantar response.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 5 year old female child presented to the casualty with recurrent seizures and left sided hemiplegia. On physical examination, a reddish skin lesion was found since birth over the right side of her forehead involving the right eye, nose and cheek. On CT imaging of the brain, the following picture was seen. What is the probable diagnosis? (Q851229)

A. Von Hippel Lindau syndrome

B. Sturge Weber syndrome

C. Neurofibromatosis

D. Ataxia telangiectasia

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 15 year old adolescent male patient came with his parents with complaints of neuropsychiatric symptoms such as tremors and an irritable mood. On physical

examination, stigmata of liver disease and the following ophthalmological finding is seen. Which of the following is correct about this condition? (Q851228)

A. Defect in P type ATP ase ATP7B protein

B. Defect in P type ATP ase ATP7A protein

C. ATP7B gene defect with increased ceruloplasmin

D. ATP7A gene defect with increased ceruloplasmin

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 30 year old male patient was brought to the ER with a history of RTA and sustained multiple injuries. On primary assessment, he was disoriented and complained of severe headache. Meningeal signs are noted. On neuroimaging the following image was seen. What is the most probable diagnosis in this patient? (Q851227)

A. Intracerebral hemorrhage

B. Subdural hemorrhage

C. Subarachnoid hemorrhage

D. Extradural hemorrhage

See Answer in Part B → Q6

@Neet_pg_bot

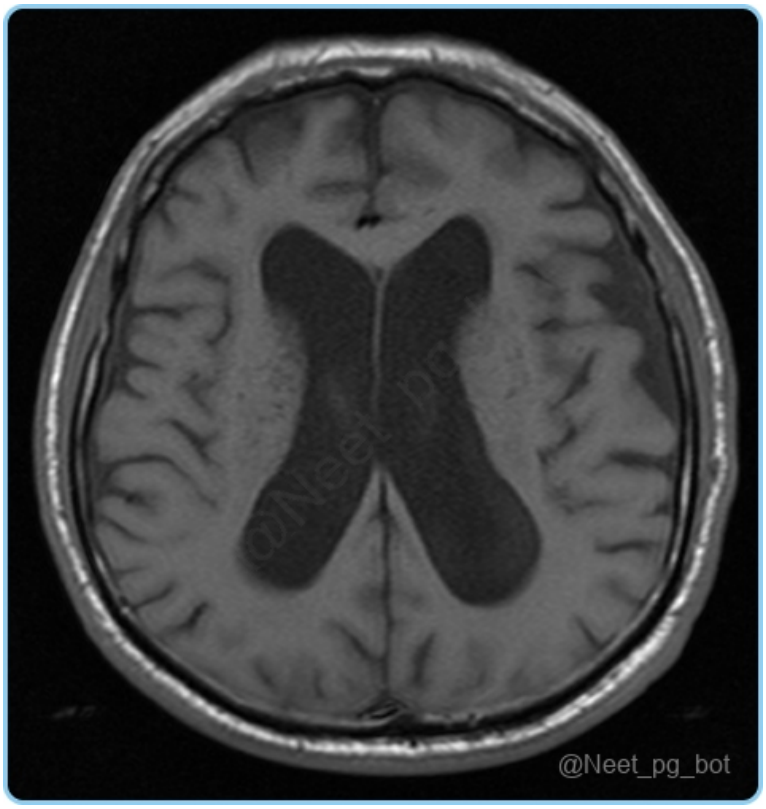
Q7: A 75 year old male patient came to the OPD with complaints of recent onset stooping, broad based abnormal gait, short-term memory loss and urge incontinence. On radiological investigation, the following image is obtained. What is the probable diagnosis? (Q851226)

A. Parkinson’s disease

B. Alzheimer’s disease

C. Normal pressure hydrocephalus

D. Idiopathic intracranial hypertension



See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 13 year old male patient presented with complaints of poor scholastic performance, history of recurrent seizures since infancy and the following incidental finding on his back. What does the incidental finding denote and probable diagnosis of this patient? (Q851225)

A. Neurofibroma and Neurofibromatosis

B. Adenoma sebaceum and Tuberous sclerosis

C. Shagreen patch and Tuberous sclerosis

D. Cafe-au-lait spots and Neurofibromatosis

See Answer in Part B → Q8

@Neet_pg_bot

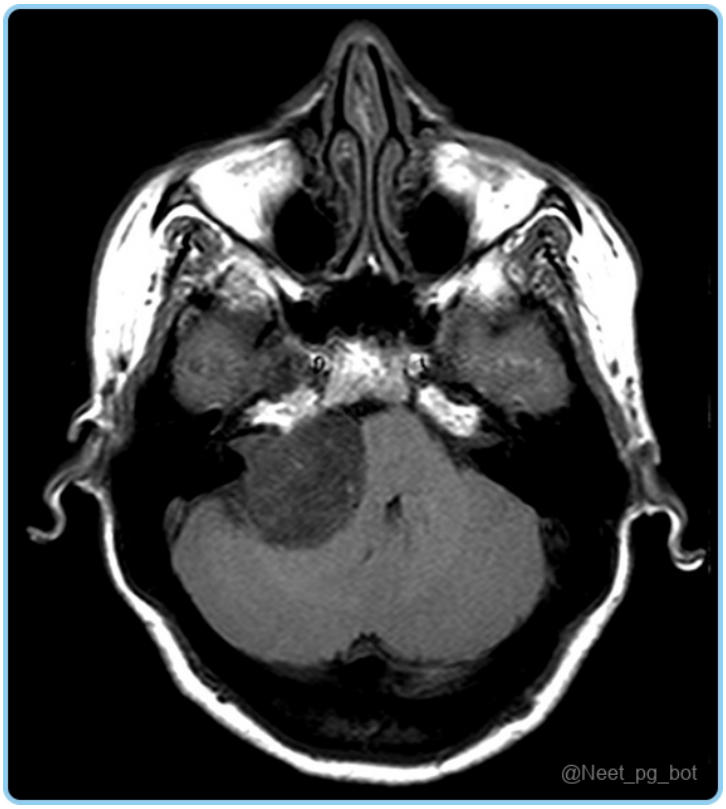
Q9: A 45-year-old woman presents with progressive hearing loss in the right ear, occasional imbalance while walking, and a sensation of fullness in the ear. On examination, she has decreased corneal reflex on the right side. MRI of the brain is shown below. Which of the following is the most likely diagnosis? (Q851224)

A. Vestibular schwannoma

B. Cerebellar Astrocytoma

C. Craniopharyngioma

D. Prion disease



See Answer in Part B → Q9

@Neet_pg_bot

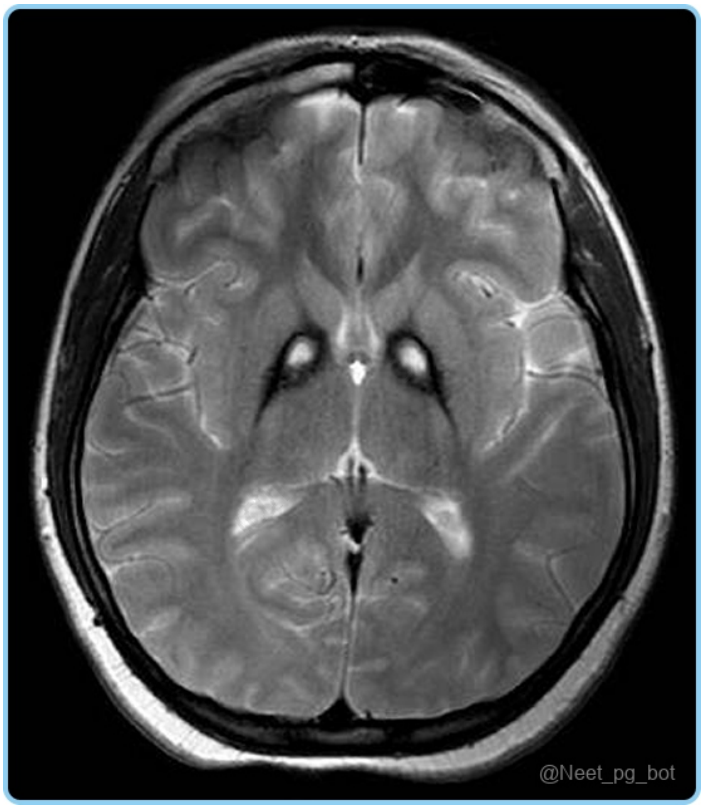
Q10: A 9-year-old child presents with progressive dystonia, difficulty walking, and slurred speech. On examination, he has oromandibular dystonia and choreoathetosis. MRI brain shows bilateral hypointensity of the globus pallidus with a central area of hyperintensity. Which of the following is the most likely diagnosis? (Q851223)

A. Pantothenate kinase-associated neurodegeneration

B. Huntington disease

C. Craniopharyngioma

D. Prion disease



See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is a CT finding of Pneumocephalus? (Q851222)

A. Mount Fuji Sign

B. Air Bubble Sign

C. Peaking Sign

D. All of the above

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 5-year-old is having daily headaches and difficulty copying from the board. He was found to have bitemporal hemianopia, and an MRI of the head was done. Which

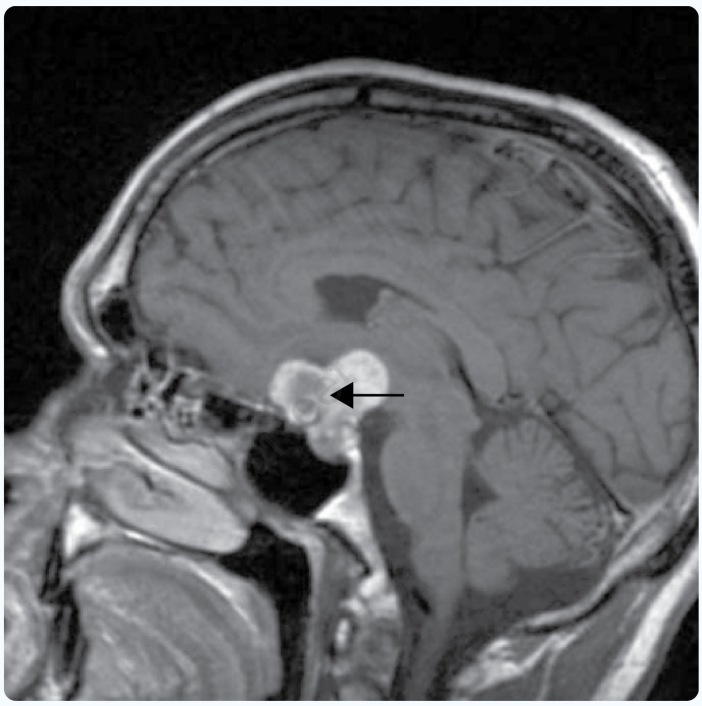
of the following is not correct about this condition? {{caption_text}} (Q851221)

A. Cystic swelling with calcification

B. Derived from Rathke pouch

C. Compression of optic chiasma

D. Leading infratentorial brain tumor in children



@Neet_pg_bot

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is incorrect about variant creutzfeldt-jakob disease? (Q851220)

A. Periodic sharp wave complexes on EEG

B. Cortical ribboning in MRI

C. Increased intensity in the basal ganglia

D. JEV-specific IgM in CSF by MAC■ELISA

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 35-year-old male presents to the ER after a fall, initially conscious but rapidly deteriorates following a brief lucid interval. The CT image is given below. What is the diagnosis? {{caption_text}} (Q851219)

A. Epidural hematoma

B. Subarachnoid hemorrhage

C. Subdural hematoma

D. Intracerebral hematoma

See Answer in Part B → Q14

@Neet_pg_bot

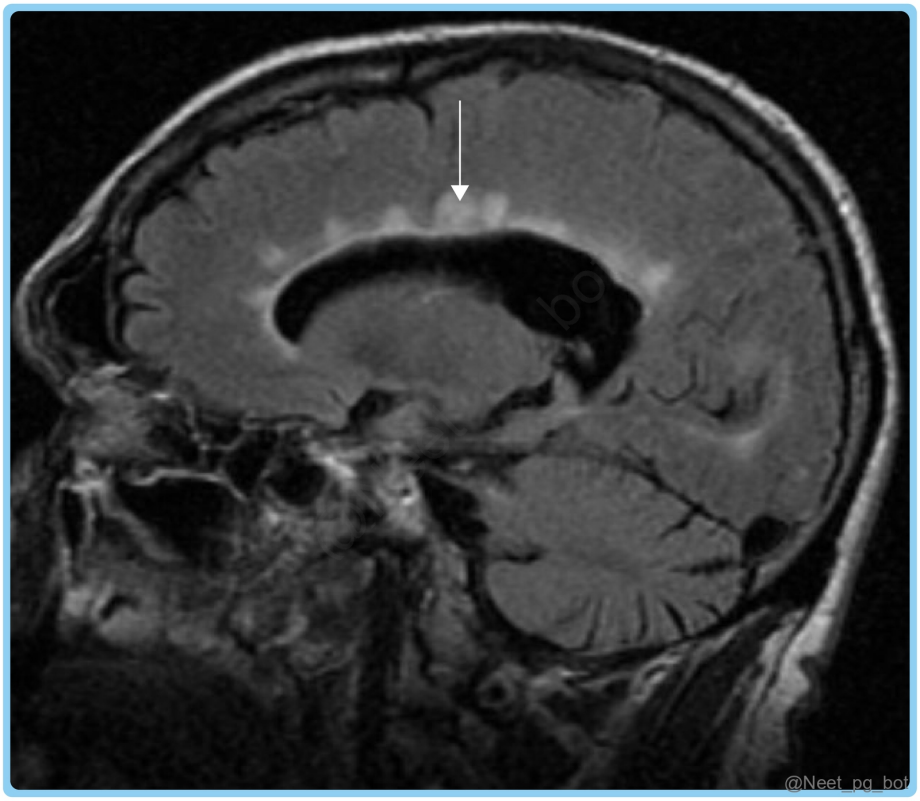
Q15: Based on the MRI finding (shown below) , Which of the following criteria and corresponding treatment used in this condition? {{caption_text}} (Q851218)

A. Brighton’s criteria, IV Steroids

B. Brighton’s criteria, IV Immunoglobulin

C. McDonald’s criteria, IV Steroids

D. McDonald’s criteria, IV Immunoglobulin



See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 68-year-old male presents to the ER with a sudden onset of headache and right-sided arm weakness that started while brushing his teeth in morning at 7 am. He is known case of hypertension and says he slept on couch last night while watching TV. On examination at 9 am he has irregularly irregular pulse, his arm weakness has improved significantly (power grade 4/5) and he can talk, drink water, chew food and walk normally. NCCT head is normal. Which of the following is the cause of this

presentation? (Q851201)

A. Spontaneous subarachnoid hemorrhage with resorption

B. Cerebral embolism with spontaneous reperfusion

C. Neuronal death due to cerebral anoxia

D. Saturday night palsy due to neurapraxia

See Answer in Part B → Q16

@Neet_pg_bot

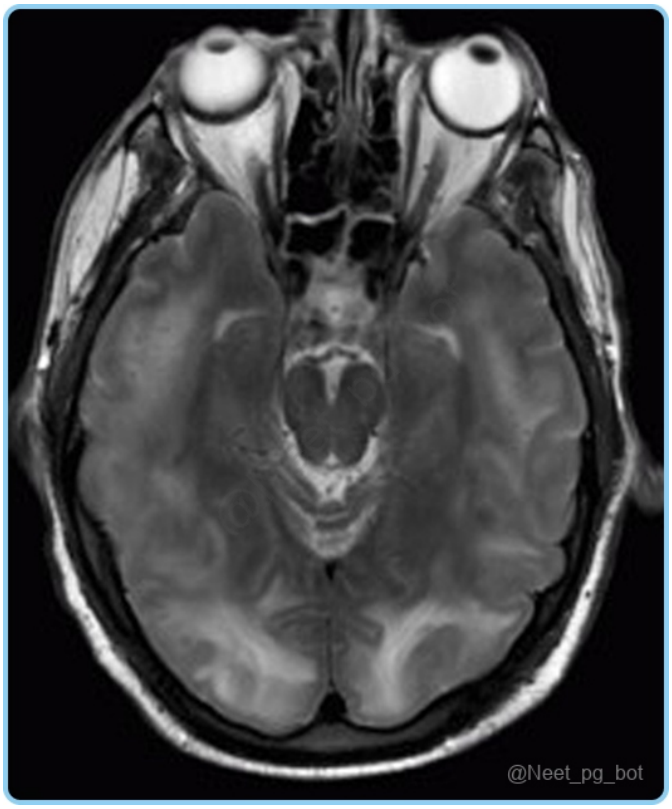
Q17: A 30-year-old female who delivered a male baby via C-section owing to eclampsia developed a sudden onset headache, seizures, visual disturbances, and altered sensorium 2 days following delivery. BP is 180/120 mm Hg. An MRI head is shown. What is the likely diagnosis? {{caption_text}} (Q851216)

A. Reversible cerebral vasoconstriction syndrome (RCVS)

B. CADASIL

C. Post partum TIA

D. Posterior reversible encephalopathy syndrome (PRES)



See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which among the following statements is/are false regarding CADASIL ? 1) Autosomal Dominant inheritance 2) Predominantly causes Large-vessel stroke 3) Characteristic symptom is Migraine with aura 4) Notch-3 gene is involved (Q851215)

A. 2

B. 1,3

C. 1,2

D. 2,3

See Answer in Part B → Q18

@Neet_pg_bot

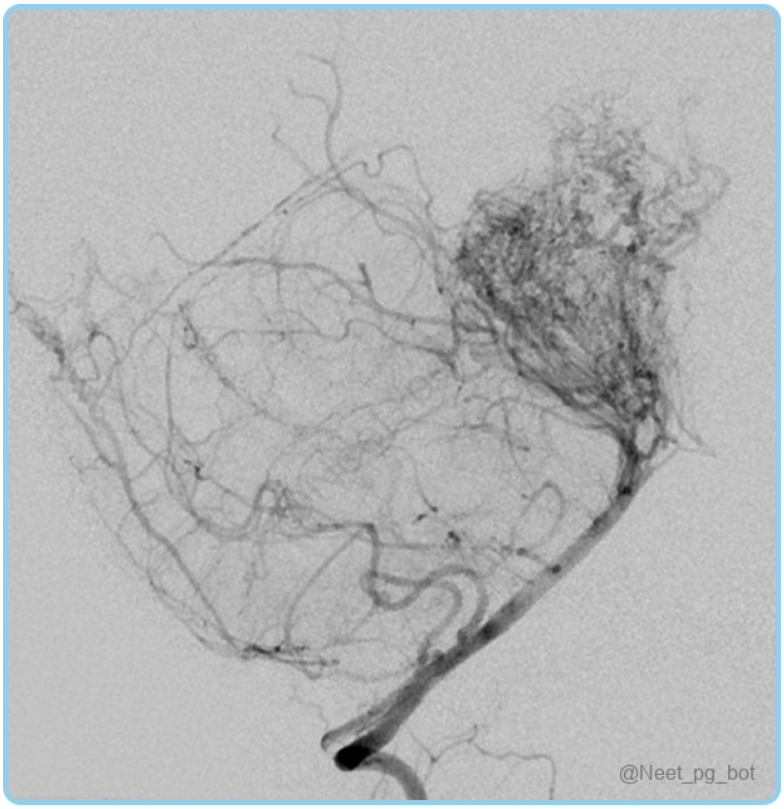
Q19: Child presented with reccurent TIA events. Cerebral angiography was performed. Which among the following is false regarding this condition? {{caption_text}} (Q851214)

A. Involves occlusion of predominantly large arteries

B. Associated with vascular inflammation

C. Anticoagulation is contraindicated

D. Can present in adults with brain hemorrhage



See Answer in Part B → Q19

@Neet_pg_bot

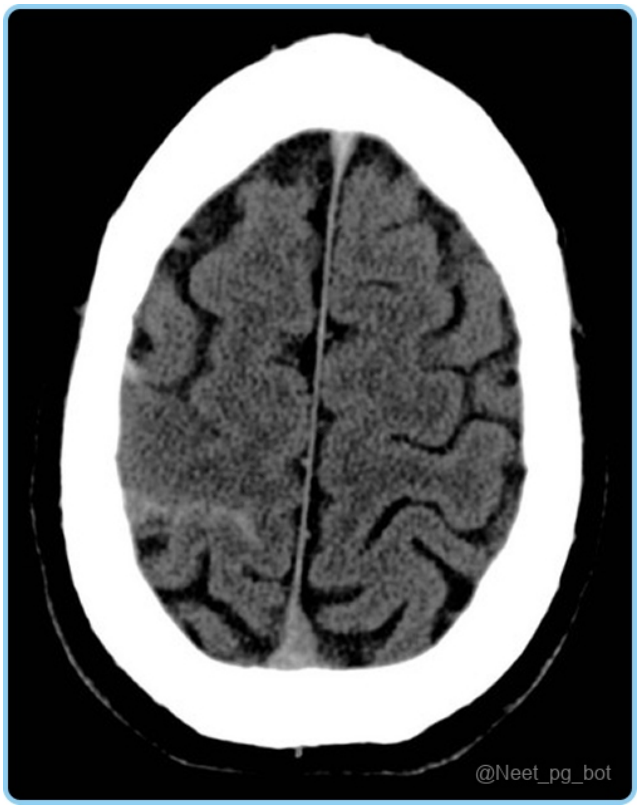
Q20: A 35 year old woman presents with sudden onset headache, seizures and focal neurological deficits. BP on admission is 160/100 mm Hg. She has a history of oral contraceptive use. CECT head is shown below. What is the most appropriate initial treatment for this patient? {{caption_text}} (Q851213)

A. Thrombolysis

B. Heparin

C. Oral warfarin immediately

D. Thrombectomy



See Answer in Part B → Q20

@Neet_pg_bot

Q21: As an intern in the medicine ward, you are asked to guide the nursing staff about the various supportive care measures to improve the outcome in of Acute ischemic stroke patients who are managed with thrombolysis. Which among the following will you not advise? (Q851212)

A. Monitor vitals and place in head end elevated position

B. Perform urinary catheterisation for input output charting

C. Pneumatic compression stockings to prevent deep vein thrombosis.

D. Give antipyretics to patients with fever to prevent infarct expansion

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following is a contraindication to thrombolysis in a patient with acute ischemic stroke? (Q851211)

A. CT showing ischemic changes in > 1/3 MCA territory

B. CT scan showing Hyperdense MCA sign

C. Large Hematochezia episode 10 days ago requiring banding

D. Recent epistaxis requiring nasal packing

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 58 year old T2DM male with hypertension presents to the emergency department 2 hours after developing sudden onset of right sided arm weakness and face asymetry. His blood pressure is 170/90 mmHg, and a NCCT head shows no hemorrhage. He is on metformin, metoprolol and atorvastatin. What is the most appropriate initial treatment for this patient? (Q851210)

A. Thrombolysis with alteplase

B. Antiplatelet therapy with aspirin

C. Mechanical thrombectomy

D. Immediate blood pressure reduction followed by Alteplase

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 50 year old male patient came to the ER with complaints of headache, blurring of vision and right sided hemiparesis for 2 hours. He is a known case of diabetes mellitus and hypertension. On examination pulse is 92/min with BP 190/110 mm Hg. What is the most appropriate statement regarding management of this patient? {{caption_text}} (Q851209)

A. Blood pressure of the patient should be reduced to <140/90 with nicardipine

B. The head end of the patient's bed should be flat to prevent coning of the brain.

C. Immediate intravenous thrombolysis is recommended since the patient is in window period

D. Urgent lowering of BP with nicardipine followed by thrombolysis since patient is in window period

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 65 year old male presents to the emergency department with a sudden onset of right sided weakness, slurred speech and facial drooping for the past 1 hour. NCCT head is normal. What is the appropriate scoring done to confirm the diagnosis of this

patient? (Q851208)

A. ABCD2

B. CHADS2VASc

C. NIHSS

D. Agatson

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 70 year old woman presents to the ER with sudden-onset slurred speech and right-sided facial weakness that resolved after 90 minutes. The resident has asked you to calculate ABCD2 score. Which of the following is not a component of this score (Q851207)

A. Blood pressure

B. History of stroke

C. Diabetes mellitus

D. Duration of symptoms

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 45-year-old man with hypertension presents to the ER at 6 am in morning with excruciating headache and sudden onset face, arm and leg weakness. On examination GCS is 8 and blood pressure is 220/110 mmHg. NCCT head is shown. Cause of this presentation is? {{caption_text}} (Q851206)

A. Ruptured saccular aneurysm

B. Rupture of penetrating arteries supplying internal capsule

C. Dural sinus thrombosis

D. Posterior reversible encephalopathy syndrome

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 60-year-old man is brought to ER with sudden onset of right-sided arm weakness and difficulty speaking. His gaze is deviated to the left, and he has a right homonymous hemianopia. Which of the following is the most likely location of the thrombus causing this patient's symptoms? (Q851203)

A. Left MCA, Non dominant hemisphere

B. Left MCA, Dominant hemisphere

C. Left PCA, Dominant hemisphere

D. Right PCA, Non Dominant hemisphere

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 60 year old man presents with sudden onset right face deviation and arm weakness for last 8 hours. BP on admission is 185/110 mm Hg. NCCT head shows hypodensity in parietal lobe and CTA shows clot in M2 segment of MCA. Which is the best intervention for this patient? (Q851202)

A. Endovascular coiling

B. CT perfusion with endovascular thrombectomy

C. Lower BP with Nicardipine followed by Tenecteplase

D. Lower BP with Nicardipine followed by Aspirin loading 325 mg

See Answer in Part B → Q29

@Neet_pg_bot

[07_Neurology] 051 Guillian Barre Syndrome And Alzheimer S Disease — Quick Jump

Q1 (p. 619) *Q2 (p. 619)* *Q3 (p. 620)* *Q4 (p. 620)* *Q5 (p. 620)* *Q6 (p. 621)*
Q7 (p. 621) *Q8 (p. 622)* *Q9 (p. 622)* *Q10 (p. 623)* *Q11 (p. 623)* *Q12 (p. 623)*
Q13 (p. 624) *Q14 (p. 624)*

Q1: A 30-year-old man from Pune presents with recurrent falls in stairs from past 3 days with leg muscle weakness and root pains in both legs. On examination flaccid paralysis is noted in both legs with arreflexia. Sensory examination shows distinct level below T10 where radicular pain is being felt. Bladder was catheterized due to urinary incontience. MRI spine shows inflammation of spinal cord. He had a diarrheal episodes 2 weeks ago. Diagnosis is? (Q851492)

A. Acute inflammatory demyelinating polyneuropathy

B. Miller Fisher syndorme

C. Transverse Myelitis

D. Chronic inflammatory demyelinating polyneuropathy

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is not correct about GBS? (Q851493)

A. Prolonged F wave latency

B. Diaphragmatic paralysis

C. Pseudo-bulbar weakness may cause difficulty in handling secretions

D. Proprioception loss

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following statements is incorrect regarding the types of Guillain-Barré syndrome? (Q851494)

A. AIDP is the most common form in adults

B. AMSAN has best prognosis amongst all variants

C. AMAN involves axonal degeneration in children and young adults

D. Miller-Fisher syndrome is associated with anti-GQ1b antibodies

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 35-year-old man presents with a 2-day history of progressive weakness that started in his legs after returning from his international trip. Today he cannot get up from bed and is having hand weakness. On examination, distal arreflexia is noted with power grade 1/5 for muscles at all joints of lower limbs and 3/5 for upper limbs. CSF study shows cytoalbuminological dissociation. Which criteria are used for diagosis of this condition? (Q851495)

A. Brighton

B. Macdonald'

C. Adam and Victor

D. Dubois

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 40-year-old man presents with a one-day history of progressive weakness, initially localised to his legs but now involving the arms. He tells about the inability to button his shirt along with fatigue during minimal exertion. On examination, there is

flaccid quadriparesis with absent deep tendon reflexes. What is the next best step in the management of this patient? (Q851496)

A. Nerve conduction studies

B. Lumbar puncture for cytoalbuminological dissociation

C. Anti GM1 and Anti GQ1 antibody titers

D. PCR stool for C. jejuni

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 50-year-old man presents with difficulty in walking due to imbalance following a recent viral illness. He also reports double vision. Examination reveals bilateral ptosis, ophthalmoplegia, and areflexia. He has a history of alcohol use but no diabetes or hypertension.What is the most appropriate treatment? (Q851497)

A. Intravenous immunoglobulin

B. Corticosteroids

C. Thiamine with dextrose

D. Dextrose

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 20-year-old female presents with acute dysphagia, particularly for liquids, and nasal regurgitation, following a recent dengue fever. Examination reveals bilateral facial weakness and areflexia in the upper limbs. Brain and cervical spine MRI is normal, while cerebrospinal fluid analysis shows elevated protein with normal opening pressure, cells and glucose. What is the most likely diagnosis? (Q851498)

A. Acute pharyngeal cervicobrachial neuropathy

B. Miller-Fisher syndrome

C. Multiple sclerosis

D. Botulism

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 75-year-old man presents with progressive memory loss, difficulty in performing daily activities, and mood changes. His family notes that he often repeats the same questions and becomes easily confused. Neurological examination reveals no focal deficits, but cognitive testing indicates significant impairment in memory and language skills. What is the possible neurotransmitter status for this condition? (Q851499)

A. Increased Acetylcholine, decreased Norepinephrine, decreased Serotonin

B. Decreased Acetylcholine, decreased Norepinephrine, decreased Serotonin

C. Normal Acetylcholine, increased Norepinephrine, normal Serotonin

D. Increased Acetylcholine, increased Norepinephrine, decreased Serotonin

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 30-year-old man with Down syndrome is being monitored for cognitive decline due to his increased risk for Alzheimer's disease. Why is this patient at a higher risk for developing Alzheimer's disease? (Q851500)

A. Presenilin 1 gene mutation

B. Overexpression of the APP gene

C. Mutation in the ApoE4 gene

D. Release of pro-inflammatory cytokines and promoting insulin resistance

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following neurodegenerative disorders is not classified as a tauopathy? (Q851501)

A. Alzheimer’s disease

B. Punch-drunk syndrome

C. Parkinson’s disease

D. Pick's disease

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 60-year-old woman has been diagnosed with early-stage Alzheimer's disease. Her husband reports that she frequently struggles to remember recent events and has begun to repeat herself in conversations. Additionally, she has difficulty managing her finances and has gotten lost while driving to familiar places. Despite these issues, she insists that she is “just fine” and is not concerned about her memory. Which term best describes the unawareness of her cognitive decline? (Q851502)

A. Subjective cognitive decline

B. Anosognosia

C. Apraxia

D. Confabulation

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 74-year-old woman is brought to a memory clinic by her daughter, who reports increasing forgetfulness over the past year. The daughter notes that her mother often misplaces items, struggles to find the right words during conversations,

and repeats questions she has just asked. Recently, she became lost while driving to her regular grocery store, which she has frequented for years. On examination, she has difficulty following a conversation, and signs of apraxia are present. There are no significant findings on routine laboratory tests, and an FDG-PET is ordered. Which finding in FDG-PET is most consistent with the diagnosis of this patient's condition? (Q851503)

A. Hypometabolism in the posterior temporal-parietal cortex

B. Cerebral atrophy

C. Widened third ventricle

D. Detection of amyloid depositions

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 75-year-old woman with moderate Alzheimer's disease has been on Donepezil for the past year. On routine follow-up, her cognitive abilities are declining further, and the physician decides to add another medication. Which treatment would be most appropriate to consider at this stage? (Q851504)

A. Rivastigmine

B. Memantine

C. Lecanemab

D. Galantamine

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following is NOT part of the clinical triad of Normal Pressure Hydrocephalus (NPH)? (Q851508)

A. Ataxia

B. Urinary incontinence

C. Dementia

D. Visual disturbances

See Answer in Part B → Q14

Q1: Which of the following is used to prevent delayed cererbral ischemia in aneurysmal bleeding? (Q851241)

A. Nifedipine

B. Amlodipine

C. Nimodipine

D. Felodipine

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 45-year-old male presents with poorly localized burning pain in the lower torso and legs. Then he noticed progressive weakness in both arms and legs over the past 3 months. On neurological examination, there is spasticity and hyperreflexia in both upper and lower limbs, with preserved perianal sensation. Which of the following is the most likely site of pathology? (Q851651)

A. Extradural compression

B. Intradural compression

C. Foramen magnum syndrome

D. Intramedullary compression

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A patient presented with complaints of radicular pain on the lower back associated with loss of sensations over sacrum and urinary incontinence. There was weakness, started over lower limbs one month back and now weakness is present over upper limbs. What is the ideal imaging of choice to diagnose this condition? (Q851650)

A. CECT

B. MRI

C. CT angiography

D. X-ray LS spine AP and lateral view

See Answer in Part B → Q3

@Neet_pg_bot

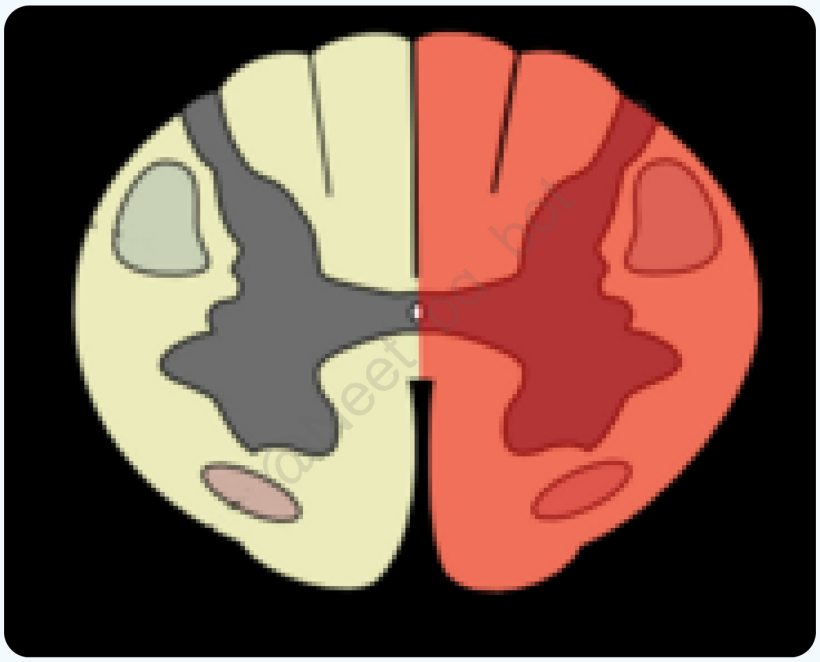
Q4: Which among the following is seen in this spinal cord lesion as shown below? (Q851253)

A. C/L loss of vibration sense below the level of lesion

B. C/L loss of thermal sensation at and above the same level

C. I/L loss of muscle tone at the level of lesion

D. C/L loss of pain 2 segments above the level of lesion



See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 30 year old female presents with complaints of progressive weakness of lower limbs, numbness, difficulty walking and recent onset forgetfulness. On examination, bilateral loss of vibration sense is noted, bilateral ankle jerks are absent with bilateral babinski sign. Romberg sign is present with eyes closed. Peripheral blood smear done was normal. What is the most likely diagnosis? (Q851252)

A. Subacute combined demyelination of Spinal cord

B. Tabes dorsalis

C. Friedrich ataxia

D. Brown sequard syndrome

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 32-year-old woman presents with sudden symmetrical onset of both lower extremity weakness, numbness, and urinary retention. She reports a history of a respiratory tract infection two weeks ago. Neurological examination reveals reduced muscle strength and sensory loss below the mid-thoracic region, along with hyperreflexia. MRI of the spine shows a focal area of increased T2 signal in the thoracic spinal cord without evidence of compression. What is the most likely diagnosis? (Q851251)

A. Multiple sclerosis

B. Guillain-Barré syndrome

C. Transverse myelitis

D. Amyotrophic lateral sclerosis

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 55-year-old man presents with multiple episodes of involuntary urine passage in clothes, lower back pain and bilateral lower limb weakness. On examination, he has saddle anesthesia, intact knee jerks and absent ankle jerks. What is the most likely diagnosis? (Q851250)

A. Conus medullaris syndrome

B. Cauda Equina Syndrome

C. Transverse myelitis

D. Spinal shock

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following findings is least likely to be seen in cauda equina syndrome? (Q851249)

A. Back pain

B. Saddle anesthesia

C. Brisk bulbocavernosus reflex

D. Impotence

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following statements is wrong about conus medullaris syndrome? (Q851248)

A. Loss of anal reflex

B. Urinary incontinence

C. Bilateral saddle anesthesia

D. Priapism

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45-year-old woman presents with progressive weakness and sensory loss in her arms, along with muscle wasting in her hands. MRI reveals a large intramedullary spinal cord tumor, with an associated syrinx. What is the management? (Q851247)

A. Tumor resection

B. Radiation therapy

C. Chemotherapy

D. Decompression

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following statements about syringomyelia is wrong? (Q851246)

A. A developmental cavity in the cervical cord

B. Symptoms begin in adolescence or early adulthood

C. The majority linked with Chiari type 2 malformation

D. Sensory loss in a cape distribution

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which gene mutation is primarily associated with hyperkalemic periodic paralysis? (Q851231)

A. KCNJ2

B. CACNA1S

C. SCN4A

D. RYR1

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 52-year-old woman presents with a sudden, severe "thunderclap" headache followed by brief loss of consciousness. NCCT head reveals blood in the basal cisterns. CT angiography shows a ruptured anterior communicating artery aneurysm. She is alert and oriented (Hunt and Hess grade II). BP on admission is 160/100 mm Hg. Which of the following is the most appropriate definitive treatment to prevent rebleeding in this patient? (Q851240)

A. Administration of nimodipine to prevent vasospasm

B. Strict blood pressure control with IV labetalol

C. Surgical clipping of the aneurysm

D. Endovascular coiling of the aneurysm

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 45-year-old patient presents to the ER with a sudden headache described as the "worst headache of their life." A non-contrast head CT is normal. Despite this, the suspicion of subarachnoid hemorrhage remains high. What is the most appropriate next step in the evaluation of this patient? (Q851239)

A. Repeat the head CT scan in 24 hours

B. Lumbar puncture to assess for xanthochromia

C. Immediate cerebral angiography

D. Perform a Time-of-Flight Magnetic Resonance Angiography (TOF-MRA)

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 26-year-old woman is brought to the emergency department with sudden-onset severe headache. On admission, her GCS is 12/15 and non-contrast CT head shows blood in the Sylvian fissure. On day 4 of hospitalization, she becomes increasingly drowsy and develops slow speech. Repeat CT reveals no new hemorrhage or infarct. She has polyuria, and her serum sodium is 125 mEq/L. On examination, she appears dehydrated. What is the most likely cause of her clinical deterioration? (Q851238)

A. Rebleeding from the aneurysm

B. Spasm of feeder vessel

C. Delayed cerebral ischemia

D. Cerebral salt-wasting syndrome

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 45-year-old woman presents with a sudden onset severe headache for past 6 hours and nuchal rigidity. CTA shows berry aneurysm at posterior communicating artery. Which of the following clinical features is most likely associated with this scenario? (Q851237)

A. 6th cranial nerve palsy

B. Visual field defects

C. 3rd cranial nerve palsy

D. Occipital pain

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 25-year-old female presents to the ER with a sudden onset of severe headache with prostration. On examination, BP 180/100 mm Hg and nuchal rigidity is noted. The NCCT head shows blood in the Sylvian fissure. Which is the next best step in the management of this patient? (Q851236)

A. Lowering of BP

B. Cerebral angiography

C. Nimodipine

D. Mannitol

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following is correct about Anderson Tawil syndrome? (Q851235)

A. Sodium channelopathy affecting the cardiac conduction system

B. Potassium channelopathy affecting skeletal muscle and cardiac conduction

C. Calcium channelopathy affecting cardiac muscle

D. Abnormal chloride transport in skeletal and cardiac muscle

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 19-year-old male presents to the emergency department with a sudden onset of generalized muscle weakness, particularly in his legs, after a day of strenuous exercise followed by a high-carbohydrate meal. He reports experiencing similar episodes of muscle weakness in the past, often triggered by exercise or large meals. What is the most appropriate first-line treatment for this patient's acute presentation? (Q851234)

A. Oral potassium supplementation

B. Intravenous potassium

C. Acetazolamide

D. Beta-blockers

See Answer in Part B → Q19

@Neet_pg_bot

Q20: An 18-year-old male presents to the emergency department with a sudden onset of severe muscle weakness, primarily in his legs, which started a few hours after consuming a large, carbohydrate-heavy meal following exercise. He reports similar episodes in the past, often triggered by large meals or after rest following physical activity. His vital signs are stable, and he has no respiratory involvement. Blood work reveals a serum potassium level of 2.3 mEq/L. What is the most likely underlying mechanism for this patient's condition? (Q851233)

A. Sodium channel dysfunction causing an inability to generate action potentials

B. Potassium channel dysfunction leading to excessive potassium loss

C. Calcium or sodium channel mutations causing abnormal potassium influx into cells

D. Excessive release of acetylcholine at the neuromuscular junction

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 23-year-old male presents to the clinic with complaints of muscle stiffness, especially in his face and hands, following exposure to cold weather. He reports that his symptoms worsen with repeated movements and improve with rest. Upon examination, his muscles are stiff but not weak. His symptoms do not improve with warming. What is the most likely diagnosis? (Q851232)

A. Myotonic Dystrophy

B. Paramyotonia Congenita

C. Hypokalemic Periodic Paralysis

D. Becker Muscular Dystrophy

See Answer in Part B → Q21

@Neet_pg_bot

• [07_Neurology] 053 Myasthenia Gravis

« Back to Folder Directory

[07_Neurology] 053 Myasthenia Gravis — Quick Jump

Q1 (p. 636) *Q2 (p. 636)* *Q3 (p. 637)* *Q4 (p. 637)* *Q5 (p. 638)* *Q6 (p. 638)*
Q7 (p. 638) *Q8 (p. 639)* *Q9 (p. 639)* *Q10 (p. 640)*

Q1: A 45-year-old woman presents with fluctuating muscle weakness that worsens with repetitive activity and improves with rest. She also reports more pronounced symptoms in the evening. Neurological examination shows normal deep tendon reflexes. Workup reveals positive anti-MuSK antibodies and negative anti-acetylcholine receptor (AChR) antibodies. Which of the following best describes the underlying mechanism of her condition? (Q851549)

A. T-cell mediated destruction of anterior horn cells

B. Autoantibodies disrupt clustering of acetylcholine receptors

C. Disruption of post synaptic voltage-gated calcium channels

D. Inhibition of acetylcholine release from synaptic vesicles

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 35-year-old woman presents with fluctuating muscle weakness, especially affecting her speech and swallowing. Repetitive nerve stimulation shows a decremental response. Her blood tests are negative for acetylcholine receptor (AChR) antibodies. Which of the following antibodies is most likely responsible for her symptoms? (Q851550)

A. Anti-dsDNA antibodies

B. Anti-MuSK antibodies

C. Anti-TPO antibodies

D. Anti-Ro antibodies

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 20-year-old woman who is known case of myasthenia gravis presents to the clinic with worsening symptoms, including difficulty in lifting her arms and shortness of breath. On examination, you notice that her eyelids are drooping, and she has double vision. What is the most significant risk associated with her current condition if not addressed promptly? (Q851551)

A. Impaired vision

B. Aspiration due to swallowing difficulties

C. Respiratory failure

D. Muscle atrophy

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 28-year-old woman presents to the ER with acute muscle weakness, double vision, and difficulty swallowing. He has a history of myasthenia gravis and has been experiencing increased fatigue over the past few days. Which of the following clinical features would best help differentiate a myasthenic crisis from a cholinergic crisis? (Q851552)

A. Muscle fasciculations

B. Small pupils

C. Response to edrophonium

D. Pallor and sweating

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 40-year-old female presents with symptoms of fluctuating double vision and drooping eyelids that worsen through the day. On neuro-examination DTRs are normal and power of all muscle groups except ocular muscles is normal. Blood tests confirms the presence of Anti-MuSK antibody. What is the most appropriate management strategy for this patient? (Q851553)

A. Initiate high-dose corticosteroids as the first-line treatment

B. Recommend immediate thymectomy regardless of symptom severity

C. Start anticholinesterase medications and consider immunosuppressants if symptoms persist

D. Advise the patient to undergo regular monitoring without any treatment

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 45-year-old woman presents with fluctuating muscle weakness, particularly affecting her eyelids and causing double vision. She also has difficulty in swallowing and develops dysarthria after speaking continously for few minutes. Which of the following diagnostic tests would confirm the suspicion of Myasthenia Gravis? (Q851554)

A. Single Fiber EMG showing increased Jitter

B. Nerve conduction velocity showing slowed conduction of impulses

C. Ice pack test

D. Tensilon test

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 28-year-old woman presents with diplopia that develops daily in evening hours along with difficulty in swallowing. On examination left eye ptosis is noted. Ice pack test shows improvement in ptosis. Repetitive nerve stimulation shows a decremental

response. The report of antibody panel is awaited. Which of the following will not be useful in management of this patient? (Q851556)

A. Physostigmine

B. Plasma Exchange

C. Pyridostigmine

D. Intravenous immunoglobulin

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old man known case of myasthenia gravis presents to the emergency department with severe muscle weakness and respiratory distress. On examination he is using accessory muscles of respiration, spO2 on room air is 85% and he cannot speak full sentences. ABG shows pH: 7.2, pC02 50 mm Hg and HCO3= 27 meq/L. Which of the following treatments is most appropriate for immediate management of this patient's condition? (Q851557)

A. IVIg

B. Endotracheal intubation and IVIg

C. High flow nasal cannula and IVIg

D. Plasma exchange (PLEX)

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 60-year-old man presents with progressive muscle weakness, dry mouth, and absent tendon reflexes. He has a history of smoking. Electrophysiological testing reveals post-tetanic potentiation of motor response to nerve stimulation at a frequency of 20–50/sec. Which of the following treatments is most appropriate for this patient? (Q851558)

A. Corticosteroids

B. 3,4-Diaminopyridine

C. Azathioprine

D. Intravenous immunoglobulin (IVIg)

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 50-year-old woman presents with arm weakness, diplopia, and ptosis. Strength improves with repeated activity, and deep tendon reflexes are absent. Repetitive nerve stimulation shows a decremental response at low frequency. Which of the following best explains the underlying defect? (Q851560)

A. Pre junctional defect affecting P/Q voltage gated calcium channels

B. Leading cause is thymic hyperplasia

C. Antibodies Target clustering of Ach receptors

D. Increased effficiency of neuromuscular transmission

See Answer in Part B → Q10

Q19 (p. 648)	*Q20 (p. 649)*				

Q1: Which of the following is not correct about neuromyelitis optica spectrum disorder? (Q851527)

A. Eye pain with eye movement

B. Longitudinally extensive transverse myelitis

C. Unilateral thinning of optic nerve

D. Afferent pupillary defect

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 45-year-old man presents with asymmetric muscle weakness in the arms and legs. Nerve conduction studies reveal focal demyelination with conduction block. Anti GM1 antibody is present. Which of the following conditions is most likely indicated by these findings? (Q851540)

A. Amyotrophic Lateral Sclerosis

B. Multifocal Motor Neuropathy with Conduction Block

C. Acute inflammatory demyelinating polyneuropathy

D. Charcot-Marie-Tooth Disease

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is not correct about Spinal muscular atrophy? (Q851539)

A. Cognitive milestones are delayed

B. Tongue fasiculations

C. Risdiplam increases the production of SMN protein

D. Respiratory infections

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old woman with Amyotrophic Lateral Sclerosis is experiencing significant difficulty swallowing . CXR shows evidence of bronchiectasis, Which treatment option is most appropriate for potentially extending survival? (Q851537)

A. Riluzole

B. Monthly broad spectrum antibiotics with N-acetlycystiene

C. Percutaneous Gastrostomy (PEG)

D. Tofersen

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 62-year-old man presents with left hand grip weakness for past one week with difficulty swallowing. On examination tongue fasiculations are present, depressed gag reflex with right leg showing spasticity with brisk knee and ankle jerks. His daughter tells that their grandfather also died due to some neurological illness. Which of the following tests will be least contributory for diagnosis of this patient? (Q851536)

A. Electromyography

B. Genetic testing

C. Spinal fluid analysis

D. Nerve conduction studies

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following signs or symptoms is not associated with Amyotrophic Lateral Sclerosis (ALS) ? (Q851535)

A. Fasciculations

B. Hoffman sign

C. Sensory loss

D. Muscle wasting

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 55-year-old man presents with progressive weakness in his limbs, accompanied by muscle wasting and dysarthria. Neurological examination reveals both upper and lower motor neuron signs. Based on the clinical features, which of the following conditions is the most likely diagnosis? (Q851533)

A. Progressive Muscular Atrophy

B. Progressive Lateral Sclerosis

C. Amyotrophic Lateral Sclerosis

D. Progressive Bulbar Palsy

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is not correct about Amyotrophic lateral sclerosis? (Q851532)

A. Bunina bodies

B. SOD1 gene mutations

C. Extraocular muscle weakness

D. Can coexist with Frontotemporal dementia

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following treatments will be used to manage acute attack of NMOSD? (Q851530)

A. Azathioprine

B. Plasmapheresis

C. Cyclophosphamide

D. Monoclonal antibodies

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 30-year-old female experiences bilateral vision loss and lower limb weakness. MRI of the spinal cord shows lesions spanning more than three vertebral segments. What is the most specific test for diagnosis? (Q851528)

A. Oligoclonal bands in CSF

B. AQP4-IgG antibody testing

C. Evoked potential studies

D. Brain MRI findings

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 28-year-old woman presents with subacute onset of blurry vision in one eye and painful eye movements. She reports tingling in both legs and occasional urinary urgency over the past few months. MRI brain shows periventricular white matter lesions perpendicular to the lateral ventricles. CSF shows oligoclonal bands. What is the most likely diagnosis? (Q851513)

A. Neuromyelitis optica

B. Acute disseminated encephalomyelitis

C. Multiple sclerosis

D. Neurosarcoidosis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: 30-year-old is diagnosed as case of Neuromyelitis optica. Which of the following cells of brain is damaged in this condition? (Q851525)

A. Neurons

B. Astrocytes

C. Oligodendrocytes

D. Microglia

See Answer in Part B → Q12

@Neet_pg_bot

Q13: 40 year old woman is diagnosed with autoimmune demyelinating astrocytopathy. Which of the following areas of brain are targetted by AQP4 antibodies seen in this condition? (Q851524)

A. Area postrema

B. Spinal cord

C. Circumventricular areas

D. All of the above

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 38-year-old African woman presents with four months of progressive bilateral visual loss and temporal headaches. Neurological examination reveals spastic paraplegia and brisk knee jerks and ankle jerks. Work up shows Anti- aquaporin-4 antibodies. Which of the following is not seen in this condition ? (Q851523)

A. Crossed hemiplegia

B. Diencephalic syndrome

C. Cloud like tumefactive lesions on MRI head

D. Intracranial hypertension

See Answer in Part B → Q14

@Neet_pg_bot

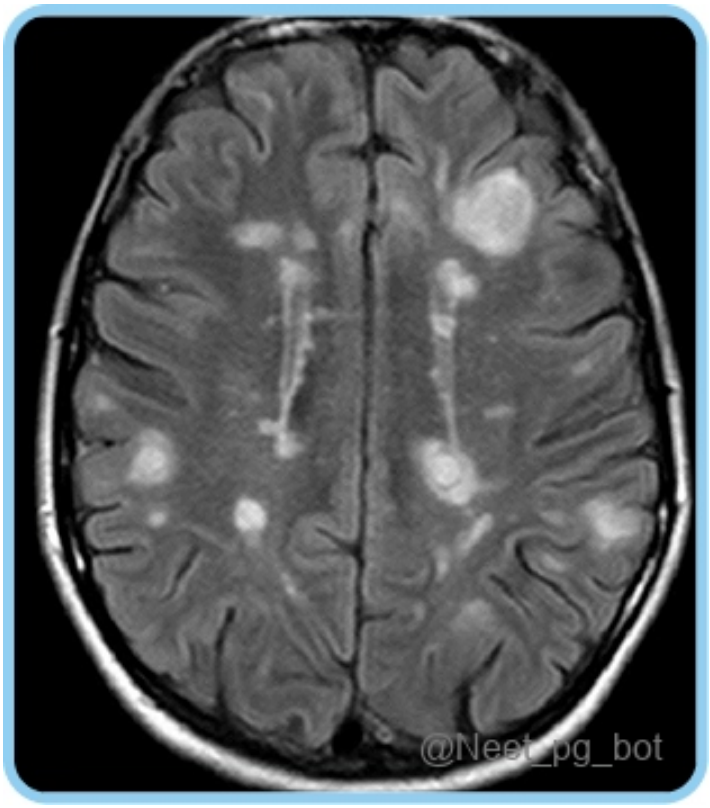
Q15: A 36-year-old caucasian woman on medical tourism visit presents with a history of recent onset left lower limb weakness, gait unsteadiness, and paresthesias. She experiences an electric shock sensation that radiates down her spine when flexing her neck. An MRI of the brain is given below. What is the most appropriate treatment for this patient's condition? (Q851522)

A. High-dose IV corticosteroids

B. Oral dimethyl fumarate

C. Ocrelizumab

D. Baclofen



See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 30-year-old woman presents with a 2-day history of acute, painful vision loss in her left eye, associated with a dull ache that worsens with eye movement. She also reports episodes of leg weakness, difficulty maintaining balance, and tingling sensations in her arms. Her medical history includes recurrent episodes of blurred vision and fatigue, particularly worsening in warm conditions. What is the diagnostic test of choice for this condition? (Q851521)

A. Visual evoked potential

B. Lumbar puncture

C. MRI of the brain and spinal cord

D. CSF electrophoresis for oligoclonal bands

See Answer in Part B → Q16

@Neet_pg_bot

Q17: What additional Mcdonald criteria are required for a diagnosis of Multiple Sclerosis in patient with 2 or more attacks and clinical evidence of 2 or more lesions? (Q851520)

A. None, dissemination in space and in time are met

B. Presence of enhancing and non-enhancing lesions on MRI

C. Presence of CSF oligoclonal bands

D. New T2 or enhancing MRI lesion compared to baseline

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following statements regarding one and a half syndrome in multiple sclerosis is not true? (Q851518)

A. It is characterized by ipsilateral horizontal gaze palsy

B. Limited adduction of the ipsilateral eye

C. The contralateral eye exhibits exotropia and abduction nystagmus.

D. Vertical gaze and convergence are impaired in this syndrome.

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 45-year-old woman who is a known case of multiple sclerosis has come for follow up consultation. On examination, the left eye has slowed adduction when

attempting to look to the right, and there is horizontal nystagmus in the right eye when it is abducting. Which of the following best explains the underlying pathology of this patient's symptoms? (Q851516)

A. Lesion in the right sixth cranial nerve

B. Lesion in the left sixth cranial nerve

C. Lesion in the left medial longitudinal fasciculus

D. Lesion in the right medial longitudinal fasciculus

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 34-year-old woman with a known diagnosis of multiple sclerosis visited a sauna in her gym. After the visit her vision becomes blurry and her leg weakness worsened that she had to be assisted by gym staff to her house. This presentation is called? (Q851515)

A. Lhermitte's symptoms

B. Uthoff's symptoms

C. Ancillary symptoms

D. Internuclear oopthalmoplegia

See Answer in Part B → Q20

Q19 (p. 659)	*Q20 (p. 660)*	*Q21 (p. 660)*			

Q1: A 40-year-old woman reports experiencing recurrent headaches that last between 6 and 48 hours. She often feels fatigued and has mood changes before the headaches begin. According to the International Headache Society's criteria, which features are essential for diagnosing her condition as migraine? (Q851065)

A. Bilateral pricking pain with nausea

B. Unilateral pain with photophobia without nausea

C. Unilateral throbbing pain with phonophobia

D. Bilateral pain with photophobia and nausea

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 35-year-old woman presents with a 9-month history of frequent headaches occurring at least 3 times per week. She describes the pain as a dull, bilateral ache that feels like a tight band around her head. The headaches are often accompanied by neck tension, stress, and fatigue. Which of the following is the most appropriate first-line treatment for this patient's condition? (Q851075)

A. Amitriptyline, starting at 20 mg daily, with gradual increases as needed.

B. Combination of Ibuprofen 400 mg plus acetaminophen 1000 mg.

C. Aspirin and Botulinum toxin type A injections

D. Combination of massage therapy and acupuncture

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 58-year-old man presents with recurrent, sharp, electric shock-like pain on the right side of her face, affecting her jaw and cheek. The pain is triggered by light touch, such as brushing her teeth or shaving. She reports these episodes happening multiple times a day and lasting only a few seconds. Which of the following statements is TRUE regarding her condition? (Q851074)

A. The most likely diagnosis is glossopharyngeal neuralgia, as the pain is localized to the jaw and oral cavity and is triggered by chewing.

B. Most commonly caused by vascular compression of the trigeminal nerve, often by the superior cerebellar artery.

C. The primary treatment is surgical decompression of the glossopharyngeal nerve.

D. This patient's condition is most likely to involve the ophthalmic branch (V1) of the trigeminal nerve.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Match the following: 1. Naratriptan a) 5-HT1F Agonist 2. Lasmiditan b) Dopamine Receptor Antagonist 3. Rimegepant c) 5-HT1B/1D Agonist 4. Prochlorperazine d) CGRP Receptor Antagonist (Q851073)

A. 1-d, 2-c, 3-b, 4-a

B. 1-a, 2-c, 3-b, 4-d

C. 1-c, 2-a, 3-d, 4-b

D. 1-b, 2-d, 3-c, 4-a

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A patient with left-sided facial paralysis and arm weakness for the last eight hours. BP on admission is 160/100 mm Hg. Her CT head is normal. What is the next step in the management of this patient? (Q851072)

A. Monitor Blood pressure and neurology consult

B. IV labetalol

C. IV thrombolysis

D. Nimodipine

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 45-year-old male presents with a history of recurrent headaches. After a thorough evaluation, he is diagnosed with a headache that has a stinging character and characterized by the following features: Duration: 5-240 seconds Attacks: 3-200 attacks per day. Which of the following treatments is most appropriate for this condition? (Q851071)

A. High-flow oxygen

B. Sumatriptan

C. IV Lidocaine

D. Verapamil

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 70-year-old female presents with a 3-month history of new-onset headaches, scalp tenderness, and jaw claudication. She also reports significant fatigue and unintentional weight loss. Laboratory studies reveal an elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). What is the most appropriate next step in the management of this patient? (Q851070)

A. Start high-dose corticosteroids

B. Perform temporal artery biopsy

C. Initiate aspirin therapy

D. Refer for imaging studies of the carotid arteries

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Match the variants of Migraine in Column A with their characteristic clinical features in Column B: Column A Column B 1. Ophthalmoplegic Migraine A. Associated with blindness and scintillating scotomas 2. Cluster Headaches B. Retro-orbital pain in males 3. Retinal Migraine C. Associated with occulomotor palsy 4. Familial Hemiplegic Migraine D. Presents with hemiplegia and can be confused with stroke E. Diagnosis often involves neuroimaging to rule out cerebrovascular accidents (Q851069)

A. 1-C, 2-E, 3-A, 4-B

B. 1-C, 2-B, 3-A, 4-D

C. 1-B, 2-E, 3-C, 4-D

D. 1-B, 2-E, 3-A, 4-B

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 35-year-old man with a history of chronic migraines visits his physician to discuss treatment options. He is interested in triptans but has some health concerns that he wants to clarify. Which of the following is NOT a contraindication for triptans based on the provided information? (Q851068)

A. History of coronary artery disease

B. History of seasonal allergies

C. Wolff-Parkinson-White syndrome

D. Concurrent use with MAO inhibitors

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 28-year-old woman completes the MIDAS questionnaire during her follow-up for chronic migraines. Her headaches have significantly impacted her work and social life. What is the primary purpose of the MIDAS assessment? (Q851067)

A. To determine the specific medication needed for treatment.

B. To assess the frequency of headache attacks.

C. To evaluate headache-related disability and its impact on daily activities.

D. To classify the type of headache.

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 35-year-old obese NRI woman presents to her doctor with a history of frequent migraines. She reports experiencing about ten migraine attacks per month. Her father is a diabetic and underwent CABG recently. She says due to ill health of her father her symptoms tend to last upto 24 hours. Her recent lipid profile is deranged. Which of the following preventive treatments is most appropriate for this patient? (Q851066)

A. Rizatriptan

B. Fremanezumab

C. Propranolol

D. Rimegepant

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 17-year-old boy is brought to the ER after collapsing at a rave party. His friends report that he had been dancing intensely and suddenly developed a severe headache followed by a generalized tonic-clonic seizure. On arrival, he is unconscious with a BP of 180/100 mmHg. NCCT brain shows an hyperdensity in the basal ganglia region. Urine toxicology screen is positive for benzoylecgonine. Which of the following is the most likely cause of his presentation? (Q851054)

A. Acute hypertensive crisis due to pheochromocytoma

B. Intracranial aneurysm rupture

C. Cocaine-induced vasospasm and hypertension

D. Amphetamine-induced serotonin syndrome

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following types of headaches is not classified as a primary headache? (Q851064)

A. Tension-type headache

B. Medication overuse headache

C. Migraine

D. Cluster headache

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A newborn delivered by forceps has a high-pitched cry and bulging anterior fontanelle. The mother notes that the baby seems unusually irritable. Which of the following is the most appropriate initial diagnostic step and management? (Q851063)

A. CT head and surgical evacuation

B. USG skull and phenobarbitone

C. USG skull with phenytoin

D. X-ray skull and lamotrigine

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 75-year-old man with atrial fibrillation on warfarin presents with progressive confusion and unsteady gait over the past month. His wife reports he had a minor fall 6 weeks ago. On examination, he is confused, has mild right sided weakness. NCCT brain is given below. Which of the following is correct about this patient? (Q851062)

A. Arterial bleeding with craniotomy

B. Arterial bleeding with craniotomy and ligation of bleeder

C. Venous bleeding with craniotomy

D. Venous bleeding with burr hole surgery

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 25-year-old man presents to the emergency department after being struck in the temporal region during a hockey game. Initially conscious at the scene, he now presents with decreasing consciousness, right-sided pupillary dilation, and left hemiparesis. CT head shows a lentiform hyperdense lesion in the right temporal region with 12mm midline shift. Which of the following is most appropriate treatment of this patient? (Q851061)

A. Observe and monitor neurological status

B. Start mannitol and hyperventilate

C. Burr hole followed by craniotomy and ligation of the bleeder

D. Conservative management with anticonvulsants

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 75-year-old man on warfarin (INR 2.5) falls and hits his head. He is initially alert and oriented, but after 2 hours, becomes progressively drowsy and confused. His CT scan is given below. Which of the following is the most likely diagnosis? (Q851060)

A. Epidural hematoma

B. Subdural hematoma

C. Intraparenchymal hemorrhage

D. Subarachnoid hemorrhage

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 52-year-old man presents with headache, left-sided facial, arm, and leg weakness. His sensorium is fast deteriorating, and he is a known case of rheumatic heart disease on warfarin. His INR is 10. The NCCT head is given below. Which of the

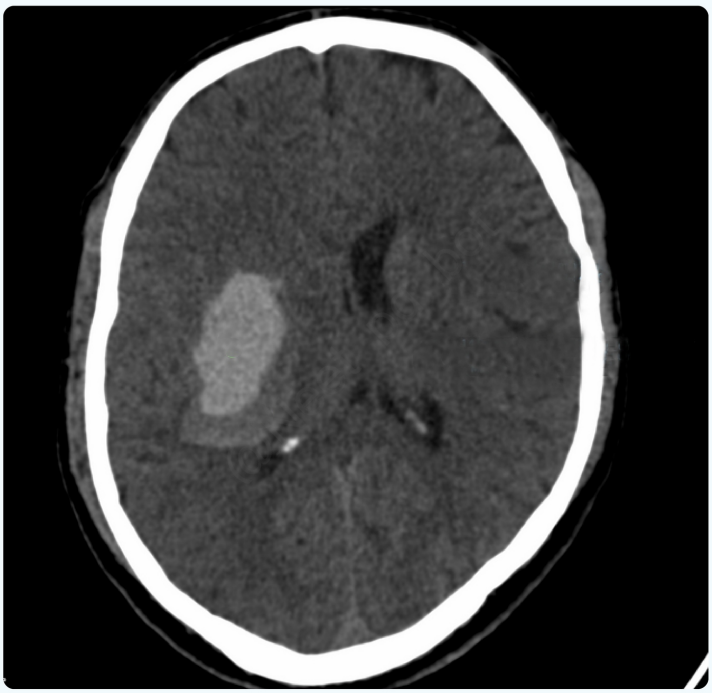
following is correct about his management? (Q851059)

A. Vitamin K 10mg IV only

B. Fast infusion of fresh frozen plasma

C. Fast infusion of fresh frozen plasma and urgent neurosurgery

D. 4-factor Prothrombin Complex Concentrate and Vitamin K 10mg IV



See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 50-year-old hypertensive man suddenly develops facial asymetry and right arm weakness during a meeting. His BP on arrival is 220/130 mmHg. CT shows putaminal hemorrhage. What is the most appropriate immediate management? (Q851058)

A. IV Mannitol

B. Immediate surgical evacuation

C. Nicardipine to achieve target BP of 140/90 mm Hg or lesser

D. Sodium nitroprusside to achieve target BP of 140/90 mm Hg or lesser

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 65-year-old hypertensive male presents with sudden onset weakness of right face and arm, along with difficulty speaking. He is unable to form words properly but appears to understand commands. Brain imaging shows an acute infarct. Which division of the MCA is most likely involved? (Q851057)

A. Superior division of left MCA

B. Inferior division of left MCA

C. Main trunk of left MCA

D. Penentrating branches of lenticulostriate artery

See Answer in Part B → Q20

@Neet_pg_bot

Q21: An 82-year-old normotensive, non-diabetic man presents with sudden onset confusion and headache. MRI shows multiple lobar hemorrhages. Which is the MOST likely diagnosis? (Q851055)

A. Cerebral amyloid angiopathy

B. Berry aneurysm rupture

C. Hypertensive crisis

D. Venous sinus thrombosis

See Answer in Part B → Q21

Q19 (p. 670)

Q1: A 60-year-old man presents with a 1-year history of progressive unsteadiness while walking, slurred speech, and frequent falls. He also reports urinary urgency and mild orthostatic dizziness. Neurological examination reveals cerebellar signs including dysmetria and truncal ataxia. MRI is shown below. Which of the following is the most likely diagnosis? (Q851452)

A. Parkinson disease

B. Progressive supranuclear gaze palsy

C. Multi-system atrophy

D. Spinocerebellar ataxia

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following pathological features is seen in Frontotemporal dementia? (Q851470)

A. α-synuclein-positive Lewy bodies

B. β-amyloid plaques and neurofibrillary tangles

C. Tau-positive neuronal inclusions

D. Prion protein accumulation in the brain

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 70-year-old man with advanced Parkinson's disease is considered for deep brain stimulation after experiencing significant motor fluctuations and dyskinesias despite optimal medication therapy. Which of the following brain structures is most commonly targeted in DBS to improve tremor, bradykinesia, and rigidity? (Q851468)

A. Ventral Intermediate Nucleus of the Thalamus

B. Subthalamic Nucleus

C. Globus Pallidus Internus

D. Caudate Nucleus

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is correct about istradefylline? (Q851467)

A. COMT inhibitor

B. Anticholinergic drug

C. Adenosine A2A receptor antagonists

D. Dopamine agonists

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 65-year-old man with Parkinson's disease is currently on levodopa with carbidopa but is experiencing significant motor fluctuations and "wearing off" between doses. His neurologist is considering adding a medication to improve his overall motor function. Which of the following is a commonly used dopamine agonist that could be added to his treatment regimen? (Q851465)

A. Apomorphine

B. Selegiline

C. Entacapone

D. Trihexyphenidyl

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 70-year-old man with a diagnosis of Parkinson's disease has been experiencing increased motor fluctuations despite being on a stable dose of levodopa for the past two years. He reports that his symptoms improve shortly after taking his medication but then return before his next dose is due. The physician considers adding a medication to help extend the effect of his current treatment. Which of the following is the most appropriate addition to his regimen? (Q851463)

A. Dopamine agonist

B. COMT inhibitor

C. Anticholinergic agent

D. Beta blocker

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 68-year-old woman presents with a 1-year history of progressive difficulty controlling her right arm. She reports that her arm occasionally moves on its own, and she has trouble performing simple tasks like buttoning her shirt. On examination, she has dystonic posturing of the right hand, mild bradykinesia, and intermittent myoclonic jerks. Her cognitive function appears intact except for mild apraxia. What is the most likely diagnosis? (Q851461)

A. Parkinson's disease

B. Corticobasal syndrome

C. Multiple system atrophy

D. Progressive supranuclear palsy

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 65-year-old man presents with his family, who report that over the past year, he has developed significant personality changes. He has become socially inappropriate, often acting impulsively and showing a lack of empathy. He also struggles to initiate tasks and frequently forgets appointments. On examination, his language production is impaired, though his comprehension remains intact. What is the most likely diagnosis? (Q851459)

A. Alzheimer's disease

B. Vascular dementia

C. Frontotemporal dementia

D. Lewy body dementia

See Answer in Part B → Q8

@Neet_pg_bot

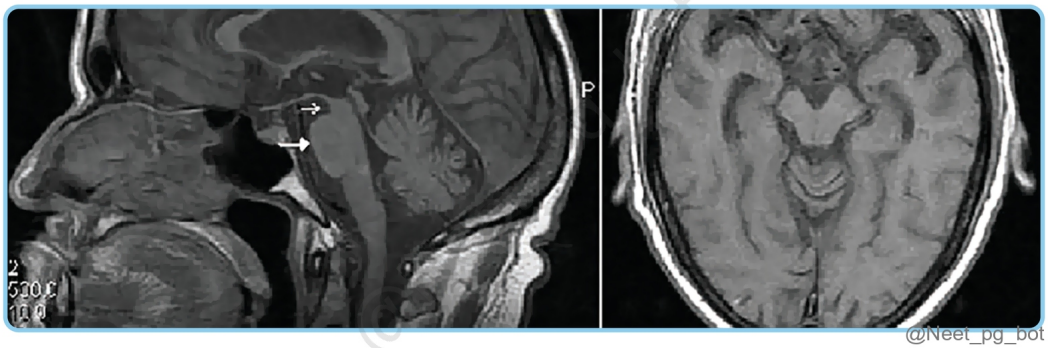
Q9: A 65-year-old male presents with frequent, unexplained falls. On examination, impaired downward gaze, neck hyperextension, and square wave jerks in his eye movements are present. MRI head is shown below. Diagnosis is? (Q851456)

A. Multiple system atrophy (MSA)

B. Progressive supranuclear gaze palsy (PSP)

C. Huntington chorea disease (HD)

D. Parkinson disease (PD)



@Neet_pg_bot

See Answer in Part B → Q9

@Neet_pg_bot

Q10: 60 year old man with multiple system atrophy is having dizzy spells and tilt table test is positive. MRI head is shown below. Which of the following is most appropriate treatment for this case? (Q851454)

A. Tertrabenazine

B. Levodopa plus Carbidopa

C. Midodrine

D. Hydrocortisone

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is a must have criteria for diagnosis of Parkinson disease ? (Q851349)

A. Bradykinesia

B. Cog wheel rigidity

C. Postural instability

D. Tremors that worsen with goal directed activity

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is not correct about managment of Parkinson disease? (Q851451)

A. Rotigotine is ergot derived D2 receptor agonist

B. Entacapone reduces wearing off phenomenon with levodopa

C. Amantadine reduces levodopa induced peak dose dyskinesias

D. Istradefylline is adjunct to levodopa to reduce off time

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which gene is responsible for development of juvenile-onset Parkinson's disease? (Q851416)

A. PARK-GBA

B. PARK-LRRK2

C. PARK-Parkin

D. All of the above

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following is not a clinical feature of atypical parkinsonism? (Q851415)

A. Slow ocular saccades

B. Resting pill rolling tremor

C. Early gait impairment

D. Poor response to Levodopa

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 15-year-old boy is brought by his parents due to involuntary movements of his hands, behavioral changes such as irritability and poor concentration affecting school performance and attendance. On examination, choreiform movements in hands are noted along with pallor. Work up shows elevated transaminases and increased PT and urine examination showing proteinuria and glucosuria. Which of the following is first differential diagnosis for this patient? (Q851414)

A. Wilson's Disease

B. Sydenham Chorea

C. Huntington's Disease

D. Spinocerebellar Ataxia

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following medications is least likely to contribute to the development of drug induced parkinsonism? (Q851412)

A. Haloperidol

B. Risperidone

C. Domperidone

D. Metoclopramide

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 68-year-old man presents with difficulty in initiating movements like getting out of a chair or toilet seat . He experiences a resting tremor in his right hand and has noticed a decline in his balance, leading to several near falls. His Family members

notice that he does not do activitites that he once liked. He is at risk of developing all of the following except? (Q851409)

A. REM sleep disorders

B. Decreased sweating

C. Restless leg syndrome

D. Urinary urgency

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following indicates that patient is having atypical parkinsonism? (Q851400)

A. Tremors that disappear on goal-directed activity

B. Recurrent falls due to downward gaze palsy

C. Pill rolling tremors with low frequency

D. Bradykinesia

See Answer in Part B → Q18

@Neet_pg_bot

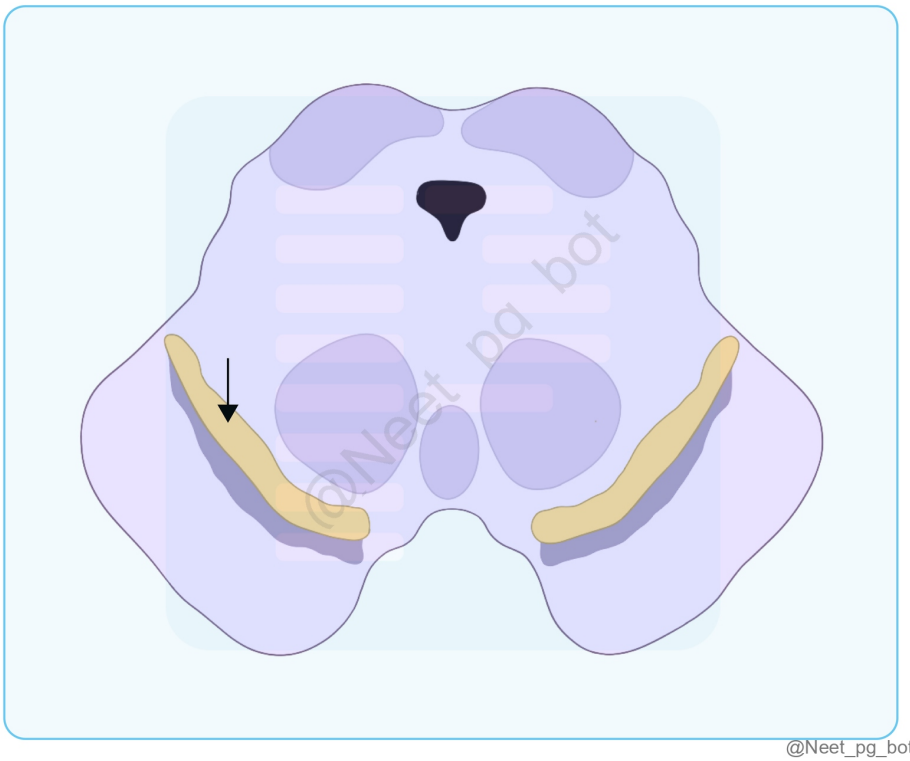
Q19: Involvement of the marked area of brain will result in which of the following disease? (Q851350)

A. Weber syndrome

B. Parkinson disease

C. Nonthangel syndrome

D. Perinaud syndrome



See Answer in Part B → Q19

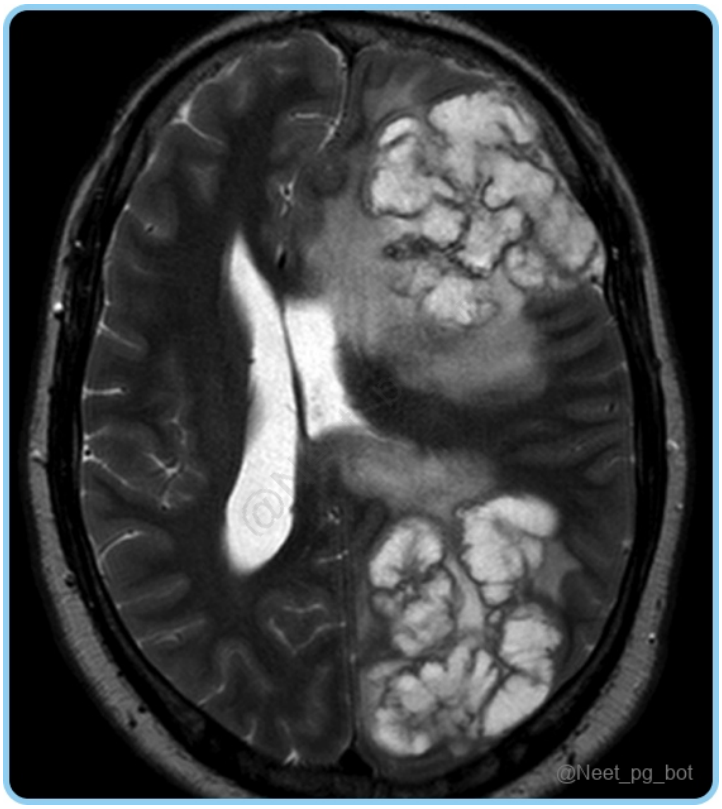
Q1: A 32 year old HIV-positive truck driver presents with fever, headache and drowsiness. Lumbar puncture is performed, and CSF shows elevated opening pressure with 20 lymphocytes /cu.mm with low sugar and protein of 60 mg/dl. MRI of the brain is shown below. Which of the following is the most likely diagnosis? (Q851546)

A. Tuberculous meningitis

B. Cryptococcal meningitis

C. Cytomegalovirus encephalitis

D. Toxoplasmosis



See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 65-year-old male presents with a gradually progressive cognitive decline over recent months and episodic, irregular jerky movements, with an EEG finding shown below. What is the most likely underlying diagnosis? (Q890931)

A. Subacute sclerosing panencephalitis

B. Progressive multifocal leukoencephalopathy

C. Creutzfeldt-Jakob disease

D. Neurosyphilis

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following findings would you not expect to see in a patient's CSF analysis with Herpes simplex virus encephalitis? (Q890929)

A. Elevated protein levels

B. Mild to moderate lymphocytic pleocytosis

C. Elevated red blood cell count

D. Profoundly decreased glucose

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 42-year-old male is brought to the emergency department with a 2-day history of high fever, confusion, and new-onset focal seizures preceded by the smell of burning rubber. Cerebrospinal fluid polymerase chain reaction is positive for a double-stranded DNA virus. MRI of the brain is most likely to reveal abnormal

hyperintensities in which of the following areas? (Q890928)

A. Bilateral cerebellar hemispheres

B. Temporal lobe

C. Basal ganglia and thalami

D. Parieto-occipital cortex

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45-year-old male with a history of untreated HIV infection presents with a 4-week history of progressively worsening headache, low-grade fever, night sweats, and recent-onset double vision. MRI of the brain reveals hydrocephalus and abnormal enhancements of the basal cisterns. Which of the following CSF profiles is most consistent with this patient's likely diagnosis? (Q890925)

A. Neutrophilic pleocytosis, low glucose, markedly elevated protein

B. Lymphocytic pleocytosis, low glucose, markedly elevated protein

C. Lymphocytic pleocytosis, normal glucose, normal protein

D. Monocytic pleocytosis, normal glucose, markedly elevated protein

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is the most appropriate empirical treatment for a suspected case of meningococcal meningitis? (Q890923)

A. Intravenous Penicillin G

B. Intravenous Ceftriaxone and Vancomycin

C. Oral Ciprofloxacin

D. Intravenous Cefotetan

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 26-year-old pregnant woman in her second trimester presents to the emergency department with a 2-day history of high-grade fever, severe headache, and vomiting. She recently attended a crowded indoor school gathering. On examination, she exhibits marked neck stiffness and a rapidly spreading petechial rash over her trunk and lower extremities. Which of the following statements is false regarding the disease she is most likely suffering from? (Q890919)

A. Deficiency of C5-C9 components significantly increases the risk of this infection.

B. Oral ciprofloxacin is the preferred agent for chemoprophylaxis in this patient.

C. Cultures typically become sterile within 24 hours of initiating appropriate therapy.

D. The causative organism is an aerobic, Gram-negative diplococcus.

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is the most frequently identified pathogen responsible for meningitis following the implantation of an indwelling central nervous system device? (Q890917)

A. Streptococcus pneumoniae

B. Coagulase-negative staphylococci

C. Pseudomonas aeruginosa

D. Group B streptococci

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 30-year-old previously healthy male presents with the acute triad of high-grade fever, severe headache, and neck stiffness. Examination reveals positive Kernig's and Brudzinski's signs. Which of the following is the most common cause of community-acquired bacterial meningitis? (Q890916)

A. Staphylococcus aureus

B. Neisseria meningitidis

C. Streptococcus pneumoniae

D. Listeria monocytogenes

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 30-year-old man from the village is admitted with high-grade fever and altered sensorium. On examination, bilateral Babinski and exaggerated ankle jerks were noted. Nuchal rigidity is absent. Workup shows Hb:7 gm%, TLC: 10K/cu.mm, platelet count: 1.5 Lac/cu.mm, elevated LDH, LFT is normal, and Serum creatinine is 1.5mg/dl. What is the best course of action for this patient? (Q851555)

A. LP followed by IV acyclovir

B. Peripheral smear followed by IV Artensunate

C. LP followed by IV Dexamethasone

D. Lateral flow assay followed by IV Sulphamethoxazole plus Trimethoprim

See Answer in Part B → Q10

@Neet_pg_bot

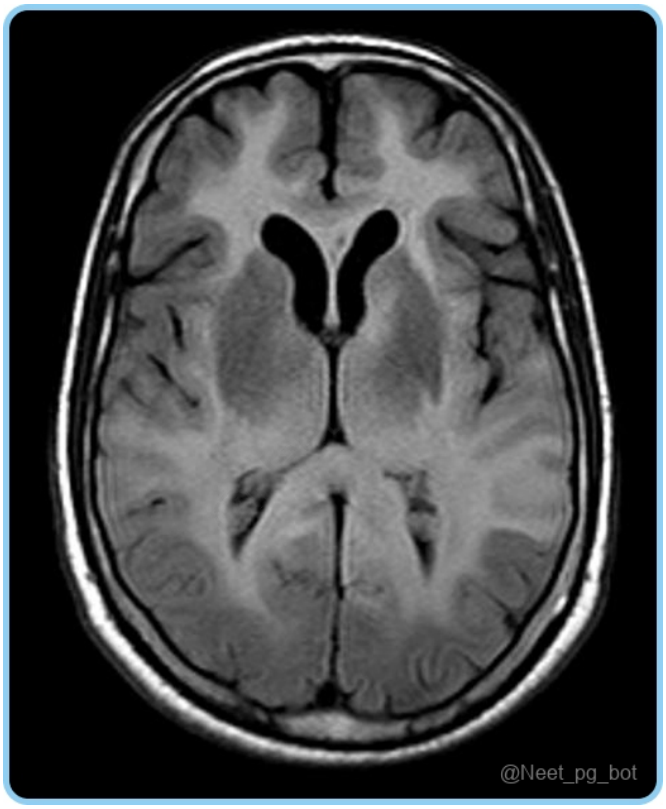
Q11: A 42■year■old HIV positive man with CD4 count 80 cells/mm³ presents with 3 weeks of visual blurring, weakness in right arm and dysarthria. MRI brain (FLAIR sequence) shows multiple asymmetric hyperintense lesions in the frontal and parietal white matter, with no mass effect and no contrast enhancement. Which of the following is the most likely cause? (Q851548)

A. JC virus

B. BK virus reactivation

C. Cerebral toxoplasmosis

D. CMV encephalitis



See Answer in Part B → Q11

@Neet_pg_bot

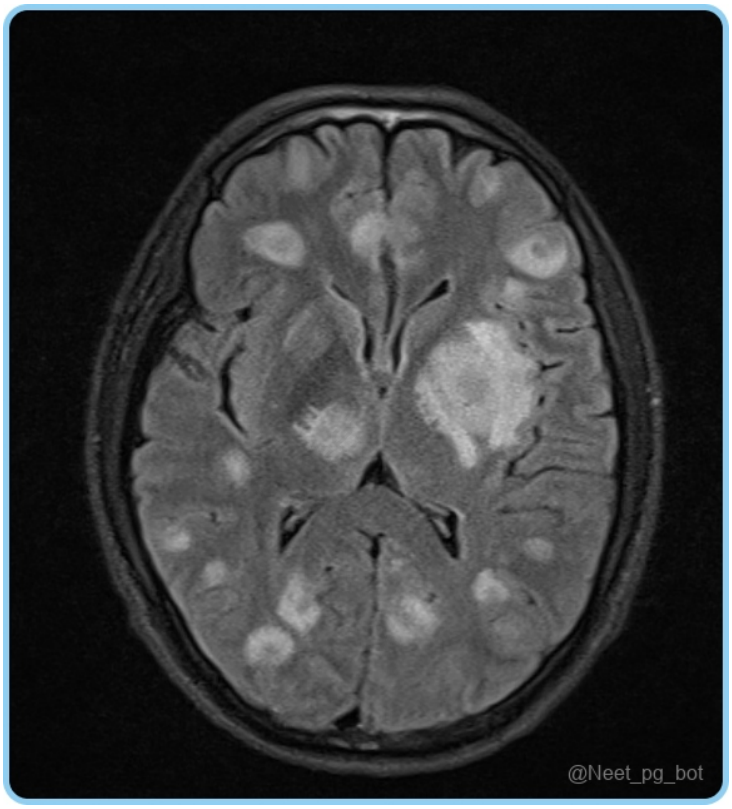
Q12: A 25 year old HIV positive man presents with complaints of a severe headache, fever, and confusion. His CD4+ T-cell count is 80 cells/μL. Neurological examination reveals right-sided hand weakness and difficulty speaking. An MRI of the patient is given below. Which of the following is the most appropriate next step in management? (Q851547)

A. Initiate treatment with sulfadiazine and pyrimethamine with leucovorin

B. Perform a brain biopsy to confirm the diagnosis.

C. Order a chest X-ray to rule out tuberculosis.

D. Start empiric treatment for bacterial meningitis.



See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 2-week-old infant presents with lethargy, poor feeding, irritability, and a bulging fontanelle. Born prematurely at 34 weeks with low birth weight, a lumbar puncture reveals cloudy cerebrospinal fluid (CSF) with high white blood cell count, decreased glucose, and elevated protein levels. Which is not a causative factor for this infant's condition? (Q851517)

A. Group B Streptococcus

B. Escherichia coli

C. Streptococcus pneumoniae

D. Listeria monocytogenes

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 34-year-old male HIV positive truck driver presents with severe headache. Examination shows nuchal rigidity and altered mental status. Lumbar puncture shows elevated opening pressure, low glucose, normal protein and encapsulated yeast on India ink staining. What is the most appropriate initial treatment? (Q851545)

A. Liposomal amphotericin B with High-dose IV fluconazole

B. Liposomal amphotericin B with capsofungin

C. Liposomal amphotericin B plus 5 Flucytosine

D. Oral corticosteroids plus broad-spectrum antibiotics

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 45 y/o patient presents with fever, headache, neck stiffness, and photophobia. On examination, the patient is lethargic and lumbar puncture reveals elevated CSF opening pressure, PMN leukocytosis, decreased glucose levels, and increased protein concentration. Which of the following will not be seen in this patient? (Q851544)

A. Woltman sign

B. Brudzinki sign

C. Jolt accentuation

D. Kernig sign

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 68 year old patient with diabetic nephropathy presents to the ER with fever, headache, and neck stiffness. Blood cultures are pending, and a lumbar puncture reveals elevated CSF protein, decreased glucose, and neutrophilic pleocytosis. Which

of the following is the most appropriate empirical antibiotic regimen? (Q851543)

A. Ceftriaxone and Vancomycin

B. Ceftriaxone and Gentamycin

C. Ampicillin + Ceftriaxone + Vancomycin

D. Meropenem and Vancomycin

See Answer in Part B → Q16

@Neet_pg_bot

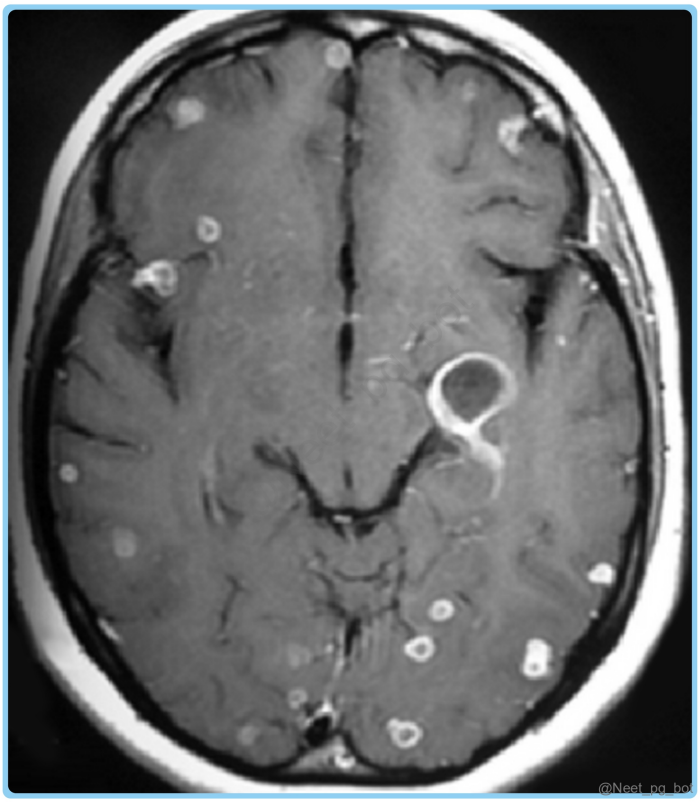
Q17: A 36 year old HIV positive patient presents with double vision, vomitting epsiodes with daily frontal headaches that dont respond to painkillers. Patient is not cooperative during physical examination due to headache. Fundus examination shows papilledema. Neuroimaging is performed. Which of the following is not correct about immediate management of this patient? (Q851542)

A. Lumbar puncture for CSF CBNAAT for MTB

B. Empirical ATT

C. IV dexamathasone

D. Mannitol



See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 38 year old man presented to ER with inability to stand and sit up in bed since yesterday evening. He reports that the weakness began as slipping in stairs multiple times in last 3 days along with tingling in his fingertips. Power in both legs at all joints is grade 2/5 and bilateral ankle jerks are absent. Which is not correct about this patient? (Q851541)

A. Electrodiagnostics show absent F waves

B. MRI shows spinal cord inflammation

C. Cytoabuminological dissociation

D. Bladder and Bowel are spared

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following is not required for management of Post dural puncture headache? (Q851538)

A. Intravenous caffeine

B. Low volume blood patch

C. Bladder catheterization and laxatives

D. Plenty of fluids

See Answer in Part B → Q19

@Neet_pg_bot

Q20: During a lumbar puncture, the needle passes through several anatomical layers before reaching the subarachnoid space. Which of the following is the correct sequence of structures pierced during this procedure? (Q851534)

A. Skin → Ligamentum flavum → Supraspinous ligament → Interspinous ligament → Dura → Arachnoid

B. Skin → Supraspinous ligament → Interspinous ligament → Ligamentum flavum → Arachnoid → Dura

C. Skin → Supraspinous ligament → Ligamentum flavum → Interspinous ligament → Dura → Arachnoid

D. Skin → Supraspinous ligament → Interspinous ligament → Ligamentum flavum → Dura → Arachnoid

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 45 y/o male with a history of HIV infection presents to the ED with headache, fever, photophobia, and neck stiffness. His CD4 count is 80 cells/mm³. Lumbar puncture reveals an elevated opening pressure, low glucose, and elevated protein levels. India ink staining of the cerebrospinal fluid showed the following picture. Which of the following is the most appropriate initial treatment regimen for this

patient? (Q851531)

A. Fluconazole monotherapy

B. Amphotericin B and Flucytosine

C. Voriconazole monotherapy

D. Caspofungin and Fluconazole

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 25 year old HIV positive male is brought to the emergency after developing high grade fever and altered sensorium for past 2 days. Meningeal signs are absent and bilateral babinski sign is noted. MRI head shows predominant temporal lobe inflammation. Which of the following is correct about immediate managment of this patient? (Q851529)

A. Start empirical Artesunate

B. Start Empirical acyclovir

C. Start empirical ATT plus dexamethasone

D. Start empirical Liposomal amphotericin B with 5 flucytosine

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following accurately describes the CSF findings in viral encephalitis caused by HSV-1? (Q851526)

A. Lymphocytic pleocytosis with low glucose levels

B. Lymphocytic pleocytosis with normal glucose levels

C. Lymphocytic pleocytosis with cob web coagulum

D. Lymphocytic pleocytosis with elevated glucose levels

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 45-year-old male presents to the emergency with fever, severe headache and confusion for last 3 days. Nuchal rigidity is present. Fundus is normal. CSF study shows 1000 cells with 10% lymphocytes and 90% PMN cells , CSF /plasma sugar 0.4 and CSF protein 80 mg/dl. What is the next best step in managment of this patient? (Q851519)

A. IV Cannula and start IV fluids at 20 ml per kg per hour

B. Empirical Ceftriaxone plus Vancomycin

C. Empirical ATT plus dexamethasone

D. NCCT head

See Answer in Part B → Q24

@Neet_pg_bot

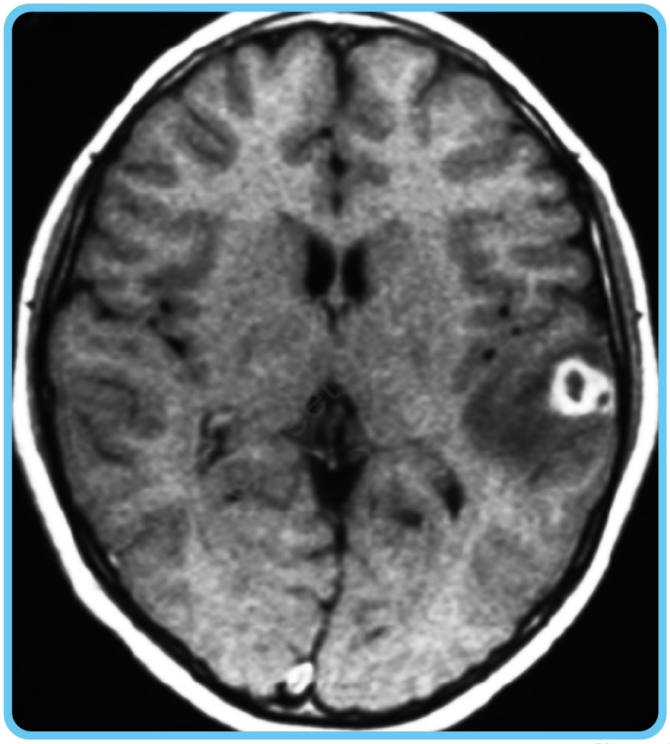
Q1: A 25 year rickshaw puller presents with daily headaches and multiple episodes of focal seizures. MRI head is shown below. Which of the following is first line intervention in this patient? (Q851450)

A. Albendazole

B. A.T.T

C. Dexamethasone

D. Albendazole and praziquental



See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 30 year old man presented with high grade fever, headache and vomitting for past 5 days. MRI head shows double rim sign in left temporal lobe . Guided aspiration from lesion shows gram positive filamentous bacteria stained with a positive modified ZN staining and paraffin bait technique. What is the likely organism causing this? (Q851514)

A. Mycobacterium Tuberculosis

B. Atypical mycobacteria

C. Actinomyces israelli

D. Nocardia

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is the most common brain tumour in childhood? (Q851512)

A. Pilocytic astrocytoma

B. Medulloblastoma

C. Ependymoma

D. Metastasis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Match the following syndromes with their most commonly seen brain tumours respectively. 1. Von Hippel Landau a) Bilateral vestibular schwannomas 2. Tuberous sclerosis b) Glioma 3. Neurofibromatosis 2 c) Hemangioblastoma of the cerebellum 4. Li Fraumeni Syndrome d) Subependymal giant cell astrocytoma (Q851511)

A. 1-c, 2-d, 3-a, 4-b

B. 1-b, 2-d, 3-c, 4-a

C. 1-d, 2-a, 3-b, 4-c

D. 1-b, 2-d, 3-a, 4-c

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 40 year old man with a known brain tumour has recently undergone radiation therapy. During a follow-up visit, his doctor ordered imaging studies to evaluate the tumour. The physician wants to determine whether the changes observed on the imaging are due to tumour progression or necrosis resulting from treatment. Which imaging technique can help differentiate between the two? (Q851510)

A. Computed Tomography

B. Gadolinium-enhanced Magnetic Resonance Imaging

C. MR Spectroscopy

D. PET CT

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 75-year-old male presents with recent onset frontal headache and seizures. Fundus reveals papilledema. MRI brain reveals a ring-enhancing lesion in the right frontal lobe with surrounding edema. MR Spectroscopy shows a high choline peak, low N-acetylaspartate (NAA), and elevated lipid-lactate peaks. Which of the following is the most likely diagnosis? (Q851509)

A. Tuberculoma

B. Neurocysticercosis

C. Brain tumor

D. Brain abscess

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Identify the correct statements on CNS tumours Calcifications are found in Meningioma and Oligodendroglioma Craniopharyngioma are present as suprasellar mass Giant cell Astrocytoma and Ependymoma occur as Intraventricular tumours Metastatic lesions occur at white matter-gray matter junction (Q851507)

A. 1,2

B. 1,2,4

C. 1,2,3

D. 1,2,3,4

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is the most common primary malignant brain tumour in adults? (Q851506)

A. Meningioma

B. Glioma

C. Metastasis from oat cell cancer of lung

D. CNS Lymphoma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 30 year female presents with repeated episodes of GTCS since last 3 months. Neuroimaging is shown below. Which of the following treatment regimens is most appropriate? (Q851505)

A. Valproate

B. Praziquantel + Valproate

C. Steroids + Albendazole + Praziquantel

D. Steroids + Albendazole + Praziquental + Valproate

See Answer in Part B → Q9

@Neet_pg_bot

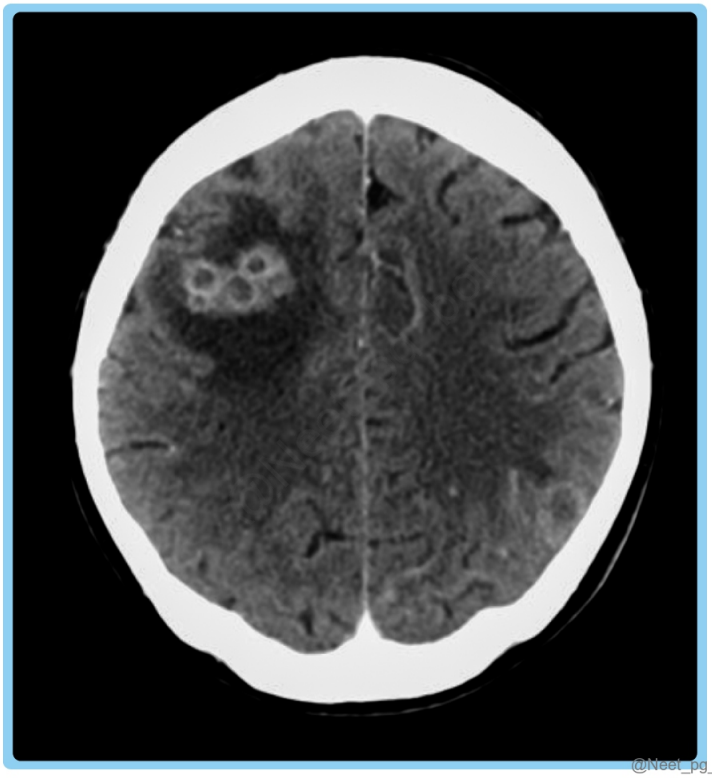
Q10: A 30-year-old man presents with progressive headaches, fever, weight loss, and left arm weakness over the past month. He remembers taking a long duration of antibiotic course for a respiratory illness in his childhood, but the specific details he is unable to recall. CT head is shown below. What is the most likely diagnosis? (Q851471)

A. Neurocysticercosis

B. Tuberculoma

C. Brain abscess

D. Metastasis



See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 28 year old female presents with recurrent headaches and occasional seizures. Neuroimaging is done. Which stage of development of parasite is shown below? (Q851458)

A. Vesicular Stage

B. Colloidal Stage

C. Granulonodular Stage

D. Calcified Stage

See Answer in Part B → Q11

@Neet_pg_bot

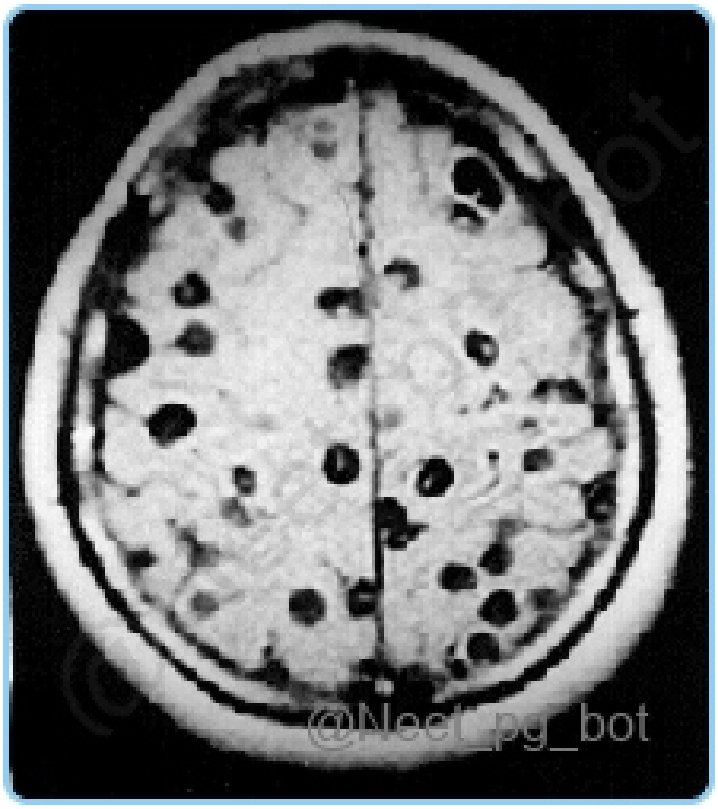
Q12: A 35 year old male presents with multiple episodes of GTCS and persistent headaches. Neuroimaging of patient is shown. Which of the following tests will help in confirmation of diagnosis of this patient? (Q851453)

A. PCR CBNAAT for MTB

B. Enzyme-Linked Immunotransfer Blot

C. Susceptibility-weighted imaging

D. Fundoscopic Exam



See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 50 year hypertensive man suddenly develops face, arm and leg weakness. Imaging confirms a large putaminal bleed. What type of brain herniation is most likely to occur in this case? (Q851296)

A. Subfalcine herniation

B. Foraminal herniation

C. Transtentorial herniation

D. Cingulate herniation

See Answer in Part B → Q13

@Neet_pg_bot

Q14: 32 year man presents with recurrent seizures. MRI brain shows multiple hypointense lesions with scolex. What is the most likely cause of his condition? 1. Consumption of semi cooked pork containing Cysticerci cellulosae 2. Feco-oral 3. Consumption of semi cooked beef containing Cysticercus bovis 4. Autoinfection (Q851369)

A. 1

B. 1,2

C. 2,4

D. 1,2,3,4

See Answer in Part B → Q14

@Neet_pg_bot

Q15: An elderly diabetic patient living alone is found unconscious and unresponsive by the maid. On admission, pulse is 100/min, BP =90/60 mm Hg. Workup shows RBS is 200 mg/dl, urine ketostix is 1+, pH =7.42, pC02= 40 mm Hg, HCO3= 26 meq, Na = 130 meq/L and K= 4.0 meq/L and procalcitonin and CRP is normal . Which is the next best step in management of this patient? (Q851367)

A. Start normal saline drip and urgent NCCT head

B. Start normal saline drip and insulin drip

C. Give 50 ml of 50% dextrose

D. Give bolus 10 units of regular insulin followed by insulin drip

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 50 year woman presents with seizure episode. She in ER she tells that she wakes up with daily early morning frontal headaches and vomiting. NCCT head shows intracranial space-occupying lesion in frontal lobe with dural tail sign. Which of the following cranial nerves is most likely to be involved in this patient? (Q851364)

A. I

B. II

C. III

D. IV

See Answer in Part B → Q16

@Neet_pg_bot

Q17: 38-year-old HIV-positive man presents with recurrent seizures and altered sensorium. MRI brain reveals multiple ring-enhancing lesions with perilesional edema in the basal ganglia and frontal lobe, showing the "concentric target" sign. What is the most likely cause of his seizures? (Q851338)

A. Cerebral toxoplasmosis

B. Primary CNS Lymphoma

C. Neurocysticercosis

D. Tuberculoma

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following is not a correct component in brain death evaluation? (Q851337)

A. Apnea test with pCO■ rise to ≥60 mmHg or ≥20 mmHg above baseline

B. Positive caloric stimulation test

C. Pupils are fixed and non reactive to light

D. Absence of blinking on touching cornea with wisp of cotton

See Answer in Part B → Q18

@Neet_pg_bot

Q19: 30-year-old biker is brought to the emergency room after a head injury. On examination, he is unconscious with an ipsilateral mid-dilated fixed pupil. NCCT head shows lenticular hyperdensity. Which of the following is the most likely cause and urgent next step? (Q851335)

A. Uncal herniation due to epidural hematoma; immediate burr hole surgery required

B. Cingulate herniation due to epidural hematoma; immediate burr hole surgery required

C. Cingulate herniation due to epidural hematoma; urgent craniotomy

D. Subdural hematoma causing contralateral pupil dilation; urgent craniotomy

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Adult patient involved in a high-speed road traffic accident had a normal CT scan on admission but died within 6 hours. Autopsy reveals petechial hemorrhages in the corpus callosum and retraction balls. The diagnosis is? (Q851333)

A. Diffuse axonal injury

B. SAH

C. SDH

D. EDH

See Answer in Part B → Q20

@Neet_pg_bot

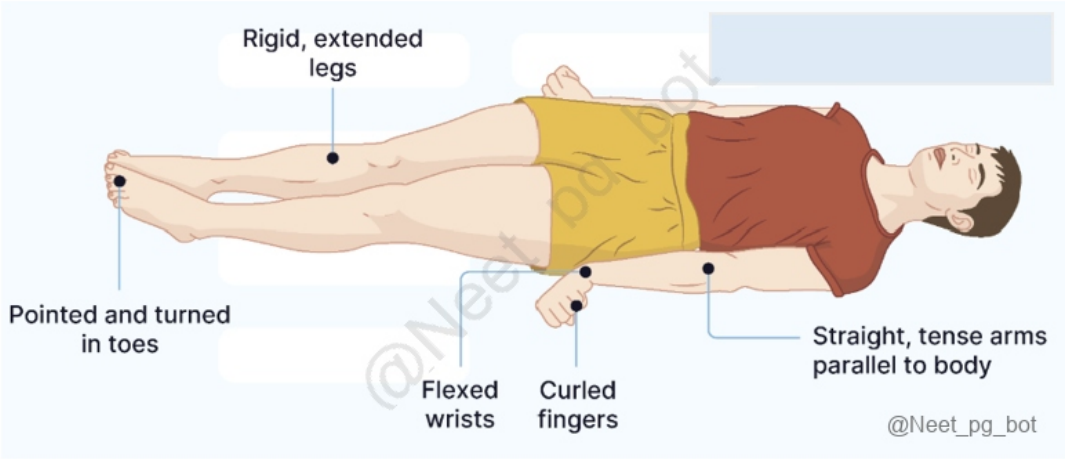
Q21: A patient diagnosed with TB meningitis develops posturing as shown in the diagram. Which of the following is correct about the cause of this presentation (Q851332)

A. Inhibition of the rubrospinal with overactivity of vestibulospinal and reticulospinal pathways

B. Stimulation of the rubrospinal tract with simultaneous facilitation of vestibulospinal and reticulospinal tracts

C. Intact or overactive rubrospinal tract with loss of extensor facilitation from vestibulospinal and reticulospinal tracts

D. Loss of rubrospinal tract activity with strong extensor inhibition from vestibulospinal and reticulospinal tracts



See Answer in Part B → Q21

@Neet_pg_bot

Q22: 60-year-old hypertensive man is brought to ER with sudden onset right-sided weakness and aphasia. His BP is 190/100 mmHg. CT scan done 1 hour after admission shows putaminal bleed and midline shift. Which of the following is not useful for management of this patient? (Q851331)

A. Ventriculostomy

B. Start IV dexamethasone

C. Mannitol

D. Labetalol

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 35 year old biker male is brought to the ED after a road traffic accident. He is unconscious with a GCS score of 9/15. Vitals are Pulse 60/min with BP: 160/100 mmHg and irregular respiration. What is the first step in managing of this patient? (Q851330)

A. Elective Hyperventilation

B. Administer mannitol

C. Elevate head end of bed and secure airway

D. Burr hole surgery

See Answer in Part B → Q23

@Neet_pg_bot

Q1: Where is the site of the lesion that leads to the occurrence of hemiballismus in a patient displaying forceful, flinging movements? (Q855718)

A. Putamen

B. Subthalamic nucleus

C. Caudate nucleus

D. Globus pallidus

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 45 year old male patient presented with a history of bilateral lower limb weakness which progressed to his upper limbs in a year. On examination, he had weakness in both lower limbs and wasting in the left upper limb. Babinski sign was positive and the deep tendon reflexes were absent. He has no sensory loss or any autonomic dysfunction. What is the likely diagnosis? (Q856621)

A. MS

B. ALS

C. GBS

D. Tropical spastic paraparesis

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following drugs is preferred in the management of primary progressive multiple sclerosis? (Q856612)

A. Natalizumab

B. Ocrelizumab

C. Fingolimod

D. Alemtuzumab

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Treatment of choice for an acute attack of cluster headache is: (Q856604)

A. Oral sumatriptan

B. Subcutaneous sumatriptan

C. 100% oxygen at 6 L/minute

D. 100% oxygen at 8 L/minute

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 50-year-old man presents with sudden right-sided weakness and aphasia for 2 hours. His blood pressure is 160/110 mmHg, and non-contrast CT of the brain is normal. To identify a possible large vessel occlusion, what is the next best step in management? (Q856595)

A. CT angiography

B. MRI to look for intact

C. Tab labetalol 10 mg stat

D. Thrombolysis

See Answer in Part B → Q5

@Neet_pg_bot

Q6: True about electroencephalogram (EEG) is all except: (Q855720)

A. 1-5% of the population can have epileptiform discharges

B. Scalp EEG may be helpful in localizing frontal lobe epilepsy

C. Doing EEG is mandatory for diagnosis of seizures

D. Progressive multifocal leukoencephalopathy shows triphasic and slow waves on EEG

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following does not show both hyperkinetic and hypokinetic movements? (Q855708)

A. Parkinson’s disease

B. Wilson’s disease

C. Neurodegeneration with brain iron accumulation

D. Huntington’s chorea

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is not a major diagnostic criterion for neuromyelitis optica? (Q855707)

A. Area postrema syndrome

B. Acute myelitis

C. Focal epilepsy

D. Optic neuritis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: What is the GCS of a patient with a head injury who opens her eyes in response to a loud voice, localizes pain and is confused and disoriented but can answer questions? (Q857650)

A. E3 M5 V4

B. E3 M6 V5

C. E4 M4 V5

D. E3 M5 V5

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 55-year-old woman is diagnosed with a slow-growing, well-circumscribed meningioma on MRI. She has mild headaches but no major neurological deficits. Histopathology confirms a WHO Grade I meningioma. What is the treatment of choice for this patient? (Q857040)

A. Reassurance

B. Surgical excision

C. Chemotherapy

D. Radiotherapy

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 20 year old male was brought for psychiatric evaluation for intellectual disability. On examination, his IQ was 45. He has a long face, large ears, large testis and a cardiac murmur and history of poor intellectual function is present in the paternal family. What is his diagnosis? (Q857039)

A. Cushing's syndrome

B. Rett syndrome

C. Fragile X syndrome

D. William syndrome

See Answer in Part B → Q11

@Neet_pg_bot

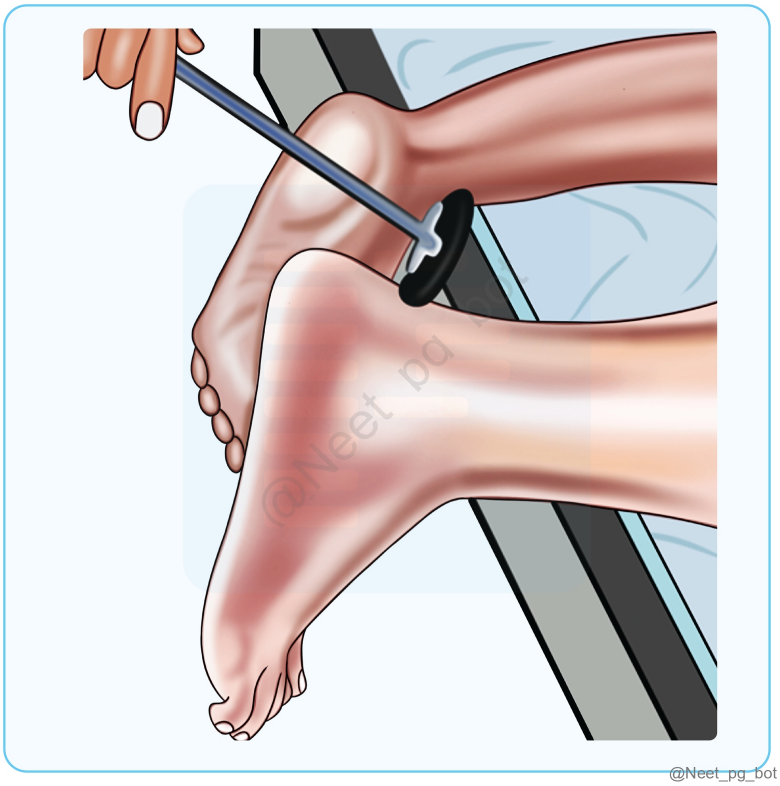
Q12: The following clinical examination was performed. What lesion would cause an exaggerated reflex? (Q855348)

A. Polyneuropathy

B. Radiculopathy

C. Upper motor neuron

D. Lower motor neuron



See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is not characteristic of Brown Sequard syndrome? (Q855338)

A. Complete transection of spinal cord

B. Ipsilateral loss of vibration & touch

C. Contralateral loss of pain & temperature

D. Ipsilateral loss of proprioception

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 37-year-old woman presents with headaches for 6 months. She has been taking analgesics regularly. The headache recently increased in severity for 3 days but was reduced by stopping the analgesic. What is the likely diagnosis? (Q856148)

A. Medication overuse headache

B. Tension headache

C. Chronic migraine

D. Cluster headache

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 50-year-old male patient presented with left-sided hemiparesis. Damage to which part of the internal capsule leads to this presentation? (Q855714)

A. Retrolentiform

B. Sublentiform

C. Anterior limb

D. Posterior limb

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Bell's palsy involves: (Q858357)

A. Ipsilateral upper and lower halves of the face

B. Contralateral upper and lower halves of the face

C. Ipsilateral lower half of the face

D. Contralateral lower half of the face

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A young male patient presents with ptosis and muscle weakness which reportedly worsens in the evening and improves in the morning. This is relieved by neostigmine. What is the likely diagnosis? (Q858354)

A. Myasthenia gravis

B. Huntington chorea

C. Amyotrophic lateral sclerosis

D. External ophthalmoplegia

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A young male patient presents with ptosis and muscle weakness which reportedly worsens in the evening and improves in the morning. This is relieved by neostigmine. What is the likely diagnosis? (Q858037)

A. Myasthenia gravis

B. Huntington chorea

C. Amyotrophic lateral sclerosis

D. External ophthalmoplegia

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A woman presents with a history of headaches for the past 9 months that worsen in a recumbent position and improves as the day progresses. She also gives a history of taking oral contraceptives. Fundal examination shows papilledema. There are no focal

neurological deficits. What is the probable cause of her headaches? (Q858028)

A. Myasthenia gravis

B. Temporal arteritis

C. Chronic migraine

D. Pseudotumor cerebri

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 26-year-old male with a history of respiratory tract infection 4 weeks ago is unable to stand or walk for the past 2 weeks and the weakness is progressive, ascending, and symmetrical in nature. The lower limbs were involved before and gradually the upper limbs were also affected. On examination you note areflexia. Pain and proprioception are preserved. Which of the following could be the diagnosis? (Q858017)

A. Guillain-Barré syndrome

B. Myasthenia gravis

C. Polymyositis

D. Multiple sclerosis

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A young patient presents with a severe headache. He has never experienced a headache of this severity before. He has hypertension and nuchal rigidity on examination. Which of the following could be the diagnosis? (Q858014)

A. Cluster headache

B. Subarachnoid haemorrhage

C. Encephalitis

D. Meningitis

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A patient presented with a fever for 11 days with neck rigidity. A lumbar puncture was done, and it showed predominantly lymphocytes, sugar- 50mg, and protein- 3000mg/dl. Cobweb coagulum was noted. Gram-staining was negative. The patient's chest X-ray shows upper lobe involvement with hilar lymph node enlargement. (Q858012)

A. Tuberculous meningitis

B. Bacterial meningitis

C. Fungal meningitis

D. Viral meningitis

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 78-year-old woman presents with a progressive decline in daily activity. She gives a history of convulsions and visual hallucinations. She does not talk to anyone and keeps looking at the sky. Pathological examination shows the presence of Lewy bodies within the neurons. What is the most probable diagnosis? (Q855496)

A. Parkinson's disease

B. Prion disease

C. Huntington's chorea

D. Alzheimer's disease

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A young female presents with ptosis showing diurnal variation. CT chest shows an anterior mediastinal mass identified as thymus gland cancer. Which receptor is affected in this patient? (Q866790)

A. Presynaptic ACh Receptor

B. Post-synaptic ACh Receptor

C. Voltage-gated calcium channels at the NMJ

D. Acetylcholinesterase

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A male patient presented to the emergency room with seizures. He has a history of fever, headache, and confusion. An MRI brain was done, and it showed inflammation involving the bitemporal lobe. What is the most likely etiology for this presentation? (Q855465)

A. Cytomegalovirus

B. Toxoplasma gondii

C. Herpes simplex virus

D. Mycobacterium tuberculosis

See Answer in Part B → Q25

@Neet_pg_bot

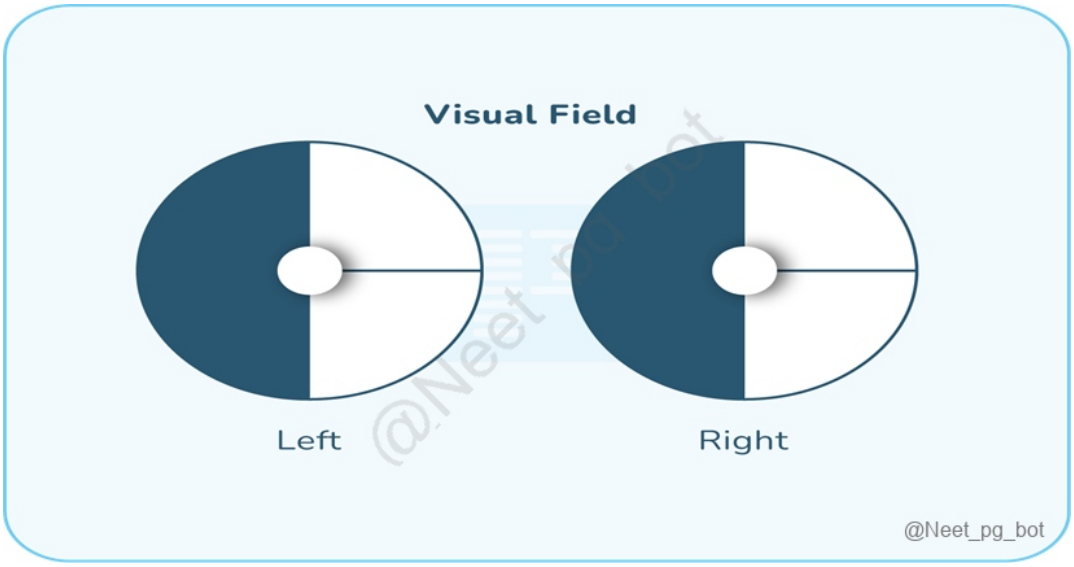
Q26: Visual field testing of a patient revealed the following type of loss. Where is the likely site of lesion in the optic pathway? (Q859569)

A. Frontal visual field

B. Occipital lobe

C. Optic radiation

D. Optic chiasma



See Answer in Part B → Q26

@Neet_pg_bot

Q27: A Patient presents with progressive back pain and weakness in both lower limbs. Which findings would support the diagnosis of compressive myelopathy? (Q879162)

A. Hypotonia

B. Absent Babinski sign

C. Knee clonus

D. Normal cremasteric reflex

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which one of the following drugs is NOT indicated in the management of status epilepticus? Valproate Ethosuximide Fosphenytoin Levetiracetam (Q879159)

A. 1, 2

B. 2, 3

C. 2, 4

D. 1, 3, 4

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A female patient presents to you with a unilateral headache. It is associated with nausea, photophobia, and phonophobia. What is the drug of choice for acute management? (Q855890)

A. Flunarizine

B. Sumatriptan

C. Propranolol

D. Topiramate

See Answer in Part B → Q29

@Neet_pg_bot

Q30: The cerebrospinal fluid (CSF) specimen of a patient is shown below, along with microscopy. The report shows mononuclear cytosis, elevated proteins, and low sugars. What is the likely etiology? (Q855849)

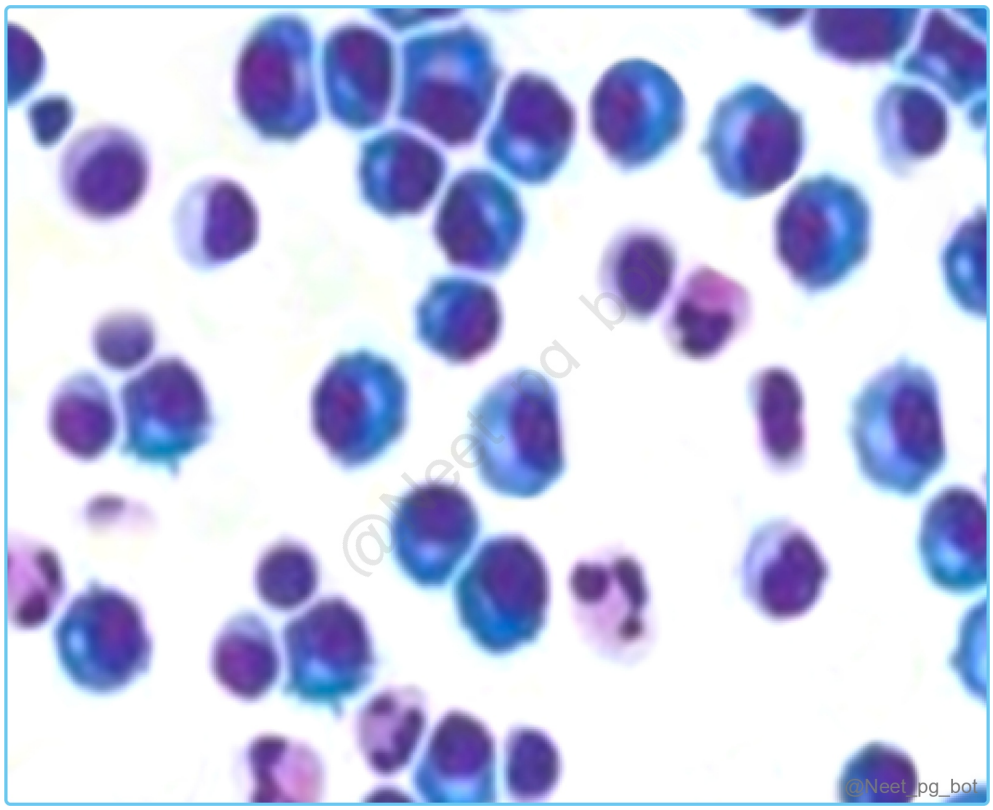
A. Tuberculous meningitis

B. Aseptic meningitis

C. Bacterial meningitis

D. Chemical meningitis

@Neet_pg_bot



See Answer in Part B → Q30

@Neet_pg_bot

Q31: Which of the following is the most important pathophysiological mechanism for Berry aneurysm? (Q859807)

A. Endothelial injury of vessel due to HTN

B. Muscle intimal elastic lamina layer defect

C. Endothelial layer defect

D. Adventitia defect

See Answer in Part B → Q31

@Neet_pg_bot

Q32: Which of the following statements about tremors are true? PD is characterized by resting tremor Tremor consist of alternate contraction of agonist and antagonist muscle in an oscillating rhythmic manner Essential tremor is an uncommon movement disorder. Normal individuals can have physiologic tremors that manifest as mild high frequency, postural or action tremors (Q859801)

A. 1,2,3 only

B. 2,3,4 only

C. 1,2,4 only

D. All of the above

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A 60-year-old woman presents with weakness in right arm for 6 hours. The weakness gradually became lesser and later resolved. She is a known case of diabetes and hypertension and is obese. Which of the following is the probable diagnosis of this case? (Q859797)

A. Compressive neuropathy

B. Transient ischaemic attack

C. Ischaemic stroke

D. Diabetic neuropathy

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A patient who is 66 years old and has a history of chronic hypertension, arrives at the emergency room with changes in mental state and high blood pressure measuring 210/110 mm Hg. A brain CT scan shows bleeding within the brain tissue. The typical location of this bleeding in similar cases is? (Q859794)

A. Putamen

B. Thalamus

C. Pons

D. Cerebellum

See Answer in Part B → Q34

@Neet_pg_bot

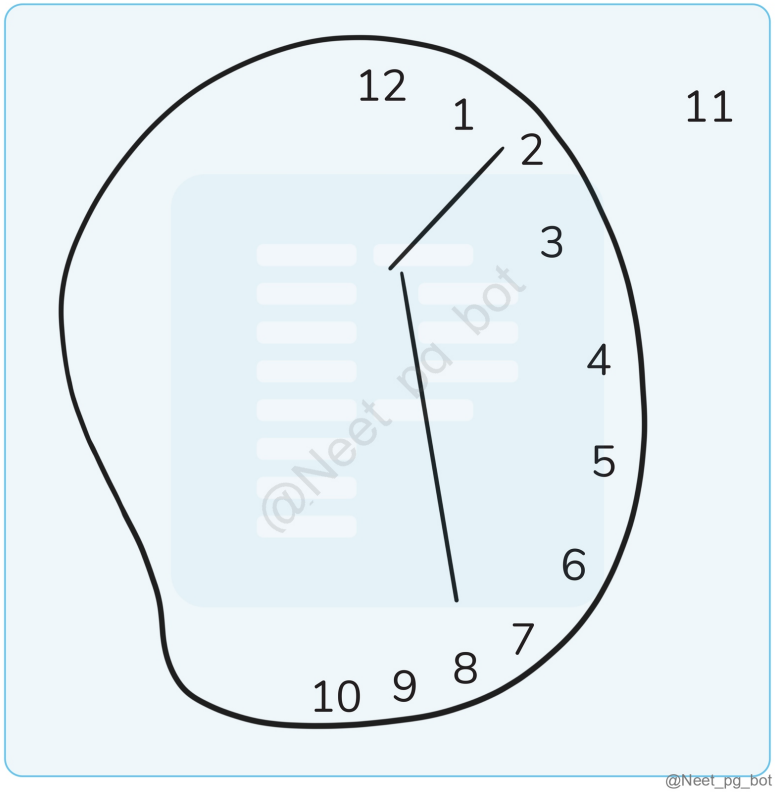
Q35: A patient was asked to copy the face of a clock and his drawing is shown below. What is the correct term to be used here? (Q859790)

A. Confabulation

B. Hemispatial neglect

C. Kinetic apraxia

D. Asterixis



See Answer in Part B → Q35

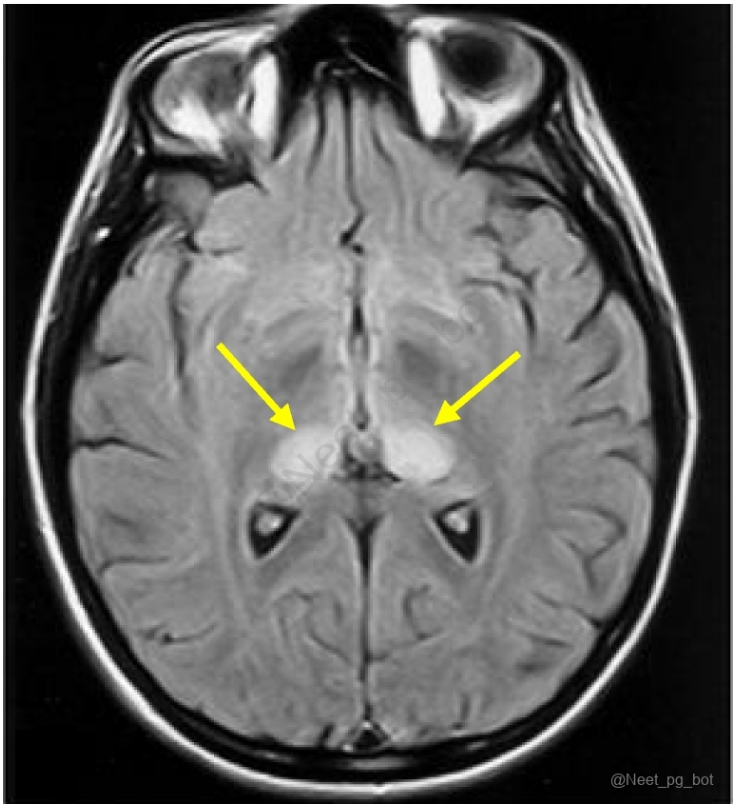
Q36: A 28-year-old patient develops rapid-onset psychiatric symptoms such as anxiety, depression, and personality changes, which are soon followed by ataxia and cognitive decline. The FLAIR MRI (shown below) demonstrates characteristic findings. What is the most likely diagnosis? (Q859752)

A. Alzheimer's disease

B. Vascular dementia

C. Sporadic CJD

D. Variant CJD



See Answer in Part B → Q36

Q37: What is the most probable cause for a 22-year-old man who has a high-grade fever, a purpuric rash, and a CSF sample showing gram-negative diplococci? (Q859751)

A. Neisseria meningitidis

B. Pseudomonas aeruginosa

C. Streptococcus pneumoniae

D. E.coli

See Answer in Part B → Q37

@Neet_pg_bot

Q38: A male patient presents with sensory loss and weakness of limbs for 3 months. He also has angular stomatitis. On examination, there is loss of proprioception, vibration sensations, UMN-type lower limb weakness, and absent ankle reflex. What is the most probable diagnosis? (Q855473)

A. Extradural cord compression

B. Amyotrophic lateral sclerosis

C. Multiple sclerosis

D. Subacute combined degeneration of the cord

See Answer in Part B → Q38

@Neet_pg_bot

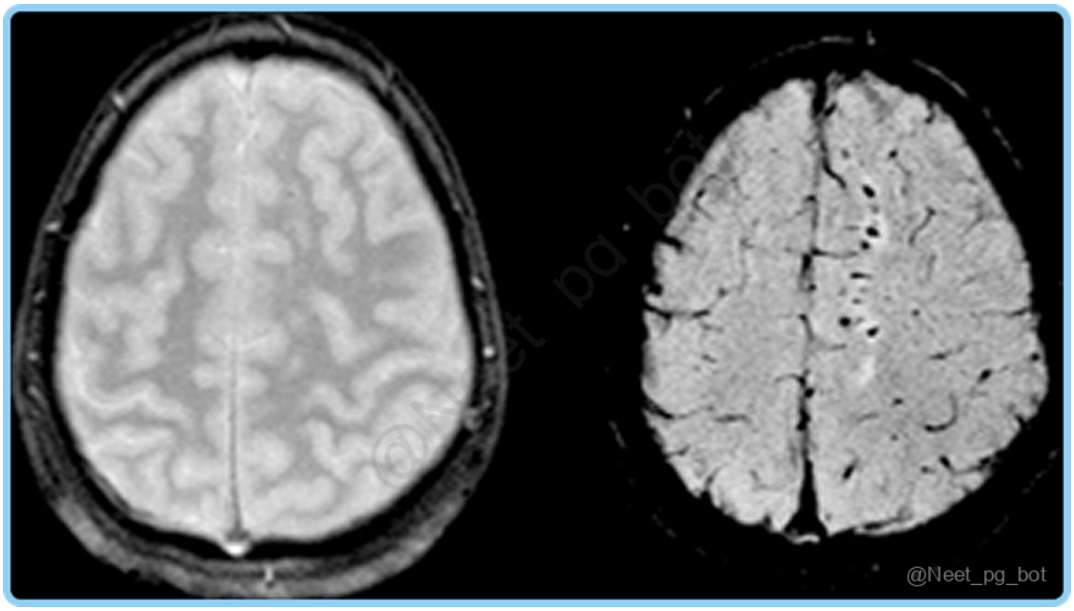
Q39: A 28-year-old male was brought to the emergency room with a history of RTA. GCS progressively declines over hours and axial T2 MRI shows multiple small hypointense lesions at the corticomedullary junction and basal ganglia. What is the diagnosis? (Q859567)

A. Diffuse axonal injury

B. Extensive subarachnoid haemorrhage

C. Hypoxic cerebral injury

D. Multiple haemorrhagic contusion



See Answer in Part B → Q39

@Neet_pg_bot

Q40: Which type of aphasia is seen in the lesions of the posterior part of the superior temporal gyrus? (Q858441)

A. Fluent

B. Non-fluent

C. Anomic

D. Conduction

See Answer in Part B → Q40

@Neet_pg_bot

Q41: An elderly woman is brought to the OPD with complaints of behavioural change, a history of multiple falls, urinary incontinence, and dementia. What is your diagnosis? (Q858429)

A. Normal pressure hydrocephalus

B. Frontotemporal dementia

C. Parkinson disease

D. Creutzfeldt-Jakob disease

See Answer in Part B → Q41

@Neet_pg_bot

Q42: A lesion at which level produces incongruous homonymous hemianopia with Wernicke's pupil? (Q855068)

A. Optic tract

B. Visual cortex

C. Optic radiation

D. Optic nerve

See Answer in Part B → Q42

@Neet_pg_bot

Q43: Which of the following causes the slowing of conduction in multiple sclerosis? (Q855012)

A. Gliosis

B. Loss of myelin sheath

C. Defect at node of Ranvier

D. Leaky Na + channel

See Answer in Part B → Q43

@Neet_pg_bot

Q44: In hemiplegia caused by an ischemic stroke, which region of the internal capsule is impacted? (Q856288)

A. Retrolentiform

B. Sublentiform

C. Anterior limb

D. Posterior limb

See Answer in Part B → Q44

@Neet_pg_bot

Q45: A 32-year-old woman who visits the clinic with complaints of frequent falls and walking difficulties. She also has a history of smoking and type-1 diabetes but no history of hypertension or coronary artery disease. During examination, the patient exhibits weakness in both lower limbs, absent DTR, as well as an unsteady gait. But, there is a decrease in proprioception and vibration sense in both lower limbs. Which

of the following statements is correct about the above condition? (Q856263)

A. Only the dorsal column is involved

B. All these patients with a neurological impairment will show macrocytosis

C. Vitamin B12 supplements do not improve this condition

D. Copper deficiency may produce similar symptoms

See Answer in Part B → Q45

@Neet_pg_bot

Q46: Calculate the GCS Score in an intubated patient, with findings of eye movements to pain and abnormal flexion? (Q857028)

A. E2VTM4

B. E2VTM3

C. E2VIM3

D. E2VNTM3

See Answer in Part B → Q46

@Neet_pg_bot

Q47: Which of the following arteries could have been involved in a patient who presents with vertigo, diplopia, hoarseness, dysphagia, left Horner's syndrome, and numbness in the left face and right side limbs? (Q856941)

A. Posterior inferior cerebellar artery

B. Superior cerebellar artery

C. Anterior inferior cerebellar artery

D. Basilar artery

See Answer in Part B → Q47

@Neet_pg_bot

Q48: Which of the following options has not been used as treatment for Guillain Barre syndrome? (Q856925)

A. Steroids

B. Plasmapheresis

C. IVIG

D. Ventilator support

See Answer in Part B → Q48

@Neet_pg_bot

Q49: A 30-year-old man presented with excessive fatiguability towards the end of the day that improved with rest. He also gives a history of ptosis and difficulty in speech and swallowing. What is the most likely diagnosis? (Q856190)

A. Myasthenia gravis

B. Lambert-Eaton syndrome

C. Duchenne muscular dystrophy

D. Systemic lupus erythematosus

See Answer in Part B → Q49

@Neet_pg_bot

Q50: Patient came with fever headache and nuchal rigidity. LP shows gram negative diplococci in gram stain. Which of the following will be used for chemoprophylaxis in close contacts of a patient with meningococcal meningitis? (Q866451)

A. Amoxicillin

B. Doxycycline

C. Ethambutol

D. Rifampicin

See Answer in Part B → Q50

@Neet_pg_bot

Q51: A patient had features of resting tremors, bradykinesia, and postural instability. He became bedridden and died due to respiratory failure. A brain biopsy is likely to show which of the following? (Q860433)

A. Lewy bodies

B. Hirano bodies

C. Guarneri bodies

D. Negri bodies

See Answer in Part B → Q51

@Neet_pg_bot

Q52: Seizures are seen in what percentage of RTA patients with brain contusion/loss of consciousness? (Q860388)

A. Development of seizures in 17%

B. Development of seizures in 45%

C. Development of seizures in 75%

D. No relation between trauma and seizures

See Answer in Part B → Q52

@Neet_pg_bot

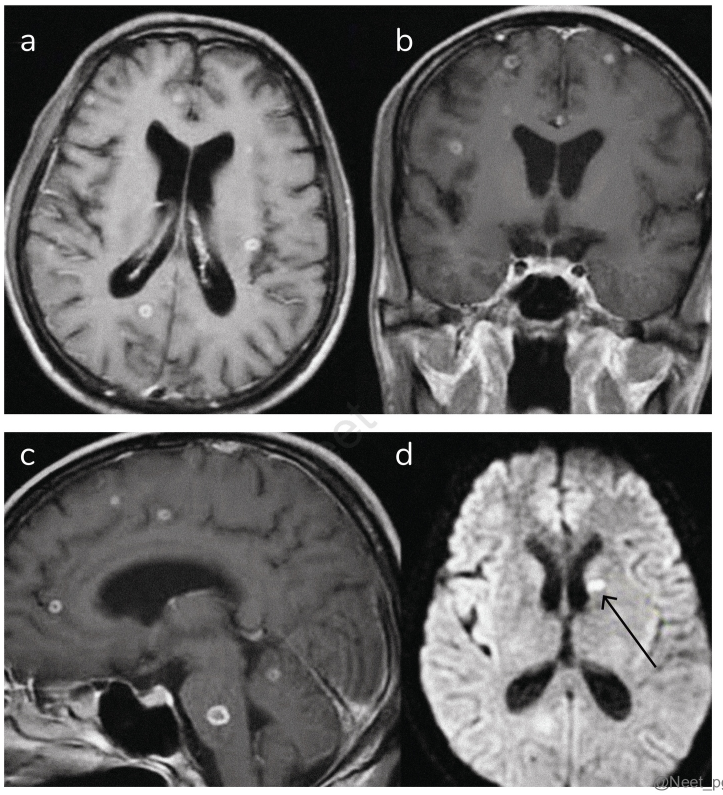
Q53: What is the confirmatory test for the above condition? (Q844325)

A. CBNAAT of CSF

B. PET Scan

C. NMR Spectroscopy

D. MRI aerial scan



See Answer in Part B → Q53

@Neet_pg_bot

Q54: Patient is having a headache and confusion. A brain tumor diagnosis is made. Family history reveals brain and kidney tumors. Choose the correct option: (Q844242)

A. Neurofibromatosis

B. Li fraumeni syndrome

C. VHL Syndrome

D. Churg strauss syndrome

See Answer in Part B → Q54

@Neet_pg_bot

Q55: A 62-year-old patient presents with left-sided arm and leg weakness, right-sided facial paralysis, and difficulty with horizontal eye movements. Based on the clinical presentation, which of the following syndromes is most consistent with these symptoms? (Q844211)

A. Foville syndrome

B. Benedict's syndrome

C. Millard-Gubler syndrome

D. Wallenberg syndrome

See Answer in Part B → Q55

@Neet_pg_bot

Q56: A 35-year-old woman presents with fluctuating muscle weakness, especially affecting her speech and swallowing. Repetitive nerve stimulation shows a decremental response. Her blood tests are negative for acetylcholine receptor (AChR) antibodies. Which of the following antibodies is most likely responsible for her symptoms? (Q852752)

A. Anti-dsDNA antibodies

B. Anti-MuSK antibodies

C. Anti-TPO antibodies

D. Anti-Ro antibodies

See Answer in Part B → Q56

@Neet_pg_bot

Q57: The CSF findings in bacterial meningitis would include which of the following? (Q852676)

A. Elevated protein and decreased glucose

B. Normal white blood cell count

C. Decreased protein and elevated glucose

D. Elevated WBC count with normal glucose

See Answer in Part B → Q57

@Neet_pg_bot

Q58: In children with Guillain-Barré Syndrome (GBS), all are true except? (Q853356)

A. Areflexia of the affected limb is a mandatory diagnostic criteria

B. Plasmapheresis is not preferred in refractory cases

C. Intravenous immunoglobulin is the first line of management

D. Albuminocytological dissociation in CSF is characteristic

See Answer in Part B → Q58

@Neet_pg_bot

Q59: LMN (Lower Motor Neuron) lesions are associated with which of the following? Decrease in muscle tone Spastic paralysis Babinski positive Fasciculations (Q853351)

A. 1, 2

B. 1, 4

C. 1, 2, 3, 4

D. 1, 2, 3

See Answer in Part B → Q59

@Neet_pg_bot

Q60: A patient presented with a blood pressure of 220/120 mmHg in an altered sensorium. He also had an episode of vomiting and a history of weakness on the left side of his body. Which of the following is incorrect regarding hypertensive management in this case? (Q853346)

A. In hemorrhagic stroke, reduce the BP to less than 160/100 mmHg with antihypertensives to prevent rebleed

B. In hemorrhagic stroke, aggressive use of IV antihypertensive if SBP > 220

C. In the ER, multiple blood pressure readings should be taken before starting antihypertensive therapy

D. In ischemic stroke, BP should be reduced to <140/90 mmHg immediately

See Answer in Part B → Q60

@Neet_pg_bot

Q61: A patient presents with sudden-onset aphasia and right-sided arm weakness for the past 4 hours. After stabilizing the patient and confirming the diagnosis of ischemic stroke with urgent neuroimaging, which investigation is most appropriate to determine the etiology of this stroke? (Q866491)

A. Transthoracic echocardiography (TTE)

B. Carotid doppler

C. Transesophageal echocardiography (TEE)

D. MRI brain

See Answer in Part B → Q61

@Neet_pg_bot

Q62: Patient came with severe headache and seizures. Sodium on admission was 98 meq/L. We have started correction with 3% saline and now after 24 hours of infusion

sodium is 110 meq/L. Patient develops mutism and altered sensorium. Which investigation will you perform now? (Q866483)

A. MRI Head

B. LP for CSF biochemistry

C. Brainstem evoked potentials

D. EEG

See Answer in Part B → Q62

@Neet_pg_bot

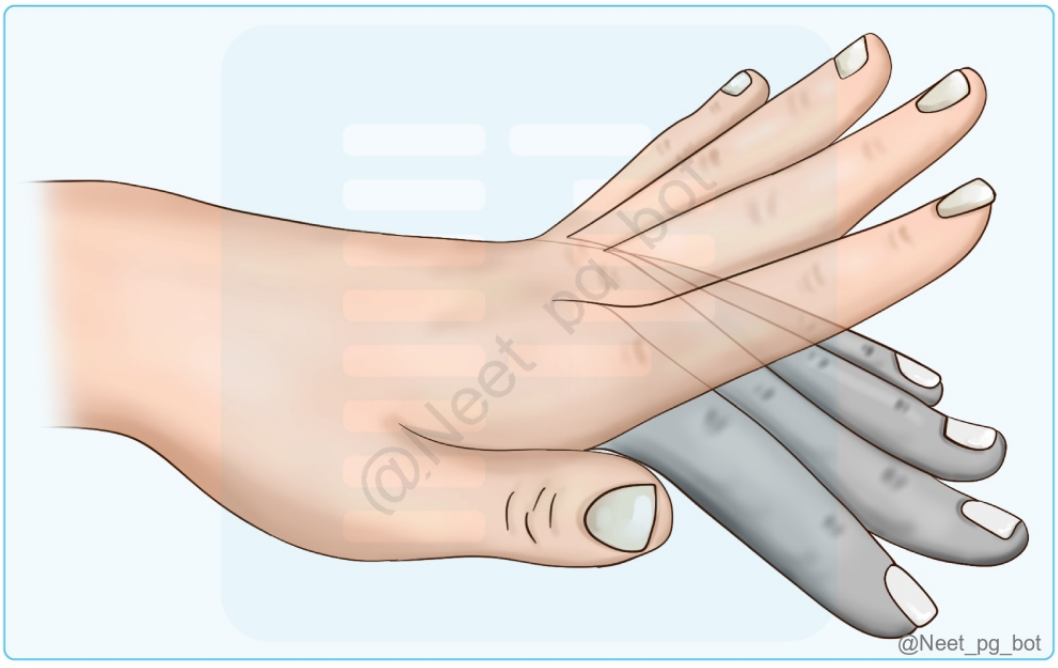
Q63: The patient is having the following hand movements. In which of the following conditions would this be seen? (Q860476)

A. Thyrotoxicosis

B. Hypercarbia

C. Hemiballismus

D. Hypoxia



See Answer in Part B → Q63

@Neet_pg_bot

Q64: A 30-year-old female with seizures was prescribed carbamazepine & erythromycin. A few days later, she developed ataxia. What is the most likely cause of her symptoms? (Q865385)

A. Carbamazepine toxicity

B. Erythromycin toxicity

C. Worsening of the underlying disease

D. A separate, unrelated neurological condition

See Answer in Part B → Q64

@Neet_pg_bot

Q65: Which of the following statements about Multiple Sclerosis (MS) is incorrect? (Q865373)

A. 70% of patients with MS develop optic neuritis during course of illness

B. Oral steroids are given for acute relapses

C. Loss of color perception and depth perception is proportional to visual loss

D. Examination of fundus can be normal and can show papillitis

See Answer in Part B → Q65

@Neet_pg_bot

Q66: A 65-year-old known case of Parkinson's disease presents with oropharyngeal dysphagia and recurrent episodes of aspiration pneumonitis, complaints of excessive respiratory secretions. Chest imaging reveals bilateral bronchiectasis. What is the most appropriate long-term management for this patient? (Q865367)

A. High-frequency chest wall oscillation therapy

B. Nebulized N-acetylcysteine (NAC) to reduce secretions

C. PEG tube placement

D. Macrolide therapy

See Answer in Part B → Q66

@Neet_pg_bot

Q67: A 20-year-old male presents with severe headache, vomiting & photophobia. On examination, neck rigidity and Brudzinski's sign are positive. A CT scan of the brain shows hydrocephalus and no haemorrhage. CSF examination is normal. What is the most likely diagnosis? (Q865322)

A. Normal Pressure Hydrocephalus

B. Bacterial Meningitis

C. Viral Encephalitis

D. Subarachnoid Haemorrhage

See Answer in Part B → Q67

@Neet_pg_bot

Q68: Which of the following is one of the earliest presenting symptoms in a patient with Multiple Sclerosis? (Q865298)

A. Sensory disturbances

B. Ataxia

C. Vertigo

D. Facial palsy

See Answer in Part B → Q68

@Neet_pg_bot

Q69: A patient presents with contralateral face, arm, and leg weakness. NCCT shows intracerebral hemorrhage (ICH). What is the most likely location of the CNS bleed? (Q866823)

A. Basal ganglia

B. Midbrain

C. Pons

D. Medulla

See Answer in Part B → Q69

@Neet_pg_bot

Q70: The infant is being evaluated for recurrent episodes of seizures. ECG shows Hypsarrhythmia. Which drug is preferred for management? (Q866822)

A. ACTH

B. Vigabatrin

C. Valproate

D. Carbamazepine

See Answer in Part B → Q70

@Neet_pg_bot

Q71: A patient had a road traffic accident (RTA). NCCT head was normal on admission. The patient later died after several days in the ICU due to coma. Brain biopsy revealed multiple punctate hemorrhages. What is the diagnosis? (Q866814)

A. Ischemic injury

B. Diffuse axonal injury

C. Intraventricular bleeding

D. Subdural hemorrhage

See Answer in Part B → Q71

@Neet_pg_bot

Q72: What is the probable diagnosis for a patient who exhibits miosis, anhidrosis, mild ptosis, and a persistent small pupil even in low light conditions? (Q866808)

A. Adie’s tonic people

B. Horner syndrome

C. Marcus Gunn pupil

D. Argyll Robertson pupil

See Answer in Part B → Q72

@Neet_pg_bot

Q73: A 30-year-old male presents with deep-seated retro-orbital pain of cluster headache. What is the best management? (Q866802)

A. Verapamil

B. Oxygen

C. Lithium

D. Topiramate

See Answer in Part B → Q73

@Neet_pg_bot

Q74: A patient presents with symmetrical leg weakness and areflexia. He had developed diarrhoea 2 weeks ago. He was diagnosed as having GBS. What is the cause? (Q866792)

A. Demyelination of A, B-fibers

B. Demyelination of B-fibers

C. Demyelination of the spinal cord

D. Cord inflammation

See Answer in Part B → Q74

@Neet_pg_bot

Q75: A 35-year-old female with progressive limb weakness for the past 1 year. On examination, muscle fasciculations and hypertonia are noted, and the sensory system is intact. What is the diagnosis? (Q866791)

A. ALS

B. Spinal muscular atrophy

C. Multifocal motor neuropathy

D. Becker muscular dystrophy

See Answer in Part B → Q75

@Neet_pg_bot

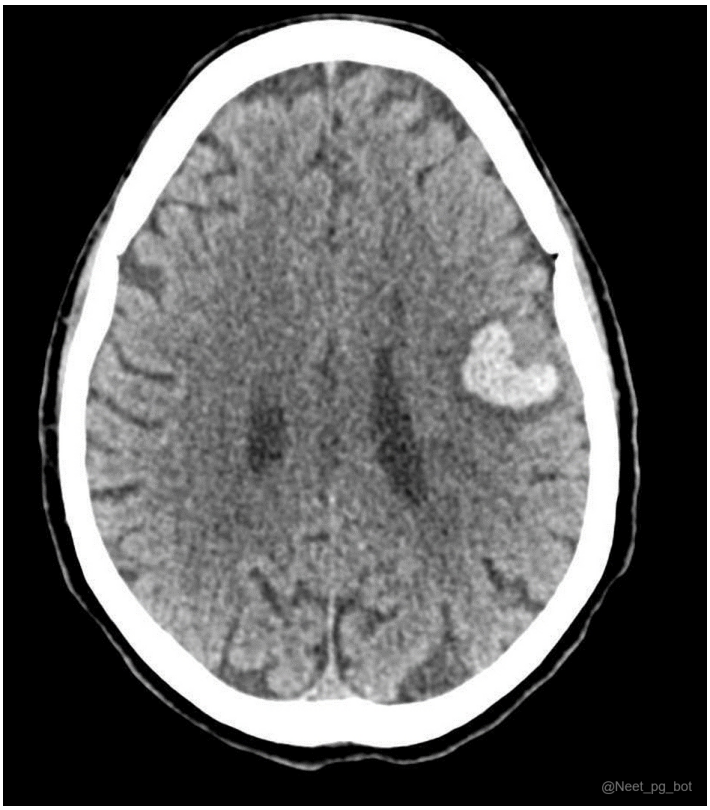
Q76: A 60 year old man present with sudden onset of right sided hemiparesis for last 3 hours. BP is 200/100 mmHg. NCCT Head showed brain bleed and right hemiparesis. All of the following are to be done for management, Except? (Q820357)

A. Thrombolysis

B. BP Control

C. Edema management

D. Elective hyperventilation



See Answer in Part B → Q76

@Neet_pg_bot

Q77: A stroke patient presents with an inability to identify objects but can determine the colour, texture, and shape of objects. Which of the following lobes is involved? (Q854720)

A. Frontal lobe

B. Parietal lobe

C. Temporal lobe

D. Occipital lobe

See Answer in Part B → Q77

@Neet_pg_bot

Q78: A 30-year-old patient presents with high-grade fever for the past week. On examination neck stiffness and Kernig's sign were positive. CSF analysis showed lymphocytosis protein - 8 g/L, glucose - 20 mg/dl while RBS = 140 mg/dl. What is your diagnosis? (Q854684)

A. Tubercular meningitis

B. Coxsackie meningitis

C. Bacterial meningitis

D. HSV -1 encephalitis

See Answer in Part B → Q78

@Neet_pg_bot

Q79: Antibody seen in Acute Inflammatory Demyelinating Polyneuropathy will belong to which class? (Q820419)

A. Ig G

B. Ig M

C. Ig E

D. Ig A

See Answer in Part B → Q79

@Neet_pg_bot

Q80: In a patient diagnosed with Dialysis Dementia, what deposition is seen in the cerebral cortex? (Q820411)

A. Amyloid β■

B. Amyloid β■ microglobulin

C. Amyloid transthyretin

D. Amyloid β

See Answer in Part B → Q80

@Neet_pg_bot

Q81: Scissoring gait will occur due to increases firing of Which of the following nerve? (Q820407)

A. Superior gluteal nerve

B. Inferior gluteal nerve

C. Obturator nerve

D. Femoral nerve

See Answer in Part B → Q81

@Neet_pg_bot

Q82: 65-year-old man is brought to the hospital with complaints of suddenly not making any sense while speaking using non-sensical grammar though he can speak quickly. He could communicate effectively prior to this. Which of the following defect is present in this patient? (Q820399)

A. Motor aphasia

B. Anomic aphasia

C. Fluent aphasia

D. Conduction aphasia

See Answer in Part B → Q82

@Neet_pg_bot

Q83: A 50-year-old man presents with movement disorder and tremors in hand, along with the development of cognitive and emotional problems. Which of the following medical disorders is the likely diagnosis? (Q820387)

A. Parkinson's disease

B. Frederich's ataxia

C. Alzheimer’s disease

D. Huntington's disease

See Answer in Part B → Q83

@Neet_pg_bot

Q84: A 60-year-old patient weighing 80 kilograms has been diagnosed with an acute ischemic stroke and is recommended for thrombolysis with alteplase. What should the initial stat dose in milligrams be? (Q820359)

A. 8

B. 10

C. 12

D. 15

See Answer in Part B → Q84

@Neet_pg_bot

Q85: A patient is brought to the OPD by his wife complaining about difficulty in expressing emotions and not taking part in daily activities. On examination, resting tremors and rigidity are noted. Given the possible diagnosis, which part of the brain is affected in this patient? (Q855454)

A. Basal ganglia

B. Hippocampus

C. Cerebellum

D. Premotor cortex

See Answer in Part B → Q85

@Neet_pg_bot

Q86: An elderly patient was brought to the OPD with complaints of tremors, stoop posture and slow movements. His son also gives a history of the patient forgetting day to day activities. What is the possible cause of this condition? (Q857283)

A. Normal pressure hydrocephalus (NPH)

B. Hypothyroidism

C. Lewy body

D. Vitamin B12 deficiency

See Answer in Part B → Q86

@Neet_pg_bot

Q87: A 35-year-old male patient suffers from schizophrenia. He is currently receiving clozapine treatment. Why does he require frequent blood monitoring? (Q857278)

A. Agranulocytosis

B. Myocarditits

C. Cerebral bleed

D. Seizures

See Answer in Part B → Q87

@Neet_pg_bot

Q88: What is observed in the case of an abnormal accumulation of misfolded protein? (Q857270)

A. Creutzfeldt jakob disease

B. Nephritic syndrome

C. Sickle cell anemia

D. Megaloblastic anemia

See Answer in Part B → Q88

@Neet_pg_bot

Q89: A 30-year-old woman presents with ptosis, diplopia, and generalized muscle weakness that worsens with activity and improves with rest. She has difficulty chewing and swallowing, especially in the evening. A Tensilon test is positive. Which investigation is most likely to confirm the diagnosis? (Q860245)

A. CT scan of the chest

B. SFEMG

C. Anti-acetylcholine receptor antibody test

D. MRI of the brain

See Answer in Part B → Q89

@Neet_pg_bot

Q90: 25 year old HIV positive patient presents with autonomic dysreflexia and flaccid quadriplegia. The results of a lumbar puncture are as follows Opening Pressure: 150 mm water Cells: 5 lymphocytes/ cu.mm Sugar: 85 mg/dl (RBS 120 mg/dl) Protein: 100 mg/dl Color: normal Based on these findings, which of the following is the most likely diagnosis? (Q860235)

A. Cryptococcal meningitis

B. Transverse myelitis

C. Tuberculosis Meningitis

D. Acute inflammatory demyelinating polyneuropathy

See Answer in Part B → Q90

@Neet_pg_bot

Q91: A 30-year-old man experiences initial paralysis in both legs, which then progresses to affect both upper limbs as well. Over time, he shows slight improvement in upper limbs but no improvement in his lower trunk and both legs. Based on this description, what is the most likely diagnosis? (Q860213)

A. Diplegia

B. Quadriplegia

C. Paraplegia

D. Monoplegia

See Answer in Part B → Q91

@Neet_pg_bot

Q92: A lumbar puncture was performed on a patient in a sitting position, and the patient is now experiencing a very severe headache. Which of the following is NOT a recommended management strategy for a post-lumbar puncture headache? (Q860155)

A. Lie in a supine position

B. Administer intravenous caffeine

C. Restrict water intake

D. Perform a low-volume blood patch

See Answer in Part B → Q92

@Neet_pg_bot

Q93: A 30-year-old woman presents with a unilateral throbbing headache that worsens with exposure to bright light. She occasionally skips breakfast. What is the most likely diagnosis? (Q860148)

A. Hunger headache

B. Migraine

C. Tension headache

D. Cluster headache

See Answer in Part B → Q93

@Neet_pg_bot

Q94: A 16-year-old girl presents with generalized muscle weakness and protrusion of the eyelids (ptosis) that worsens as the day progresses. What is the most likely diagnosis? (Q860120)

A. Myasthenia Gravis

B. Fibromyalgia

C. Myotonic Dystrophy

D. Guillain-Barré Syndrome

See Answer in Part B → Q94

@Neet_pg_bot

Q95: All of the following is a risk factor for secondary headache and need further workup except? (Q840124)

A. 50 years old with first severe headache

B. Presence of cord-like vessels in the temporal area

C. Cocaine abuse

D. Subacute worsening of headache symptoms

See Answer in Part B → Q95

@Neet_pg_bot

Q96: A 45-year-old male presents to the outpatient department with complaints of daytime sleepiness and nighttime sleeplessness. His wife reports that he snores at night. Which of the following statements about his condition is incorrect? (Q840105)

A. The tone of the pharyngeal muscles is increased

B. Low oxygen saturation triggers waking up at night

C. Episodes of apnea increase stress on the heart

D. Low oxygen stimulates respiratory effort

See Answer in Part B → Q96

@Neet_pg_bot

Q97: Which of the following type of hypersensitivity reactions is seen in myasthenia gravis? (Q793907)

A. Type 1 hypersensitivity reaction

B. Type 2 hypersensitivity reaction

C. Type 3 hypersensitivity reaction

D. Type 4 hypersensitivity reaction

See Answer in Part B → Q97

@Neet_pg_bot

Q98: What is the diagnosis for a 24-year-old female patient who presents with fever, headache, ataxia, nausea, and vomiting for the past 3 days? The patient exhibits neck rigidity and hip and knee flexion upon passive flexion of the neck. A lumbar puncture was performed, and the CSF findings are provided below. Opening pressure – increased Color – cloudy white WBCs – 7000/µl; neutrophil predominant Sugar – 15 mg/dl CSF/serum glucose ratio – 0.2 Protein – 70 mg/dl Latex agglutination – positive Limulus lysate test – negative (Q793904)

A. Bacterial meningitis

B. Tubercular meningitis

C. Viral meningitis

D. Fungal meningitis

See Answer in Part B → Q98

@Neet_pg_bot

Q99: A patient with a unilateral hypoglossal nerve (CN XII) lesion is asked to protrude the tongue. What finding is expected? (Q793874)

A. Tongue deviation to the contralateral side

B. Tongue deviation to the same side

C. Falling of the tongue

D. Inability in tongue protrusion

See Answer in Part B → Q99

@Neet_pg_bot

Q100: A child is brought with a 2-week history of not feeding well and excessive irritability. History of TB for sister is present and is taking treatment for it. In workup, LP was performed. Which of the following is likely to be found in CSF? (Q820371)

A. Lymphocytosis, low sugar, and high protein

B. Lymphocytosis, high sugar, and high protein

C. Neutrophils, low sugar and low protein

D. Neutrophils, low sugar and high protein

See Answer in Part B → Q100

[08_Rheumatology] 060 Vasculitis Syndromes - I — Quick Jump

Q1 (p. 746)	*Q2 (p. 746)*	*Q3 (p. 747)*	*Q4 (p. 747)*	*Q5 (p. 748)*	*Q6 (p. 748)*
Q7 (p. 748)	*Q8 (p. 749)*	*Q9 (p. 749)*	*Q10 (p. 750)*	*Q11 (p. 750)*	*Q12 (p. 751)*
Q13 (p. 751)	*Q14 (p. 751)*	*Q15 (p. 752)*			

Q1: A 68-year-old female presents with a new-onset severe headache, scalp tenderness, and jaw pain while chewing. Laboratory investigations reveal ESR 85 mm/hr, CRP 45 mg/L, and mild normochromic anemia. A biopsy of the temporal artery shows panarteritis with inflammatory mononuclear cell infiltrates and giant cell formation. In the analysis of T cells from the arterial lesion, which cytokines are primarily produced and play a crucial role in disease progression? (Q851671)

A. IL-4 and IL-5

B. IL-2 and IFN-γ

C. IL-10 and TGF-β

D. IL-6 and TNF-α

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 72-year-old female presents with a new-onset headache, jaw claudication, and visual symptoms. Her ESR is 92 mm/hr and CRP is elevated. Temporal artery biopsy is planned, but immediate treatment is necessary. Which of the following is the most appropriate initial management strategy? (Q851675)

A. Wait for biopsy results before starting any treatment

B. Start prednisone 40-60 mg/day immediately

C. Begin methotrexate and low-dose aspirin

D. Start tocilizumab alone

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 6-year-old boy presents with a bilateral lower extremity rash that appeared 2 weeks after an upper respiratory tract infection. He also complains of abdominal pain and joint pain. On examination, there is a symmetrically distributed palpable purpuric rash present over both lower extremities, predominantly on the extensor surfaces. Which of the following is the most likely diagnosis based on the clinical presentation and image findings? (Q851678)

A. Immune thrombocytopenic purpura (ITP)

B. IgA vasculitis (Henoch-Schönlein purpura)

C. Meningococcemia

D. Kawasaki disease

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 7-year-old boy presents with palpable purpura, abdominal pain, and joint pain. Laboratory studies show normal platelet count with elevated IgA levels. Which of the following statements about this condition is incorrect? (Q851680)

A. Renal biopsy is essential for confirming the diagnosis

B. Glucocorticoids help reduce arthralgias and abdominal discomfort

C. Glucocorticoids have not proven benefit in treating skin and renal manifestations

D. Complement levels are typically normal in this condition

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 19-year-old Asian female presents with persistent malaise, fever, night sweats, and unequal blood pressure readings in both arms (right arm 130/80 mmHg, left arm 100/70 mmHg). ESR is elevated at 85 mm/hr, and MR angiography shows ostial narrowing of the left subclavian artery with pan-arteritis. Which statement describes the pathogenesis and initial management? (Q851682)

A. Primarily intimal disease; start anti-TNF therapy

B. Panarteritis; tocilizumab superior to steroids

C. Adventitial inflammation; methotrexate first-line

D. Panarteritis with intimal proliferation; start prednisone

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 4-year-old child presents with fever, rash, and strawberry tongue. The child has circumoral pallor and a sandpaper-like rash. Laboratory investigations reveal elevated inflammatory markers. Which of the following statements is most likely to be true regarding this presentation? (Q851684)

A. IVIG with high-dose aspirin is the first-line treatment

B. The rash begins over the face and shows circumoral erythema

C. Throat culture is essential for diagnosis and Penicillin is the treatment of choice

D. Coronary artery involvement is seen in the majority of untreated cases

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Match the markers (Column B) with the correct vasculitis (Column A). a. Granulomatosis with Polyangiitis (GPA) 1. C-ANCA b. Polyarteritis Nodosa (PAN) 2. P-ANCA 3. Proteinase-3 4. Myeloperoxidase (Q851686)

A. a → 1,3 b → 2,4

B. a → 2,4 b → 1,3

C. a → 1,3 b → None

D. a → None b → 1,3

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old patient presents with fever, purpura, and arthralgias. Biopsy shows small vessel vasculitis with absent immune deposits. Lab tests reveal C-ANCA antibodies. Which of the following is most consistent with this clinical picture? (Q851688)

A. Microscopic polyangiitis with segmental necrotizing glomerulonephritis

B. Granulomatosis with polyangiitis with pauci-immune glomerulonephritis

C. Churg-Strauss syndrome with peripheral eosinophilia

D. Mixed cryoglobulinemia with Hepatitis-C

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 25-year-old man from Turkey presents with recurrent painful oral ulcers, genital ulcers, and bilateral red eyes. Examination reveals bilateral anterior uveitis and erythema nodosum on his legs. After the needle prick, he develops an erythematous papule in 48 hours. Laboratory studies show elevated IL-1, TNF-α, and increased neutrophil activity. Which of the following best describes the pathogenesis and clinical features of this condition? (Q851690)

A. ANCA-mediated vasculitis with small vessel involvement

B. Auto-inflammatory vasculitis with T-cell mediated immunity and neutrophilic inflammation

C. Antibody-mediated disease with preferential renal involvement

D. IgA-mediated vasculitis with predominant GI manifestations

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 30-year-old man presents with recurrent oral ulcers, genital ulcers, and bilateral uveitis. He develops pustules 48 hours after the needle prick. Further examination reveals erythema nodosum and non-erosive arthritis of the knees. Based on clinical criteria, Behcet's Disease is diagnosed. Which of the following represents the most appropriate initial management strategy? (Q851692)

A. High-dose steroids alone for all manifestations

B. Targeted therapy based on organ involvement: colchicine for mucocutaneous, topical steroids for anterior uveitis

C. Immediate cyclophosphamide for all patients

D. Anticoagulation alone for all manifestations

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 4-year-old Asian boy presents with 6 days of fever, bilateral conjunctival injection without exudate, strawberry tongue, and cervical lymphadenopathy >1.5 cm. On day 7, he develops erythema of palms and soles. Laboratory studies show elevated TNF-α and pro-BNP. Which of the following best describes the pathogenesis of this condition? (Q851694)

A. Direct viral invasion of coronary vessels with late thrombosis

B. Immune-mediated medium vessel vasculitis with coronary artery predilection

C. Bacterial toxin-mediated endothelial damage with early thrombosis

D. Primary autoimmune arteritis with small vessel involvement

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 3-year-old boy presents with 6 days of fever, bilateral conjunctivitis, strawberry tongue, and polymorphous rash. Initial labs show elevated CRP, ESR, and thrombocytosis. Which of the following represents the most appropriate initial diagnostic test and treatment strategy? (Q851695)

A. Blood culture and broad-spectrum antibiotics

B. Echocardiogram and IVIG 2g/kg plus high-dose aspirin

C. Throat culture and penicillin

D. Viral panel and supportive care

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 40-year-old man with a history of asthma presents with worsening dyspnea, peripheral neuropathy, and palpable purpura on his lower limbs. He also has a history of sinusitis. Blood tests reveal marked eosinophilia and a positive p-ANCA. What is the most likely diagnosis? (Q851696)

A. Wegener's Granulomatosis

B. Churg-Strauss Syndrome

C. Microscopic Polyangiitis

D. Polyarteritis Nodosa

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following vasculitis syndromes is not classified as an ANCA-associated vasculitis according to the Chapel Hill Classification? (Q851697)

A. Granulomatosis with Polyangiitis (GPA)

B. Microscopic Polyangiitis (MPA)

C. Eosinophilic Granulomatosis with Polyangiitis (EGPA)

D. Polyarteritis Nodosa (PAN)

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 4-year-old kid comes to your clinic with his mother. His mother complains that he has had an acute fever and abdominal pain for 2 days. You examine the child and find out that the skin on the buttocks and extensor surfaces of arms and legs are covered with small round patches of blue-purple discoloration. You also find out that the kid has hematuria. You have diagnosed it as a case of Henoch Schonlein Purpura. Henoch-Schonlein purpura, a vasculitis, is characterized by which of the following symptoms? (Q882172)

A. Erythromelalgia

B. Glomerulonephritis, hematochezia and palpable purpura

C. Lhermitte’s sign

D. Virchow’s triad

See Answer in Part B → Q15

Q1: A 25-year-old woman presents with fatigue, joint pain, and a photosensitive rash. She reports mouth ulcers and hair loss. Laboratory tests show positive ANA and elevated anti-ds DNA antibodies. Further examination reveals elevated levels of IFN-α. Which of the following is a consequence of elevated IFN-α in this condition? (Q851381)

A. Decreased B cell activation

B. Enhanced clearance of apoptotic cells

C. Suppression of T cell activity

D. Increased antibodies production

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 30-year-old woman presents with a history of recurrent fever, myalgia, photosensitivity, and joint pain. On examination, multiple erythematous plaques with adherent scales are noted on her face and scalp. What is the most likely diagnosis? (Q851385)

A. Urticarial eruptions

B. Malar rash

C. Subacute cutaneous lupus erythematosus (SCLE)

D. Discoid lupus erythematosus

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 26-year-old woman presents with chest pain worsened by deep breathing, shortness of breath, fatigue, joint pain, and a photosensitive facial rash. Physical examination reveals tenderness over the chest wall and mild joint swelling. Laboratory tests show positive ANA and elevated anti-dsDNA antibodies. A chest X-ray shows mild pleural effusion. Which of the following pulmonary complications is most likely associated with her condition? (ARDS: Acute Respiratory Distress Syndrome) (Q851390)

A. ARDS

B. Shrinking lung syndrome

C. Pulmonary hypertension

D. Pleuritis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 28-year-old woman presents with joint pain and skin rashes after being treated with trimethoprim-sulfamethoxazole for a recent infection. She has a history of Systemic lupus erythematosus. Laboratory tests reveal positive anti-dsDNA antibodies. Which of the following antibodies would be more specific for diagnosing the cause of her symptoms? (Q851392)

A. Anti-Ro

B. Anti-RNP

C. Anti-C1q

D. Antihistone

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 27-year-old woman presents with joint pain, fatigue, and a malar rash. Laboratory tests reveal positive ANA and anti-dsDNA antibodies. According to the EULAR/ACR classification criteria, which of the following criteria is not required for diagnosis? (Q851394)

A. Antiphospholipid antibodies

B. Serositis

C. Neuropsychiatric symptoms

D. Ocular symptoms

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 25-year-old woman presents with fatigue, a malar rash, and joint pain. Laboratory tests show positive anti-dsDNA, anti-Smith antibodies, and a positive

ANA. She undergoes a renal biopsy that reveals features consistent with lupus nephritis. Based on the SLICC criteria, which of the following statements is true? (Q851395)

A. Four clinical criteria must be met to confirm SLE

B. Renal biopsy indicating lupus with lupus autoantibodies is sufficient

C. At least 2 clinical criteria with one antibody confirms SLE

D. Presence of Anti-ds, Anti-Sm and ANA confirms SLE

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 32-year-old woman with known systemic lupus erythematosus presents with new-onset hypertension and elevated creatinine. Urinalysis shows hematuria and proteinuria. Renal biopsy reveals glomerular inflammation involving >50% of glomeruli. Which class of lupus nephritis does this most likely represent? (Q851398)

A. Class V

B. Class II

C. Class III

D. Class IV

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 28-year-old woman with a history of SLE presents with increased fatigue, severe joint pain and pleuritis with features suggestive of coronary artery disease. Laboratory tests indicate elevated serum creatinine. Which of the following management strategies is most appropriate for this patient? (Q851403)

A. High-dose glucocorticoids and Cyclophosphamide

B. Hydroxychloroquine and NSAIDs for symptom relief

C. Low-dose glucocorticoids, along with azathioprine

D. Conservative management with close monitoring and supportive care

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 35-year-old woman with a history of hypertension presents with fever, rash, and joint pain. Laboratory tests show positive ANA and anti-histone antibodies. She has no signs of renal or neurological involvement. Which of the following medications is most likely responsible for her symptoms? (Q851405)

A. Metoprolol

B. Hydrochlorothiazide

C. Hydralazine

D. Amlodipine

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45-year-old man with TB on ATT isoniazid therapy presents with fatigue, fever, joint pain, and a rash. Laboratory tests reveal a positive antinuclear antibody (ANA) test, and anti-histone antibodies are detected. Which of the following ANA staining patterns is most likely found in this patient? (Q851407)

A. Diffuse

B. Speckled

C. Nucleolar

D. Centromere

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 35-year-old woman with a history of recurrent miscarriages and recent episodes of deep vein thrombosis is found to have elevated anti-β2-glycoprotein I antibodies. Which of the following pathophysiological mechanisms is primarily responsible for her condition? (Q851410)

A. Deactivation of the complement pathway

B. Increased apoptosis of endothelial cells

C. Decreased platelet activation

D. Impaired fibrinolysis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 30-year-old woman presents with a history of recurrent miscarriages, having experienced three miscarriages before 10 weeks of gestation and an unprovoked deep vein thrombosis (DVT) in her left leg six months ago, which required anticoagulation therapy. She is diagnosed with antiphospholipid syndrome. Which of the following is not a diagnostic criterion of antiphospholipid syndrome? (Q851413)

A. Vascular thrombosis of artery, vein or any small vessel

B. 3 or more unexplained consecutive miscarriages before 10 weeks of gestation

C. Positive titer for APLA antibodies on a single occasion

D. One or more unexplained deaths of a normal fetus at or after 10 weeks

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 32-year-old woman with a known history of antiphospholipid syndrome (APS) was admitted to the hospital due to arterial thrombosis. She had a history of deep vein

thrombosis (DVT) one year ago, for which she was treated with warfarin. She has been adherent to her warfarin therapy, with a target INR of 2.5. Investigations show the following reports. INR: 2.1 Lupus antibody: Positive Anticardiolipin antibody: Positive Anti-β2 glycoprotein I antibodies: Positive What would be the most appropriate adjustment to her treatment after this arterial thrombosis episode? (Q851418)

A. Administration of oral hydroxychloroquine

B. Increase the dose of warfarin with a target INR of 3.0 to 4.0

C. Switch to direct oral thrombin inhibitor

D. Switch to low-dose aspirin with prophylactic dose low molecular weight heparin.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following assay tests cannot detect lupus anticoagulant antibodies? (Q851421)

A. Enzyme-linked immunosorbent assay

B. Activated thromboplastin time

C. Kaolin clotting time

D. Dilute Russell viper venom test

See Answer in Part B → Q14

@Neet_pg_bot

[08_Rheumatology] 062 Rheumatoid Arthritis — Quick Jump

Q1 (p. 760) *Q2 (p. 760)* *Q3 (p. 761)* *Q4 (p. 761)* *Q5 (p. 762)* *Q6 (p. 762)*
Q7 (p. 763) *Q8 (p. 763)* *Q9 (p. 764)* *Q10 (p. 764)* *Q11 (p. 765)*

Q1: A 45-year-old female complains of morning stiffness lasting over an hour and pain in her hands and wrists. On examination, there is swelling and tenderness of multiple small joints in her hands. Laboratory results show a positive rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) antibodies. X-ray reveals soft tissue swelling and early joint space narrowing. Which of the following joint involvement patterns is most characteristic of this condition? (Q851422)

A. Symmetrical involvement of small joints, particularly the MCP and PIP joints

B. Asymmetrical involvement of small joints, particularly the MCP and PIP joints

C. Symmetrical involvement of the DIP joints

D. Asymmetrical involvement of the DIP joints

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 52-year-old woman presents with joint pain and swelling, particularly in her hands and wrists, over the past 6 months. She has a family history of autoimmune diseases, and laboratory tests show positive rheumatoid factor (RF) and anti-citrullinated protein antibodies (anti-CCP). Which of the following statements is true regarding the etiopathogenesis of this patient's condition? (Q851424)

A. Crystal disposition in the joint spaces leads to joint inflammation

B. Presence of HLA-DR β 1 is strongly associated with this condition

C. Joint destruction occurs due to mechanical damage to the articular cartilage

D. Pregnancy can aggravate the symptoms of this condition

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 32-year-old woman with long-standing rheumatoid arthritis presents with difficulty extending the DIP joint and flexing the PIP joint of her middle finger. On examination, the PIP joint is flexed while the DIP joint is hyperextended. Which of the following deformities best matches this presentation? (Q851426)

A. Boutonniere deformity

B. Swan neck deformity

C. Z-line deformity

D. Mallet finger deformity

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old male presents to the clinic with joint pain and morning stiffness lasting more than one hour. Based on the EULAR classification criteria for rheumatoid arthritis, which of the following combinations of clinical, serological, and laboratory findings is most likely to lead to a definitive diagnosis of rheumatoid arthritis? (Q851428)

A. Swelling in 3 small joints, positive anti-citrullinated protein antibodies (ACPA) at high titers, and elevated C-reactive protein (CRP), symptoms for 8 weeks

B. Swelling in 1 large joint, positive rheumatoid factor at low titers, normal ESR, and symptoms for 4 weeks

C. Swelling in 6 small joints, negative ACPA, elevated ESR, and symptoms for 5 weeks

D. Swelling in 4 large joints, positive ACPA at low titers, normal CRP, and symptoms for 12 weeks

See Answer in Part B → Q4

@Neet_pg_bot

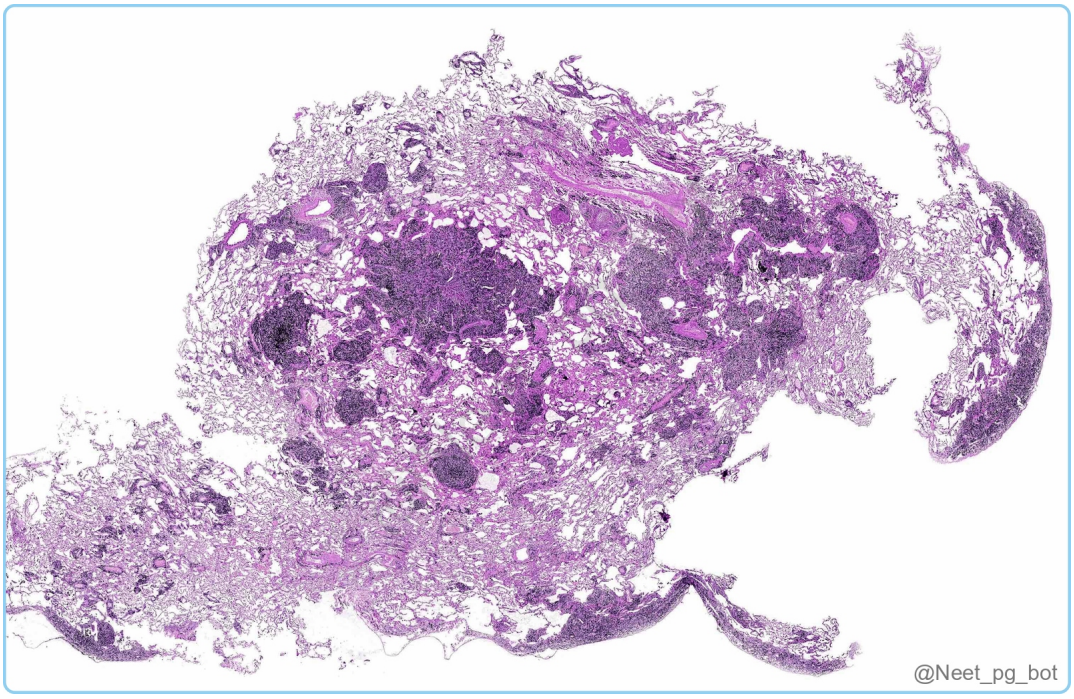
Q5: A 60-year-old male with a history of working in coal mines presents with progressive shortness of breath and a chronic cough. He reports that years ago, he was diagnosed with a joint condition that caused swelling and stiffness, particularly in his hands and wrists. Laboratory testing reveals he is positive for HLA-DR4. A chest X-ray shows multiple rounded opacities in both lung fields. A lung biopsy showed the following picture. What is the most likely diagnosis? (Q851430)

A. Caplan syndrome

B. Secondary Sjögren's syndrome

C. Felty syndrome

D. Lofgren syndrome



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 32-year-old male presents with multiple subcutaneous nodules on his arms and back, along with joint pain and stiffness primarily affecting his hands and knees. He

has erythema nodosum and a positive family history of similar conditions. Which of the following is a common ocular extra-articular manifestation associated with this condition? (Q851432)

A. Keratoconjunctivitis sicca

B. Uveitis

C. Iritis

D. Iridocyclitis

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 52-year-old man presents with bilateral pain, swelling, and stiffness in his hands and wrists for the past 4 months. His symptoms are worse in the morning and improve throughout the day. The physical exam shows synovitis in the metacarpophalangeal joints. Considering the high specificity for rheumatoid arthritis, which initial investigation is most appropriate to confirm the diagnosis in this patient? (Q851434)

A. Anti-nuclear antibody test

B. Anti-cyclic citrullinated peptide antibody

C. Synovial fluid analysis

D. MRI of the affected joints

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old female patient presents with significant joint pain, stiffness, and swelling affecting multiple joints. Her Disease Activity Score (DAS28) is 5.4, indicating high disease activity. She has not responded adequately to lifestyle modifications and NSAIDs. Which medication is considered this patient's first-line disease-modifying antirheumatic drug (DMARD)? (Q851435)

A. Sulfasalazine

B. Methotrexate

C. Leflunomide

D. Hydroxychloroquine

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old female patient with rheumatoid arthritis presents with persistent joint pain and swelling despite being on methotrexate and low-dose prednisolone for the past six months. Her Disease Activity Score (DAS28) is 5.4, indicating high disease activity. What is the most appropriate next step in her management? (Q851437)

A. Increase the dose of methotrexate

B. Initiate oral triple therapy

C. Switch from methotrexate to leflunomide

D. Continue methotrexate for 3 more months

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 60-year-old man with rheumatoid arthritis is being evaluated for remission after 6 months of treatment. According to the ACR/EULAR remission criteria, which of the following is NOT correct? (Q851438)

A. Tender joint count ≤1

B. Simplified Disease Activity Index (SDAI) score of ≤ 3.2

C. CRP ≤1 mg/dL

D. Patient global assessment ≤ 1

See Answer in Part B → Q10

Q11: Match the following: 1. Swan neck deformity a) {{caption_text}} 2. Boutonniere deformity b) 3. Z-line deformity c) 4. Mallet finger deformity d) {{caption_text}} (Q851440)

A. 1-c, 2-b, 3-d, 4-a

B. 1-b, 2-d, 3-a, 4-c

C. 1-a, 2-c, 3-b, 4-d

D. 1-d, 2-a, 3-c, 4-b

Q7 (p. 771) *Q8 (p. 771)* *Q9 (p. 772)* *Q10 (p. 773)*

Q1: A 62-year-old man presents with sudden, severe pain in his right big toe, waking him from sleep. The joint is swollen, red, and extremely tender. He has a history of high uric acid levels and recently consumed protein-rich meals. What is the most likely diagnosis? (Q851618)

A. Pseudogout

B. Saturnine gout

C. Podagra

D. Psoriatic arthritis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 43-year-old man presents with severe pain in his right big toe, redness, and swelling, as shown in the image. He has a history of hypertension and recently increased her consumption of red meat. Which of the following best explains the pathophysiological process leading to her condition? (Q851620)

A. Increased renal tubular secretion of uric acid

B. Decreased production of purines

C. Impaired renal excretion of uric acid

D. Increased breakdown of uric acid

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 60-year-old woman with a history of elevated uric acid levels reports that she experienced a painful episode in her right big toe two months ago. Since that time, she has had no symptoms and feels completely normal. She is concerned about the possibility of future attacks. What stage of the associated condition is this patient most likely experiencing now? (Q851621)

A. Asymptomatic Hyperuricemia

B. Acute Gout Attack

C. Intercritical Gout

D. Chronic Gouty Arthritis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 58-year-old man presents with a sudden onset of severe pain in his left knee, accompanied by swelling and redness. He has a history of elevated uric acid levels. The physician suspects gout and plans to perform a joint aspiration for diagnostic purposes. Which of the following findings would most likely confirm the diagnosis of gout? (Q851622)

A. The presence of rhomboid-shaped crystals under polarised light

B. Elevated white blood cell count with neutrophilic predominance

C. Needle-shaped crystals exhibiting negative birefringence

D. Thickened synovial fluid with a high percentage of lymphocytes

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 46-year-old man presents to the OPD with severe pain, redness, and swelling in his right knee. Examination reveals tender swelling and redness at the base of the right 1st toe. Serum urate levels are normal, but arthrocentesis reveals negatively birefringent needle-shaped crystals under polarised light. Which of the following is the drug of choice for this acute attack? (Q851623)

A. Canakinumab

B. Oral colchicine

C. Intra-articular glucocorticoid injection

D. Allopurinol

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 48-year-old man had an acute gout attack treated successfully with NSAIDs. His labs show markedly elevated serum uric acid and high 24-hour urinary uric acid excretion. Which drug is the best choice for long-term management? (Q851624)

A. Pegloticase

B. Allopurinol

C. Febuxostat

D. Anakinra

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 45-year-old male with stage 2 chronic kidney disease presents with painful swelling at the base of his left big toe. He was diagnosed with an acute gouty attack and treated with oral glucocorticoids. Which anti-gout medication can be used to reduce the risk of another attack without dose modification? (Q851625)

A. Probenecid

B. Allopurinol

C. Febuxostat

D. Lesinurad

See Answer in Part B → Q7

@Neet_pg_bot

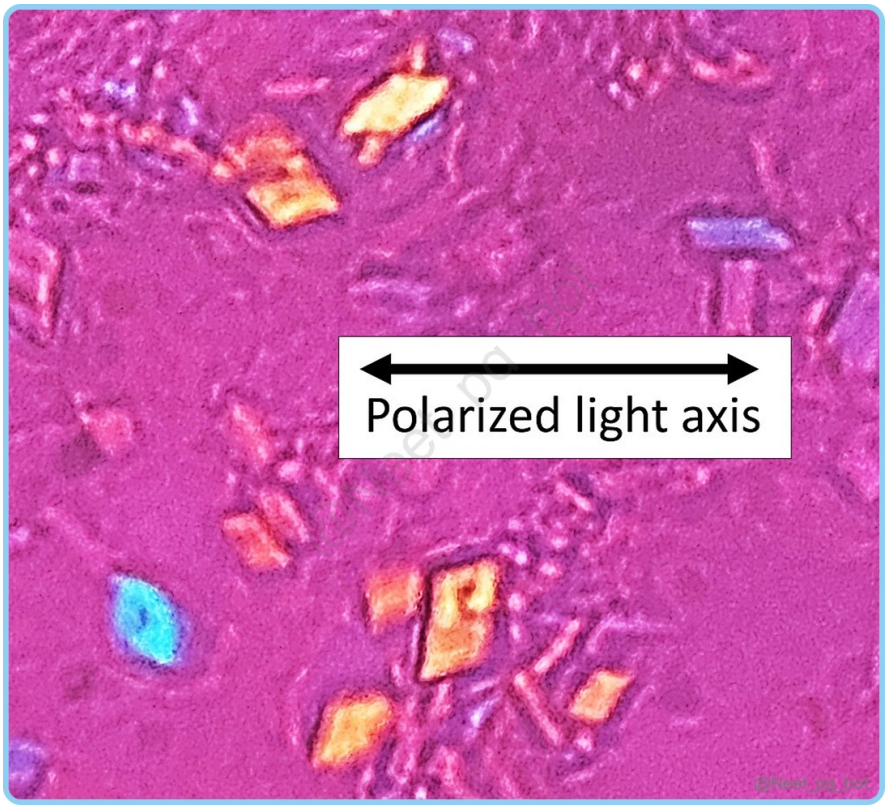
Q8: A 65-year-old man presents to the emergency department with sudden swelling, redness, and severe pain in both knees. He has experienced intermittent joint pain for the past few months. Polarised light microscopy of joint aspiration reveals rhomboid-shaped crystals exhibiting positive birefringence. Which statement best explains the pathogenesis of his condition? (Q851627)

A. Excessive mechanical wear and tear of the articular cartilage

B. Deposition of calcium pyrophosphate crystals in cartilage matrix vesicles

C. Excess purine production causes crystal deposition in the joints

D. Autoimmune reaction leading to pannus formation in the joint



See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 75-year-old woman presents to the clinic with chronic pain and swelling in her shoulder joint. Radiographs reveal calcific tendinitis in the rotator cuff. A joint aspiration is performed, and the synovial fluid is analysed. If this patient has calcium apatite deposition disease, what type of crystal is most likely to be seen in the patient's synovial fluid? (Q851629)

A. Positively birefringent rhomboid-shaped crystals

B. Strong birefringent bipyramidal crystals

C. Negatively birefringent needle-shaped crystals

D. Microcrystals with no birefringence

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Match each condition with its corresponding key synovial fluid characteristics: Conditions Key Characteristics 1. Normal a. Yellow, Cloudy, >50,000 WBC 2. Non-inflammatory b. Colorless, Clear, <200 WBC 3. Inflammatory c. Yellow, Opaque, Positive Gram Stain 4. Septic d. Xanthochromic or Red, Bloody 5. Hemarthrosis e. Straw-like, Clear, 200 - 2000 WBC (Q851630)

A. 1 - b, 2 - e, 3 - a, 4 - c, 5 - d

B. 1 - a, 2 - b, 3 - e, 4 - d, 5 - c

C. 1 - c, 2 - d, 3 - b, 4 - e, 5 - a

D. 1 - b, 2 - c, 3 - a, 4 - d, 5 - e

Q1: A 45-year-old lady presents with skin changes, reporting that her fingers have become thick and tight. She has developed painful ulcers on her fingertips that heal slowly. The physician notes shiny, taut skin on her face and limited neck extension. The given image shows the patient's facial features. Which of the following findings is not typically associated with the skin changes observed in this patient? {{caption_text}} (Q851373)

A. Bilateral symmetrical skin thickening

B. Hyperpigmentation in sun-exposed areas

C. Fixed flexion contractures of the fingers

D. Telangiectasia on the face and hands

See Answer in Part B → Q1

@Neet_pg_bot

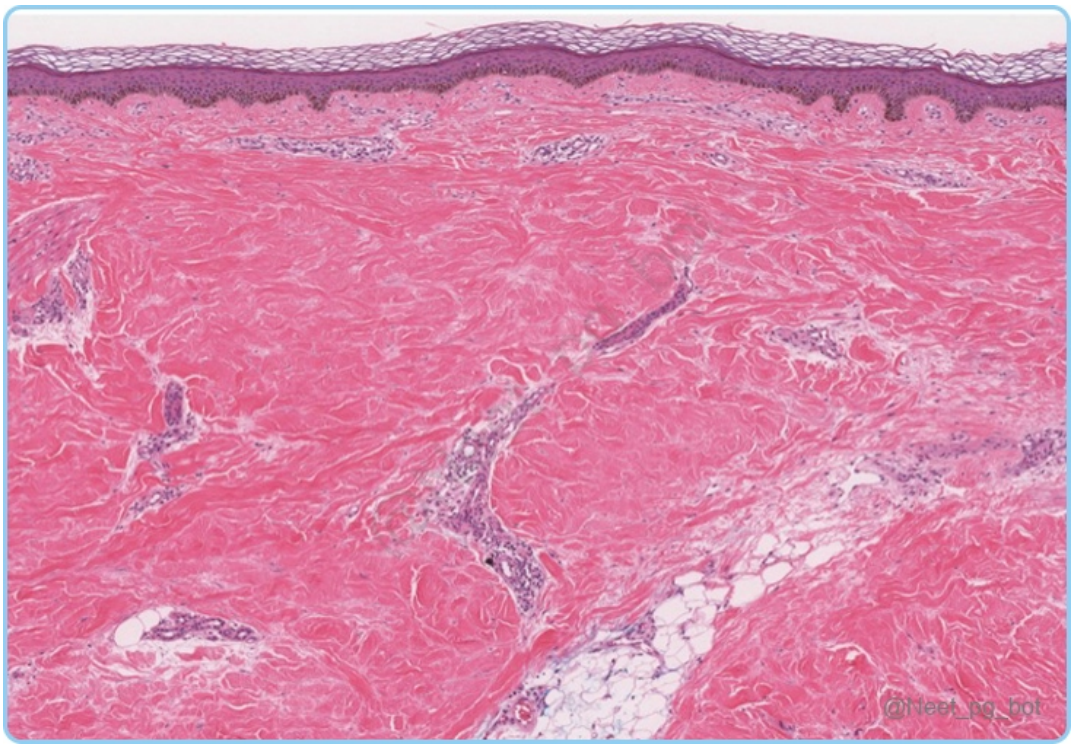
Q2: Which of the following statements about the histopathological examination (HPE) of the images is correct? A) {{caption_text}} B) {{caption_text}} Image A shows a thickened dermis with collagen accumulation and loss of adipose tissue. Image B demonstrates normal glomerular architecture with no signs of injury. Image B shows vascular lesions and ischemic glomerular changes. Image A is characterized by alveolar septal fibrosis leading to gas exchange impairment. (Q851375)

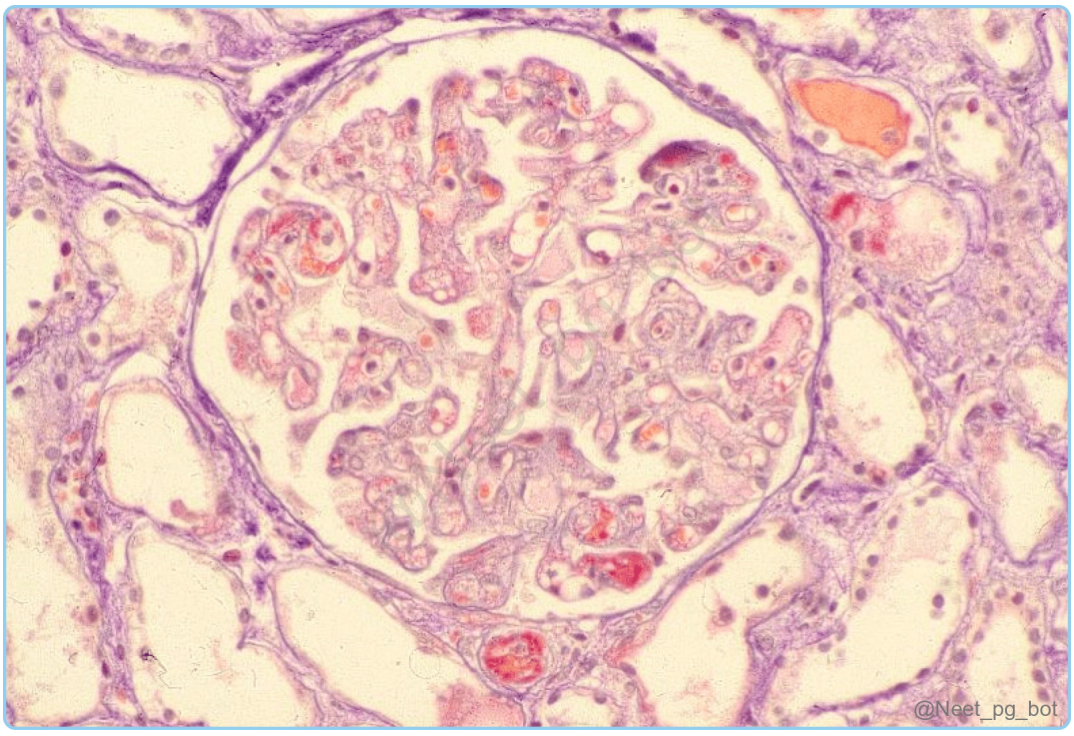
A. 3 and 4

B. 2 and 4

C. Only 2

D. 1 and 3





See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 52-year-old woman presents with skin changes, including thickened and tight skin on her fingers, as well as pain and ulcerations at the fingertips. On examination, she has a shiny appearance to her skin and visible telangiectasia on her face. Which of the following options includes one pulmonary and one cardiac manifestation correctly associated with her clinical features? (Q851376)

A. Tuberculosis; Congestive cardiac failure

B. Cavitation; Pericarditis

C. Pulmonary arterial hypertension; Constrictive pericarditis

D. Non-caseating granuloma; Atrial myxoma

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old woman with systemic sclerosis presents with new-onset hypertension and episodes of cold-induced finger discoloration. Which statement about her renal and vascular manifestations is false? (Q851377)

A. Scleroderma renal crisis presents with accelerated hypertension and can cause renal failure.

B. Raynaud's phenomenon is the most common extracutaneous feature and can lead to ulcers.

C. Anti-centromere antibodies increase the risk of scleroderma renal crisis.

D. Nailfold capillaroscopy distinguishes between primary and secondary Raynaud’s.

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45-year-old woman presents with symptoms including skin thickening on her fingers, fatigue, and shortness of breath with episodes of painful swelling in her fingertips and difficulty swallowing. During her examination, a specific immunofluorescence test is performed, revealing the presence of several autoantibodies. Which of the following auto-antibodies is most likely associated with severe skin involvement and interstitial lung disease in this patient? (Q851378)

A. Centromere Proteins

B. Topoisomerase I (Scl-70)

C. RNA Polymerase III

D. U1-RNP

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 60-year-old woman presents with severe fatigue, dry mouth, difficulty swallowing, and episodes of coldness and color changes in her fingers. She reports dyspnea on exertion and has a history of gastrointestinal reflux. There is no visible skin thickening. Laboratory tests show positive anti-nuclear antibodies and anti-Scl-70 antibodies. Which condition is she most likely experiencing? (Q851379)

A. Limited Scleroderma

B. Diffuse Scleroderma

C. Sine Sclerosis

D. Sjögren's Syndrome

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 25-year-old female presents with episodes of sequential color changes in her fingers (white, blue, and red) triggered by cold exposure. She has no underlying conditions, normal nail fold capillaroscopy, and symmetric involvement. Which of the following is the most likely diagnosis (Q851380)

A. Secondary Raynaud's Due To Scleroderma

B. Primary Raynaud's Phenomenon

C. Acrocyanosis

D. Secondary Raynaud's Due To SLE

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 42-year-old female with diffuse cutaneous systemic sclerosis presents with severe headache, blurred vision, and blood pressure of 180/100 mmHg. Laboratory findings show creatinine of 2.8 mg/l, without thrombocytopenia or fragmented RBCs in peripheral smear. She has recently started on prednisolone 20mg daily for severe skin involvement. Which of the following is the most appropriate immediate management? (Q851382)

A. Start calcium channel blockers and taper steroids

B. Immediate initiation of short-acting ACE inhibitors

C. Start plasmapheresis for suspected TTP

D. Increase steroid dose to control inflammation

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 42-year-old female with diffuse cutaneous systemic sclerosis presents with worsening dyspnea and reduced lung function tests showing a restrictive pattern. Which of the following is the most appropriate treatment choice? (Q851383)

A. High-dose oral glucocorticoids

B. Cyclophosphamide

C. Hydroxychloroquine

D. Thalidomide

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45-year-old woman presents with dry eyes and a dry mouth that has been persistent for the past 8 months. She also reports joint stiffness, fatigue, and recent dental caries. Histology reveals lymphocytic infiltration in the salivary glands. Which of the following factors is most directly implicated in the pathogenesis of her condition? (Q851386)

A. CD8+ T cell infiltration in exocrine glands

B. Hypergammaglobulinemia with elevated B-cell activation

C. Mutations in the CFTR gene

D. Eosinophilic infiltration in minor salivary glands

See Answer in Part B → Q10

@Neet_pg_bot

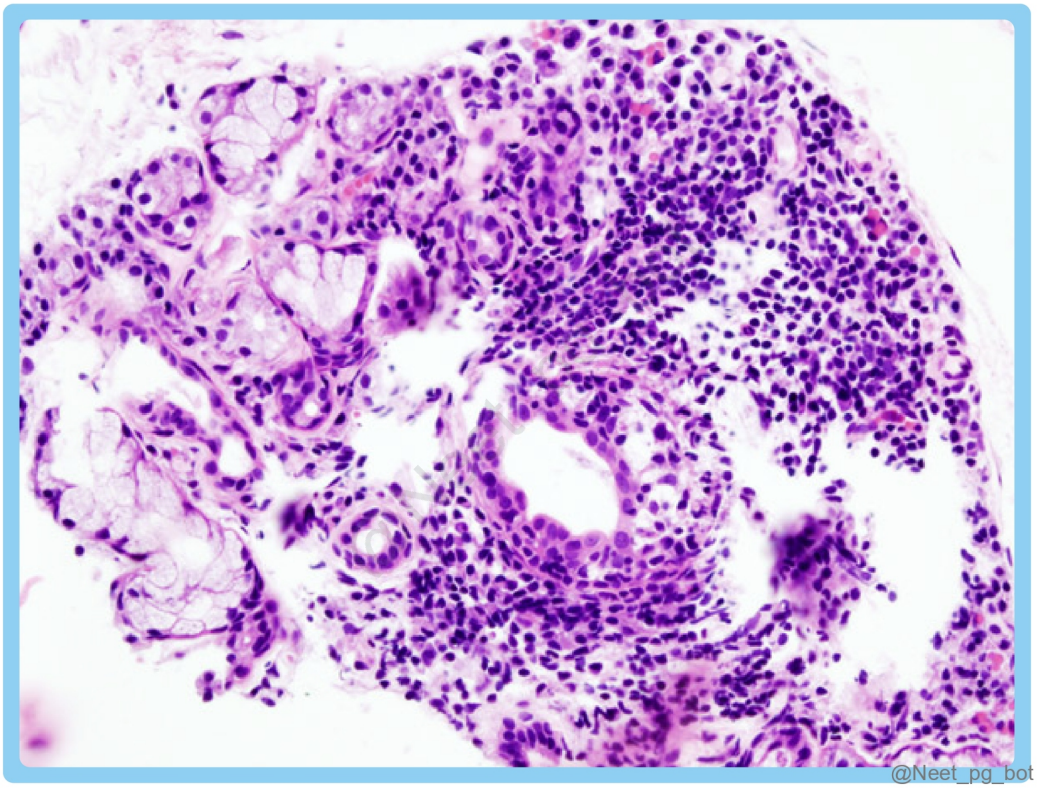
Q11: A 47-year-old female presents with a history of persistent dry mouth and a gritty sensation in her eyes. Her clinical evaluation is significant for dry mucous membranes and parotid gland swelling. A labial salivary gland biopsy is performed, and the histopathological examination reveals inflammatory infiltration. Based on the histopathological findings in the provided image, which of the following features would most specifically support a diagnosis? (Q851391)

A. Presence of multiple non-caseating granulomas

B. Lymphocytic foci surrounding ducts with a focus score ≥ 1 per 4 mm^2 area

C. Diffuse infiltration predominantly by neutrophils

D. Eosinophilic infiltration with periductal fibrosis



See Answer in Part B → Q11

@Neet_pg_bot

Q12: A patient diagnosed with Sjogren Syndrome reports persistent dry eyes, despite using artificial tears. Which of the following treatments would be considered next to alleviate the ocular symptoms? (Q851397)

A. Oral corticosteroids

B. Antihistamines

C. Topical cyclosporine eye drops

D. NSAIDs

See Answer in Part B → Q12

Q13 (p. 790)	*Q14 (p. 791)*	*Q15 (p. 791)*	*Q16 (p. 791)*		

Q1: A 30 y/o woman presents with a persistent cough, fatigue, and painful red nodules on her lower legs. Her ACE levels were found to be elevated and her chest x-ray findings are given below. She has a family history of autoimmune diseases and carries the HLA-DRB1*03 haplotype. What pathophysiological feature is most likely contributing to her condition? (Q851419)

A. Accumulation of neutrophils and eosinophils in lung tissue.

B. Interaction between antigen-presenting cells and T-helper cells leading to granuloma formation.

C. Decreased production of cytokines such as IL-2 and IFN-γ.

D. High levels of cyclosporine in the serum affecting T-cell activity.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 35-year-old woman presents to the ED with severe chest pain and palpitations. She has a history of recurrent cough and fatigue over the past year. O/E, she has slight oedema in her lower extremities and a heart murmur. The chest X-ray of the patient is given below. Which of the following features is least likely associated with this patient's condition? (Q851423)

A. Anterior uveitis leading to vision changes.

B. Elevated alkaline phosphatase and portal hypertension.

C. Hypocalcemia and hypocalciuria with increased PTH.

D. Congestive heart failure

See Answer in Part B → Q2

@Neet_pg_bot

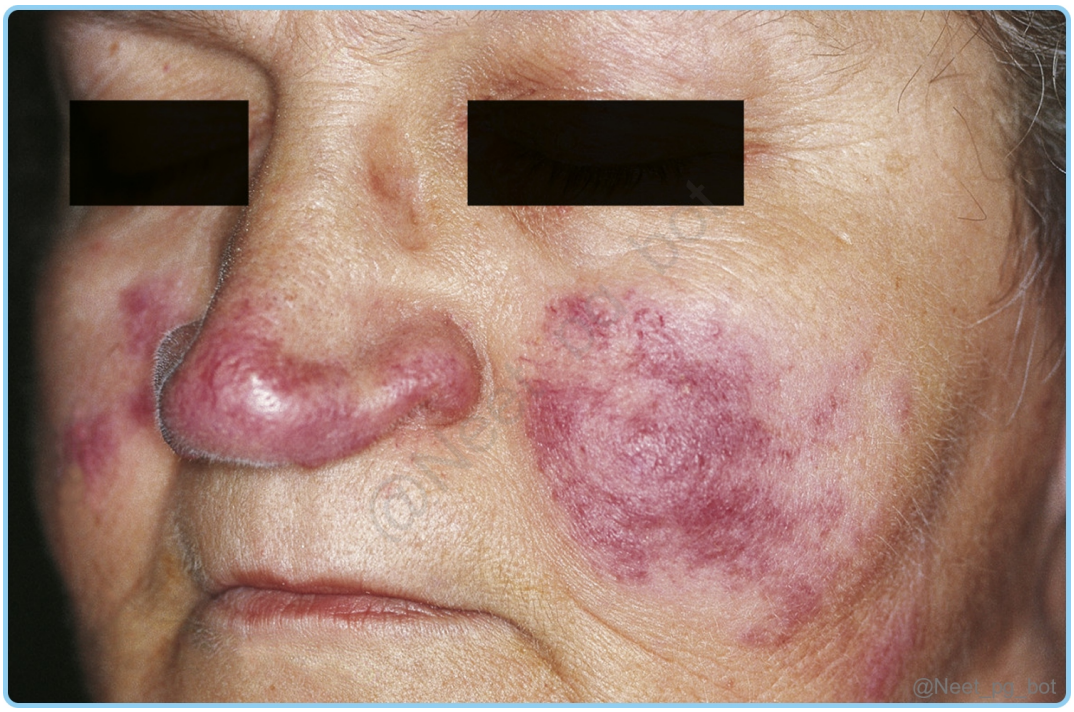
Q3: A 40-year-old woman has been suffering from a persistent cough, progressive shortness of breath, and fatigue for the past several months. A chest X-ray shows bilateral hilar lymphadenopathy. The patient also has a skin rash, as shown in the image below. Which of the following statements regarding this patient's diagnosis is false? (Q851425)

A. HRCT scan shows reticulonodular opacities.

B. PET scan indicates increased metabolic activity.

C. CD4:CD8 T-cell ratio in BAL < 3.5.

D. Biopsy shows non-caseating granulomas.



See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45 y/o woman diagnosed with sarcoidosis presents with worsening pulmonary symptoms, including shortness of breath and a persistent dry cough. She has also developed erythema nodosum on her legs. After a thorough evaluation, her physician decides that treatment is necessary to improve her quality of life and prevent complications. Which of the following treatment options is considered first-line for this patient's condition? (Q851427)

A. Methotrexate 10–20 mg/week.

B. Prednisolone 20–40 mg/day.

C. Infliximab at higher doses.

D. Hydroxychloroquine 200 mg/day.

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following organs is least commonly involved in sarcoidosis? (Q851429)

A. Spleen

B. Heart

C. Skin

D. Brain

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 45 y/o woman presents with progressive muscle weakness and a distinctive rash on her eyelids and knuckles. She also exhibits a rash like in the given image. She reports difficulty swallowing and has experienced some joint pain. Which of the following statements about this patient's condition is false? (Q851431)

A. The rash may precede or accompany the muscle weakness.

B. Weakness is typically asymmetric, affecting distal muscles more than proximal.

C. Nail bed telangiectasias are a common finding.

D. Patients may present with only a rash and no muscle weakness.

See Answer in Part B → Q6

@Neet_pg_bot

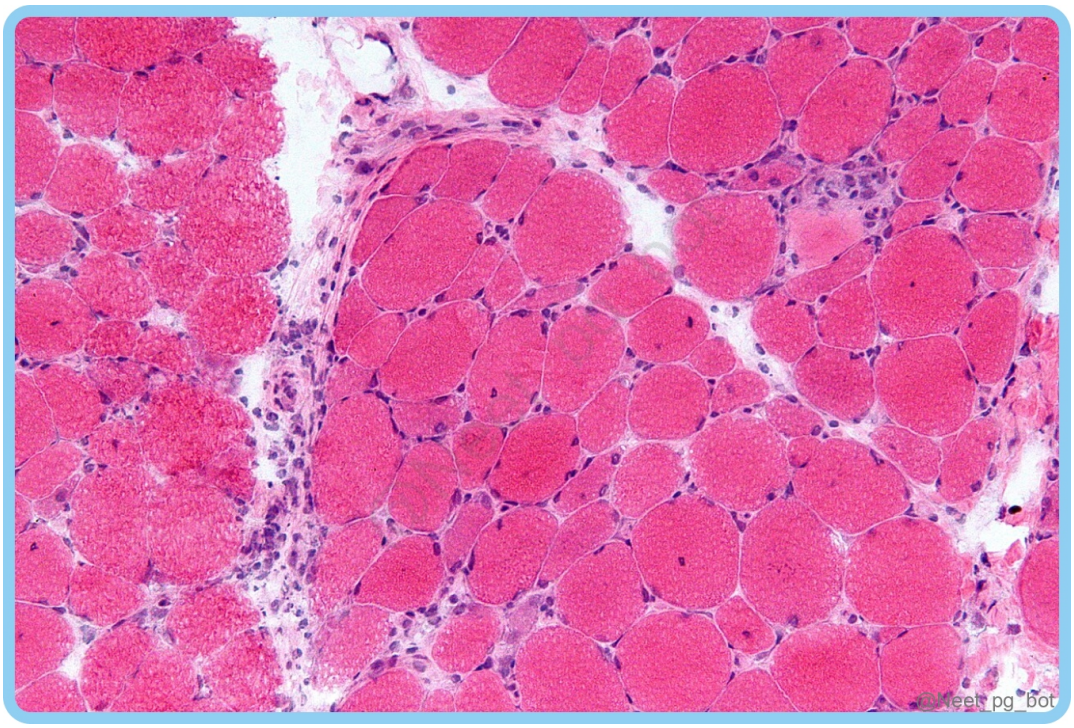
Q7: A 50 y/o woman presents with muscle weakness that has progressively worsened over the last 2 months. She also reports a red rash on her knuckles and upper eyelids. The histopathology image of muscle biopsy is given below. MxA staining is positive. Which of the following statements regarding her condition is false? (Q851433)

A. Serum CK is elevated

B. Anti-TIF1 antibodies are associated with a favourable prognosis.

C. Perifascicular atrophy is characteristic of dermatomyositis.

D. Anti-MDA5 antibodies are linked to a higher risk of rashes, ulcers and ILD.



See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old woman has 3 months of progressive proximal muscle weakness, difficulty climbing stairs, and elevated creatine kinase (CK) levels. EMG indicates inflammatory myopathy, and a muscle biopsy shows endomysial infiltration with CD8+ T cells. What is the most likely diagnosis? (Q851436)

A. Polymyositis

B. Antisynthetase syndrome

C. Dermatomyositis

D. Overlap syndrome

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 35 y/o male presents with painful, recurrent oral ulcers lasting around 20 days. He also reports a history of genital ulcers and occasional skin lesions resembling erythema nodosum. Recently, he has developed blurred vision and redness in both eyes. Examination reveals anterior uveitis and multiple deep oral ulcers. A pathergy test is positive. What is the most likely diagnosis? (Q851439)

A. Behçet's disease

B. Cogan syndrome

C. Overlap syndrome

D. Antisynthetase syndrome

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 34 y/o male presents with a 2-year history of lower back stiffness and pain that improves with activity. He also has occasional knee and hip pain. Examination reveals reduced lumbar spine mobility and tenderness over the sacroiliac joints. What additional clinical feature is most likely associated with this condition? (Q851441)

A. High fever and night sweats

B. Symmetrical small joint swelling

C. Generalized muscle weakness

D. Recurrent anterior uveitis

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 26 year old male is evaluated for long-standing back pain and stiffness. Modified Schober’s test shows restricted lumbar flexion. Physical examination reveals limited chest expansion. Which additional finding would most likely be present? (Q851442)

A. Free lateral bending of the spine

B. Loss of lumbar lordosis

C. Hypermobile cervical spine

D. Absence of tenderness over the sacroiliac joints

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 20 y/o male presents with persistent back pain that improves with physical activity. He has a family history of inflammatory arthritis and shows HLA-B27 positivity. Imaging reveals sacroiliitis. Which of the following combinations fulfils the diagnostic criteria for axial spondyloarthritis? (Q851443)

A. History of joint pain plus normal X-ray findings

B. HLA-B27 positivity plus a history of allergic rhinitis

C. HLA-B27 positivity plus two other spondyloarthritis features

D. Elevated CRP levels plus a positive Schober's test

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 35 y/o female with ankylosing spondylitis is experiencing episodes of uveitis. Which would be the most appropriate drug to address both her uveitis and her underlying condition? (Q851444)

A. Anakinra

B. Adalimumab

C. Sulfasalazine

D. Tofacitinib

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which organ is most commonly associated with inflammatory pseudotumour in children? (Q851445)

A. Lungs

B. Liver

C. Brain

D. Kidneys

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 65 y/o male presents with abdominal pain, jaundice, and weight loss. Imaging reveals a mass in the liver, and laboratory tests show elevated IgG4 levels. A biopsy is performed to confirm the diagnosis. What is most likely associated with IgG4-related inflammatory pseudotumor? (Q851446)

A. Epithelioid cell granulomas

B. Caseating granulomas

C. Necrotising vasculitis

D. Storiform fibrosis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 45 y/o patient presents with mild abdominal pain, weight loss, and obstructive jaundice. Imaging reveals a "sausage-shaped" pancreas and a subsequent CT scan shows diffuse pancreatic enlargement. The patient's condition is suspected to be related to an inflammatory process rather than malignancy. Which of the following is the most appropriate first-line treatment for this condition? (Q851447)

A. Rituximab

B. Surgical resection

C. Glucocorticoids

D. Antibiotics

See Answer in Part B → Q16

@Neet_pg_bot

Q1: Which among the following is more common in limited cutaneous systemic sclerosis when compared to diffuse cutaneous systemic sclerosis? (Q855000)

A. Esophageal dysmotility

B. Myopathy

C. Interstitial lung disease

D. Scleroderma renal crisis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A young patient presents to the clinic with erythematous lesions over the exposed areas of the skin, like hands, arms, and chest. He also complains of arthralgia and breathlessness. Measuring which among the following antibodies will be useful in diagnosing the underlying conditions? (Q855716)

A. Antihistone antibodies

B. Anti-dsDNA antibodies

C. Anticentromere antibodies

D. Antinuclear antibodies

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A patient presents with severe pain and swelling in his knee joint for 10 days. He also complains of pain and discomfort during urination. He says that he had diarrhea one month ago and he has been unwell since then. What is the most likely diagnosis? (Q857037)

A. Reactive arthritis

B. Enteropathic arthritis

C. Rheumatoid arthritis

D. Psoriatic arthritis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Takayasu arteritis most commonly involves: (Q857628)

A. Pulmonary artery

B. Coronary arteries

C. Abdominal aorta

D. Arch of aorta

See Answer in Part B → Q4

@Neet_pg_bot

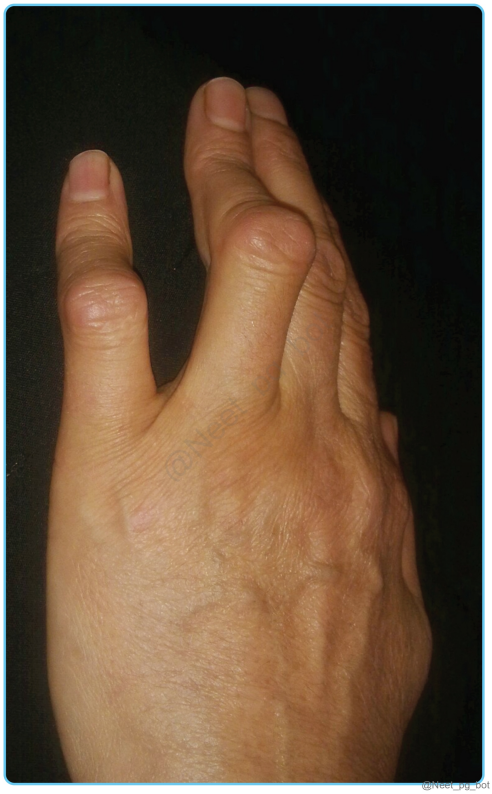
Q5: Identify the deformity depicted in the image: (Q857669)

A. Swan neck deformity

B. Boutonniere deformity

C. Z line deformity

D. Mallet finger deformity



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A patient presents with flaccid bullous lesions as shown in the image below involving the entire trunk and oral cavity. Acantholytic cells are seen on Tzank smear. What is the most probable diagnosis? (Q857670)

A. Pemphigus foliaceus

B. Pemphigus vulgaris

C. Dermatitis herpetiformis

D. Bullous pemphigoid

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A patient presented with sinusitis, ulcerative lesions on the nasopharynx, nodular lesions with cavitations of the lung, and renal failure. Which of the following is the most useful investigation in this patient? (Q855703)

A. Test for ANCA

B. Biopsy to show granuloma

C. AFB staining of sputum

D. BAL

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A patient with giant cell arteritis presented with headache, jaw claudication, polymyalgia rheumatica, and mononeuritis multiplex. What should be the first-line treatment for this patient? (Q856110)

A. Abatacept

B. Tocilizumab

C. Steroids

D. Aspirin

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A woman presents with numbness of her fingertips. On examination, her face is tightened. The antinuclear antibody(ANA) is found to be positive and immunofluorescence shows the nucleolar pattern. What is the likely diagnosis? (Q856134)

A. Systemic sclerosis

B. Sjogren's syndrome

C. Systemic lupus erythematosus

D. Rheumatoid arthritis

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 36-year-old woman presented with claudication in the forearm, transient loss of vision, and abdominal pain. Femoral pulses were weak. Fundus examination revealed retinal haemorrhages. What is the likely diagnosis? (Q856162)

A. Polyarteritis nodosa

B. Thromboangitis obliterans

C. Takayasu arteritis

D. Microscopic polyangiitis

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following conditions is not associated with Iritis ? (Q856936)

A. SLE

B. Behcet’s disease

C. Ulcerative colitis

D. Rheumatoid arthritis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is not a first-line drug for the management of a patient with rheumatoid arthritis? (Q855602)

A. Sulfasalazine

B. Hydroxychloroquine

C. Methotrexate

D. Azathioprine

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is true about polyarteritis nodosa? (Q855005)

A. Necrotising inflammation of large vessels

B. Patient has hypogammaglobulinemia

C. 90% is associated with ANCA positivity

D. 30% is associated with Hepatitis B

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following is associated with pauci-immune glomerulonephritis? (Q855062)

A. SLE nephritis

B. Anti-GBM glomerulonephritis

C. IgA nephropathy

D. Granulomatosis with polyangiitis (GPA)

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 54-year-old female patient visits you with symptoms of finger swelling, heartburn, and occasional joint pain. During the examination, her hands appeared shiny, tight, and thickened with non-pitting oedema. Additionally, she has interstitial lung disease and tests positive for ANA antibodies, topoisomerase I antibodies, and anti-RNA polymerase III antibodies. What is the likely diagnosis? (Q859521)

A. Limited cutaneous systemic sclerosis

B. Diffuse cutaneous systemic sclerosis

C. Raynaud's phenomenon

D. Peutz-jeghers syndrome

See Answer in Part B → Q15

@Neet_pg_bot

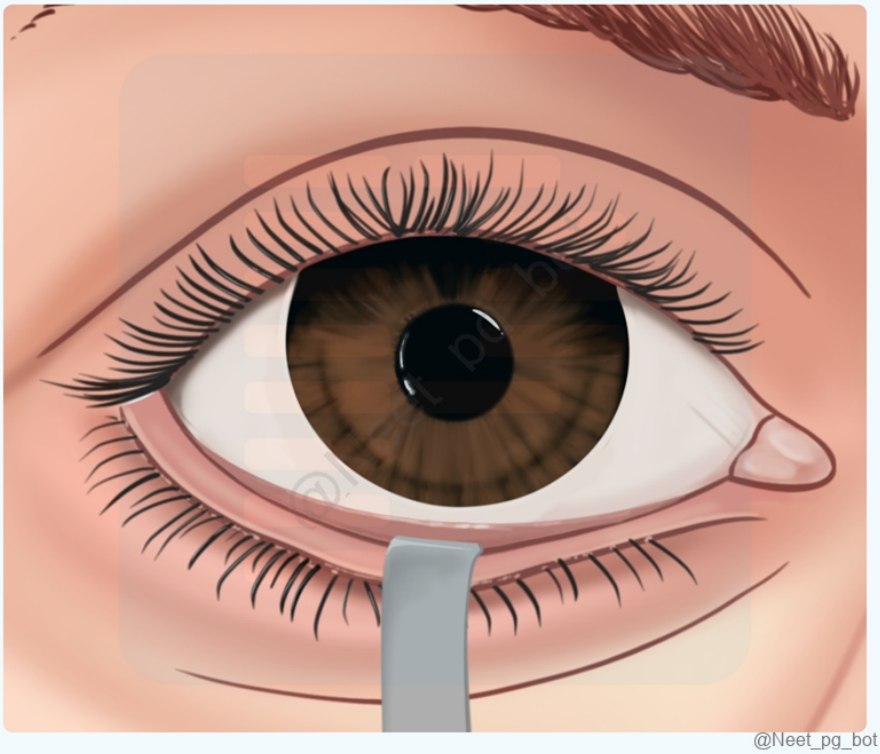
Q16: A 45-year-old woman complains of dryness in her mouth and eyes and has positive anti-Ro and anti-La antibodies. The image below shows a positive test result with a score of less than 5 mm in 5 minutes without anaesthesia. What is the probable diagnosis? (Q859562)

A. Scleroderma

B. Dehydration

C. Lacrimal duct stones

D. Sjogren syndrome



See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 21-year-old woman with no comorbidities presented with numbness and paraesthesia of the fingers of both hands along with the characteristic finding as shown in the image below. She has no other illnesses and she says these episodes occur

when she is under excess stress or during cold climates. What is the most likely diagnosis? (Q859563)

A. Primary Raynaud’s phenomenon

B. Secondary Raynaud’s phenomenon

C. Cold sores

D. Scleroderma

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 65-year-old man is experiencing chronic pain in his hands, knees, and hips, with increased pain in the hands during writing or typing. Additionally, he has morning stiffness in his joints that lasts for about 30 minutes. On examination, Heberden's and Bouchard's nodes are visible in the hands, and an X-ray of the knee shows narrowed joint space with osteophytes. What is the most likely diagnosis? (Q859786)

A. Osteoporosis

B. Osteoarthritis

C. Rheumatoid arthritis

D. Bone tumour

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 52-year-old woman presented with changes in the hand as shown below. There is decreased motion in the small joints and loss of wrinkle lines on the facial skin. Her chest radiograph showed prominent bilateral lower lobe infiltrates. Which of the following is the most likely diagnosis? (Q859796)

A. Rheumatoid arthritis

B. Scleroderma

C. Systemic lupus Erythematosus

D. Pneumonia

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A woman presents with fever, arthralgia, ulcers, fatigue for the past six months, and new-onset hematuria. Urine examination reveals RBC casts and proteinuria. What is the likely diagnosis? (Q855963)

A. Acute interstitial nephritis

B. Post-streptococcal glomerulonephritis

C. Lupus nephritis

D. IgA nephropathy

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 40-year-old female patient presents with dry mouth and a gritty sensation in the eyes. She has normal anion gap metabolic acidosis and hypokalemia. She also has enlarged salivary glands. What is the best investigation to arrive at a diagnosis? (Q879214)

A. Serum ACE levels and chest x-ray

B. Improvement on trial with methylprednisolone

C. Schirmer test and auto-antibody measurement

D. Salivary gland scintigraphy

See Answer in Part B → Q21

@Neet_pg_bot

Q22: After confirming a diagnosis of gout, which of the following drugs is a purine analog that would be most appropriate for management? (Q860474)

A. Allopurinol

B. Capecitabine

C. Cytarabine

D. Febuxostat

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A child presents with kawasaki disease with multiple small coronary artery aneurysms. Treatment is? (Q866821)

A. Aspirin lifelong

B. Aspirin for 4 weeks

C. Aspirin for 6 weeks

D. Aspirin and clopidogrel for 6 weeks

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following is the most common clinical feature observed during the progression of systemic lupus erythematosus (SLE)? (Q865303)

A. Photosensitivity

B. Nephrotic syndrome

C. Arthralgia & myalgia

D. Anemia and thrombocytopenia

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A patient presents with morning stiffness and tests positive for anti-CCP antibodies. Which of the following histological features is most characteristic of the underlying disease? (Q866467)

A. Pannus formation and erosive joint damage

B. Non-caseating granulomas

C. Subepidermal blister with IgA deposits

D. Tophi with monosodium urate crystals

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Patient presents with dry cough, dyspnea and stridor since 1 month. HPE of hilar LN shows stellate granulomas with giant cells and circular lamellated concretions on histopathology. Which of the following is the most likely diagnosis? (Q866484)

A. Sarcoidosis

B. Tuberculosis

C. GPA

D. Hypersensitivity pneumonitis

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Anti-Scl-70 (anti-topoisomerase I) antibody in systemic sclerosis is most commonly associated with which of the following manifestations? (Q866490)

A. Interstitial Lung Disease

B. Raynaud's phenomenon

C. Calcinosis cutis

D. Gastric Antral Vascular Ectasia

See Answer in Part B → Q27

@Neet_pg_bot

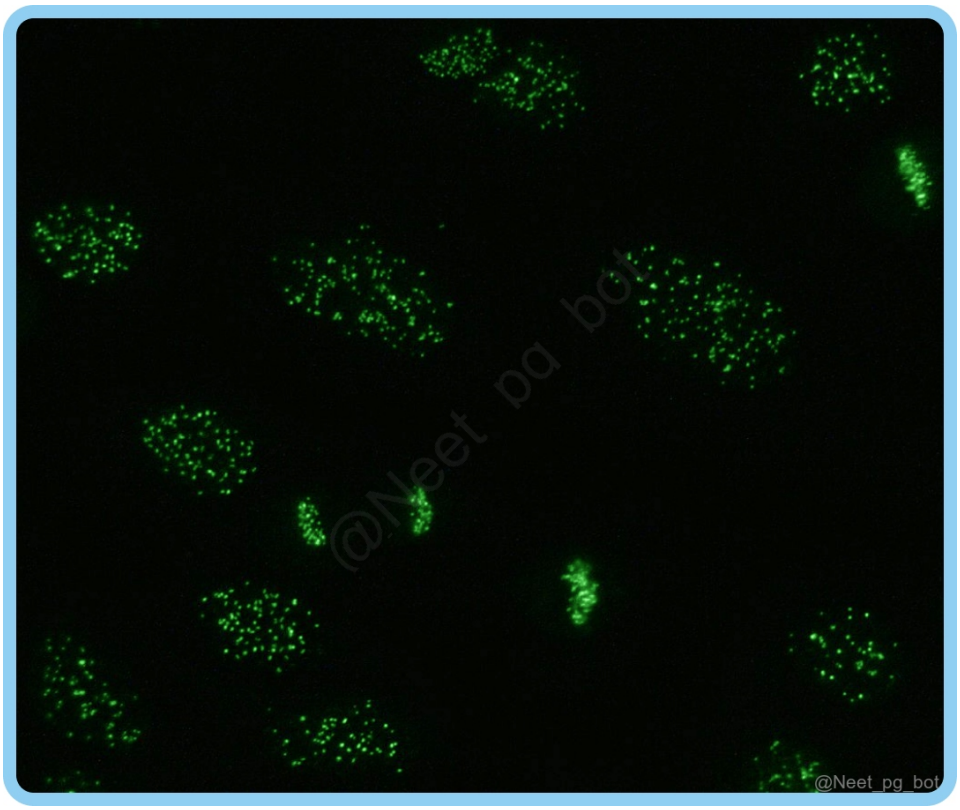
Q28: A 42-year-old woman presents with recurrent bluish discoloration of her fingers on exposure to cold, tightening of the skin over her hands and face, difficulty swallowing, and shortness of breath. On examination, she has shiny, taut skin over her fingers and visible telangiectasias. What does this ANA pattern indicate, and what is the most likely diagnosis? {{caption_text}} (Q853354)

A. Speckled pattern, SLE

B. Nuclear pattern, SLE

C. Anti-centromere pattern, CREST

D. Homogeneous pattern, systemic sclerosis



See Answer in Part B → Q28

@Neet_pg_bot

Q29: A patient presented with uveitis, enthesitis, and sacroiliitis. Which of the following is most likely associated with this condition? (Q853359)

A. HLA-B27

B. HLA-B57

C. HLA-B51

D. HLA-B5

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A male patient presents with oral ulcers and ulcers in the anal canal. He is diagnosed with Behçet's disease. Which of the following is not seen in this condition? (Q853361)

A. Ulcer over the dorsum of the penis

B. It is more similar to Crohn's disease than ulcerative colitis

C. Bilateral panuveitis

D. Pathergy test positive is a criterion of ISG diagnostic criteria

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A patient presents with joint swelling, a pan systolic murmur, negative rheumatoid factor (RF), and elevated ESR. What is the most likely diagnosis? (Q844177)

A. Acute rheumatic fever

B. Seronegative rheumatoid arthritis (RA)

C. Juvenile spondyloarthropathy

D. Ankylosing spondylitis

See Answer in Part B → Q31

@Neet_pg_bot

Q32: A 35-year-old male has had chronic hypercalcemia for the last 1.5 years, but PTH levels are normal. Which of the following is most likely the cause? (Q866804)

A. Malignancy

B. Sarcoidosis

C. Parathyroid hyperplasia

D. C.K.D

See Answer in Part B → Q32

@Neet_pg_bot

Q33: Which of the following is not true about ankylosing spondylitis? (Q840125)

A. Affect males more than females

B. HLA B27 associated

C. Involvement of sacroiliac joints

D. Its non erosive and only joints are affected

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A 35-year-old woman experiences skin thickening, muscle weakness, and pale peripheries upon cold exposure. Her creatine kinase is increased with positive ANA, and biopsy revealed scl-70 positivity and perifascicular infiltration. What is the antibody linked to this condition? (Q857284)

A. Anti PM /Scl antibody

B. Anti Jo1 antibody

C. Anti centromere antibody

D. Antinuclear antibody

See Answer in Part B → Q34

@Neet_pg_bot

Q35: 40 year lady presents with difficulty in eating due to persistent dry mouth. She also has grittiness in eyes due to dry eyes. On examination, dental caries is noted with enlarged cervical lymph nodes. Possible diagnosis is: (Q820431)

A. MCTD

B. Sarcoidosis

C. Sjogren syndrome

D. Wegener’s granulomatosis

See Answer in Part B → Q35

@Neet_pg_bot

Q36: A 38-year-old male patient complains of paranasal sinus pain and bloody nasal discharge over the past few days. He has a history of previous hemoptysis and hematuria. Imaging studies reveal multiple bilateral nodular cavitary infiltrates. Which of the following antibodies is likely to be positive in this patient? (Q830817)

A. c-ANCA

B. ANA

C. Anti-histone antibodies

D. Anti-Jo 1 antibodies

See Answer in Part B → Q36

@Neet_pg_bot

Q37: A 40-year-old woman presents with bilateral symmetrical tenderness in the joints of her hands and wrists. She also complains of early morning stiffness of > 1 hour. On examination, no erythema or redness was found. What could be the diagnosis? (Q854728)

A. Osteoarthritis

B. Psoriatic Arthritis

C. Gout

D. Rheumatoid arthritis

See Answer in Part B → Q37

@Neet_pg_bot

Q38: A young man came to the medical OPD with complaints of early morning backache and stiffness, which improves on exercise, and persistent red eyes. On examination, lung expansion was less than 3 cm. X-ray is shown in the image given below. What is the most probable diagnosis? (Q855417)

A. Ankylosing Spondylitis

B. Paget's Disease

C. Healed Tuberculosis

D. Osteopetrosis

See Answer in Part B → Q38

@Neet_pg_bot

Q39: A 50-year-old woman presented with difficulty in activities like climbing stairs, getting up from a chair, and combing hair. Violaceous erythema of the upper eyelids was noted. What is the most probable diagnosis? (Q858036)

A. Inclusion body myositis

B. Dermatomyositis

C. Polymyositis

D. Scleroderma

See Answer in Part B → Q39

@Neet_pg_bot

Q40: A 50-year-old woman presented with difficulty in activities like climbing stairs, getting up from a chair, and combing hair. Violaceous erythema of the upper eyelids was noted. What is the most probable diagnosis? (Q858351)

A. Inclusion body myositis

B. Dermatomyositis

C. Polymyositis

D. Scleroderma

See Answer in Part B → Q40

@Neet_pg_bot

Q41: What is the most probable diagnosis for a young male patient who experiences drooping eyelids that worsens as the day progresses, along with increased fatigue towards the end of the day which improves with rest? Additionally, the patient notices a significant decrease in drooping when placing an ice pack over their eyes. (Q793852)

A. Myasthenia gravis

B. Huntington chorea

C. Amyotrophic lateral sclerosis

D. External ophthalmoplegia

See Answer in Part B → Q41

Q1: A 45-year-old patient presents with elevated liver enzymes and is suspected to have Hepatitis C. Which of the following statements regarding the investigations for Hepatitis C is correct? (Q851477)

A. Antibodies appear within 1-2 weeks.

B. Hepatitis C RNA confirms active infection.

C. Biopsy is essential for all diagnoses.

D. Genotype 1 has higher spontaneous clearance.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Hepatitis C Virus is most commonly associated with which of the following? (Q851491)

A. SLE

B. Scleroderma

C. Cryoglobulinemia

D. Polyarteritis Nodosa

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following statements regarding Occult Hepatitis B Infection is false? (Q851490)

A. OBI can lead to hepatitis B transmission through blood products.

B. Individuals with seropositive OBI have detectable HBsAg in their serum

C. OBI may lead to reactivation of HBV in immunocompromised patients.

D. OBI can contribute to the development of HCC.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old patient presents with gas gangrene and signs of acute liver injury. Which of the following management strategies is most appropriate for this patient? (Q851489)

A. Initiate antiviral therapy with acyclovir and provide supportive care.

B. Start high-dose intravenous penicillin and perform aggressive surgical débridement.

C. Administer a combination of ampicillin, gentamicin, and metronidazole.

D. Implement hyperbaric oxygen therapy and monitor for bleeding complications.

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45-year-old male presents to the emergency department with jaundice, fatigue, and right upper quadrant pain. He has a history of heavy alcohol use, and reports increased consumption over the past month. Laboratory tests show elevated aminotransferases and bilirubin levels. Which of the following investigations is most appropriate to determine the cause of his acute liver injury? (Q851488)

A. Liver Biopsy

B. Ultrasound of the abdomen

C. Toxicology Screen

D. Viral Hepatitis Serology

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 40-year-old woman presents to the emergency department with complaints of fatigue, nausea, and right upper quadrant discomfort. O/E, she appears mildly jaundiced with yellowing of the sclera. She is drowsy but can be easily aroused. Her family reports that she has been more irritable than usual, displaying some behavioural changes. She denies any recent travel or known infections but admits to consuming alcohol excessively over the past month. Which of the following signs or symptoms is most characteristic of the severity of her condition? (Q851487)

A. Elevated serum bilirubin levels

B. Normal liver function tests

C. Increased appetite

D. Significant weight loss

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 60-year-old male with a history of cirrhosis presents to the hospital with confusion and altered mental status. On examination, he is disoriented to time and space, exhibits lethargy, is somnolent but arousable, and displays bizarre behavior. According to the West Haven Criteria, what is the appropriate grade of his hepatic encephalopathy? (Q851486)

A. Grade 1

B. Grade 2

C. Grade 3

D. Grade 4

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old male with a history of heavy alcohol consumption presents to the emergency department with fatigue, jaundice, and right upper quadrant abdominal pain. Laboratory tests reveal elevated direct bilirubin, alkaline phosphatase, and lactate dehydrogenase levels. His reticulocyte count is high, and the Coombs test is negative. The clinical features are consistent with Zieve syndrome. Which of the following is the most appropriate management for this patient? (Q851485)

A. Initiate corticosteroid therapy

B. Recommend immediate liver transplantation

C. Advise complete abstinence from alcohol

D. Start intravenous fluids and monitor in the hospital

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 48-year-old woman with a BMI of 32 kg/m² presents to the clinic with fatigue and mild abdominal discomfort. Laboratory tests reveal elevated liver transaminases, and an abdominal ultrasound shows hepatic steatosis. To further evaluate her condition, it is essential to exclude other potential causes of liver disease. Which of the following investigations should be performed first to rule out other liver diseases? (Q851484)

A. Liver biopsy

B. Blood tests for viral hepatitis markers

C. CT scan of the abdomen

D. NAFLD Fibrosis Score

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 50-year-old male with a history of obesity and type 2 diabetes presents for a routine check-up. His liver function tests show mildly elevated transaminases, and an ultrasound of the abdomen reveals fatty infiltration of the liver. He denies any alcohol consumption. His BMI is 35 kg/m², and his blood pressure is 145/90 mmHg. Based on these findings, he is diagnosed with non-alcoholic fatty liver disease (NAFLD). Which of the following is the most likely initiating factor in the pathogenesis of NAFLD in this patient? (Q851483)

A. Hepatitis C infection

B. Alcohol consumption

C. Insulin resistance

D. Autoimmune hepatitis

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 35-year-old male with chronic Hepatitis B presents with symptoms of fatigue, jaundice, and abdominal discomfort. Laboratory tests reveal elevated liver transaminases and the presence of Hepatitis D virus (HDV). His viral load is moderately elevated, and liver biopsy shows moderate fibrosis. The patient has no contraindications to antiviral therapy. Which of the following is the most appropriate treatment option for Hepatitis D in this patient? (Q851482)

A. Entecavir

B. Lamivudine

C. Pegylated Interferon-α

D. Hepatitis B Immunoglobulin

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old man with a history of chronic Hepatitis B virus (HBV) infection presents to the clinic with new-onset fatigue and abdominal discomfort. Laboratory tests reveal the presence of high titers of IgM antibodies against Hepatitis D virus (HDV). Based on the information provided, which of the following statements is true regarding the serological response to HDV infection in this patient? (Q851481)

A. The delta antigen is consistently present in the blood during the infection.

B. The presence of IgM anti-HDV indicates a simultaneous infection with HBV and HDV.

C. Anti-HDV antibodies are not necessary for diagnosing HDV infection.

D. The patient will develop IgG anti-HDV antibodies immediately after infection.

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 35-year-old intravenous drug user presents to the clinic with fatigue and jaundice. Testing reveals infection with Hepatitis D virus (HDV). Which of the following statements about HDV transmission is true? (Q851480)

A. HDV is an independent RNA virus.

B. HDV is commonly transmitted via close personal contact in non-endemic regions.

C. Effective Hepatitis B vaccination indirectly prevents HDV infection.

D. Mother-to-child transmission is the primary route of HDV spread globally.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 50-year-old patient with Hepatitis C genotype 1 seeks treatment. Which statement about Hepatitis C therapy is correct? (Q851479)

A. Pre-2011 therapy achieved an SVR of 70% for genotype 1 after 6 months.

B. DAAs offer effective, well-tolerated interferon-free regimens.

C. Ribavirin is free of major side effects like anemia or teratogenicity.

D. Liver transplantation eliminates the risk of reinfection and cirrhosis in grafts.

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 32-year-old man presents with fatigue and mild abdominal discomfort. He reports that he recently experienced nausea and dark urine. Laboratory tests reveal elevated liver enzymes. Which of the following is the most likely finding in this patient's blood tests? (Q851448)

A. Positive HBsAg

B. Positive anti-HBs

C. Negative HBsAg

D. Positive IgG anti-HBc

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 30-year-old male presents to the outpatient clinic for routine screening. He admits to a history of injection drug use. Which of the following is the most likely mode of Hepatitis C transmission in this patient? (Q851476)

A. Sexual contact

B. Vertical transmission from mother to child

C. Sharing needles and injecting equipment

D. Blood transfusion with screened blood products

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 35-year-old male presents with symptoms of nausea, jaundice, and abdominal pain after returning from a trip to a region with poor sanitation. He has no significant medical history. His liver function tests show elevated bilirubin, ALT, and AST levels. HEV IgM antibodies are positive. What is the most appropriate treatment plan for this patient? (Q851475)

A. Ribavirin therapy

B. Peginterferon

C. Supportive care with hydration and rest

D. Both A and C

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 40-year-old male presents with nausea, fatigue, and mild abdominal pain for the past week. He recently returned from a camping trip in a developing country. On examination, he has mild jaundice and tender hepatomegaly. His lab tests show elevated liver enzymes (ALT, AST), and positive anti-HAV IgM antibodies. What is the most likely mode of transmission for his condition? (Q851474)

A. Sharing needles

B. Fecal-oral route

C. Sexual contact

D. Respiratory droplets

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A newborn infant is delivered to an HBsAg-positive mother. What is the most appropriate post-exposure prophylaxis for this infant? (Q851473)

A. Hepatitis B vaccine only

B. Hepatitis B Immune Globulin (HBIG) only

C. HBIG and Hepatitis B vaccine

D. No intervention is necessary

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 38-year-old female with a 5-year history of chronic Hepatitis B presents for evaluation. Her most recent lab results show HBsAg positive, HBeAg positive, ALT at 200 IU/L, and total bilirubin at 1.2 mg/dL. She is experiencing fatigue and mild abdominal discomfort. She has a history of taking herbal supplements for liver health and consumes alcohol occasionally. Which of the following is not an appropriate treatment plan for this patient? (Q851472)

A. Start tenofovir or entecavirir

B. Consider lamivudine as a second-line treatment

C. Stop alcohol completely

D. Continue herbal supplements for liver support

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 50-year-old male presents to the emergency department with acute jaundice, fever, fatigue, and right upper quadrant pain. He has a history of heavy alcohol use. On examination, he has icterus of the sclera and tenderness in the right upper. His laboratory results are as follows: HBsAg: Positive HBeAg: Positive ALT: 150 IU/L AST: 120 IU/L Total Bilirubin: 3.0 mg/dL Alkaline Phosphatase: 100 IU/L Which

management strategy is most appropriate? (Q851469)

A. Start entecavir therapy immediately

B. Begin tenofovir therapy immediately

C. Supportive care and stop alcohol

D. Both A and C

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 45-year-old male with acute Hepatitis B presents with the following lab results: ALT 4100 IU/L AST 3900 IU/L Total bilirubin 60 μmol/L (3.5 mg/dL) Despite the very high aminotransferase levels, his bilirubin remains moderately elevated. What does this suggest about the severity of liver cell damage? (Q851466)

A. Severe liver cell damage causing acute liver failure

B. The severity of damage cannot be determined from ALT levels alone

C. Mild liver cell damage causing fulminant hepatitis

D. Transition to chronic Hepatitis B with moderate liver damage

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 30-year-old male presents to the clinic for routine screening. He reports no recent illness but has a history of multiple sexual partners. He is concerned about Hepatitis B infection due to a friend's recent diagnosis. Laboratory tests are conducted to assess his Hepatitis B status. Test Result HBsAg Negative Anti-HBs Positive HBeAg Negative Anti-HBe Negative Anti-HBc Negative What does this lab profile indicate about the patient's Hepatitis B status? (Q851464)

A. Has an active acute Hepatitis B infection.

B. Has recovered from a previous Hepatitis B infection.

C. Is a healthy carrier of Hepatitis B.

D. Has been immunized against Hepatitis B.

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A public health nurse is conducting an educational session on Hepatitis B transmission in a community with a high prevalence of the virus. During the session, she discusses various transmission routes and their associated risks for chronic infection. Which of the following statements about Hepatitis B transmission is incorrect? (Q851462)

A. Vertical transmission occurs from an HBsAg-positive mother to her infant.

B. Risk of chronic infection is higher in individuals infected at a younger age.

C. Sharing needles among drug users is a common mode of transmission.

D. Chronic infection is primarily associated with sexual transmission in adults.

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 26-year-old man presents with complaints of fatigue, loss of appetite, and mild abdominal discomfort. His partner recently tested positive for Hepatitis B. Laboratory tests reveal mildly elevated liver enzymes. Which of the following findings would you least likely find in this patient? (Q851460)

A. Mild splenomegaly

B. Cervical lymphadenopathy

C. Tender liver

D. Caput medusae

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 30-year-old man presents to the clinic for evaluation of elevated liver enzymes. He reports feeling fatigued and has noticed some jaundice. His medical history is significant for recent unprotected sexual contact with a partner who is Hepatitis B positive. Laboratory tests reveal that HBsAg is positive, and further testing shows the presence of HBeAg. Which of the following does the presence of HBeAg indicate in this patient? (Q851457)

A. Low viral replication and reduced infectivity

B. Active viral replication and high infectivity

C. Recovery from a previous Hepatitis B infection

D. Chronic infection with no active viral replication

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 28-year-old woman presents to the clinic with fatigue, loss of appetite, and mild jaundice. She reports that she had a recent exposure to a friend who was diagnosed with Hepatitis B. Laboratory tests reveal that HBsAg is negative, but her liver enzymes are elevated. Which of the following is the most likely finding in this patient's blood tests? (Q851455)

A. Positive anti-HBs only

B. Positive IgM anti-HBc

C. Positive IgG anti-HBc

D. Positive HBcAg

See Answer in Part B → Q27

Q13 (p. 831)	*Q14 (p. 832)*	*Q15 (p. 832)*	*Q16 (p. 833)*		

Q1: Give the correct sequencing of the pathophysiology of hepatorenal syndrome. Renal vasoconstriction Systemic vasodilation Vasopressin release Cytokine release (Q851281)

A. 1,2,3,4

B. 4,3,2,1

C. 4,2,3,1

D. 3,4,2,1

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is not a feature of hepatorenal syndrome? (Q851282)

A. Stepwise decrease in serum creatinine

B. Jaundice which begins in the sclera

C. Altered mental status

D. Increased risk of bleeding

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 56-year-old man with a history of cirrhosis due to chronic hepatitis C presents with worsening ascites, oliguria, and fatigue. Physical examination reveals tense ascites, mild jaundice, and peripheral edema. Laboratory investigations show: Serum creatinine: 2.3 mg/dL (baseline: 0.9 mg/dL) Serum sodium: 126 mEq/L Urine sodium: <10 mEq/L Albumin infusion is planned as part of his management. What is the recommended dosage of albumin infusion for this patient? (Q851283)

A. 1g/kg per day

B. 5g/kg per day

C. 2g/kg per day

D. 3g/kg per day

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is not a characteristic feature of Type 1 hepatorenal syndrome? (Q851284)

A. Doubling of serum creatinine over 2 weeks

B. Urine output less than 500mL/day

C. Normal urine sediment

D. High urinary sodium

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 52-year-old male with a long history of cirrhosis presents to the clinic with worsening shortness of breath over the past few months. He reports that his breathlessness worsens when standing and improves when lying down. Physical examination reveals spider angiomas. Pulse oximetry shows an oxygen saturation of 85% on room air. A contrast-enhanced echocardiogram (bubble study) is performed,

and delayed bubbles are seen in the left atrium. What is the most likely diagnosis? (Q851285)

A. Hepatopulmonary syndrome

B. Atelectasis

C. Chronic obstructive pulmonary disease (COPD)

D. Recurrent pulmonary emboli

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following conditions causes intrapulmonary shunting? (Q851286)

A. Hepatopulmonary syndrome (HPS)

B. Portopulmonary hypertension

C. Recurrent pulmonary emboli

D. Pneumonia

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 45-year-old male with a history of cirrhosis presents with worsening dyspnea.Physical examination reveals clubbing and cyanosis, which worsen when the patient sits upright and decrease in oxygen saturation when the patient changes position from supine to upright.Which of the following is considered the gold standard diagnostic method for confirming this condition? (Q851287)

A. Pulmonary angiography

B. Transesophageal echocardiogram (TEE)

C. Radioactive lung perfusion scan

D. Bubble contrast echocardiography

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following laboratory findings does not typically indicate alcoholic hepatitis? (Q851288)

A. Serum bilirubin more than 3 mg/dL

B. Elevated aspartate aminotransferase (AST) to 50 U/L - 400 U/L

C. AST:ALT (alanine aminotransferase) ratio of more than 1.5

D. Absolute value of AST/ALT greater than 600 U/L

See Answer in Part B → Q8

@Neet_pg_bot

Q9: What amount of alcohol consumption is generally considered to significantly increase the risk of developing alcoholic hepatitis? (Q851289)

A. More than 10 grams per day

B. More than 20 grams per day

C. More than 30 grams per day

D. More than 50 grams per day

See Answer in Part B → Q9

@Neet_pg_bot

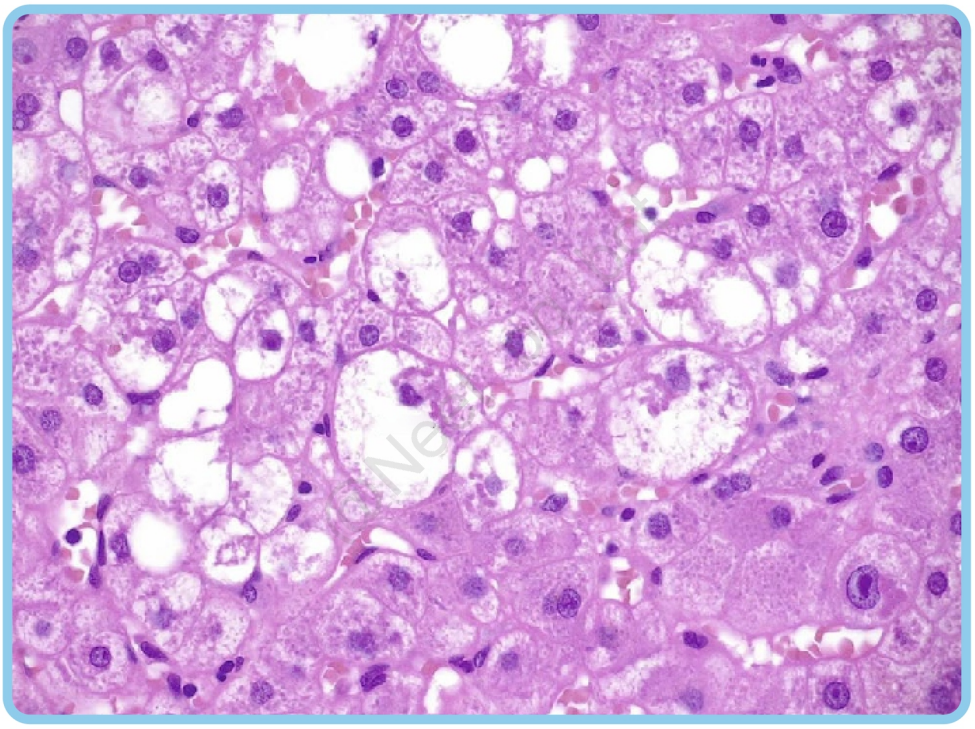
Q10: A 52-year-old man with a history of heavy alcohol consumption presents with jaundice, abdominal pain, and fatigue. A liver biopsy is performed to assess the extent of liver damage. Which of the following findings is most characteristic of this condition? Histopathology image given below: (Q851290)

A. Russell bodies

B. Dutcher bodies

C. Mallory-Denk bodies

D. Kamino bodies



See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 50-year-old male with a history of heavy alcohol use presents with jaundice and altered sensorium. Laboratory tests reveal elevated bilirubin, AST > ALT, hypoalbuminemia, and prolonged PT/INR. Which of the following findings is most suggestive of the presence of hepatic encephalopathy in this patient? (Q851291)

A. Asterixis

B. Hyperbilirubinemia

C. Ascites

D. Gynaecomastia

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old man with a long history of heavy alcohol use presents with fatigue, jaundice, and abdominal distension. Physical examination reveals hepatomegaly, spider angiomas, and ascites. What is the most specific investigation to diagnose his condition? (Q851292)

A. γ-glutamyl transferase assay (GGT)

B. PT/INR

C. Serum bilirubin

D. AST/ALT ratio

See Answer in Part B → Q12

@Neet_pg_bot

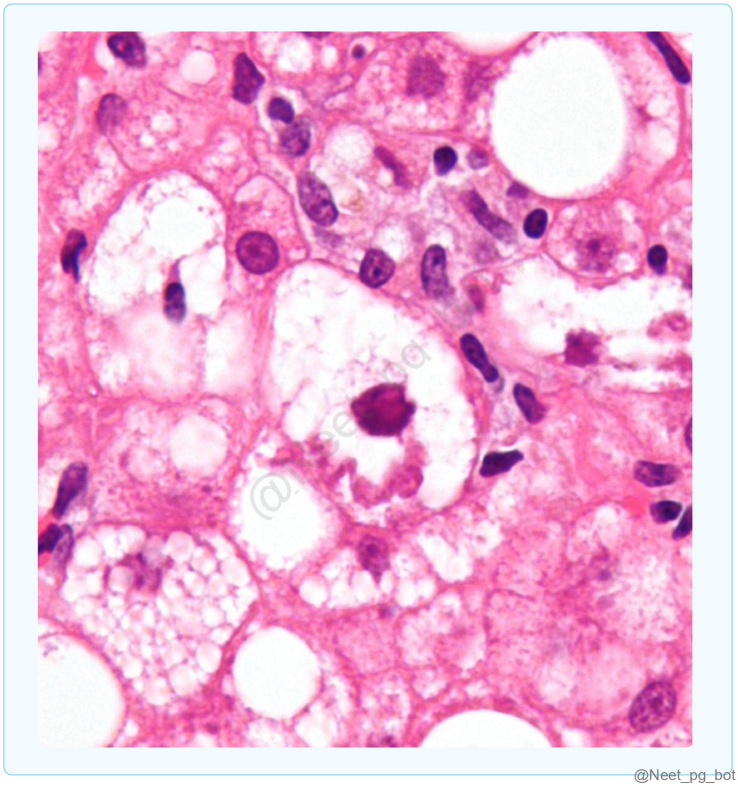
Q13: A 30-year-old male patient succumbed to death, history revealed that the patient was admitted for liver failure 1 week back. Biopsy done is as shown below. What type of inclusions are seen in the biopsy, and what is the likely diagnosis? {{caption_text}} (Q851293)

A. Intracytoplasmic - ALD

B. Intranuclear - ALD

C. Intracytoplasmic - Viral hepatitis

D. Intranuclear - Viral hepatitis



See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which among the following are components of the MELD 3.0 score? 1) Male sex 2) Albumin 3) Creatinine 4) AST 5) INR 6) Serum Na+ (Q851294)

A. 1,2,3,5,6

B. 2,3,5,6

C. 1,3,4,5,6

D. 2,3,4,5

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A female patient who is a known alcoholic presented to OPD with jaundice and malaise. Her initial reports were PT: 24 sec (N: 11-14sec); AST: 70 Units/L (N: 10-40 U/L) ; ALT: 70 Units/L (N: 8-55 U/L); Bilirubin: 2 mg/dL (N: 0.2-1.3 mg/dL). What is the preferred management of choice? (Q851295)

A. Only lifestyle modifications

B. Oral steroids

C. Zinc + Vit-E supplements

D. Liver transplant

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which among the following is not a component of Liver FibroTest? (Q851297)

A. Haptoglobin

B. Hyaluronic acid

C. γ-GT (GGT)

D. Total bilirubin

See Answer in Part B → Q16

Q1: A 12 y/o girl has elevated liver enzymes. She has vitiligo and is asymptomatic. Labs show ALT 320 U/L, AST 280 U/L, negative ANA and ASMA, and polyclonal hypergammaglobulinemia. Viral hepatitis serologies are negative. Which of the following autoantibodies is most specific for this subtype? (Q890466)

A. Antimitochondrial antibody (AMA)

B. Anti-liver kidney microsome type 1 (anti-LKM1)

C. Anti-soluble liver antigen (anti-SLA)

D. Perinuclear antineutrophil cytoplasmic antibody (pANCA)

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following autoantibodies is found in approximately 65% of patients with primary sclerosing cholangitis (PSC) and can aid in distinguishing it from other cholestatic liver diseases? (Q890481)

A. Antimitochondrial antibody (AMA)

B. Anti-smooth muscle antibody (ASMA)

C. Perinuclear antineutrophil cytoplasmic antibody (pANCA)

D. Anti-liver kidney microsome type 1 (anti-LKM1)

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 48 y/o woman has 6 months of fatigue and nocturnal pruritus and has Hashimoto thyroiditis. The exam shows excoriations and xanthelasma. Ultrasound reveals a normal biliary tree. Labs show: Alkaline phosphatase: 450 U/L (↑↑), AST: 55 U/L, ALT: 60 U/L, Total bilirubin: 1.0 mg/dL, ANA: positive (1:40). What is the most appropriate next step to confirm the diagnosis? (Q890480)

A. Endoscopic retrograde cholangiopancreatography (ERCP)

B. Serum antimitochondrial antibody (AMA) titer

C. Percutaneous liver biopsy

D. Serum IgG4 level

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A patient with primary biliary cholangitis (PBC) fails to achieve an adequate biochemical response to first-line therapy with ursodeoxycholic acid (UDCA). Which of the following agents is an established second-line treatment shown to produce significant biochemical improvement in this subset of patients? (Q890479)

A. Azathioprine

B. Prednisone

C. Obeticholic acid

D. Ribavirin

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 52 y/o woman presents with progressive fatigue and generalised pruritus, worse in the evening. Examination shows excoriations and xanthelasma. Laboratory results are as follows: Total bilirubin: 1.2 mg/dL, Alkaline phosphatase: 580 U/L (↑↑), AST: 65 U/L, ALT: 72 U/L, GGT: 350 U/L. Which of the following serologic markers is most likely to be positive? (Q890478)

A. Antinuclear antibody (ANA)

B. Antimitochondrial antibody (AMA)

C. Anti-smooth muscle antibody (ASMA)

D. Perinuclear antineutrophil cytoplasmic antibody (pANCA)

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following pairs of symptoms represents the most prominent and characteristic clinical manifestations in symptomatic patients with primary biliary cholangitis? (Q890477)

A. Right upper quadrant pain and fever

B. Fatigue and pruritus

C. Arthralgias and skin rash

D. Nausea and vomiting

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following autoantibodies detected in patients with autoimmune hepatitis is specifically associated with a worse prognosis? (Q890476)

A. Antinuclear antibody (ANA)

B. Anti-smooth muscle antibody (ASMA)

C. Anti-soluble liver antigen (anti-SLA)

D. Anti-liver kidney microsome type 1 (anti-LKM1)

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A patient with autoimmune hepatitis is treated with standard first-line therapy, including corticosteroids and azathioprine, but fails to achieve biochemical remission. The clinician plans to escalate immunosuppressive therapy. Which of the following agents is the next drug of choice in this setting? (Q890475)

A. Methotrexate

B. Cyclosporine

C. Mycophenolate mofetil

D. Ursodeoxycholic acid

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A patient with mild autoimmune hepatitis (aminotransferases <2× the upper limit of normal) requires initial corticosteroid therapy with minimal systemic effects. Which of the following corticosteroids is an alternative first-line option in this setting? (Q890474)

A. Dexamethasone

B. Methylprednisolone

C. Budesonide

D. Hydrocortisone

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A patient with acute hepatitis is HBsAg positive with anti-HDV antibodies. To represent HDV superinfection on chronic hepatitis B rather than HBV-HDV coinfection. Which antibody profile confirms HDV superinfection? (Q890472)

A. IgM anti-HBc positive

B. IgG anti-HBc positive

C. Anti-HBs positive

D. IgM anti-HAV positive

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following autoantibodies is considered the serologic hallmark of Type II autoimmune hepatitis? (Q890470)

A. Antinuclear antibody (ANA)

B. Anti-smooth muscle antibody (ASMA)

C. Anti-liver kidney microsome type 1 antibody (anti-LKM1)

D. Anti-soluble liver antigen (anti-SLA)

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A patient on long-term antibiotic therapy develops chronic hepatitis with elevated aminotransferases. Serologic testing reveals positive ANA and anti-smooth muscle antibodies. Which antimicrobial agent is associated with this pattern of hepatotoxicity? (Q890468)

A. Amoxicillin-clavulanate

B. Erythromycin estolate

C. Ciprofloxacin

D. Nitrofurantoin

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 30-year-old woman presents to the clinic with fatigue, jaundice, and abdominal discomfort. Lab tests show elevated liver enzymes (AST and ALT). Further testing reveals positive antinuclear antibodies (ANA) and anti-smooth muscle antibodies (ASMA). A liver biopsy demonstrates interface hepatitis with plasma cell infiltration . Given the specific autoantibody profile and the histological findings, which of the following options is associated with the condition and is most relevant to consider in this patient? (Q851299)

A. Type 1 Autoimmune Hepatitis

B. Type 2 Autoimmune Hepatitis

C. Primary Biliary Cholangitis

D. Drug-Induced Liver Injury

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 7-year-old girl presents 20 hours after accidentally ingesting a large amount of iron supplements. Initially, she had abdominal pain, vomiting, and diarrhea, but these symptoms have resolved. Her vital signs are stable. What stage of iron toxicity is she experiencing? (Q851309)

A. Stage I

B. Stage II

C. Stage III

D. Stage IV

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 35-year-old man presents with complaints of nausea and abdominal pain after ingesting 20 paracetamol tablets approximately 8 hours ago. His vital signs are stable, but he has mild jaundice. Which of the following is the most appropriate next step in management? (Q851308)

A. Administer activated charcoal orally.

B. Start intravenous N-acetylcysteine therapy.

C. Perform a liver biopsy to assess damage.

D. Refer for liver transplantation.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 28-year-old woman presents with a 2-day history of fatigue, jaundice, and dark urine after taking high doses of acetaminophen for headaches over the past week. Laboratory tests reveal elevated aminotransferases (>10,000 IU/L) and an INR of 2.5. What is the most likely underlying cause of her clinical presentation? (Q851307)

A. Glutathione depletion with NAPQI buildup

B. Enhanced glucuronidation of acetaminophen

C. Increased glutathione levels leading to liver injury

D. Inhibition of CYP2E1 by acetaminophen

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 26-year-old patient is treated with a combination of oxycodone and acetaminophen (325 mg per tablet). The patient has a history of opioid tolerance. What is a potential risk associated with this combination? (Q851306)

A. Increased risk of renal toxicity.

B. Decreased effectiveness of acetaminophen.

C. Greater likelihood of unintentional acetaminophen overdose.

D. Development of opioid dependency.

See Answer in Part B → Q17

@Neet_pg_bot

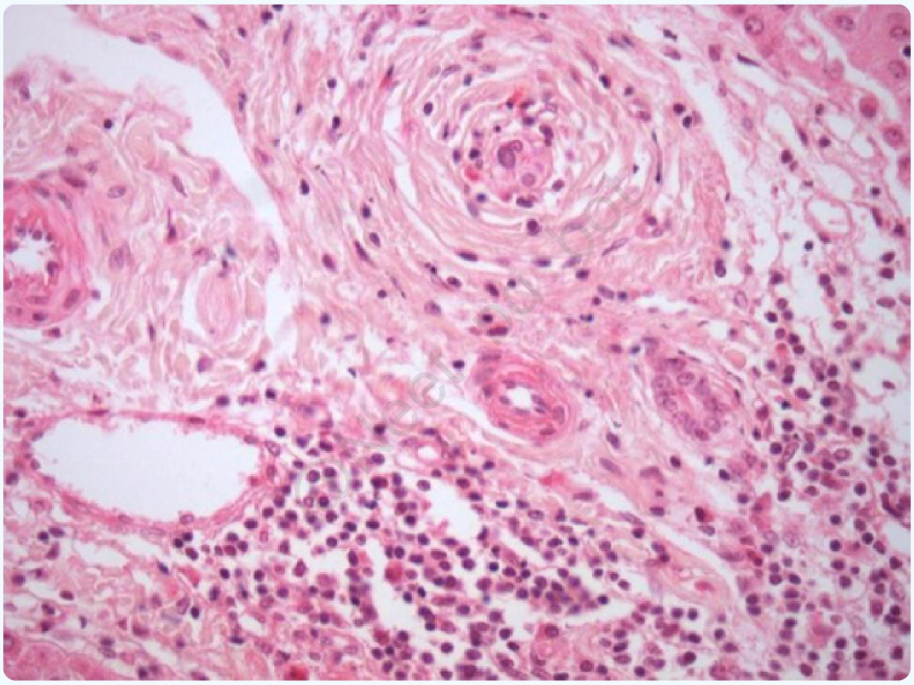
Q18: A 30-year-old woman presents with progressive jaundice and pruritus. She has a past medical history of ulcerative colitis. Her LFT revealed an elevated alkaline phosphatase & gamma-glutamyl transferase (GGT) and a prolonged prothrombin time. The liver biopsy is shown below. Which of the following serologic findings is most likely to be present in this patient? {{caption_text}} (Q851305)

A. Anti-liver kidney microsomal-1 antibodies (Anti-LKM-1)

B. Anti-mitochondrial antibody (AMA)

C. Perinuclear anti-neutrophil cytoplasmic antibody (pANCA)

D. Anti-centromere antibody



See Answer in Part B → Q18

@Neet_pg_bot

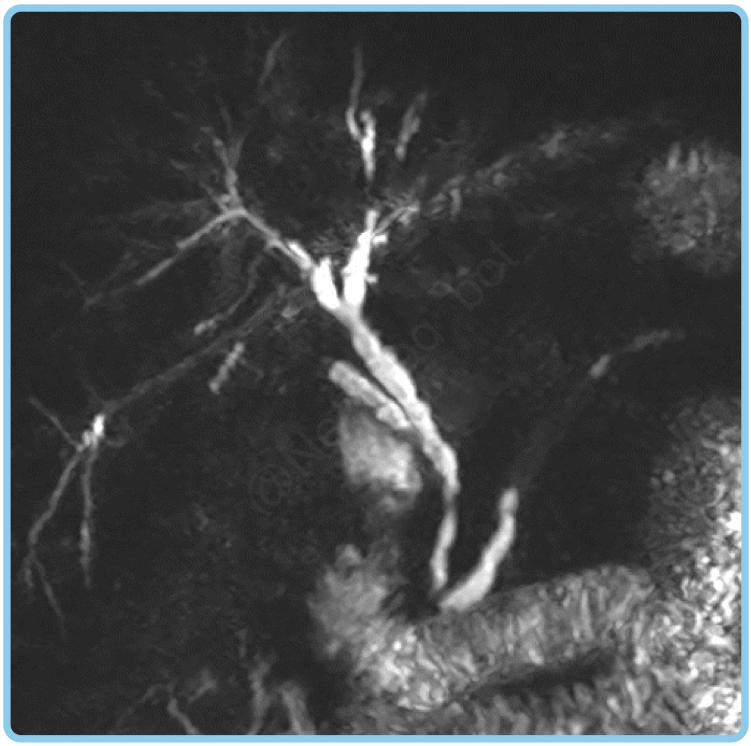
Q19: A 40-year-old male presents with a 6-month history of progressive fatigue and pruritus. He reports a recent onset of jaundice. His past medical history is significant for ulcerative colitis. Laboratory tests reveal elevated serum alkaline phosphatase and bilirubin, and atypical pANCA are positive. An MRCP is given below. Which of the following is the most likely diagnosis? {{caption_text}} (Q851304)

A. Primary Biliary Cholangitis

B. Primary Sclerosing Cholangitis

C. Choledocholithiasis

D. Chronic Pancreatitis



See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 50-year-old woman presents with fatigue and pruritus. Laboratory tests show elevated alkaline phosphatase and positive antimitochondrial antibodies (AMAs). Which of the following is the most appropriate next step in the management of this patient? (Q851303)

A. Initiate ursodeoxycholic acid therapy

B. Schedule for liver transplantation evaluation

C. Start antiviral therapy for hepatitis

D. Refer for endoscopic retrograde cholangiopancreatography (ERCP)

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following best describes the primary underlying mechanism of injury in Primary Biliary Cholangitis (PBC)? (Q851302)

A. Autoimmune-mediated destruction of bile ducts

B. Genetic mutation affecting bile acid metabolism

C. Viral infection leading to bile duct inflammation

D. Cholestasis due to gallstone obstruction

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following statements regarding Autoimmune Hepatitis is False? (Q851301)

A. SGPT is significantly raised

B. Albumin ↓ and γ-globulin ↑↑

C. It is a diagnosis of exclusion

D. RA factor is negative

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 45-year-old woman presents with fatigue, jaundice, abdominal discomfort, and significant weight loss for three months. She reports itchy skin. Laboratory tests show elevated liver enzymes and positive antinuclear antibodies (ANA) and anti-smooth muscle antibodies (ASMA). She has a family history of autoimmune diseases. Which of the following clinical features is most commonly associated with the above scenario? (Q851300)

A. Splenomegaly

B. Weight gain

C. Presence of anti-mitochondrial antibodies (AMA)

D. Elevated alkaline phosphatase levels

See Answer in Part B → Q23

Q1: A 55-year-old male with a history of liver cirrhosis presents to the emergency department with hematemesis and signs of shock. He is diagnosed with acute variceal bleeding. What is the most appropriate initial management? (Q851351)

A. Administer intravenous terlipressin followed by prophylactic intravenous antibiotics

B. Start intravenous antibiotics and perform urgent endoscopy for band ligation

C. Administer intravenous vasopressin and initiate fresh frozen plasma transfusion

D. Begin intravenous corticosteroids and monitor for signs of hepatic encephalopathy

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 50-year-old male with a history of alcohol abuse and long-term hypertension presents with hematemesis, abdominal distension, and splenomegaly. He is hypotensive and tachycardic, with elevated liver enzymes, low platelets, and a high INR. Endoscopy reveals esophageal varices. Which of the following most likely explains the development of this condition? (Q851361)

A. Portal venous thrombosis leads to increased collateral circulation

B. Increased portal blood flow to the liver

C. Increased portal pressure forcing blood into collateral vessels

D. Reduced portal vascular resistance

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 62-year-old man with alcoholic cirrhosis presents to the emergency department with confusion, disorientation, and asterixis. His family reports increasing drowsiness and difficulty concentrating over the past few days. Investigations reveal normal electrolytes and elevated ammonia levels. What is the most appropriate initial treatment to lower ammonia? (Q851360)

A. Increase the protein intake

B. Zinc supplementation

C. Rifaximin

D. Lactulose

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 60-year-old woman with decompensated cirrhosis due to hepatitis B presents for evaluation of liver transplantation. All the following are indications for liver transplantation except? (Q851359)

A. Autoimmune hepatitis

B. Caroli’s disease

C. Fulminant hepatitis

D. Portal vein thrombosis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 62-year-old male with a history of cirrhosis due to chronic hepatitis C presents with worsening abdominal distension, jaundice, and decreased urine output over the past week. He exhibits signs of confusion and ascites resistant to diuretics. Laboratory tests reveal a serum creatinine level of 2.5 mg/dL. Given this presentation, which of the following is the most definitive management of this condition? (Q851358)

A. Hemodialysis

B. Liver transplantation

C. Vasoconstrictor therapy with Terlipressin

D. Albumin infusion

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 54-year-old female with diabetes, obesity, and recent laparoscopic surgery presents to the emergency department with high fever, chills, rapid heart rate, extreme fatigue, and worsening abdominal pain. The physician suspects Systemic Inflammatory Response Syndrome (SIRS) and decides to perform an investigation as part of the diagnostic criteria. Which investigation should be performed? (Q851357)

A. Blood culture

B. Urine culture

C. Urine routine microscopy

D. Complete blood count

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 62-year-old male with malnutrition and alcoholic liver disease presents with increasing abdominal distension, shortness of breath, fever, and significant weight loss. The ascitic fluid shows a neutrophil count greater than 250/μL. Which of the following statements about this condition are true? 1. Ascitic fluid appears

transparent 2. Most commonly caused by Escherichia coli 3. Cefotaxime can be used for treatment 4. Norfloxacin administration may help to prevent it (Q851356)

A. 1, 2, 3

B. 1, 2, 4

C. 2, 3, 4

D. 1, 2, 3, 4

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 70-year-old male with a history of congestive heart failure, hypertension, and chronic kidney disease is scheduled for a procedure as depicted in the image below. What is the name of the procedure? {{caption_text}} (Q851355)

A. Pericardiocentesis

B. Thoracentesis

C. Paracentesis

D. Diagnostic peritoneal lavage

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 58-year-old female with chronic alcoholism, hepatitis C, and hypertension presents with abdominal distension, shortness of breath while lying flat, and fatigue. Ultrasound shows splenomegaly and an increased amount of peritoneal fluid. What are the expected serum-ascites albumin gradient (SAAG) and ascitic protein levels in this case? (Q851354)

A. <1.1 g/dL and <2.5 g/dL

B. ≥1.1 g/dL and <2.5 g/dL

C. <1.1 g/dL and ≥2.5 g/dL

D. ≥1.1 g/dL and ≥2.5 g/dL

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 62-year-old male with chronic liver disease, hepatitis C, and diabetes presents to the emergency department with worsening abdominal distension, shortness of breath, and fatigue. His swelling has worsened despite cutting sodium intake and increasing diuretics, and a fluid thrill is noted on examination. Which of the following medications is contraindicated in this case? (Q851353)

A. Clonidine

B. Amiloride

C. Midodrine

D. Propranolol

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 58-year-old man with chronic hepatitis and alcohol use presents with abdominal distension, discomfort, shortness of breath, and a weight gain of 5 kg over two weeks. Physical examination reveals thrombocytopenia, splenomegaly, and ascites. With approximately 120 mL of peritoneal fluid, which physical examination sign is most likely to be observed? (Q851352)

A. Fluid thrill

B. Shifting dullness

C. Puddle sign

D. All of the above

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 52-year-old male presents with progressive fatigue, abdominal distension, and worsening jaundice over the past three months. Examination reveals ascites, spider angiomata, and palmar erythema. Laboratory tests show elevated liver enzymes with

a significantly elevated AST/ALT ratio, and an ultrasound indicates a nodular liver. What role do kupffer cells play in the pathogenesis of this condition? (Q851339)

A. Activate CYP2E1

B. Increase the fatty acid uptake

C. Convert acetaldehyde to acetate

D. Induce cytokine production

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 60-year-old male with a history of alcohol use and chronic hepatitis presents with abdominal swelling, fatigue, difficulty eating, dark stools, and black vomitus. Examination shows splenomegaly, ascites and dilated veins around the umbilicus. Which of the following is the investigation of choice for this condition? (Q851348)

A. CT imaging

B. Blood counts

C. Endoscopy

D. Doppler ultrasound

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 58-year-old obese female with a history of DVT and recent appendectomy presents with worsening abdominal pain, swelling, fatigue, dark stools, and leg swelling. Examination reveals splenomegaly and findings, which are shown in the image below. Which of the following pathologies is most likely responsible for this condition? (Q851347)

A. Constrictive pericarditis

B. Veno-occlusive disease

C. Portal vein thrombosis

D. Inferior vena caval webs

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 55-year-old male with a history of chronic alcohol use presents with worsening abdominal swelling, fatigue, dizziness, increased abdominal size, and loss of appetite. Examination shows a hepatic venous pressure gradient (HVPG) of over 5 mm Hg. What is one of the earliest signs of this condition? (Q851346)

A. Puddle sign

B. Splenomegaly

C. Coffee ground vomitus

D. Caput medusae

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 52-year-old male with chronic hepatitis presents with fatigue, mild abdominal discomfort, decreased appetite, and occasional jaundice over the past few months but denies significant weight loss or night sweats. A liver biopsy showed fibrosis with expansion of most portal zones and occasional bridging. What Metavir fibrosis stage does this indicate? (Q851345)

A. F1

B. F2

C. F3

D. F4

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 47-year-old woman with a history of non-alcoholic fatty liver disease (NAFLD) presents for routine follow-up. She reports mild fatigue but denies significant abdominal pain or jaundice. On examination, she has no stigmata of chronic liver disease. The physician wants to assess the degree of liver fibrosis. Which of the following is the best non-invasive test to evaluate liver stiffness? (Q851344)

A. Computed tomography

B. Abdominal ultrasound

C. Magnetic resonance imaging

D. Transient elastography

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 58-year-old female with a history of chronic hepatitis C and cirrhosis presents with increasing abdominal distension, jaundice, and fatigue. On examination, she has ascites and spider nevi. Laboratory tests reveal elevated bilirubin levels, low albumin, and elevated liver enzymes. All of the following are criteria for Child-Pugh score classification except? (Q851343)

A. Ascites

B. Albumin

C. Bilirubin

D. AST/ALT

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 62-year-old male with cirrhosis presents to the emergency department with upper gastrointestinal bleeding and a Child-Pugh score of 10. Which scoring system is most appropriate for assessing his mortality risk related to liver disease? (Q851342)

A. PELD score

B. Rockall risk score

C. Forrest classification system

D. MELD score

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 68-year-old man with a history of cirrhosis presents with increased fatigue, and examination reveals multiple vascular lesions on the skin. His liver function tests show significant elevations in AST and ALT. What is the primary pathophysiological mechanism responsible for the formation of these lesions in cirrhosis? (Q851341)

A. Due to engorged superficial veins

B. Chronic Hypoxia

C. Because of platelet-derived growth factor

D. Increased vascularity due to estrogen

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 72-year-old male with chronic hepatitis C presents with severe fatigue, confusion, and increasing abdominal girth. Examination reveals jaundice, asterixis, and bilateral oedema. Laboratory tests show elevated bilirubin, transaminases, prolonged prothrombin time, and thrombocytopenia. An endoscopy shows the presence of non-bleeding varices. What is the most likely diagnosis? (Q851340)

A. Compensated cirrhosis

B. Alcoholic hepatitis

C. Acute liver failure

D. Decompensated cirrhosis

See Answer in Part B → Q21

@Neet_pg_bot

• [09_Hepatobiliary System] 071 Wilson Disease And Hemochromatosis

Q13 (p. 866)

Q1: A 25-year-old male presents with fatigue, tremors, jaundice, and cognitive impairment. On examination, hepatomegaly is noted, and an ophthalmologic evaluation reveals a distinctive finding. Laboratory tests show elevated liver enzymes and increased copper levels. What is the underlying pathological mechanism causing this condition? (Q851384)

A. Reduced renal filtration of copper

B. Increased degradation of ceruloplasmin

C. Defective biliary excretion of copper

D. Impaired hepatic metabolism of ceruloplasmin

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 9-month-old pediatric patient presents with hypotonia, seizures, and delays in achieving developmental milestones. The child exhibits characteristic facial features, including a prominent forehead, sparse eyebrows, and distinct hair appearance. Laboratory results reveal decreased levels of copper and ceruloplasmin. What is the pattern of inheritance for this condition? (Q851387)

A. Autosomal recessive

B. Mitochondrial inheritance

C. X-linked recessive

D. Autosomal dominant

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 22-year-old male presents with symptoms of fatigue, jaundice, and abdominal pain. He also exhibits neurological manifestations, including tremors, dystonia, and personality changes. Laboratory investigations reveal elevated free serum copper levels, and liver function tests show increased ALT and AST. Based on these findings, which area of the brain is primarily implicated in the neurological symptoms of this condition? (Q851388)

A. Corpus callosum

B. Basal ganglia

C. Cerebellum

D. Hippocampus

See Answer in Part B → Q3

@Neet_pg_bot

Q4: During an eye camp, an elderly patient presented with a distinct ring around the cornea, as given below. The patient was referred to a higher centre for further evaluation. Several weeks later, the patient returned from the higher centre, reporting a progressive loss of vision. Upon examination, it was noted that a cataract had developed. Based on the initial observation and the current condition. Which of the following types of cataracts is most likely to be observed in this patient? (Q851389)

A. Stellate cataract

B. Snowflake cataract

C. Oil droplet cataract

D. Sunflower cataract

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following investigation parameters is not generally considered definitive for the evaluation of Wilson's disease? (Q851393)

A. Serum copper levels

B. MRI of the brain

C. Liver biopsy

D. 24-hour urine excretion of copper

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 22-year-old patient presents with neurological symptoms such as tremors, dysarthria, and gait disturbances. An MRI of the brain is performed and reveals hyperintensities at the sites given below. Based on these findings and the clinical presentation, what is the most likely diagnosis? (Q851396)

A. Huntington's disease

B. Multiple sclerosis

C. Wilson’s disease

D. Parkinson’s disease

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 24-year-old patient presents with the following symptoms: tremors, dysarthria, irritability, and impulsive behavior, along with jaundice and the presence of Kayser-Fleischer rings on slit-lamp examination. What is the best treatment approach for this condition? (Q851399)

A. Penicillamine

B. Trientine

C. Zinc acetate

D. Dimercaprol

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 28-year-old patient who is a known case of Wilson's disease presents to the emergency department with acute liver failure. He has neurological symptoms and liver dysfunction. Upon evaluation, laboratory results reveal the following: Serum bilirubin: 12 mg/dL. Serum aspartate transferase (AST): 250 IU/L. Prothrombin time prolongation: 15 seconds. Based on these results, calculate the NAZER prognostic score for this patient and the next step in treatment accordingly. (Q851401)

A. NAZER score of 5; no need for transplantation

B. NAZER score of 8; medical management is sufficient

C. NAZER score of 9; liver transplantation is indicated

D. NAZER score of 11; monitor the patient without intervention

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 38-year-old woman presents with symptoms of fatigue, arthralgia, and new-onset diabetes. Her family history reveals that her father was diagnosed with hemochromatosis. Further evaluations show significantly elevated serum ferritin and transferrin saturation levels and that she carries both the C282Y and H63D mutations in the HFE gene. Based on her clinical presentation and genetic findings, which type of hemochromatosis is she most likely experiencing? (Q851402)

A. Type 1

B. Type 2

C. Type 3

D. Type 4

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45-year-old male presents to the clinic with complaints of fatigue, joint pain, and a noticeable change in skin color, described as a slate-gray hue. He reports a

family history of liver disease and diabetes. Blood tests reveal elevated serum ferritin and transferrin saturation levels. Which of the following clinical features, once developed, progresses even after successful treatment of the condition? (Q851404)

A. Hepatomegaly

B. Cardiac arrhythmia

C. Arthropathy

D. Hypogonadism

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 45-year-old man presents with fatigue, joint pain, and new-onset diabetes. He has a family history of liver disease and reports high alcohol intake. Which biochemical test would be a strong indicator of hemochromatosis in this patient? (Q851406)

A. Plasma iron levels

B. Serum ferritin levels

C. Fasting serum transferrin saturation

D. Liver biopsy

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 25-year-old female comes with fatigue, joint pains, and a slate-gray appearance of the skin. After evaluation and detailed history, the physician suspects hemochromatosis. Which of the following statements about screening for hemochromatosis is false? (Q851408)

A. All adult first-degree relatives should be tested for C282Y and H63D mutations.

B. Genetic testing for the C282Y and H63D mutations is recommended if screening tests are abnormal.

C. Children of diagnosed individuals under 18 years old should always be screened for hemochromatosis.

D. Screening is done using transferrin saturation and ferritin levels.

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 45-year-old male patient with a confirmed diagnosis of hereditary hemochromatosis presents with symptoms of fatigue, diabetes, and joint pain. Laboratory tests reveal elevated serum ferritin levels of 2000 μg/dl. Which of the following is the most appropriate initial treatment for this patient? (Q851411)

A. Deferoxamine parenteral chelation therapy

B. Liver transplantation

C. Deferiprone oral chelation therapy

D. Phlebotomy

See Answer in Part B → Q13

@Neet_pg_bot

• [09_Hepatobiliary System] 072 Hereditary Hyperbilirubinemia Budd Chiari Syndrome

« Back to Folder Directory

[09_Hepatobiliary System] 072 Hereditary Hyperbilirubinemia Budd Chiari Syndrome — Quick Jump

Q1 (p. 867) *Q2 (p. 867)* *Q3 (p. 868)* *Q4 (p. 868)* *Q5 (p. 869)* *Q6 (p. 869)*
Q7 (p. 870) *Q8 (p. 870)* *Q9 (p. 870)*

Q1: A 3-month-old infant presents with jaundice. Laboratory tests reveal elevated bilirubin levels, with a higher proportion of unconjugated bilirubin. The infant's mother mentions that the jaundice has been present since birth and that the infant has not shown any signs of hemolysis. What is the most likely underlying cause of this infant's condition related to bilirubin metabolism? (Q851561)

A. Impaired uptake of bilirubin by hepatocytes

B. Defective conjugation of bilirubin due to UGT1A1 mutation

C. Reduced biliary excretion of bilirubin due to MRP2 mutation

D. Increased production of bilirubin due to hemolysis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 17-year-old male presents to the clinic for a routine check-up. His laboratory tests reveal serum bilirubin levels of 45 μmol/L (2.6 mg/dL) with normal liver function tests. He reports occasional mild jaundice, particularly after periods of stress and fasting. There is no history of hemolysis or liver disease. The patient has been asymptomatic otherwise. What is the most likely diagnosis for this patient based on the provided information? (Q851562)

A. Crigler-Najjar Syndrome Type I

B. Crigler-Najjar Syndrome Type II

C. Dubin-Johnson Syndrome

D. Gilbert Syndrome

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 2-week-old infant is brought to the emergency department due to jaundice. The mother reports that the infant's skin has become increasingly yellow since birth. Laboratory tests reveal a serum bilirubin level of 450 μmol/L (26 mg/dL), and the infant appears lethargic. There are no signs of hemolysis, and a physical examination shows no other abnormalities. What is the most likely diagnosis for this infant based on the provided information? (Q851563)

A. Crigler-Najjar Syndrome Type I

B. Crigler-Najjar Syndrome Type II

C. Dubin-Johnson Syndrome

D. Rotor Syndrome

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 30-year-old woman presents to the clinic with intermittent jaundice that worsens during her menstrual cycle and when taking oral contraceptives. Laboratory tests reveal elevated conjugated bilirubin levels, but her liver function tests are otherwise normal. A liver ultrasound shows no significant abnormalities, and she has no history of significant liver disease. What is the most likely diagnosis for this patient based on the provided information? (Q851564)

A. Dubin-Johnson Syndrome

B. Rotor Syndrome

C. Budd-Chiari Syndrome

D. Crigler-Najjar Syndrome Type II

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 28-year-old man presents to the clinic with intermittent jaundice and dark urine. His laboratory tests show elevated conjugated bilirubin levels and urine tests reveal bilirubinuria. An ultrasound of the liver is unremarkable, and a cholecystography shows a normal gallbladder. The patient has no significant past medical history and is otherwise asymptomatic. What is the most likely diagnosis for this patient based on the provided information? (Q851565)

A. Crigler-Najjar Syndrome Type I

B. Gilbert Syndrome

C. Rotor Syndrome

D. Dubin-Johnson Syndrome

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 35-year-old woman presents to the emergency department with abdominal pain, severe ascites, and jaundice that developed over the past month. On examination, she has hepatomegaly and splenomegaly. Laboratory tests show elevated liver enzymes and bilirubin levels. A Doppler ultrasound of the abdomen reveals occlusion of multiple hepatic veins. What is the most likely diagnosis for this patient based on the provided information? (Q851566)

A. Dubin-Johnson Syndrome

B. Budd-Chiari Syndrome

C. Gilbert Syndrome

D. Rotor Syndrome

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 32-year-old woman presents with 2 months of progressive abdominal pain and distension. On examination, she has spider angiomas, hepatomegaly, and moderate ascites. Laboratory studies show haemoglobin 18.2 g/dL, WBC 13,000/μL, platelets 650,000/μL, and normal liver enzymes. Doppler ultrasound reveals hepatic vein thrombosis. Which of the following is the most common cause of the suspected condition? (Q851567)

A. Myeloproliferative disorders

B. Vitamin B12 deficiency

C. Inflammatory bowel disease

D. Chronic hepatitis C

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 35-year-old woman presents with 3 weeks of progressive abdominal pain and ascites. Laboratory studies show elevated LFTs and a prolonged PT. Doppler ultrasound reveals hepatic vein thrombosis. After initial diagnosis, which of the following represents the most appropriate sequential management approach? (Q851568)

A. Proceed directly to liver transplantation

B. Initiate anticoagulation, followed by assessment for predisposing causes and TIPS if needed

C. Start diuretics alone and monitor symptoms

D. Perform surgical shunting as primary therapy

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following statements is true regarding how the Bromsulphthalein test helps distinguish between Rotor syndrome and Dubin-Johnson syndrome? (Q851569)

A. Dubin johnson syndrome - prolonged retention of BSP in the bloodstream Rotor syndrome - BSP is rapidly cleared.

B. Dubin Johnson syndrome - delayed excretion with prolonged retention of BSP occurs, Rotor syndrome - early excretion with no delayed retention.

C. Both Rotor syndrome and DJS show prolonged retention of BSP, making the test ineffective in differentiation.

D. Dubin Johnson syndrome - BSP is taken up slowly by the liver but is excreted rapidly, Rotor syndrome - BSP is taken up rapidly by the liver but is excreted slowly

See Answer in Part B → Q9

Q1: Which of the following conditions leads to the development of wing beating tremor? (Q857675)

A. Wilson’s disease

B. Huntington’s chorea

C. Parkinsonism

D. Sydenham’s chorea

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 45-year-old man with known alcoholic cirrhosis presents with confusion and 3 days of hematemesis. Examination reveals icterus, hepatosplenomegaly, tense ascites, and asterixis. Vitals: BP 100/60 mmHg, pulse 104/min. Which of the following is appropriate in the initial management of this patient? Start propranolol to stop variceal bleeding Perform a diagnostic ascitic tap to rule out spontaneous bacterial peritonitis (SBP) Start IV antibiotics and IV octreotide infusion Give IV albumin after large-volume paracentesis or if renal dysfunction develops (Q879181)

A. 1,2

B. 2,3,4

C. 1,2,3

D. 1,2,3,4

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A patient presents with fever, jaundice, and malaise. Based on the serology reports provided, what is the most likely diagnosis? Serology Reports: HBsAg: Positive Anti-HBc: Positive Anti-HCV: Negative (Q856023)

A. Acute hepatitis D

B. Acute hepatitis B

C. Chronic hepatitis B

D. Chronic hepatitis C

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Laboratory investigations of a patient being evaluated for jaundice show elevated bilirubin and alkaline phosphatase levels. Levels of the remaining liver enzymes are normal. What is the likely diagnosis? (Q855949)

A. Obstructive jaundice

B. Hemolytic jaundice

C. Hepatic jaundice

D. Prehepatic jaundice

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A patient with a history of chronic liver disease presents with abdominal distension, jaundice, and pruritis. Ascitic fluid analysis revealed a neutrophil count of

650 per cubic mm. What is the most likely diagnosis? (Q855935)

A. Spontaneous bacterial peritonitis

B. Malignant ascites

C. Tubercular ascites

D. Intestinal obstruction

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A patient presents to the emergency department with a history of ingestion of ten tablets of paracetamol. He has developed oliguria, and liver function tests show deranged values. Which of the following can be used in the management of this condition? (Q855921)

A. N-acetylcysteine

B. Dopamine

C. Ursodeoxycholic acid

D. Furosemide

See Answer in Part B → Q6

@Neet_pg_bot

Q7: What clinical examination is being performed in the image? (Q859798)

A. Shifting dullness

B. Ascites

C. Puddle sign

D. Fluid thrill

See Answer in Part B → Q7

@Neet_pg_bot

Q8: What is the most probable diagnosis for a 40-year-old man whose lab reports indicate positive IgG Anti-HBc and negative HBsAg? (Q859795)

A. Recovering from hepatitis B

B. Hepatitis B in the remote past

C. Immunization with HBsAg

D. Both B & C

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 53-year-old patient was brought to the emergency room with a history of alcohol abuse, altered sensorium, and rapid shallow breathing. His abdomen is distended with palpable hepatomegaly and splenomegaly and sclerae are icteric. The other examination findings are given below. Laboratory tests show that the AST: ALT ratio is 3:1. What is the most likely cause of this patient's presentation? (Q859785)

A. Alcoholic liver disease

B. Acute viral hepatitis

C. Autoimmune hepatitis

D. Acetaminophen poisoning

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 30-year-old female presents with unsteady gait, forgetfulness, and labile moods. During a physical exam, the neurologist notices the findings shown in the image below. The most likely diagnosis is: (Q859784)

A. Neurofibromatosis 2

B. Wilson's disease

C. Neurofibromatosis 1

D. Cataract

See Answer in Part B → Q10

@Neet_pg_bot

Q11: What is the child-Turcotte-Pugh class for the patient who has a serum bilirubin 2.5 mg/dl, serum albumin 3 g/dl, prothrombin time 5 seconds (INR =2), no encephalopathy, and mild ascites? (Q854983)

A. Class A

B. Class B

C. Class C

D. Class D

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A chronic alcoholic male patient presented with abdominal distension, reduced urine output, and pedal oedema. His serum creatinine was 1.6 mg/dL. What is the next line of management for this patient? (Q856197)

A. Methylprednisolone

B. Heparin

C. Torsemide

D. Octreotide plus albumin

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A young male patient has the following serological status: HbsAg positive, IgM anti Hbc negative, IgG Anti-Hbc positive and HBeAg positive. Select the best treatment for this patient? (Q866810)

A. Lamivudine

B. Ombitasvir

C. Ritonavir

D. Abacavir

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 20-year-old male presented with a history of yellowing of the skin and eyes for last one week after trekking on weekend. He had experienced a similar episode of yellowing 2 years ago for 2 weeks. Labs shows S. bilirubin level 2.4 mg/dL, unconjugated bilirubin at 2.1 mg/dL and conjugated bilirubin at 0.3 mg/dL. His AST and ALT levels are normal. What is the most likely diagnosis for this patient? (Q857009)

A. Dubin-Johnson syndrome

B. Crigler-Najjar type 1 syndrome

C. Gilbert syndrome

D. Rotor syndrome

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which benzodiazepine is suitable for the safe administration to a 40-year-old chronic alcoholic experiencing withdrawal symptoms, based on the liver function tests that indicated AST levels of 140 IU/L, ALT levels of 110 IU/L, and GGT levels of 500 IU/L? (Q855317)

A. Diazepam

B. Alprazolam

C. Clonazepam

D. Lorazepam

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following is not a component of Child-Pugh scoring? (Q858010)

A. Albumin

B. Bilirubin

C. Prothrombin Time

D. Serum Creatinine

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 30-year-old male is found to be positive for HBsAg and HBeAg and is diagnosed with chronic hepatitis B. The viral load of the patient was 2 × 10■ IU/mL, and SGPT is found to be doubled. What is the appropriate management in this patient? (Q855436)

A. Lamivudine for 30+ weeks

B. Tenofovir for >40 weeks

C. Pegylated interferon for 52 weeks

D. Combined pegylated interferon with lamivudine

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 40-year-old patient presents with right upper quadrant discomfort and grade Il steatohepatitis of the liver. He has a history of regular intake of 2-3 alcoholic drinks daily and has a BMI of 29. What will be the most appropriate advice to the patient? (Q854719)

A. Lifestyle modification + Regular exercise

B. Lifestyle modification + vitamin E + Ursodeoxycholic acid

C. Lifestyle modification + Pioglitazone

D. Lifestyle modification

See Answer in Part B → Q18

@Neet_pg_bot

Q19: The work-up of a 25-year-old hotel worker shows the following profile: HbsAg = Negative Anti HBsAg= Negative HBeAg = Negative Anti Hbe = Negative Total anti-HBc = IgG positive What is the diagnosis? (Q854667)

A. Chronic hepatitis B

B. Inactive carrier

C. Hepatitis B in remote past

D. Window period/ Gap period

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 55-year-old man with a history of chronic alcoholism presents unconscious and hypotensive. He stopped drinking 7 days ago. Ultrasound shows coarse liver echotexture and mild portal vein dilatation. There is no history of recent alcohol withdrawal symptoms. What is the most appropriate next step in management? (Q840114)

A. Administer lactulose and wait for stool passage.

B. Perform emergency endoscopy to assess for varices.

C. Initiate treatment with thiamine and chlordiazepoxide.

D. Conduct a CT scan of the brain.

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Patient presents with fatigue, pruritus and jaundice. Examination reveals hepatomegaly. LFT shows gross SAP elevation and elevated conjugated bilirubin. What is the most specific test to support diagnosis of PBC? (Q866508)

A. Anti-mitochondrial antibody

B. Antinuclear antibody

C. Anti-smooth muscle antibody

D. Anti L.K.M-1

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 5 year old boy presented with hematemesis and was found to have splenomegaly, on examination. There was a past history of exchange transfusion in this child for neonatal jaundice. What is the probable diagnosis? (Q866830)

A. Splenic vein thrombosis

B. Portal vein thrombosis

C. Budd chiari syndrome

D. Liver cirrhosis

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 20-year-old male presented with a 1 weak history of yellow skin and sclerae but is otherwise asymptomatic . He gives a history of viral upper respiratory infection 10 days ago, which resolved 2 days back. There is a history of a similar episode of icterus 2 years back when the patient had long hours of basketball practice . The current serum bilirubin is 2.4 mg/dl, unconjugated bilirubin is 2.1mg/dl, and conjugated bilirubin is 0.3mg/dl. Serum AST and ALT levels are normal . Which of the following is the most likely diagnosis ? (Q793887)

A. Dubin-Johnson syndrome

B. Criggler-Najar type 1 syndrome

C. Gilbert syndrome

D. Rotor syndrome

See Answer in Part B → Q23

Q13 (p. 888) *Q14 (p. 888)* *Q15 (p. 889)* *Q16 (p. 890)*

Q1: A 16-year-old female with cystic fibrosis presents with increased productive cough, fever, and worsening shortness of breath. Her sputum culture grows Pseudomonas aeruginosa. Which of the following best explains why this organism commonly causes respiratory infections in cystic fibrosis patients? (Q851570)

A. Defective neutrophil chemotaxis to the site of infection

B. Abnormal periciliary fluid layer leading to impaired mucociliary clearance

C. Direct immunosuppressive effect of the CFTR protein mutation

D. Increased expression of bacterial adhesion molecules on respiratory epithelium

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 3-month-old infant presents with failure to thrive, recurrent respiratory infections, and elevated sweat chloride. Genetic testing reveals two copies of the F508del mutation in the CFTR gene. This mutation results in a protein that fails to reach the cell surface due to degradation in the endoplasmic reticulum. Which class of CFTR mutation does this represent, and what percentage of CF patients carry at least one copy of this mutation? (Q851571)

A. Class I mutation; ~30% of patients

B. Class II mutation; ~70% of patients

C. Class III mutation; ~50% of patients

D. Class IV mutation; ~40% of patients

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 3-year-old boy comes to the emergency department with difficulty breathing and a productive cough. He has a history of recurrent sinusitis and otitis media and usually responds well to antibiotics. Crackles and wheezing are heard on pulmonary auscultation and CVS examination shows the cardiac point of maximum impulse on the right 5th intercostal space. Which of them is not seen in this condition? (Q851572)

A. Dynein arm defect

B. Normal sweat chloride test

C. CFTR mutation

D. Defective mucociliary clearance

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 7-year-old child presents with a chronic productive cough, nasal polyps, and poor weight gain despite normal appetite. Which of the following is the most likely associated condition? (Q851573)

A. Primary ciliary dyskinesia

B. Asthma

C. Cystic fibrosis

D. Bronchopulmonary dysplasia

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 2-month-old infant presents with recurrent respiratory infections and failure to thrive. Physical examination reveals digital clubbing and productive cough. A sweat test shows elevated chloride levels, but the genotype analysis for common CFTR mutations is inconclusive. Which of the following investigations is the next best step for confirming the diagnosis of cystic fibrosis in this patient? (Q851574)

A. Bronchoalveolar lavage

B. Nasal potential difference measurement

C. Chest X-ray

D. Genetic panel including rare CFTR mutations

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A newborn screening for CF shows elevated immunoreactive trypsinogen (IRT) levels. What is the next best step in the diagnostic process? (Q851575)

A. Repeat the IRT test in 6 months

B. Genetic testing for CFTR mutations

C. Chest X-ray

D. Fecal elastase levels

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following therapies directly targets the basic molecular defect in cystic fibrosis for a patient with a G551D mutation? (Q851576)

A. Pancreatic enzyme supplements

B. Lumacaftor

C. Ivacaftor

D. Hypertonic saline nebulization

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old obese male (BMI- 40) presents with complaints of loud snoring and daytime sleepiness. His wife reports that he complains of disturbed sleep due to waking up out of breath because of an obstruction of the airway. Polysomnography reveals repetitive episodes showing: Sharp inspiratory uptake Flattened/plateau wave Scooped out breathing pattern Flow limitation Oxygen desaturation What is the correct sequence of pathophysiologic events leading to his symptoms? (Q851577)

A. REM sleep → Hypoxia → Pharyngeal dilator muscle relaxation → Airway narrowing → snoring

B. Pharyngeal dilator muscle relaxation → Airway narrowing → Flow limitation → Hypoxia → Cortical arousal

C. Obesity → Flow limitation → Airway collapse → Snoring → Bradycardia → Hypoxia

D. Hypoxia → Airway collapse → Flow limitation → Bradycardia → Cortical arousal

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old man presents with complaints of daytime sleepiness and morning headaches, and his wife reports loud snoring with episodes of gasping during sleep. His BMI is 32 kg/m², neck circumference is 44 cm, and he has retrognathia. His blood pressure is 148/92 mmHg. Which of the following combinations of additional clinical features and diagnostic findings would not be seen with obstructive sleep apnea in this patient? (Q851578)

A. Fragmented sleep on PSG

B. Central obesity, elevated sweat chloride, pancreatic insufficiency

C. Nondipping nocturnal blood pressure pattern

D. Frequent arousals with oxygen desaturation

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following statements is incorrect regarding risk factors of Obstructive Sleep Apnea? (Q851579)

A. Premenopausal women have the same risk for OSA as postmenopausal women

B. A 10% increase in body weight is associated with a >30% increase in apnea-hypopnea index (AHI)

C. Approximately 40-60% of OSA cases are attributable to excess body weight

D. Men have approximately twice the risk of developing OSA compared to women

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 52-year-old man presents to his primary care physician with complaints of excessive daytime sleepiness and his spouse reports loud snoring with disturbed sleep due to breathing pauses during sleep. His BMI is 34 kg/m² and neck circumference is 43 cm. Which of the following should be the INITIAL step in evaluating this patient? (Q851580)

A. Order an overnight polysomnography immediately

B. Start CPAP therapy based on symptoms

C. Obtain detailed sleep history with standardized sleepiness questionnaires and perform focused physical examination

D. Order overnight home oximetry

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old man is diagnosed with moderate obstructive sleep apnea (AHI=22/hour) based on polysomnography. He has daytime sleepiness, BMI of 35

kg/m², and hypertension. Which of the following is the most appropriate initial treatment approach for this patient? (Q851581)

A. Prescribe oral appliance therapy as first-line treatment

B. Initiate CPAP therapy with appropriate pressure titration and provide supportive care

C. Recommend uvulopalatopharyngoplasty without trying conservative measures

D. Lifestyle modification and weight loss

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 45-year-old male reports persistent daytime sleepiness, often dozing off during meetings and while watching television. He completes the Epworth Sleepiness Scale (ESS) and scores 12. What does a score of 12 indicate? (Q851583)

A. Unlikely to be abnormally sleepy.

B. Average daytime sleepiness.

C. Possibly excessively sleepy; consider medical attention.

D. Excessively sleepy; seek immediate medical attention.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 52-year-old obese male presents to the clinic with excessive daytime sleepiness hypoventilation and difficulty breathing at night. His BMI is 32 kg/m², and arterial blood gas analysis shows a Paco2 of 48 mmHg recorded during the day. The patient reports loud snoring and episodes of gasping during sleep. He has a history of severe obesity and is suspected of having obstructive sleep apnea. Based on the scenario, which of the following diagnoses is most likely? (Q851594)

A. Central Hypoventilation Syndrome

B. Obesity Hypoventilation Syndrome

C. Congenital Central Hypoventilation Syndrome

D. Simple Obstructive Sleep Apnea

See Answer in Part B → Q14

@Neet_pg_bot

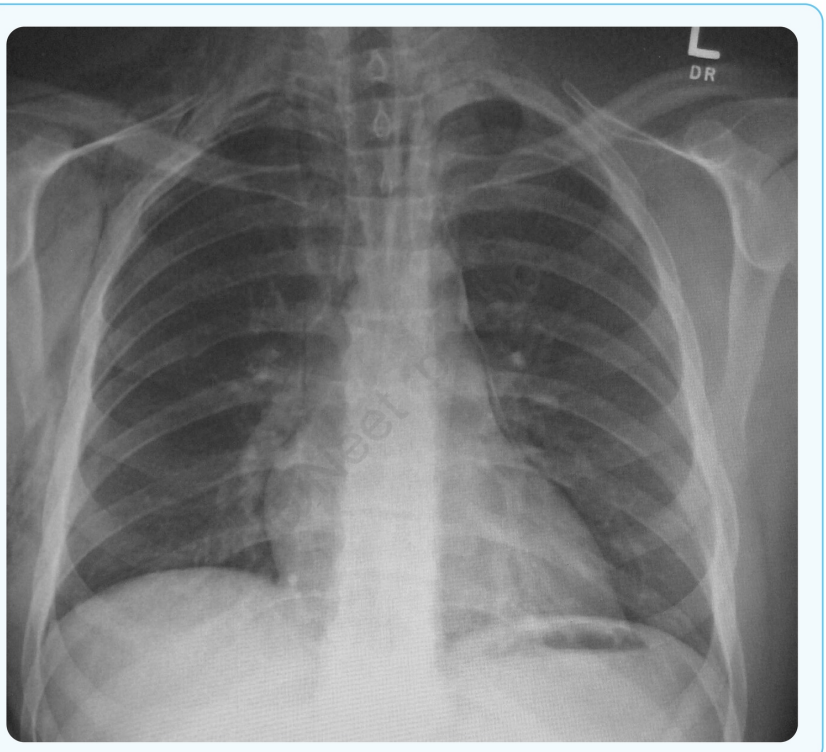
Q15: A 25-year-old tall male presents to the emergency department with acute retrosternal chest pain and difficulty breathing after a vigorous bout of coughing. He reports having experienced frequent coughing spells over the past week due to a respiratory infection. On physical examination, subcutaneous emphysema is noted in the neck region. The chest X-ray of the patient is given below. Which of the following statements best describes a potential cause of this patient's condition? (Q851595)

A. The condition is likely caused by a foreign body in the airway.

B. Increased intra-alveolar pressure from excessive coughing can lead to alveolar rupture.

C. This condition is primarily associated with high BMI individuals.

D. Always a result of blunt trauma.



@Neet_pg_bot

See Answer in Part B → Q15

@Neet_pg_bot

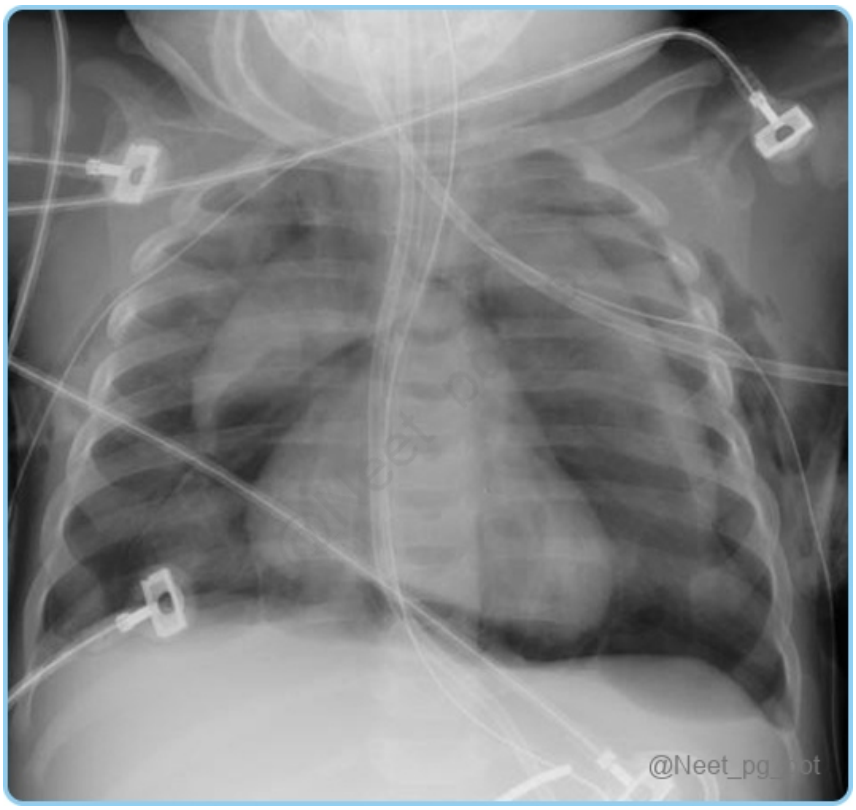
Q16: A 7-year-old boy presents to the emergency department with chest pain and difficulty breathing after experiencing a severe coughing fit. A chest X-ray is performed and is given below. Which of the following statements is true regarding the management of this condition? (Q851597)

A. The primary diagnostic tool for this condition is a CT scan.

B. Surgical intervention is always required for treatment.

C. Conservative management is usually sufficient for most patients with this condition.

D. Prophylactic antibiotics are necessary for all patients diagnosed.



See Answer in Part B → Q16

Q13 (p. 897)	*Q14 (p. 898)*	*Q15 (p. 898)*			

Q1: A 30-year-old male develops respiratory distress, confusion, and a chest petechial rash two days after surgery for multiple long bone fractures from a motor vehicle accident. Suspecting Fat Embolism Syndrome (FES), which diagnostic test is used to detect fat in this condition? (Q851917)

A. Chest CT

B. Bronchoalveolar lavage (BAL)

C. Intracranial Doppler ultrasonography

D. Head CT

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 60 y/o woman presents with sudden shortness of breath and pleuritic chest pain. She had a total hip replacement 10 days ago. O/E, she is tachycardic with low oxygen levels. What is the most likely cause of her symptoms? (Q851892)

A. Fat embolism

B. Tumor emboli

C. Air emboli

D. Pulmonary embolism

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following statements regarding causes of DVT is true? (Q851893)

A. Factor V Leiden increases the effectiveness of activated protein C.

B. Prothrombin gene mutation decreases the concentration of prothrombin in the blood.

C. Cancer increases the risk of DVT fourfold compared to the general population.

D. Pregnancy reduces the risk of venous stasis.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 62 y/o hypertensive woman with a history of recent surgery presents with sudden onset of dyspnea and chest pain. ABG analysis reveals hypoxemia. A CT angiogram confirms the presence of a pulmonary embolism. What describes changes in the lung in this condition? (Q851895)

A. Increased pulmonary compliance

B. Decreased alveolar-arterial oxygen gradient

C. Increased physiologic dead space

D. Improved gas exchange efficiency

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45 y/o man presents with chest pain and dyspnea. A CT scan shows multiple pulmonary emboli. He is diagnosed with right ventricular dysfunction secondary to the emboli. Which of the following best explains the cause of the same? (Q851896)

A. Left ventricular failure

B. Microinfarctions of the right ventricle

C. Decreased pulmonary vascular resistance

D. Improved coronary perfusion

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 58 y/o woman with a history of DVT presents to the hospital with sudden onset chest pain, tachycardia, and cyanosis. She is diagnosed with a massive pulmonary embolism. What is the most likely clinical finding that indicates acute cor pulmonale? (Q851898)

A. Loud S1 heart sound

B. Jugular venous distention

C. Bradycardia

D. Elevated blood pressure

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 62 y/o male presents to the emergency with a history of prolonged immobility after recent hip surgery. His vital signs are as follows: respiratory rate of 28 bpm, heart rate of 110 bpm, and blood pressure of 90/60 mmHg. The D-dimer level is 900 mg/dL, and the CTPA scan shows filling defects. What is the most common symptom associated with this condition at the initial stage of presentation? (Q851900)

A. Syncope

B. Pleuritic chest pain

C. Unexplained dyspnea

D. Hemoptysis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 62 y/o woman with a history of breast cancer is treated with chemotherapy. She presents with swelling and localised tenderness in her right leg. She was recently hospitalised for surgery and has been bedridden for the past three weeks. Examination shows pitting edema confined to the right leg, but no collateral veins and no previous DVT history. What is the patient's risk for DVT based on the Wells Criteria? (Q851901)

A. DVT unlikely

B. Low probability

C. Moderate probability

D. High probability

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 65y/o man presents to the emergency department with a sudden onset of pleuritic chest pain, dyspnea, and mild hypotension. His echocardiogram shows right ventricular (RV) dysfunction, but his systemic arterial pressure remains normal. Which of the following is the most appropriate next step in management? (Q851904)

A. Immediate anticoagulation and observation

B. Fibrinolytic therapy

C. Catheter-directed thrombolysis

D. Surgical embolectomy

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 60 y/o male with a history of recent surgery presents with acute onset dyspnea and pleuritic chest pain. His ECG findings show sinus tachycardia. Which of the following investigations would most directly confirm the diagnosis of pulmonary embolism (PE)? (Q851906)

A. Chest X-ray

B. Ventilation-perfusion (V/Q) scan

C. CT pulmonary angiogram

D. D-Dimer

See Answer in Part B → Q10

@Neet_pg_bot

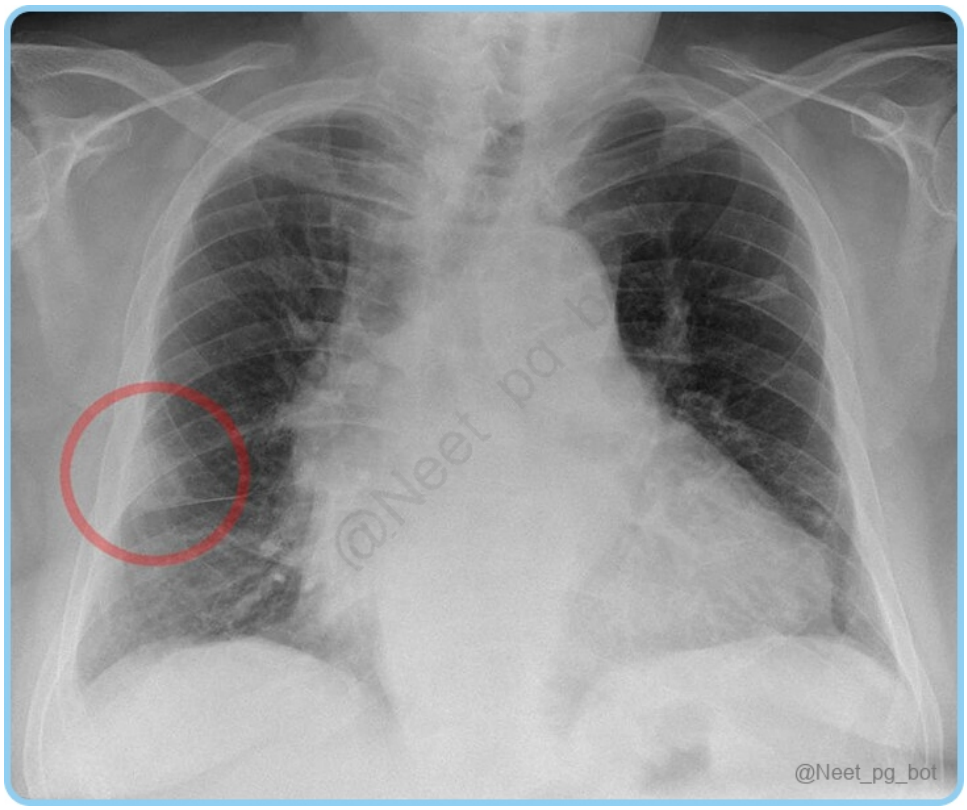
Q11: A 70-year-old woman with atrial fibrillation presents with sudden-onset dyspnea and pleuritic chest pain. She is hypotensive, tachycardic, and confused. Chest X-ray shows a wedge-shaped opacity in the right lung as shown in image. What is the most appropriate initial management? {{caption_text}} (Q851909)

A. Initiation of oral anticoagulation

B. Starting her on intravenous unfractionated heparin

C. Administration of thrombolytic therapy

D. Performing a surgical embolectomy



See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 72 y/o woman presents to the ED with sudden onset dyspnea and chest pain. On examination, she is hypotensive (systolic BP 85 mm Hg), has tachycardia, and exhibits signs of altered consciousness. An echocardiogram shows right ventricular (RV) dysfunction. What is the most likely diagnosis? (Q851910)

A. Submassive pulmonary embolism

B. Massive pulmonary embolism

C. Pneumonia

D. Myocardial infarction

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 28 y/o man is admitted to the ED following a motorcycle accident resulting in multiple fractures of the right femur and left humerus. Two days post-injury, he developed sudden onset dyspnea, altered mental status, and a petechial rash around his neck and conjunctiva. What is the most likely diagnosis? (Q851911)

A. Acute Respiratory Distress Syndrome (ARDS)

B. Fat Embolism Syndrome (FES)

C. Pulmonary Embolism (PE)

D. Deep Vein Thrombosis (DVT)

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 28 y/o male presents to the ED after sustaining multiple long bone fractures in a motorcycle accident. Two days post-injury, he exhibits tachypnea, confusion, and a petechial rash on his torso. Which of the following is NOT a part of the diagnostic criteria for the patient's likely condition? (Q851913)

A. Sudden thrombocytopenia

B. Elevated white blood cell count

C. Elevated erythrocyte sedimentation rate (ESR)

D. Petechial rash

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 40-year-old male presents to the emergency department after sustaining multiple long bone fractures in a car accident. Two days later, he developed respiratory distress, confusion, and a petechial rash. His oxygen saturation is dropping, and the medical team begins supportive care, including fluid resuscitation and monitoring. Which of the following is the best option for expanding plasma volume and potentially limiting lung injury in this patient with FES? (Q851918)

A. Normal saline

B. Ringer lactate solution

C. Albumin

D. Corticosteroids

See Answer in Part B → Q15

@Neet_pg_bot

Q1: Which of the following statements are false regarding primary lung abscesses? (Q851712)

A. Most cases are polymicrobial infections.

B. Hematologic dissemination is one of the causes

C. Poor dental hygiene is an independent risk factor for developing lung abscesses

D. Staphylococcus aureus can cause lung abscesses in individuals with alcohol use disorder.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 55-year-old patient presents with fever, productive cough, and pleuritic chest pain. A chest CT scan reveals a fluid collection in the pleural space with a thickened pleura. Which of the following is the most likely diagnosis? (Q851740)

A. Empyema

B. Lung abscess

C. Pneumonia

D. Pulmonary edema

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55-year-old patient presents with a productive cough, fever, and shortness of breath. A chest X-ray reveals a lobar consolidation. Which of the following is the most likely causative organism of community-acquired pneumonia in this patient? (Q851739)

A. Klebsiella pneumoniae

B. Haemophilus influenzae

C. Streptococcus pneumoniae

D. Pseudomonas aeruginosa

See Answer in Part B → Q3

@Neet_pg_bot

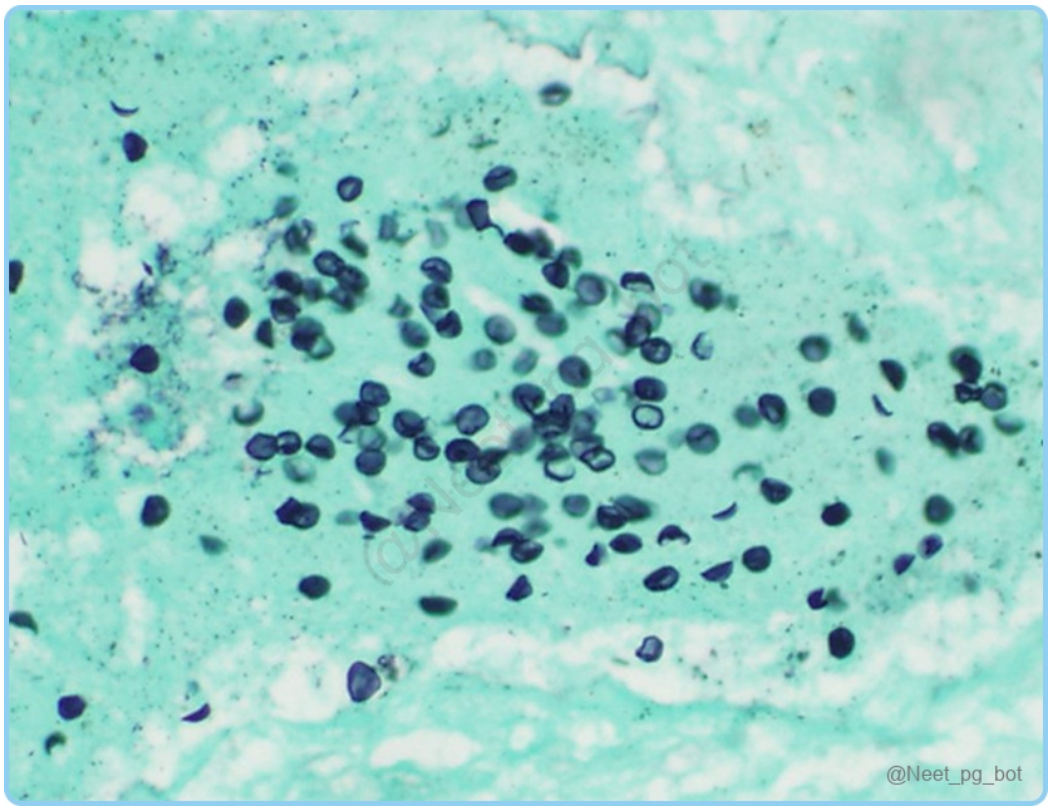
Q4: A 35-year-old HIV-positive patient presents with a non-productive cough, dyspnea, and low-grade fever. A Gomori methenamine silver stain of a bronchoalveolar lavage specimen was done. What is the most appropriate treatment for this patient? (Q851738)

A. Azithromycin

B. Amphotericin B

C. Co-trimoxazole

D. Itraconazole



See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 60-year-old male presents with fever, cough, and chest discomfort. His chest X-ray reveals right lower lobe consolidation. Which of the following features would be more consistent with atypical pneumonia? (Q851737)

A. Gradual onset with a dry cough

B. High-grade fever

C. Lobar consolidation on chest X-ray

D. Productive cough with purulent sputum

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 70 y/o man with COPD presents with 3 days of worsening shortness of breath, fever, and productive cough. He appears confused and has a respiratory rate of 32/min, BP of 85/55 mmHg, and BUN of 25 mg/dL. What is the most appropriate management? (Q851736)

A. Outpatient treatment with azithromycin

B. Inpatient treatment with levofloxacin and azithromycin

C. ICU admission with piperacillin-tazobactam and vancomycin

D. Inpatient treatment with amoxicillin alone

See Answer in Part B → Q6

@Neet_pg_bot

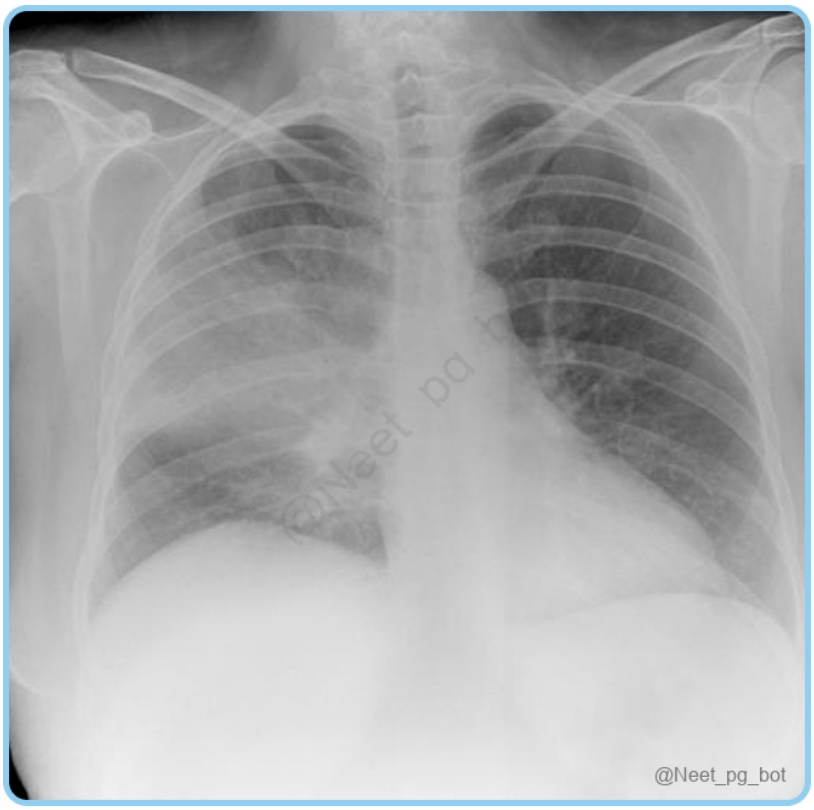
Q7: A 65 y/o woman is admitted to the hospital with a high fever, productive cough, and pleuritic chest pain. A physical examination reveals diminished breath sounds on the right side, and she appears confused. The chest X-ray is given below. Despite this, the physician considers further testing. Which of the following investigations should be prioritized next to confirm the causative organism of the suspected diagnosis? (Q851725)

A. Sputum Gram stain and culture

B. Complete Blood Count

C. CT chest

D. Influenza testing



See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements are true regarding breath sounds? (Q851724)

A. Vesicular breath sounds are soft, low-pitched sounds heard at the bronchus

B. Bronchial sounds are loud, high-pitched best heard at lung bases of normal lung

C. Egophony is the increased resonance of voice sounds heard when auscultating the lungs

D. Whispered pectoriloquy rules out the presence of lung consolidation

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 65 year old man presents to the ED with a 5-day history of fever, productive cough, and worsening shortness of breath. On examination, he exhibits tachypnea, and

his sputum is thick and yellowish. He complains of sharp pleuritic chest pain when taking deep breaths. The physician notes increased vocal fremitus and egophony on examination. Based on the clinical features presented, which of the following findings is most likely to be noted upon auscultation of this patient's lungs? (Q851723)

A. Absence of breath sounds

B. Wheezing

C. Ronchi

D. Presence of crackles and bronchial breath sounds

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Match the following conditions of pneumonia to their respective causative organisms: 1. Alcoholic patient with Pneumonia a) Legionella pneumophila 2. Pneumonia due to contact with Bats b) Coxiella burnetii 3. Pneumonia after Hotel/cruise c) Pneumococcus pneumonia 4. Pneumonia due to contact with Goat/sheep d) Histoplasmosis (Q851722)

A. 1-c, 2-d, 3-a, 4-b

B. 1-d, 2-b, 3-a, 4-c

C. 1-a, 2-b, 3-d, 4-a

D. 1-b, 2-c, 3-d, 4-a

See Answer in Part B → Q10

@Neet_pg_bot

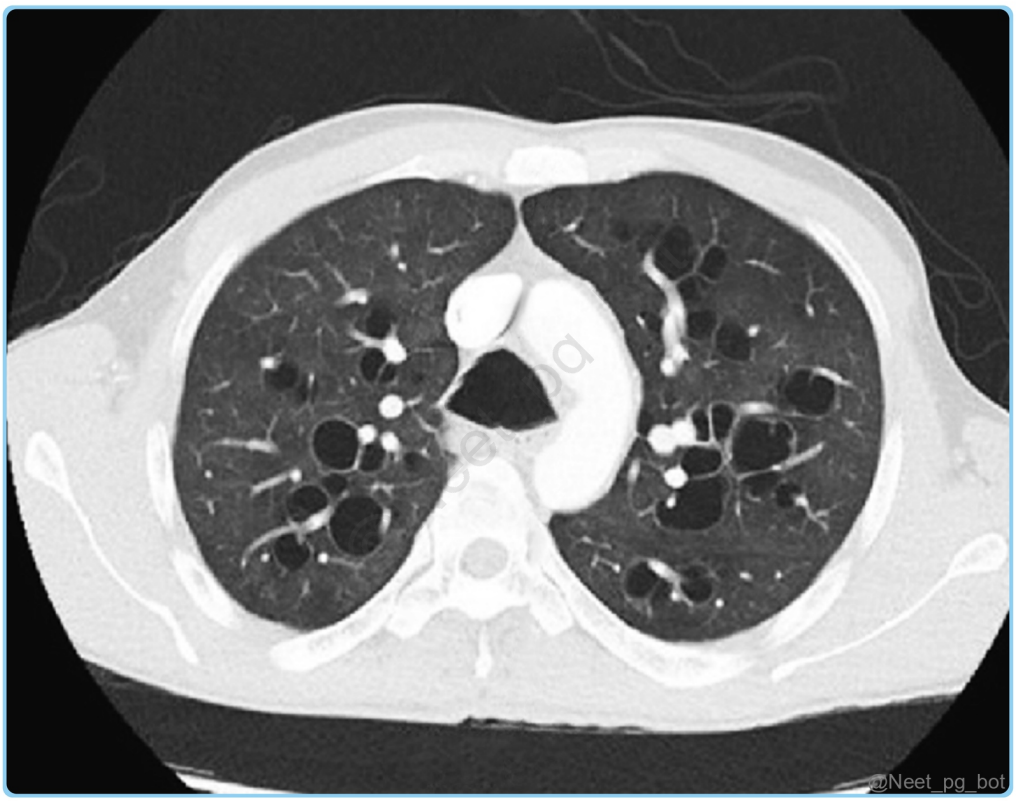
Q11: A 60 y/o woman presents with the characteristic fingers as shown in the image, along with chronic cough, daily production of large amounts of purulent sputum and a history of recurrent lung infections over the past several years. Her CT scan revealed the following findings. A biopsy of the affected lung tissue is performed. Which of the following histopathological findings is most likely present? (Q851702)

A. Chronic inflammatory destruction of bronchial walls with loss of smooth muscle and elastic tissue

B. Presence of caseating granulomas

C. Extensive alveolar damage

D. Bronchiectatic cavities lined exclusively by ciliated epithelium



See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 25-year-old student presents with a 10-day history of dry cough, mild fever, and fatigue, but has been able to attend daily activities. Chest X-ray shows patchy infiltrates and a physical exam reveals mild crackles. Which of the following is the least likely causative agent of this patient's condition? (Q851711)

A. Mycoplasma pneumoniae

B. Chlamydia pneumoniae

C. Legionella pneumophila

D. Klebsiella pneumoniae

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 70 y/o male with a h/o DM presents to the ER with a persistent cough, high fever, and shortness of breath. He recently returned from a week-long cruise in the Caribbean. O/E, he has decreased breath sounds on one side, and a chest X-ray reveals infiltrates that are suggestive of pneumonia. Given the patient's history and recent travel, which of the following is the most likely causative organism for his pneumonia? (Q851710)

A. Streptococcus pneumoniae

B. Legionella species

C. Haemophilus influenzae

D. Mycoplasma pneumoniae

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following represents the correct order of pathological stages in classic pneumonia? (Q851709)

A. Edema Stage → Gray Hepatization → Red Hepatization → Resolution Stage

B. Edema Stage → Red Hepatization → Gray Hepatization → Resolution Stage

C. Gray Hepatization → Red Hepatization → Edema Stage → Resolution Stage

D. Red Hepatization → Resolution Stage → Edema Stage → Gray Hepatization

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 45 y/o man with a history of bronchiectasis presents for follow-up after sputum analysis reveals Mycobacterium avium complex (MAC) infection. What is the recommended treatment regimen for this patient's infection? (Q851708)

A. Itraconazole + Rifampin + Ethambutol

B. Macrolide + Rifampin + Ethambutol

C. Macrolide + Isoniazid + Ethambutol

D. Rifampin + Isoniazid + Pyrazinamide

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 35 y/o male presents with a chronic productive cough, dyspnea, and occasional hemoptysis. A chest radiograph of the patient is given. Which investigation would be most appropriate for confirming the provisional diagnosis? (Q851707)

A. Sputum analysis

B. Chest computed tomography (CT)

C. Pulmonary function tests (PFTs)

D. Bronchoscopy

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 30 y/o woman with a history of recurrent lung infections presents to the emergency. She reports increased sputum volume and a change in sputum colour. O/E, she demonstrates wheezing and crackles. What does the change in sputum production most likely indicate? (Q851706)

A. Initiation of effective airway clearance therapy

B. Worsening infection and inflammation

C. The onset of remission in chronic lung disease

D. Onset of allergic reaction

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following is commonly associated with bronchiectasis affecting the lower lobes? (Q851705)

A. Cystic Fibrosis

B. Allergic Bronchopulmonary Aspergillosis

C. Nontuberculous mycobacterial infection

D. Chronic Recurrent Aspiration

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 40 y/o man, a non-smoker, presents with shortness of breath, chronic cough, and repeated respiratory infections. His chest CT shows emphysema and bronchiectasis. Lab results indicate low alpha-1 antitrypsin levels. What is the most likely reason for the bronchiectasis seen in this patient? (Q851704)

A. Idiopathic airway dilation

B. Recurrent infections due to defective chloride transport

C. Impaired ciliary function leading to mucus retention

D. Increased neutrophil elastase activity causing damage

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 35 y/o female with asthma presents with worsening cough, wheezing, and episodes of hemoptysis. Chest imaging reveals central bronchiectasis, and blood tests show elevated total IgE levels and eosinophil count. What is the most likely cause of the bronchiectasis? (Q851703)

A. Cystic fibrosis

B. Primary ciliary dyskinesia

C. Allergic bronchopulmonary aspergillosis (ABPA)

D. Idiopathic bronchiectasis

See Answer in Part B → Q20

Q1: A 55-year-old male with a history of heavy smoking presents with a cough and sputum production for 4 months. Which statement is true regarding his condition? (Q851771)

A. Diagnosis requires symptoms for at least 2 consecutive months.

B. Smoking cessation is the only intervention that positively impacts COPD

C. Inhaled bronchodilators are the primary treatment for chronic bronchitis.

D. Hemoptysis is the initial symptom indicative of chronic bronchitis.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 68-year-old male patient with COPD presents with severe respiratory distress. Before initiating Non-Invasive Ventilation (NIV), which of the following conditions would be considered as absolute contraindication? (Q852141)

A. Severe hypoxemia with pH < 7.1

B. Lack of spontaneous breathing or gasping

C. Post upper gastrointestinal surgery

D. Massive retention of secretions despite bronchoscopy

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following statements regarding the management of COPD is correct ? (Q852140)

A. Inhaled corticosteroids (ICS) should be used as monotherapy in all COPD patients

B. Long-acting bronchodilators are the mainstay of treatment for moderate to severe COPD

C. Antibiotics are routinely prescribed for the prevention of COPD exacerbations

D. Pulmonary rehabilitation is only recommended for patients with mild COPD

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 62-year-old male with chronic obstructive pulmonary disease (COPD) reports increasing breathlessness over the past few months. He now has to stop for breath after walking about 100 metres on level ground. According to the modified Medical Research Council (mMRC) dyspnoea scale, which grade best describes his level of breathlessness? (Q852139)

A. Grade 1

B. Grade 2

C. Grade 3

D. Grade 4

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following interventions has been shown to significantly improve survival in patients with chronic obstructive pulmonary disease (COPD)? (Q852138)

A. Pulmonary rehabilitation

B. Smoking cessation

C. Oral glucocorticoids during exacerbations

D. Pneumococcal vaccination

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 65-year-old male with a history of chronic obstructive pulmonary disease (COPD) presents for routine follow-up. He reports increased breathlessness while walking on level ground and has experienced two exacerbations in the past year. According to the 2023 GOLD classification, which group does this patient belong to? (Q852137)

A. Group A: Low risk, low symptoms

B. Group B: Low risk, high symptoms

C. Group C: High risk, low symptoms

D. Group D: High risk, high symptoms

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 68-year-old woman with a history of Chronic Obstructive Pulmonary Disease (COPD) is evaluated for her BODE Index score. Her current Body Mass Index (BMI) is 20 kg/m², her post-bronchodilator FEV1 is 42% of the predicted value, she reports a mMRC dyspnoea score of 3, and she walks 340 metres during a 6-minute walk test. What is her total BODE Index score? (Q852136)

A. 4

B. 5

C. 6

D. 7

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 70-year-old male with a long-standing history of chronic obstructive pulmonary disease (COPD) presents to the clinic with worsening breathlessness and cough. His smoking history is significant for 45 pack-years. O/E, he has bilateral wheezes and a respiratory rate of 24 breaths per minute. His oxygen saturation is 89% on room air, and spirometry confirms a post-bronchodilator FEV1/FVC ratio of 60%. Which of the following is the most appropriate first-line treatment to improve his breathlessness and reduce the risk of exacerbations? (Q852135)

A. Oral theophylline combined with ICS

B. Long-acting bronchodilator (LABA) combined with an inhaled glucocorticoid

C. Long-term oxygen therapy

D. Pulmonary rehabilitation

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 62-year-old woman with a history of chronic obstructive pulmonary disease (COPD) presents with increased breathlessness, cough, and sputum production over the last two days. She appears distressed and has a respiratory rate of 28 breaths per minute. Her oxygen saturation is 88% on room air. Which of the following management strategies is most appropriate for her immediate treatment? (Q852134)

A. Initiate high-flow oxygen therapy to maintain oxygen saturation above 95%

B. Start nebulised bronchodilator therapy with salbutamol and ipratropium

C. Begin intravenous glucocorticoids immediately

D. Order a chest X-ray before any treatment is provided

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 55-year-old man presents with a 6-month history of worsening breathlessness, chronic cough, and occasional sputum production. He has a 30-pack-year smoking history. On examination, there is no finger clubbing, and pulse oximetry shows oxygen saturation of 92% on room air. Spirometry reveals an FEV1/FVC ratio of 60% post-bronchodilator. What is the most appropriate next investigation to assess the severity of his condition? (Q851777)

A. Chest X-ray

B. Blood gas analysis

C. High-resolution computed tomography (HRCT)

D. Spirometry with post-bronchodilator FEV1%

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 65-year-old man with a 40-pack-year smoking history presents with chronic productive cough, worsening breathlessness. Physical examination shows hoover sign with drowsiness. ABG shows PC02 =70 mm Hg and PO2= 70 mm Hg. Which of the following is best for immediate management of this patient? (Q851776)

A. Long term of oxygen therapy

B. Non invasive ventilation

C. LABA + LAMA

D. LABA + LAMA + ICS

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 65-year-old male patient presents with a history of chronic cough and sputum production for the past several years. He is thin and exhibits significant breathlessness primarily during physical activity, but he reports minimal symptoms at rest. Arterial blood gas analysis shows a normal PaCO2. Which of the following is the most likely diagnosis for this patient? (Q851775)

A. Chronic bronchitis

B. Asthma

C. Emphysema

D. Interstitial lung disease

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 65-year-old patient with a history of chronic obstructive pulmonary disease (COPD) presents with worsening shortness of breath and edema. Right heart catheterization reveals a mean pulmonary artery pressure of 30 mmHg. Which of the following statements about pulmonary hypertension (PH) in this patient is most accurate? (Q851773)

A. Pulmonary hypertension in COPD is primarily caused by increased left atrial pressure.

B. The prognosis of COPD is directly proportional to age.

C. Right ventricular hypertrophy may be observed on an electrocardiogram (ECG).

D. Treatment options for pulmonary hypertension in COPD primarily include corticosteroids.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 60-year-old male with a long history of smoking presents to the clinic with chronic cough and wheezing. He mentions that he had multiple respiratory infections during childhood and was born with low birth weight. Which of the following factors is most likely to have the greatest impact on the progression of his Chronic

Obstructive Pulmonary Disease (COPD)? (Q851772)

A. Airway hyper-reactivity

B. Tobacco smoke

C. Recurrent infections

D. Impaired lung growth

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 10-year-old boy presents with wheezing and shortness of breath, worsening at night. His symptoms are triggered by dust and pet dander. Spirometry shows an obstructive pattern that improves with a bronchodilator. What is the underlying mechanism? (Q851755)

A. IgG-mediated immune complexes.

B. IgE-mediated mast cell degranulation.

C. Bronchial irritation from pollutants.

D. Viral infection causing airway remodeling.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 65-year-old male presents with progressive dyspnea and a history of smoking for 25 years. Imaging studies reveal abnormal enlargement of air spaces distal to the terminal bronchioles. Which of the following types of emphysema is most likely seen in this patient? (Q851770)

A. Panacinar emphysema

B. Paraseptal emphysema

C. Centriacinar emphysema

D. Bullous emphysema

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 58-year-old male, with a 30-year history of smoking, presents with a chronic productive cough for the last 2 years, worsening shortness of breath, and recent weight loss. Examination reveals bilateral wheezing and peripheral edema imaging shows alveolar wall destruction beyond terminal bronchiole. Which of the following pathophysiological mechanisms is primarily responsible for his condition? (Q851768)

A. Pulmonary vascular remodeling

B. Alpha-1 antitrypsin deficiency

C. Airflow limitation due to loss of elastic tissue

D. Hypersecretion of mucus from goblet cells

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 42-year-old woman presents to the emergency department with worsening asthma symptoms, fever, and a rash consisting of purpura on her lower extremities. Laboratory findings reveal eosinophilia (1200 cells/μL) and elevated inflammatory markers. A biopsy of the skin lesion shows extravascular granulomas. Which of the following statements about her condition is false? (Q851767)

A. Patients often present with systemic symptoms like malaise and weight loss.

B. The condition typically involves necrotizing vasculitis affecting small and medium-sized blood vessels.

C. Cardiac involvement may lead to complications such as myocarditis and pericarditis.

D. It primarily affects large blood vessels, leading to significant vascular occlusion.

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 45-year-old male presents with chronic shortness of breath, dry cough, fatigue, and weight loss for the past six months. He works in a pigeon breeding facility and reports worsening symptoms over time. High-resolution CT (HRCT) of the chest reveals reticular changes, ground-glass opacities, and traction bronchiectasis. Which of the following statements about his condition is true? (Q851766)

A. It is caused by a Type I hypersensitivity reaction mediated by IgE antibodies.

B. Pulmonary fibrosis is a known complication of chronic HP.

C. Acute HP presents with symptoms several days after antigen exposure.

D. HRCT is typically normal in hypersensitivity pneumonitis.

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following statements best characterizes brittle asthma? (Q851765)

A. Symptoms develop gradually over a few days, allowing time for preventive action.

B. It is characterized by sudden exacerbations with little or no warning.

C. Patients with brittle asthma typically have heightened awareness of airway narrowing.

D. The primary cause of brittle asthma is well understood and easily managed.

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 35-year-old male with a history of asthma presents with symptoms occurring four times a week, occasional nighttime awakenings, and the need for rescue inhaler use three times a week. His post-bronchodilator FEV1 is 72% of the predicted value. According to the asthma classification guidelines, how would you categorize the severity and control of his asthma? (Q851764)

A. Mild asthma, controlled

B. Moderate asthma, partly controlled

C. Severe asthma, uncontrolled

D. Moderate asthma, uncontrolled

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 30-year-old patient with a history of asthma presents with symptoms occurring more than three times a week and nocturnal awakenings at least once a week. After evaluating the patient's condition, the physician decides to initiate treatment. Which of the following is the most appropriate initial step in the management of this patient? (Q851763)

A. Increase the dose of short-acting β2-agonist.

B. Start regular inhaled glucocorticoids (ICS).

C. Start prednisolone at the lowest effective dose.

D. Add a long-acting β2-agonist (LABA).

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 24-year-old male presents with recurrent episodes of chest tightness, wheezing, and shortness of breath 10 minutes after running. The symptoms usually resolve within 30 minutes. Which of the following is the most appropriate pre-exercise treatment? (Q851762)

A. Long-acting beta agonist (LABA) taken daily

B. Short-acting beta agonist (SABA) used 15 minutes before exercise

C. Inhaled corticosteroid (ICS) used immediately after exercise

D. Leukotriene receptor antagonist (LTRA) taken during an acute episode

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 28-year-old woman presents with a history of recurrent wheezing and shortness of breath, particularly during the winter months. She reports that her symptoms worsen with cold air and after respiratory infections. She does not have any known allergies, and her skin prick tests for common allergens are negative. What is the most likely diagnosis? (Q851761)

A. Atopic asthma

B. Occupational asthma

C. Intrinsic asthma

D. Cough-variant asthma

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 10-year-old girl presents with recurrent wheezing and difficulty breathing, especially during spring. Her symptoms worsen at night and with exercise. She has a family history of asthma. Physical examination reveals wheezing and a skin prick test shows positive reactions to grass pollen. What is the most likely diagnosis? (Q851760)

A. Exercise-induced asthma

B. Extrinsic asthma

C. Intrinsic Asthma

D. Non-atopic asthma

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 40-year-old man presents to the clinic with a history of asthma. He reports that he has been using his rescue inhaler (SABA) more frequently, experiencing symptoms on most days and waking up at least twice a week due to shortness of breath. His current management includes as-needed SABA but no regular controller medication. What is the most appropriate next step in his asthma management? (Q851758)

A. Continue current treatment and monitor symptoms.

B. Start low-dose inhaled corticosteroids for daily control.

C. Increase the dosage of the SABA.

D. Add a leukotriene receptor antagonist for better control.

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 35-year-old man presents with complaints of wheezing and shortness of breath that have worsened over the past few weeks. He notes that his symptoms often occur at night and are triggered by exposure to dust and exercise. Spirometry shows a FEV1/FVC ratio of 65%. After using a short-acting β2-agonist, his FEV1 increases by 20%. Which of the following findings would most likely be observed in this patient? (Q851757)

A. Increased total lung capacity

B. Decreased DLCO

C. Increased forced vital capacity

D. Decreased residual volume

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which of the following statements about the Hygiene hypothesis is incorrect? (Q851756)

A. Clean environments may impair immune system maturation in children.

B. Endotoxin exposure is essential for proper immune development.

C. Fetal immune system is suppressed to prevent rejection of maternal tissue.

D. Lack of exposure to germs is linked to a decreased risk of developing asthma.

See Answer in Part B → Q28

Q1: What is the duration of the longer MDR-TB regimen? (Q851824)

A. 18-20 months

B. 12 months

C. 6-10 months

D. 24-36 months

See Answer in Part B → Q1

@Neet_pg_bot

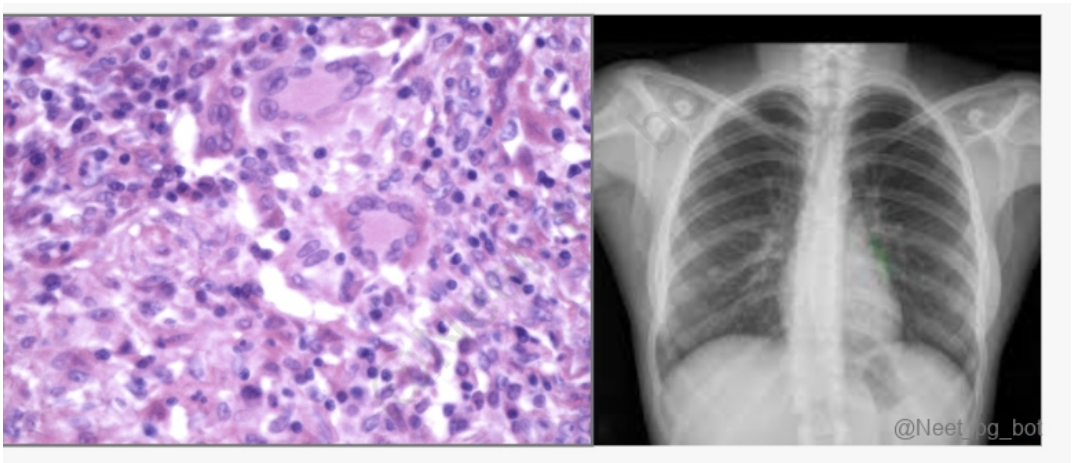
Q2: A 35-year-old woman presents with a enlarged cervical lymph nodes on left side with matted consistency. CXR and excision lymph node biopsy report is shown below . What is the most likely diagnosis? (Q851779)

A. Hodgkin’s lymphoma

B. Metastatic carcinoma

C. Tuberculous lymphadenitis

D. Sarcoidosis



See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 40-year-old man presents with fever, pleuritic chest pain, and dyspnea. Physical examination revealed dullness to percussion and absent breath sounds on the left side. Chest X-ray shows a left-sided pleural effusion. Thoracentesis reveals straw-coloured fluid with a protein concentration of 5 g/dL and a WBC count of 1500/μL with lymphocyte predominance. The acid-fast bacilli (AFB) smear is negative. What is the most likely diagnosis? (Q851780)

A. Parapneumonic effusion

B. Tuberculous pleuritis

C. Malignant pleural effusion

D. Congestive heart failure

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 25-year-old man presents with a 2-week history of headaches, low-grade fever, irritability, and confusion. On examination, he has neck stiffness and cranial nerve VI palsy. Lumbar puncture reveals a CSF leukocyte count of 800/μL (lymphocyte predominance), protein of 400 mg/dL, and low glucose. AFB smear is negative. What

is the most likely diagnosis? (Q851782)

A. Viral meningitis

B. Bacterial meningitis

C. Tuberculous meningitis

D. Cryptococcal meningitis

See Answer in Part B → Q4

@Neet_pg_bot

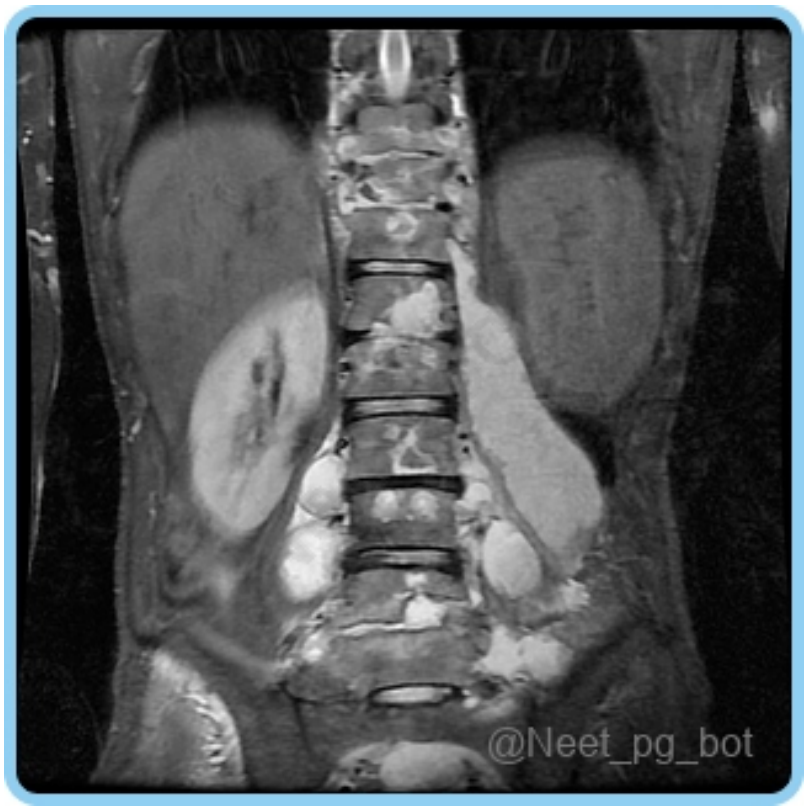
Q5: A 30-year-old man presents with chronic back pain, fatigue, and weight loss. MRI of the spine reveals destruction of the lower thoracic vertebrae with a paravertebral abscess tracking into the psoas muscle. What is the most likely diagnosis? (Q851785)

A. Pyogenic bacterial osteomyelitis

B. Spinal tuberculosis

C. Vertebral metastasis

D. Disc herniation



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 40-year-old woman presents with a history of pelvic pain, menstrual irregularities, and frequent urination over the past few months. She reports that her symptoms have worsened and she experiences occasional hematuria. Urinalysis shows pyuria, but urine cultures are negative. A pelvic ultrasound reveals abnormalities in the fallopian tubes. What is the most likely diagnosis? (Q851786)

A. Urinary tract infection

B. Genitourinary tuberculosis

C. Pelvic inflammatory disease (PID)

D. Can be either B or C

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 9-year-old boy presents with fever and pleuritic chest pain. Chest X-ray shows a small calcified lesion in the lower right lung and enlarged hilar lymph nodes. He also has a rash on his legs resembling erythema nodosum. What is the most likely diagnosis? (Q851793)

A. Acute bacterial pneumonia

B. Primary pulmonary tuberculosis

C. Cystic fibrosis

D. Viral lower respiratory tract infection

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which finding is not typically present in primary tuberculosis? (Q851795)

A. Hilar lymphadenopathy

B. Perihilar infiltrate

C. Non-caseating granuloma

D. Pleural effusion

See Answer in Part B → Q8

@Neet_pg_bot

Q9: In the pathophysiology of postprimary tuberculosis, which of the following immunological events is most critical for the development of cavitary lesions in the lung apices and how does it contribute to tissue destruction? (Q851798)

A. Activation of B cells leads to antibody production, which facilitates phagocytosis of M. tuberculosis.

B. Release of IL-4 and IL-10 from T-helper cells, promoting a Th2 response that leads to fibrosis and walling off of the infection.

C. Secretion of TNF-α and IFN-γ by activated T cells, resulting in macrophage activation and the subsequent formation of caseous necrosis.

D. Induction of a robust innate immune response mediated by neutrophils, resulting in rapid clearance of bacteria and prevention of necrosis.

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following matches the type of tuberculosis focus with its correct location? Type of TB Focus Location 1. Assman Focus a. Subpleural 2. Ghon Focus b. Infraclavicular 3. Puhl Lesion c. Supraclavicular 4. Rich Focus d. Brain (Q851800)

A. 1-b, 2-a, 3-c, 4-d

B. 1-a, 2-c, 3-d, 4-b

C. 1-c, 2-d ,3-a, 4-b

D. 1-d, 2-b, 3-c, 4-a

See Answer in Part B → Q10

@Neet_pg_bot

Q11: What is the primary purpose of Interferon-gamma release assays (IGRAs) to tuberculosis? (Q851801)

A. To confirm active TB disease

B. To diagnose latent TB infection

C. To monitor treatment response

D. To assess the severity of lung disease

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following best describes the principle behind the LAMP test? (Q851805)

A. Amplifying RNA to detect TB

B. Isothermal amplification of DNA at a constant temperature

C. PCR amplification with thermal cycling

D. Culture growth of Mycobacterium tuberculosis

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 34-year-old man with advanced HIV infection (CD4 count of 50 cells/mm³) is diagnosed with pulmonary tuberculosis (TB) and started on anti-tuberculosis treatment. Two weeks later, he initiated antiretroviral therapy (ART). After 3 weeks on ART, he returns to the clinic complaining of worsening cough, fever and night sweats. Physical examination reveals enlarged cervical lymph nodes and increased lung crackles on auscultation. His viral load has dropped significantly, but his CD4 count remains low. What is the most likely diagnosis? (Q851807)

A. Drug-resistant TB

B. Immune reconstitution inflammatory syndrome (IRIS)

C. ART toxicity

D. New opportunistic infection

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Match the drugs used in the initial treatment of tuberculosis with their dosage. Drugs Dosage (mg/kg) a.Isoniazid i.10 b.Rifampicin ii.15 c.Pyrazinamide iii.5 d.Ethambutol iv.25 (Q851819)

A. a-iii,b-i,c-iv,d-ii

B. a-i,b-ii,c-iii,d-iv

C. a-iv,b-iii,c-ii,d-i

D. a-ii,b-iii,c-iv,d-i

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following is not a component of the shorter MDR-TB regimen? (Q851822)

A. 6 months of levofloxacin

B. 5 months of clofazimine

C. 5 months of ethambutol

D. 5 months of isoniazid

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 41-year-old man with a history of night sweats, fever, and weight loss presents with anal fistulae. Physical examination and imaging suggest an abscess near the rectum. Which diagnostic step should be prioritized to investigate a possible cause? (Q851825)

A. Evaluation for rectal tuberculosis

B. Screening for Crohn’s disease

C. Colonoscopy with biopsy for malignancy

D. Culture and sensitivity of fistula discharge

See Answer in Part B → Q16

@Neet_pg_bot

[10_Pulmonology] 079 Respiratory Physiology And Failure — Quick Jump

Q1 (p. 933) *Q2 (p. 933)* *Q3 (p. 934)* *Q4 (p. 934)* *Q5 (p. 935)* *Q6 (p. 938)*
Q7 (p. 938) *Q8 (p. 938)*

Q1: A 72 y/o male, a k/c/o COPD presents to the ED with shortness of breath and confusion. He has been experiencing increased fatigue and worsening dyspnea over the past few days. O/E he has a respiratory rate of 30 bpm. Arterial blood gas analysis shows: PaO2: 58 mmHg, PaCO2: 52 mmHg and pH: 7.2. Which type of respiratory failure is most likely in this patient? (Q852142)

A. Type 1 Respiratory Failure

B. Type 2 Respiratory Failure

C. Type 3 Respiratory Failure

D. Type 4 Respiratory Failure

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 65 y/o female undergoes elective hip replacement surgery. Postoperatively, she develops shortness of breath and a decreased oxygen saturation level. She reports significant pain at the surgical site and is reluctant to take deep breaths due to discomfort. O/E, her respiratory rate is elevated, and auscultation reveals diminished breath sounds at the bases. A chest X-ray shows areas of atelectasis. What type of respiratory failure is most likely in this patient? (Q852143)

A. Type 1 Respiratory Failure

B. Type 2 Respiratory Failure

C. Type 3 Respiratory Failure

D. Type 4 Respiratory Failure

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55 y/o male with h/o pneumonia is admitted to the hospital with severe shortness of breath. O/E, his oxygen saturation is 85%, and arterial blood gas analysis shows: PaO2: 55 mmHg PaCO2: 40 mmHg pH: 7.38 He is anxious and struggling to breathe. What is the most appropriate initial treatment for this patient's respiratory failure? (Q852144)

A. Intubation and mechanical ventilation

B. Noninvasive ventilation (NIV)

C. Oxygen therapy via a nonrebreathing mask

D. Continuous positive airway pressure (CPAP)

See Answer in Part B → Q3

@Neet_pg_bot

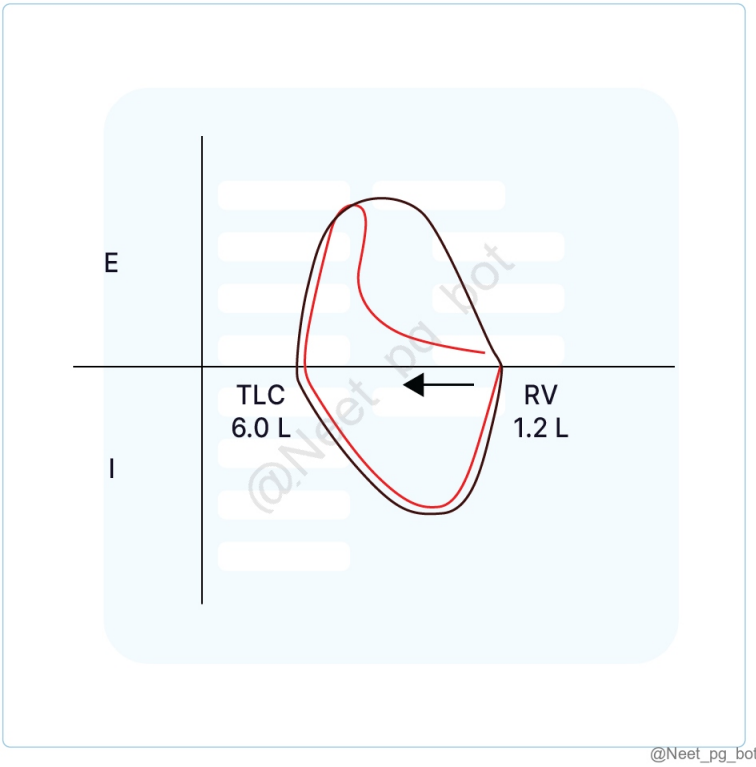
Q4: A 30 y/o female presents with h/o wheezing and shortness of breath. A pulmonary function test shows a flow-volume loop with a distinct "scooped" appearance during expiration, particularly at lower lung volumes. Which condition does this flow-volume loop most likely represent? (Q852145)

A. Pulmonary Fibrosis

B. Asthma

C. Retrosternal Goiter

D. Normal



See Answer in Part B → Q4

@Neet_pg_bot

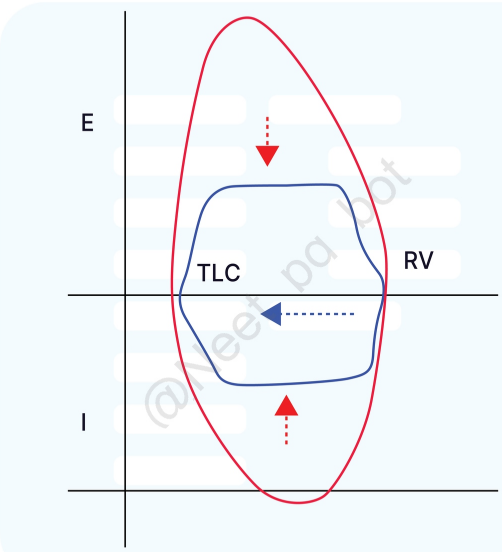
Q5: Match the following diseases with their respective flow volume curves: 1. Asthma a) 2. Extrathoracic Obstruction b) 3. Fixed Obstruction c) 4. Restrictive Airway Disorders d) (Q852146)

A. 1-d, 2-a, 3-c, 4-b

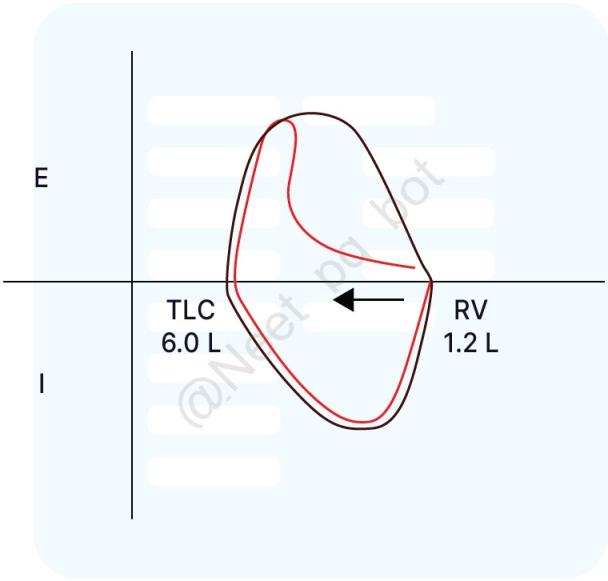
B. 1-a, 2-c, 3-d, 4-b

C. 1-b, 2-d, 3-a, 4-c

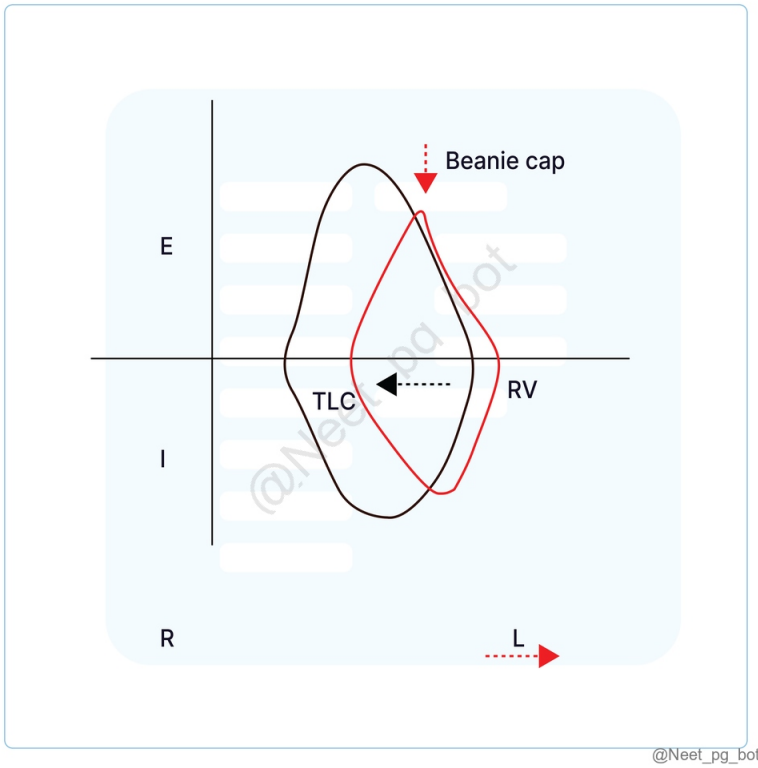
D. 1-c, 2-b, 3-d, 4-a



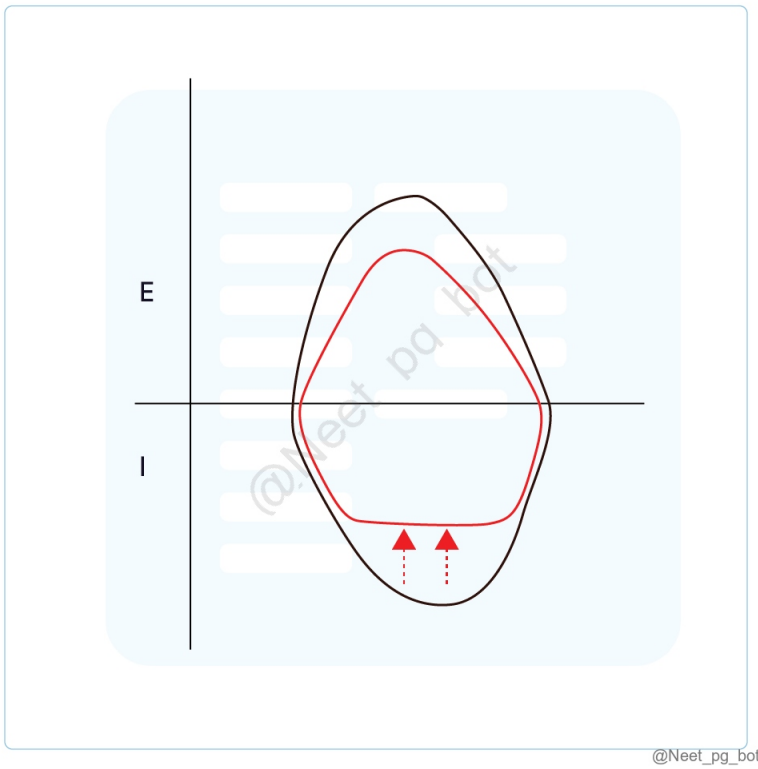
@Neet_pg_bot



@Neet_pg_bot



@Neet_pg_bot



@Neet_pg_bot

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 72-year-old female patient presents with progressive shortness of breath and a persistent dry cough. She has a history of pulmonary fibrosis diagnosed two years ago. Spirometry shows reduced lung volumes. Which of the following is most likely true regarding this patient's spirometry results? (Q852147)

A. FVC is likely to be increased.

B. FEV1/FVC ratio is likely > 80%.

C. TLC is likely normal or increased.

D. RV is likely normal or increased.

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 45 y/o man with a history of COPD presents with shortness of breath, cough, and increased sputum production. His arterial blood gas (ABG) analysis shows hypoxemia, and his calculated A-a gradient is elevated. Which of the following is the most likely cause for the elevated A-a gradient in this patient? (Q852148)

A. Ventilation-perfusion mismatch

B. Hypoventilation

C. Reduced cardiac output

D. Low-inspired oxygen (FiO2)

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 50 y/o male presents with worsening dyspnea. His pulmonary function test reveals a significant reduction in DLCO. Which of the following is the most likely cause for the low DLCO? (Q852149)

A. Pulmonary hemorrhage

B. Obesity

C. Pulmonary fibrosis

D. Acute Congestive Heart Failure

See Answer in Part B → Q8

@Neet_pg_bot

Q13 (p. 946)

Q1: A 50-year-old man who has worked in the glass manufacturing industry for over 20 years presents with progressive dyspnea, a chronic dry cough, and fatigue. On examination, he has bilateral crackles on auscultation. A high-resolution CT scan reveals a crazy-paving pattern in the lungs. What is the most likely cause of his condition? (Q851836)

A. Hypersensitivity pneumonitis

B. Idiopathic pulmonary fibrosis

C. Asbestosis

D. Silicosis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 45-year-old man with a history of working in mining for over 20 years presents with chronic cough, shortness of breath, and fatigue. Chest X-ray reveals nodular opacities, primarily in the upper lobes. Which of the following complications is he at an increased risk of? (Q851837)

A. Pulmonary embolism

B. Pneumothorax

C. Tuberculosis

D. Pleural effusion

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 70-year-old retired shipyard worker presents with exertional dyspnea and a persistent dry cough. Pulmonary function tests reveal a restrictive pattern. Which of the following radiographic findings is most characteristic of asbestosis? (Q851838)

A. Upper lobe nodular opacities

B. Cavitary lesions

C. Bilateral pleural plaques

D. Hyperinflated lungs

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old man with a long history of smoking presents with worsening dyspnea and a recent diagnosis of lung cancer. A lung biopsy reveals changes consistent with interstitial lung disease. Which type of ILD is most commonly associated with smoking? (Q851839)

A. Lymphangioleiomyomatosis

B. Lymphocytic interstitial pneumonitis

C. Pulmonary Alveolar Proteinosis

D. Langerhans cell histiocytosis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 42-year-old woman presents with worsening asthma, shortness of breath, and wheezing. She has a history of recurrent sinusitis and recent purpuric skin lesions on her legs. Lab tests show eosinophilia and positive p-ANCA. A chest CT reveals ground-glass opacities and lower lobe consolidation. What is the most likely diagnosis? (Q851840)

A. Wegener Granulomatosis

B. Sarcoidosis

C. Hypersensitivity pneumonia

D. Churg Strauss Syndrome

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 55-year-old man presents with worsening dyspnea on exertion and a dry cough. Examination reveals finger clubbing. Which findings might be observed during an interstitial lung disease (ILD) evaluation? Wheeze Inspiratory crackles Dullness to percussion Pigeon Breeder's Lung Increased tactile fremitus (Q851841)

A. 1,3,5

B. 2,3,4

C. 3,4,5

D. 1,2,4

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 55-year-old male presents with a 6-week history of cough, dyspnea, fever, and fatigue. Respiratory examination reveals inspiratory rales and pulmonary function tests reveal restrictive lung features. HRCT of the thorax shows patchy subpleural consolidative opacities with a ground-glass appearance and a reversed halo sign. A lung biopsy shows a uniform appearance of granulation tissue within the alveolar sac. What is the most likely diagnosis? (Q851842)

A. Atypical pneumonia

B. Cryptogenic organising pneumonia

C. Interstitial pulmonary fibrosis

D. Acute respiratory distress syndrome

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Match the following types of hypersensitivity pneumonitis with their respective causative antigen. Disease Antigen 1. Farmer's lungs A. Mycobacterium Avium complex 2. Tobacco grower's lungs B. Isocyanates 3. Hot tub lungs C. Thermophilic actinomyces 4. Chemical worker lungs D. Penicillium casei 5. Cheese washer's lungs E. Aspergillus clavatus (Q851843)

A. 1-E, 2-A, 3-D, 4-C, 5-B

B. 1-C, 2-E, 3-A, 4-B, 5-D

C. 1-D, 2-C, 3-B, 4-E, 5-A

D. 1-A, 2-B, 3-E, 4-D, 5-C

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 60-year-old male with a history of smoking presents with progressively worsening dyspnea and a non-productive cough for the past 6 months. HRCT findings, including subpleural reticulation, honeycombing, and traction bronchiectasis, suggest idiopathic pulmonary fibrosis (IPF). What is the treatment of choice for this condition? (Q851844)

A. Monotherapy with Corticosteroid

B. Pirfenidone + Nintedanib

C. Prednisolone + Rituximab

D. Lung transplantation

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 62-year-old woman with a history of progressive dyspnea and a chronic dry cough is being evaluated for suspected interstitial lung disease (ILD). She denies any history of smoking or exposure to environmental toxins. Physical examination reveals fine bibasilar inspiratory crackles. Which of the following is the investigation of choice for confirming the diagnosis? (Q851845)

A. Pulmonary function test

B. Bronchoalveolar lavage

C. Fiberoptic bronchoscopy with cryo biopsy

D. HRCT of thorax

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 59-year-old man presents with recurrent cough, dyspnea, and fatigue for 8 months. His occupation as a bird breeder with exposure to bird droppings suggests hypersensitivity pneumonitis. Pulmonary function testing (PFT) reveals a restrictive pattern. Which of the following disorders should be considered in the differential diagnosis based on the PFT restrictive pattern? (Q851846)

A. COPD

B. Idiopathic interstitial pneumonia

C. Asthma

D. Bronchiectasis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 50-year-old woman presents with worsening shortness of breath and cough, producing copious sputum containing gelatinous material. Laboratory tests reveal no evidence of infectious processes. The physician suspects pulmonary alveolar

proteinosis. Which mechanism is most responsible for her condition? (Q851847)

A. Deficiency of surfactant proteins due to genetic mutation

B. Autoimmune response leading to GM-CSF blockade

C. Exposure to silica dust causing alveolar damage

D. Allergic reaction to environmental pollutants

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 52-year-old male presents with progressive dyspnea and a chronic cough with gelatinous sputum. Pulmonary function tests show a restrictive pattern and a normal FEV1/FVC ratio. A chest X-ray reveals bilateral patchy opacifications and a high-resolution CT shows a crazy paving pattern with no signs of infection. What is the most characteristic finding of this condition? (Q851848)

A. Increased neutrophilic infiltration

B. Positive Periodic Acid-Schiff (PAS) staining

C. Granuloma formation

D. Honeycombing fibrosis

See Answer in Part B → Q13

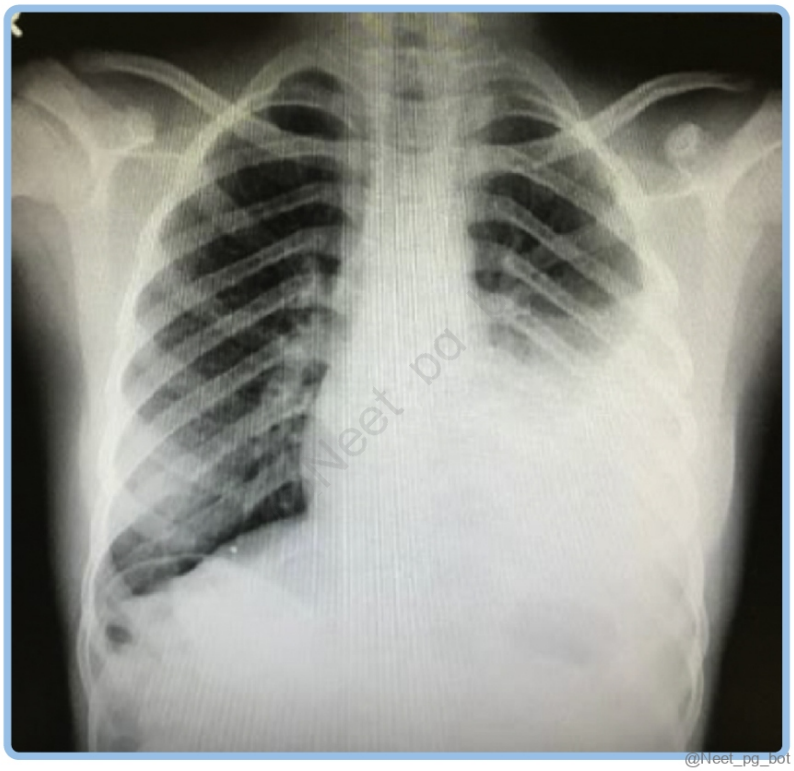
Q1: A 35-year-old male presents with fever, left-sided chest pain, and dyspnea. Upon physical examination, decreased breath sounds are noted on the left side. A chest X-ray reveals the findings presented below. A thoracentesis is performed, yielding a milky white fluid with elevated lactate dehydrogenase (LDH) and the presence of cholesterol crystals. Considering these findings, what underlying agent could be responsible for this presentation? (Q851878)

A. Pneumococcus

B. Staphylococcus aureus

C. Malignancy

D. Mycobacterium tuberculosis



See Answer in Part B → Q1

@Neet_pg_bot

Q2: Match the ABG values in Column A with their corresponding acid-base disorders in Column B. Column A Column B 1. pH 7.48, pCO2 45, HCO3 35 A. Fully compensated respiratory acidosis 2. pH 7.32, pCO2 28, HCO3 14 B. Partially compensated metabolic alkalosis 3. pH 7.40, pCO2 30, HCO3 20 C. Partially compensated metabolic acidosis 4. pH 7.38, pCO2 68, HCO3 32 D. Fully compensated respiratory alkalosis (Q851993)

A. 1-B, 2-C, 3-D, 4-A

B. 1-C, 2-B, 3-A, 4-D

C. 1-A, 2-D, 3-C, 4-B

D. 1-D, 2-A, 3-B, 4-C

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 35-year-old male presents with severe substernal chest pain, difficulty breathing, and puffy swelling of the chest wall after multiple episodes of vomiting due to binge drinking. Upon examination, auscultation reveals a characteristic crunching sound. A chest X-ray demonstrates the presence of subcutaneous emphysema. Based on the clinical presentation, what is the next best step in managing this patient? (Q851890)

A. Administer intravenous antibiotics

B. Perform an urgent thoracotomy

C. Provide supplemental oxygen

D. Obtain a CT scan of the chest

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 35-year-old male presents to the emergency department after experiencing sudden chest pain and shortness of breath. He is a long-time smoker with no history of lung disease. A chest X-ray confirms a right-sided pneumothorax. Which type of pneumothorax is this patient most likely experiencing? (Q851889)

A. Secondary spontaneous pneumothorax

B. Traumatic pneumothorax

C. Primary spontaneous pneumothorax

D. Tension pneumothorax

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 55-year-old female with a history of COPD presents to the emergency department with sudden onset left-sided chest pain. A chest X-ray reveals a small

left-sided pneumothorax with a depth of 0.5 cm. The patient is otherwise stable, with no significant respiratory distress and a normal vital sign profile. What is the most appropriate management for this patient? (Q851887)

A. Administer high-flow oxygen and observe for 24 hours

B. Perform needle aspiration

C. Discharge with follow-up in 2-4 weeks

D. Thoracoscopy with pleural abrasion

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 28-year-old male presents to the emergency department after a motorcycle accident. He is experiencing severe shortness of breath and sharp left-sided chest pain. On examination, he has tachycardia and low oxygen saturation. A chest X-ray confirms a large left-sided pneumothorax. Vitals are HR: 120 bpm, BP: 70/40. What would be the most appropriate first step in the management of this patient? (Q851886)

A. Insert a thoracostomy tube

B. Administer supplemental oxygen

C. Perform needle decompression

D. Schedule video-assisted thoracoscopic surgery (VATS)

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A patient with chest pain and shortness of breath with a heart rate of 145 beats per minute is being examined in the casualty. Which of the following clinical features is not seen in a pneumothorax? (Q851885)

A. Absent breath sounds

B. Hamman’s sign

C. Jugular venous distension

D. Hypotension

See Answer in Part B → Q7

@Neet_pg_bot

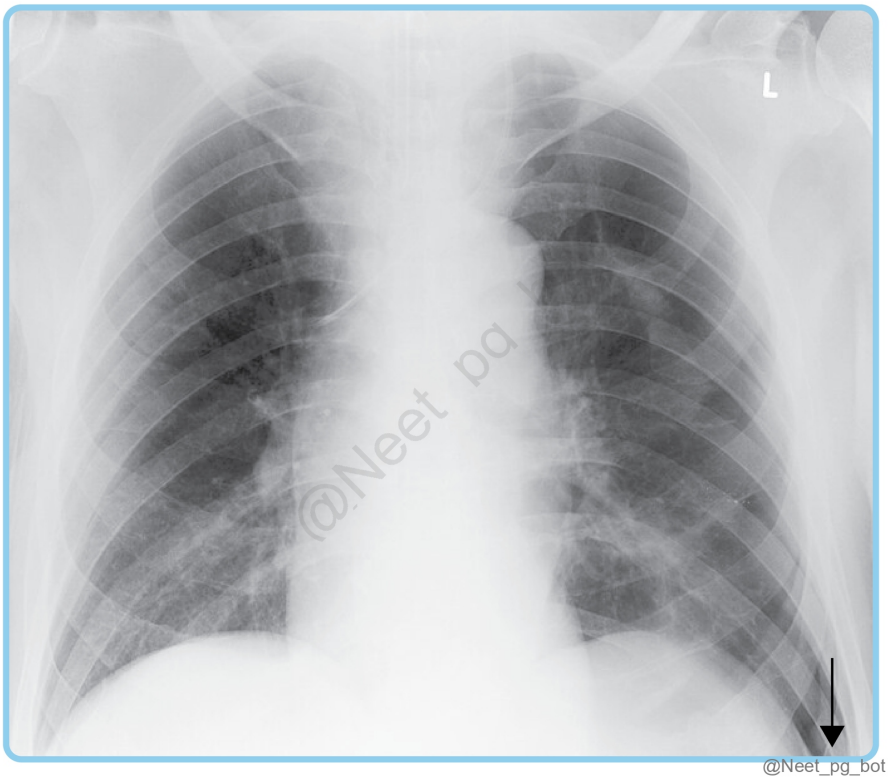
Q8: A child was brought to the hospital with noticeable difficulty in breathing. On examination, he has tachycardia, tachypnea, and asymmetrical lung expansion. A supine chest X-ray is taken and shown below. Identify the marked sign/structure in this patient's chest radiograph. (Q851883)

A. Collapsed lung

B. Visceral pleura

C. Hemidiapraghm depression

D. Deep sulcus sign



See Answer in Part B → Q8

@Neet_pg_bot

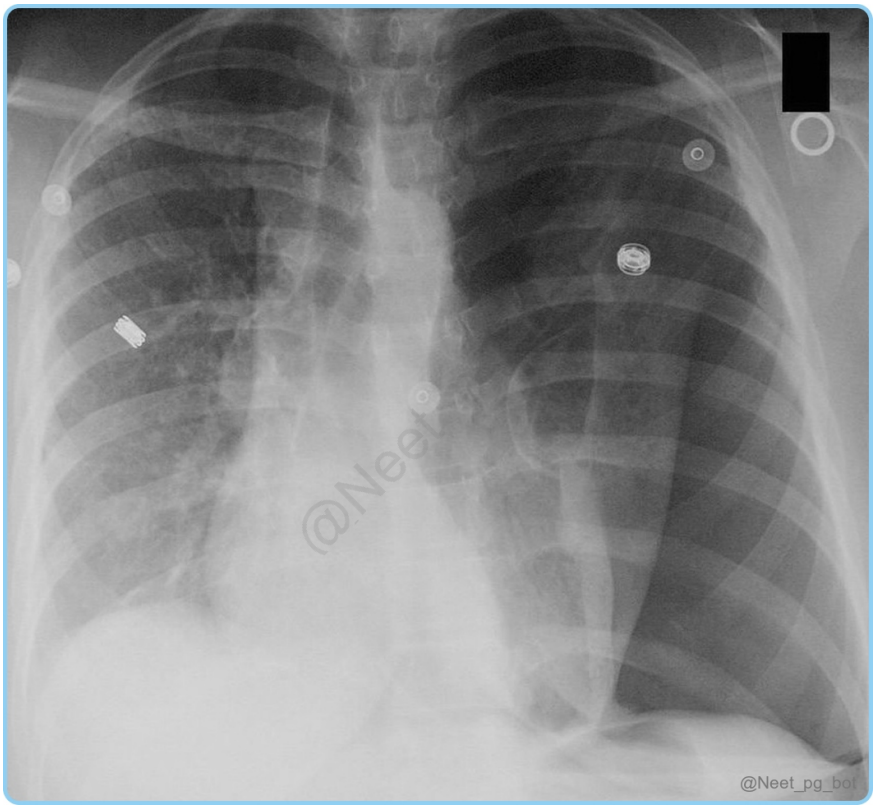
Q9: A 45-year-old male comes to the emergency department after a fall from height. He developed shortness of breath, tachypnea, and chest pain since the fall. A chest X-ray was taken shown below. What would be the pathophysiology for the development of this condition? (Q851882)

A. Rupture of apical pleural blebs

B. Preexisting COPD

C. Blunt trauma to the chest

D. Iatrogenic injury



See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following statements regarding normal pleural fluid characteristics is accurate? (Q851855)

A. Normal pleural fluid typically contains over 3,000 WBCs/mm^3.

B. The glucose level in normal pleural fluid is typically lower than that of plasma.

C. Normal pleural fluid pH ranges from 7.60 to 7.64.

D. Lactate dehydrogenase (LDH) levels in normal pleural fluid are similar to those in plasma.

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 65-year-old male patient with Parkinson's disease has been experiencing fluctuations in his motor function, To help manage these "on-off" features, new medication to his treatment regimen. However, the patient later presented with respiratory distress, chest discomfort, and diminished breath sounds on examination. Which medication is likely to be the possible cause of these respiratory symptoms? (Q851876)

A. Amantadine

B. Levodopa

C. Bromocriptine

D. Pramipexole

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 55-year-old male who has worked in the shipyard industry presents with shortness of breath and persistent pain in the right lower chest. On examination, there is dullness to percussion and decreased breath sounds on the right side. A CT scan reveals diffuse pleural thickening and nodular masses. A biopsy is performed to confirm the diagnosis. Which immunohistochemical marker is most likely to be positive? (Q851873)

A. CD-117

B. Chromogranin

C. Calretinin

D. Vimentin

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 63-year-old female with metastatic adenocarcinoma of the lung presents with worsening dyspnea and a moderate-sized left-sided pleural effusion. After therapeutic thoracentesis reveals exudative fluid with low glucose levels and positive cytology for malignant cells, her symptoms improve, but the effusion is expected to reaccumulate. What is the most appropriate next step for long-term symptomatic relief? (Q851870)

A. Insertion of a small indwelling pleural catheter

B. Serial therapeutic thoracentesis

C. Tube thoracostomy without a sclerosing agent

D. Initiation of diuretics and oxygen therapy

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A resident physician is preparing to perform a thoracentesis on a patient with a large pleural effusion. The patient is seated, and the procedure is to be performed under ultrasound guidance. Which of the following steps is crucial for the correct execution of the thoracentesis procedure? (Q851868)

A. Insert the needle below the lower rib to avoid injury

B. Perform the procedure at the 2nd intercostal space in the midclavicular line

C. Ensure the patient is in a supine position for optimal access

D. Insert the needle above the upper border of the lower rib in the targeted intercostal space

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 55-year-old woman presents with shortness of breath and cough. Chest X-ray shows a left-sided pleural effusion. Thoracentesis reveals the following findings. Using Light's criteria, which statement is true regarding this pleural effusion? Pleural fluid protein: 4.0 g/dL Serum protein: 6.8 g/dL Pleural fluid LDH: 280 U/L Serum LDH: 450 U/L (Q851865)

A. It is definitely transudative.

B. It meets the criteria for an exudative effusion.

C. It cannot be classified without further testing.

D. It is likely due to congestive heart failure.

See Answer in Part B → Q15

@Neet_pg_bot

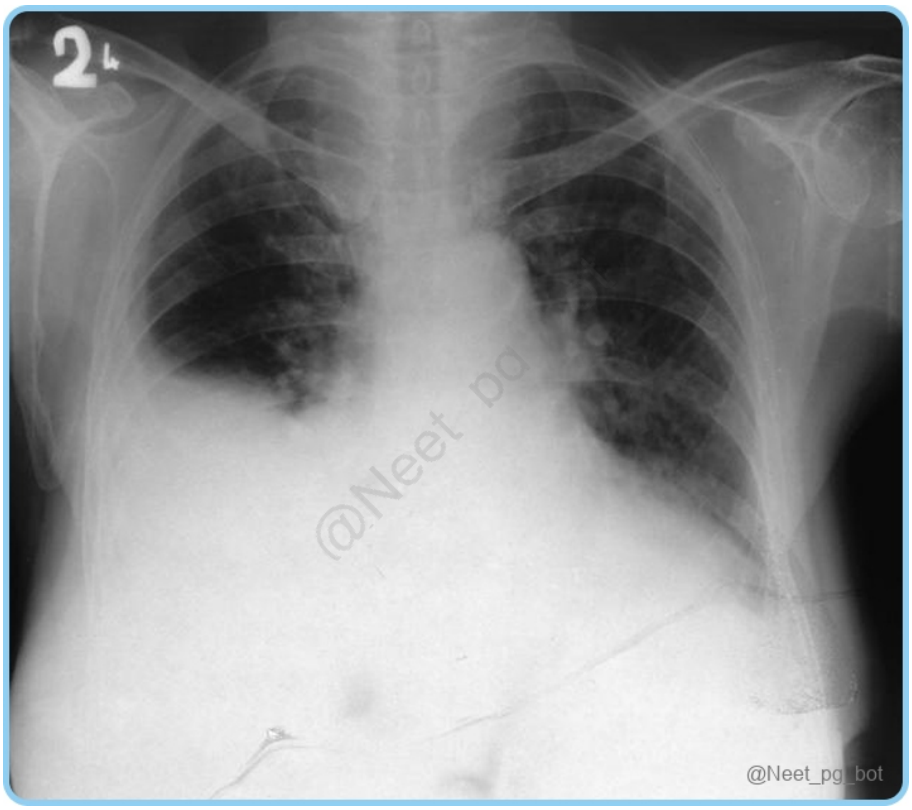
Q16: A 60-year-old female with a known diagnosis of metastatic mesothelioma presents with worsening dyspnea and right-sided chest pain that is constant. Chest imaging is given below. What clinical finding is most likely to be present? (Q851861)

A. Hyperresonance to percussion

B. Egophony at the superior aspect of the effusion

C. Increased tactile fremitus

D. Bronchial breath sounds over the effusion



See Answer in Part B → Q16

@Neet_pg_bot

Q17: A patient presents with dyspnea and pleuritic chest pain. A chest X-ray shows a pleural effusion. Pleural fluid analysis reveals elevated protein and LDH levels. Which of the following conditions is the likely cause of this exudative pleural effusion? (Q851857)

A. Urinothorax

B. Esophageal rupture

C. Congestive heart failure

D. Nephrotic syndrome

See Answer in Part B → Q17

Q1: A 45-year-old woman presents to the emergency department with diarrhea for the past three days. She reports fatigue and mild abdominal cramping. Laboratory tests show the following: Arterial blood gas pH 7.30 HCO■■ 15 mmol/L PaCO■ 38 mmHg Serum electrolytes Na■ 140 mmol/L Cl■ 115 mmol/L K■ 4.5 mmol/L What is the type of acidosis? (Q851932)

A. Normal Anion Gap Metabolic Acidosis

B. High Anion Gap Metabolic Acidosis

C. Respiratory Acidosis

D. None of the above

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 35-year-old male presents to the emergency complaining of chronic pain. He was diagnosed with lymphoma 6 months back. His HR is 96/min, and his RR is 38/min. An ABG sample is withdrawn, which shows pH 7.42, pCO 2 =25 mmHg, and HCO3=18 mmHg. What is the likely acid-base disorder? (Q882164)

A. Metabolic acidosis, partially compensated

B. Respiratory acidosis, partially compensated

C. Respiratory acidosis, fully compensated

D. Respiratory alkalosis, fully compensated

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Match the acid base disorder with their respective etiology Condition Acid - base disorder 1. Ureterostomy a. High anion gap Metabolic acidosis 2. Opium poisoning b. Normal anion gap metabolic acidosis 3. Prolonged NG suction c. Respiratory acidosis 4. Salicylate poisoning d. Metabolic alkalosis (Q851995)

A. 1-b, 2-a, 3-c, 4-d

B. 1-b , 2-c ,3-d, 4-a

C. 1-c, 2-d, 3-a, 4-b

D. 1-d, 2-b, 3-a, 4-c

See Answer in Part B → Q3

@Neet_pg_bot

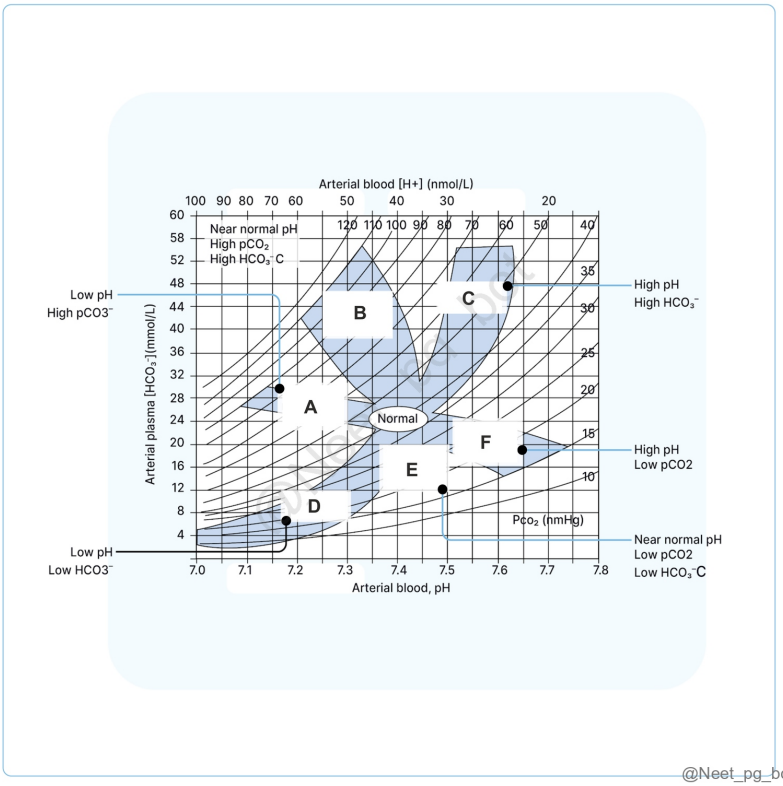
Q4: A 28-year-old woman at 32 weeks gestation presents with severe abdominal pain, vomiting, and rapid breathing. Vitals: BP 110/70 mmHg, HR 112/min, RR 28/min. Based on the Davenport diagram, which areas represent her acid-base status initially and after 12 hours if untreated? (Q851994)

A. Initially: Area C, After 12 hours: Area F

B. Initially: Area D, After 12 hours: Area F

C. Initially: Area A, After 12 hours: Area B

D. Initially: Area F, After 12 hours: Area C



@Neet_pg_bot

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 50-year-old alcoholic presents with severe abdominal pain. His ABG shows pH: 7.20 HCO3: 12 mEq/L Na+: 140 mEq/L Cl-: 98 mEq/L. Which of the following options correctly justifies the diagnosis? (Q851992)

A. Delta ratio 0.4 - Pure NAGMA

B. Delta ratio 1.5 - Pure HAGMA

C. Delta ratio 0.6 - Mixed HAGMA and NAGMA

D. Delta ratio 2.2 - HAGMA with metabolic alkalosis

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 45-year-old diabetic patient presents to the emergency department with nausea and vomiting for 2 days. ABG shows: pH: 7.28 pCO■: 35 mmHg HCO■■: 12 mEq/L Na■: 138 mEq/L Cl■: 102 mEq/L What is the most likely acid-base disorder? (Q851991)

A. Simple metabolic acidosis

B. Metabolic acidosis with respiratory alkalosis

C. Metabolic acidosis with respiratory acidosis

D. Metabolic alkalosis and respiratory alkalosis

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 68-year-old woman with a history of chronic kidney disease and recent severe pneumonia is admitted to the intensive care unit. She has been experiencing increased shortness of breath, confusion, and fatigue. Laboratory tests reveal the following: Arterial blood gas: pH 7.28, HCO■■ 18 mmol/L, PaCO■ 50 mmHg Serum electrolytes: Na■ 140 mmol/L, K■ 4.2 mmol/L, Cl■ 100 mmol/L Based on the laboratory results and clinical presentation, what type of acid-base disorder is this patient experiencing? (Q851990)

A. Metabolic acidosis—respiratory alkalosis

B. Metabolic acidosis—respiratory acidosis

C. Metabolic alkalosis—respiratory acidosis

D. Metabolic acidosis—metabolic alkalosis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 72-year-old man with a history of chronic kidney disease and COPD presents to the emergency department with confusion, shortness of breath, and fatigue. He has been experiencing increased nausea and vomiting over the past week. Laboratory tests

reveal: Arterial blood gas: pH 7.29, HCO■■ 18 mmol/L, PaCO■ 60 mmHg Serum electrolytes: Na■ 138 mmol/L, K■ 4.8 mmol/L, Cl■ 102 mmol/L Based on the provided laboratory results, what type of acid-base disorder is this patient experiencing? (Q851989)

A. Respiratory acidosis

B. Metabolic acidosis

C. Mixed respiratory and metabolic acidosis

D. Fully compensated metabolic acidosis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 65-year-old man with a history of chronic obstructive pulmonary disease presents to the emergency department with light-headedness and confusion along with tingling sensation of his limbs. He has also been experiencing persistent vomiting for the past three days due to food poisoning. Arterial blood gas shows the following findings pH - 7.48 HCO3- - 38 mEq/L PaCO2 - 40 mm hg Which of the following is correct about this patient? (Q851988)

A. Fully compensated metabolic alkalosis

B. Partially compensated metabolic alkalosis

C. Uncompensated metabolic alkalosis

D. Normal acid-base balance

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 50-year-old woman with a history of hypertension presents to the emergency department with confusion and muscle cramps. She reports having persistent vomiting for the last two days after taking an over-the-counter medication for indigestion. On examination, she has a blood pressure of 130/85 mmHg and shows

signs of mild dehydration. Laboratory results reveal: Arterial blood gas: pH 7.48, HCO■■ 30 mmol/L, PaCO■ 45 mmHg Serum electrolytes: Na■ 140 mmol/L, K■ 3.0 mmol/L, Cl■ 88 mmol/L What is the most likely diagnosis for this patient based on the laboratory findings? (Q851987)

A. Respiratory acidosis

B. Metabolic acidosis

C. Metabolic alkalosis

D. Respiratory alkalosis

See Answer in Part B → Q10

@Neet_pg_bot

Q11: 60-year-old man with a history of chronic kidney disease presents to the emergency department with fatigue and extreme shortness of breath. Laboratory tests reveal: Arterial blood gas: pH 7.30, HCO■■ 12 mmol/L, PaCO■ 30 mmH Serum electrolytes: Na■ 140 mmol/L, Cl■ 104 mmol/L, K■ 5.0 mmol/L Which of the following is correct about this patient's status? (Q851933)

A. Metabolic acidosis with respiratory alkalosis

B. Metabolic acidosis with respiratory acidosis

C. Uncompensated metabolic acidosis

D. Metabolic acidosis with metabolic alkalosis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 62-year-old female with known COPD presents with increased muscle weakness and difficulty in breathing. On examination she appears confused and her arterial blood gas (ABG) results are as follows: pH: 7.29 PaCO■: 65 mm Hg HCO■■: 26 mEq/L PaO■: 65 mm Hg. Which of the following best describes the underlying mechanism for this patient's presentation? (Q851791)

A. Increased metabolic rate leading to excess CO■ production

B. Impaired ventilatory control due to central respiratory depression

C. Impaired responsiveness of the respiratory reflexes to states of hypoxia and hypercapnia

D. Decreased oxygen-carrying capacity of the blood

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 30-year-old male presents with: ABG: pH: 7.20, PaCO2: 25 mmHg, HCO3-: 10 mEq/L, Na+: 140 mEq/L, Cl-: 100 mEq/L, and Blood lactate: 12 mmol/L. Calculate: Anion gap Expected PaCO2 compensation (Q851931)

A. AG=30, Expected PaCO2=25±2

B. AG=30, Expected PaCO2=30±2

C. AG=25, Expected PaCO2=25±2

D. AG=25, Expected PaCO2=30±2

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 75-year-old man presents to the emergency department with severe abdominal pain, vomiting, frequent urination, confusion, and labored, deep breathing and he is difficult to arouse. Lab investigations reveal the following findings Na+ - 135 mEq/L K+ - 5.2 mEq/L Cl - 100 mEq/L HCO3 - 15 mEq/L Serum pH - 7.15 What is the least likely cause of these findings? (Q851930)

A. Methanol poisoning

B. Diabetic ketoacidosis

C. Renal tubular acidosis

D. Renal failure

See Answer in Part B → Q14

@Neet_pg_bot

Q15: An intern reviews the following electrolyte levels for a patient: Sodium (Na■): 140 mEq/L Chloride (Cl■): 100 mEq/L Bicarbonate (HCO■■): 24 mEq/L Potassium (K■): 4.0 mEq/L What is the calculated anion gap for this patient? (Q851929)

A. 12 mEq/L

B. 16 mEq/L

C. 20 mEq/L

D. 24 mEq/L

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 28-year-old anxious female presents with hyperventilation during a panic attack. ABG shows: pH: 7.48 PaCO2: 20 mmHg HCO3-: 22 mEq/L Which acid-base disorder is present? (Q851919)

A. Uncompensated respiratory alkalosis

B. Partially compensated respiratory alkalosis

C. Fully compensated respiratory alkalosis

D. Mixed respiratory and metabolic alkalosis

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 65-year-old male with severe COPD presents with worsening breathlessness. His ABG shows: pH: 7.28, PaCO2: 65 mmHg, HCO3-: 30 mEq/L Which stage of respiratory acidosis does this represent? (Q851915)

A. Uncompensated respiratory acidosis

B. Partially compensated respiratory acidosis

C. Fully compensated respiratory acidosis

D. Mixed respiratory and metabolic acidosis

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following statements regarding the test shown in the image, done prior to arterial blood sampling is not true? (Q851905)

A. Preferred site for arterial sampling is the radial artery between the flexor carpi radialis tendon and the styloid process

B. Both ulnar and radial arteries should be released simultaneously after occlusion

C. The presence of collaterals is confirmed if the hand becomes flushed after releasing one artery

D. Pressure should be applied to the site for 5 minutes after blood sampling to prevent hematoma

@Neet_pg_bot

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 28-year-old woman presents to the emergency department with anxiety, dizziness, and circumoral numbness. She also reports chest tightness and difficulty taking a deep breath. Physical examination reveals tachypnea and carpopedal spasms. Arterial blood gas shows pH: 7.48, PaCO2: 28 mmHg, HCO3: 22 mEq/L, PaO2: 98 mmHg. Which of the following sets of additional findings would be most consistent with this acid-base disorder? (Q851902)

A. Hypoxemia, cyanosis, and metabolic acidosis

B. Paresthesias, reduced cerebral blood flow and decreased ionized calcium

C. Hypertension, pulmonary edema, and increased ionized calcium

D. Somnolence, asterixis, and increased cerebral blood flow

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 25-year-old pregnant woman at 28 weeks gestation presents with light-headedness and tingling sensations in her fingers. Her respiratory rate is 24/min. Arterial blood gas shows: pH: 7.46 PaCO■: 32 mmHg HCO■■: 23 mEq/L Which of the following best explains the pathogenesis of her acid–base disturbance? (Q851802)

A. Direct CNS depression causing decreased respiratory drive

B. Progesterone-mediated increase in ventilatory response

C. Compensatory hyperventilation from metabolic acidosis

D. Increased tidal volume due to mechanical pressure of the gravid uterus

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 65-year-old man with severe COPD presents with worsening confusion and somnolence. Arterial blood gas shows: pH: 7.25 PaCO2: 70 mmHg HCO3: 32 mEq/L PaO2: 55 mmHg. Which of the following represents the most appropriate initial management approach? (Q851796)

A. Rapidly normalize PaCO2 with mechanical ventilation

B. Provide controlled oxygen therapy and treat underlying COPD exacerbation

C. Give sodium bicarbonate to correct acidemia

D. Observe and monitor without intervention

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 68-year-old man with severe COPD presents with progressive confusion, daytime sleepiness, and morning headaches over the past month. On examination, he has a coarse tremor and asterixis. Arterial blood gas shows pH 7.32, PaCO2 68 mmHg, HCO3- 34 mEq/L. Which combination of additional findings would be most consistent with this patient's acid-base disorder? (Q851794)

A. Acute anxiety, hallucinations, and respiratory distress

B. Sleep disorders, personality changes, and polycythemia

C. Acute dyspnea, psychosis, and normal bicarbonate

D. Muscle weakness, confusion, and metabolic acidosis

See Answer in Part B → Q22

@Neet_pg_bot

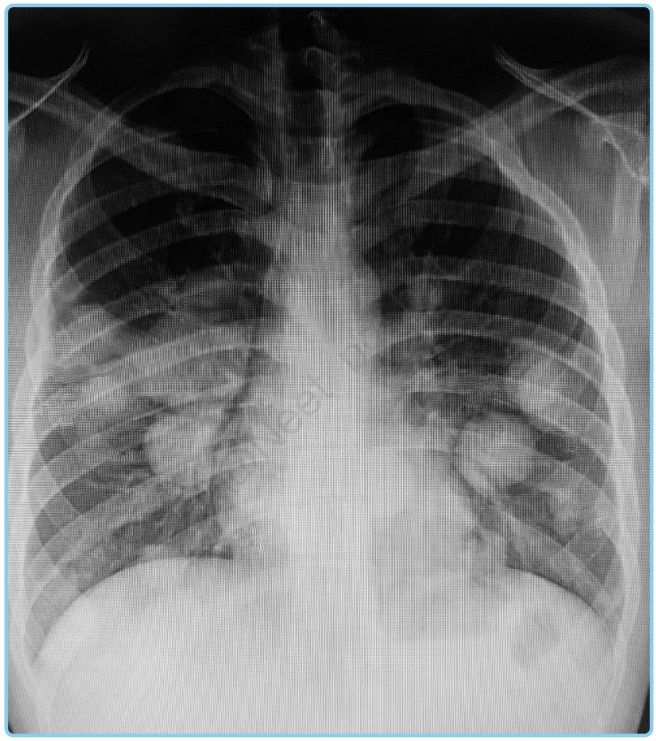
Q1: A 62-year-old male with a history of smoking presents with chronic cough, weight loss, and recent hemoptysis. A chest X-ray is done and is provided below. Which of the following is the most likely primary source of this lesion? (Q851891)

A. Renal cell carcinoma

B. Breast carcinoma

C. Gastric adenocarcinoma

D. Thyroid carcinoma



@Neet_pg_bot

See Answer in Part B → Q1

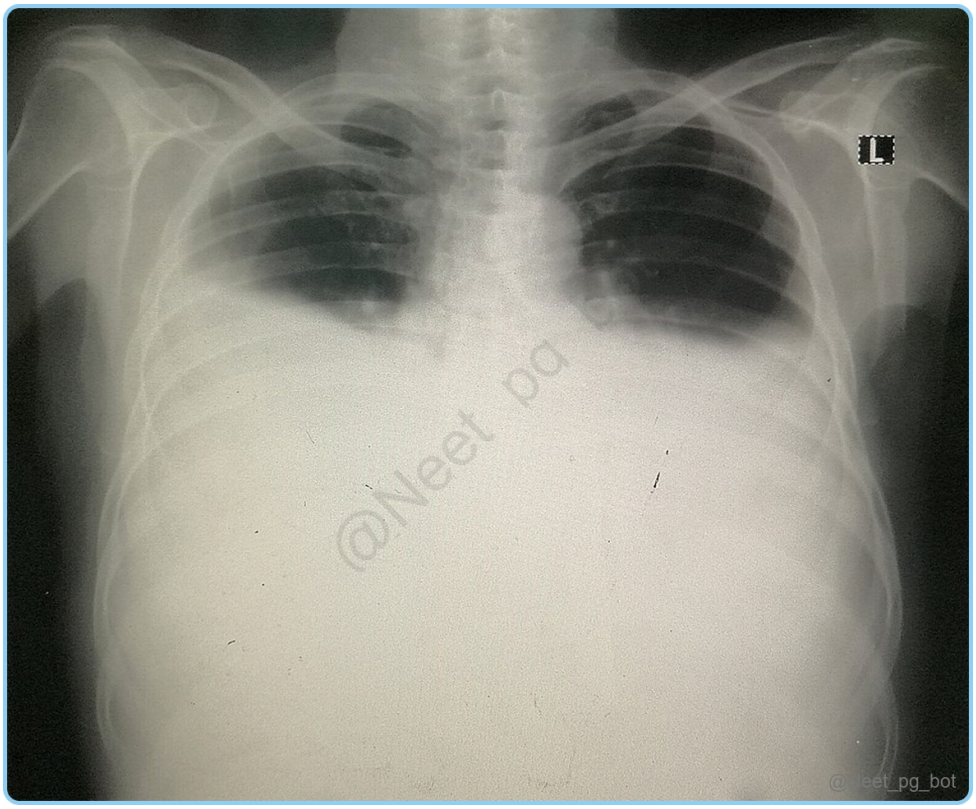
Q2: A 65-year-old male with a history of chronic liver disease presents with progressive shortness of breath, fatigue, and mild chest discomfort over the past few weeks. On examination, there is decreased bilateral breath sound intensity with dullness on percussion at the lung bases. A chest X-ray shows the following features. What is the most likely diagnosis? (Q851894)

A. Bilateral Hydrothorax

B. Empyema Thoracis

C. Hydropneumothorax

D. Congestive Heart Failure with Pleural Effusion



See Answer in Part B → Q2

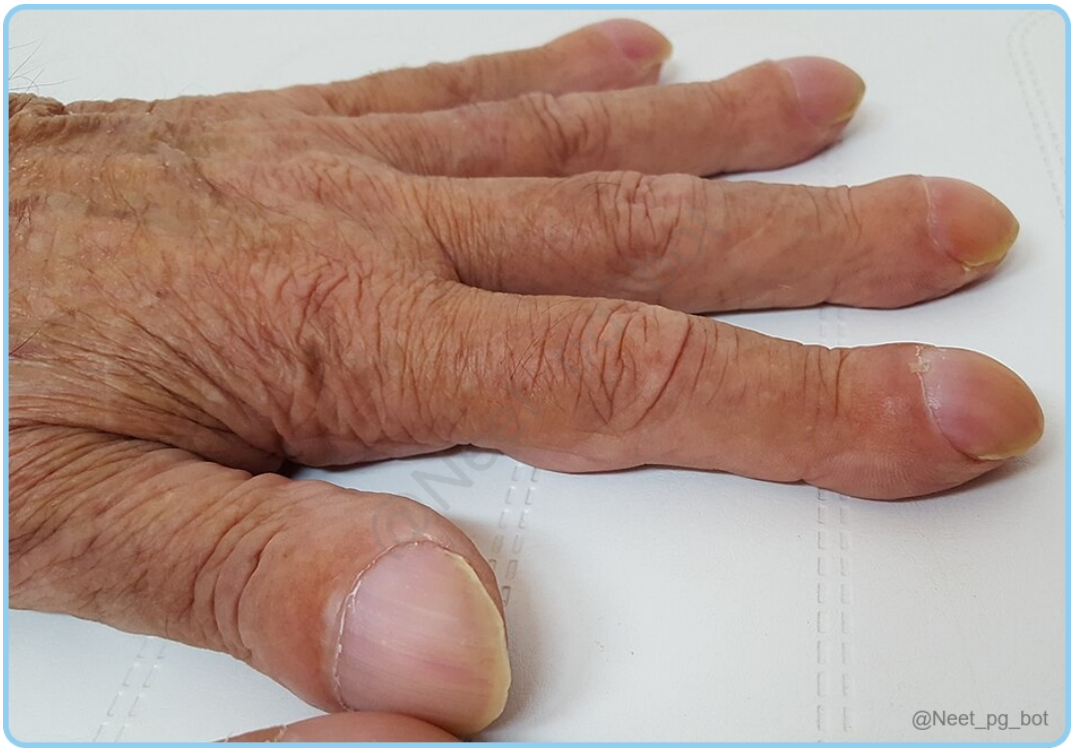
Q3: A 65-year-old man visits OPD with the following presentation as shown in the image. His chest CT shows bronchiectasis. Which of the following statements is incorrect regarding this patient's digital finding? (Q851897)

A. The condition involves proliferation of connective tissue at the nail base

B. It can be associated with cystic fibrosis and lung cancer

C. The condition always indicates irreversible tissue changes

D. The pathogenesis involves platelet-derived growth factors



See Answer in Part B → Q3

@Neet_pg_bot

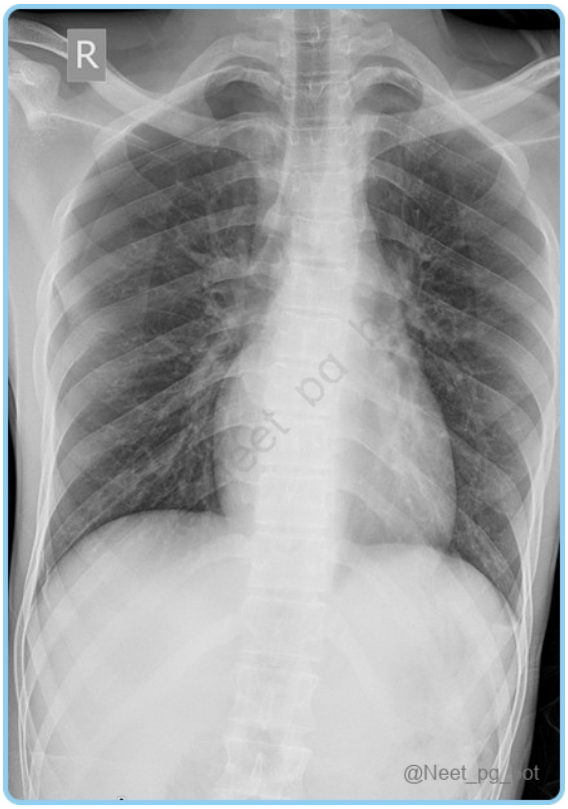
Q4: A 25-year-old male presents to the emergency department with sudden onset of right-sided chest pain and mild shortness of breath. He is tall, thin, and a smoker. Physical examination reveals decreased breath sounds on the right side with hyperresonance on percussion. Chest X-ray is given below. The patient is hemodynamically stable with oxygen saturation of 96% on room air. What is the most appropriate initial management? (Q851899)

A. Discharge with follow-up in 2-4 weeks

B. Needle aspiration

C. Immediate tube thoracostomy

D. High-flow oxygen and observation for 24 hours



See Answer in Part B → Q4

@Neet_pg_bot

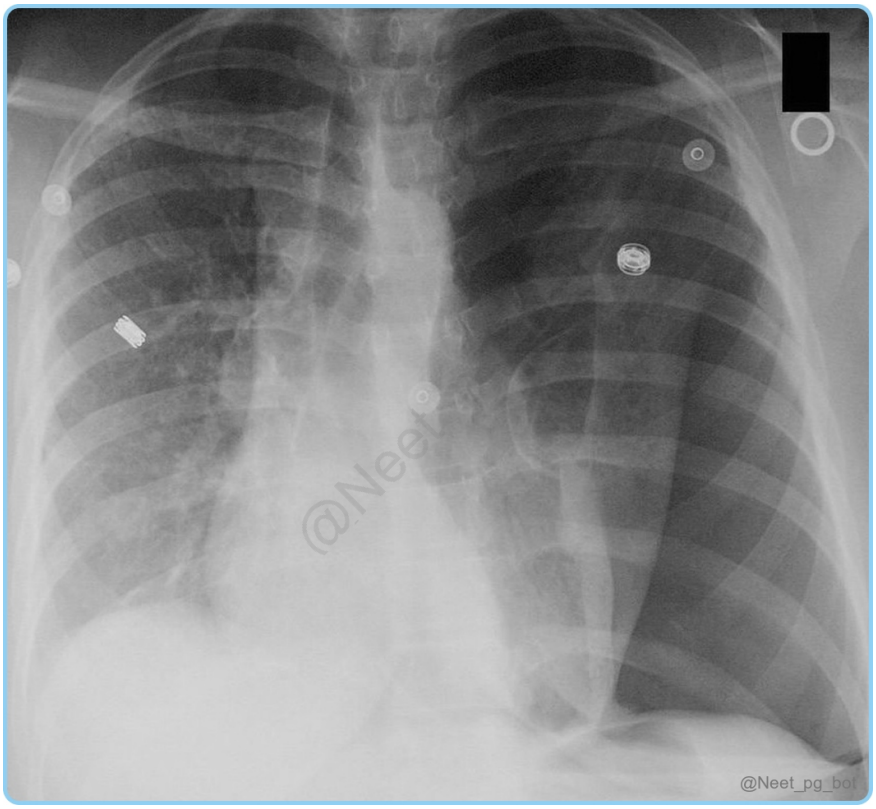
Q5: A 28-year-old male is brought to the emergency department after a motor vehicle accident with chest trauma. He is in severe respiratory distress with BP 80/50 mmHg, HR 142/min, RR 32/min. Physical examination reveals absent breath sounds. The X-ray is attached below. What is the most appropriate next step in management? (Q851903)

A. CT Head for identifying possible cerebral injury

B. Start high-flow oxygen

C. Immediate needle decompression

D. Intercostal tube



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 68-year-old female receiving a blood transfusion for severe anemia develops acute dyspnea, tachypnea, and hypertension 30 minutes into the transfusion. Her blood pressure is 168/95 mmHg, and chest auscultation reveals bilateral crackles. Which of the following represents the most appropriate immediate management? (Q851908)

A. Continue transfusion but at a slower rate

B. Stop transfusion and administer diuretics

C. Administer acetaminophen and continue transfusion

D. Stop transfusion and start steroids

See Answer in Part B → Q6

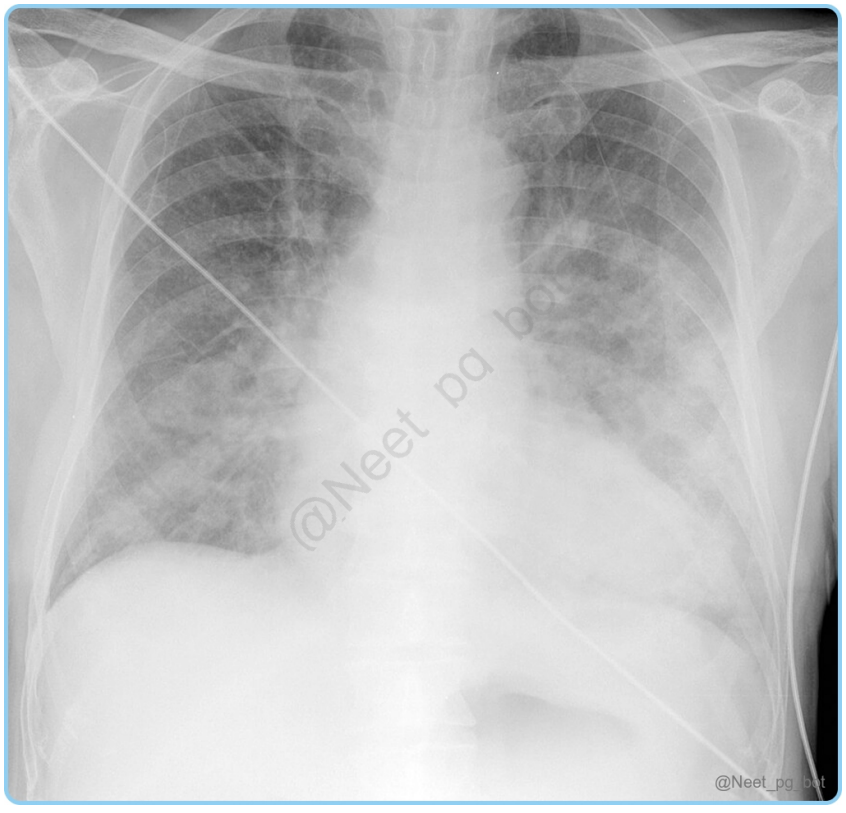
Q7: A 65-year-old male presents to the emergency department with acute dyspnea and bilateral crackles. His blood pressure is 160/90 mmHg, heart rate 110/min, and respiratory rate 28/min. Physical examination reveals jugular venous distention, bilateral pedal edema, and an S3 gallop. Chest X-ray is given below. His pulmonary capillary wedge pressure (PCWP) is 25 mmHg. Which of the following is the most appropriate initial management? (Q851914)

A. High-flow oxygen and observation

B. Immediate intubation

C. IV furosemide and nitrates

D. Antibiotics and steroids



See Answer in Part B → Q7

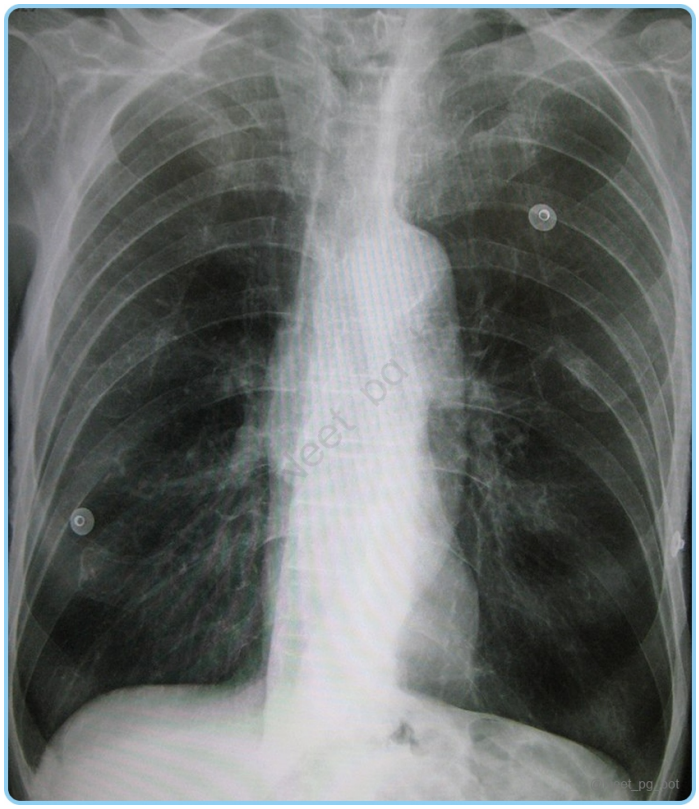
Q8: A 65-year-old male with a 40-pack-year smoking history presents with progressive dyspnea, productive cough, and weight loss. Physical examination reveals a barrel chest, decreased breath sounds, and prolonged expiration. Chest X-ray is given below. His FEV1/FVC ratio is 0.65 and doesn't improve with bronchodilators. Which of the following is the most likely pathological finding in this patient? (Q851921)

A. Inflammation of bronchial walls with mucus hypersecretion

B. Permanent enlargement of airspaces distal to terminal bronchioles

C. Bronchial wall thickening with reversible airway obstruction

D. Interstitial fibrosis with restrictive pattern



See Answer in Part B → Q8

@Neet_pg_bot

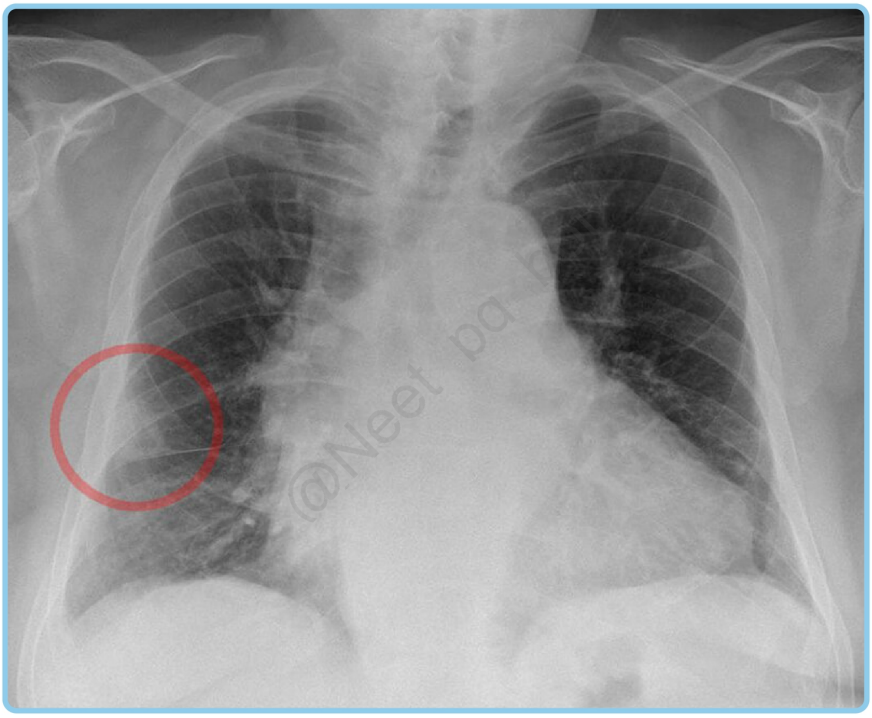
Q9: A 55-year-old man with a history of deep vein thrombosis is brought to the emergency department by his wife after he suddenly developed sharp, stabbing chest pain and shortness of breath while at home. He describes the pain as worse when taking a deep breath. The X-ray taken is displayed below. What is the most likely diagnosis? (Q851924)

A. Pneumonia

B. Atelectasis

C. Pulmonary infarction due to pulmonary embolism

D. Lung abscess



See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 65-year-old male patient presents to the pulmonary clinic with a history of progressive shortness of breath and a chronic cough. He is a long-term smoker and has a family history of respiratory diseases. A spirometry test is performed, and the

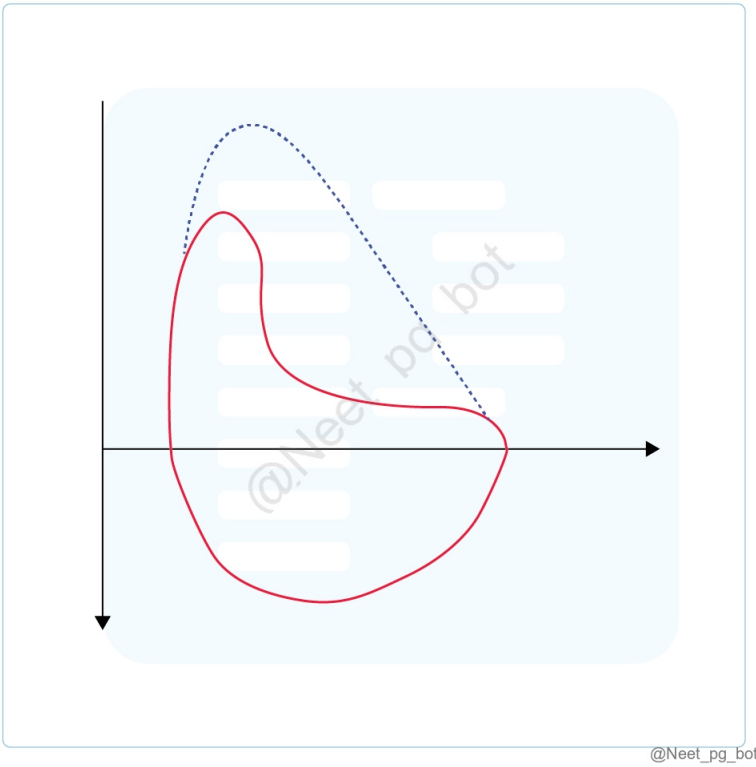
flow-volume loop is plotted. What is the most likely diagnosis based on the patient's symptoms and the shape of his flow-volume loop? (Q851927)

A. Restrictive lung disease

B. Obstructive lung disease

C. Normal lung function

D. Fixed upper airway obstruction



See Answer in Part B → Q10

@Neet_pg_bot

Q11: Match the Condition with the Correct Description on X-ray: 1. Pneumatocele a. 2. Tuberculosis (TB) b. 3. Miliary TB c. 4. Lung Abscess d. (Q851928)

A. 1 - b, 2 - c, 3 - a, 4 - d

B. 1 - a, 2 - b, 3 - c, 4 - d

C. 1 - d, 2 - c, 3 - b, 4 - a

D. 1 - c, 2 - b, 3 - d, 4 - a

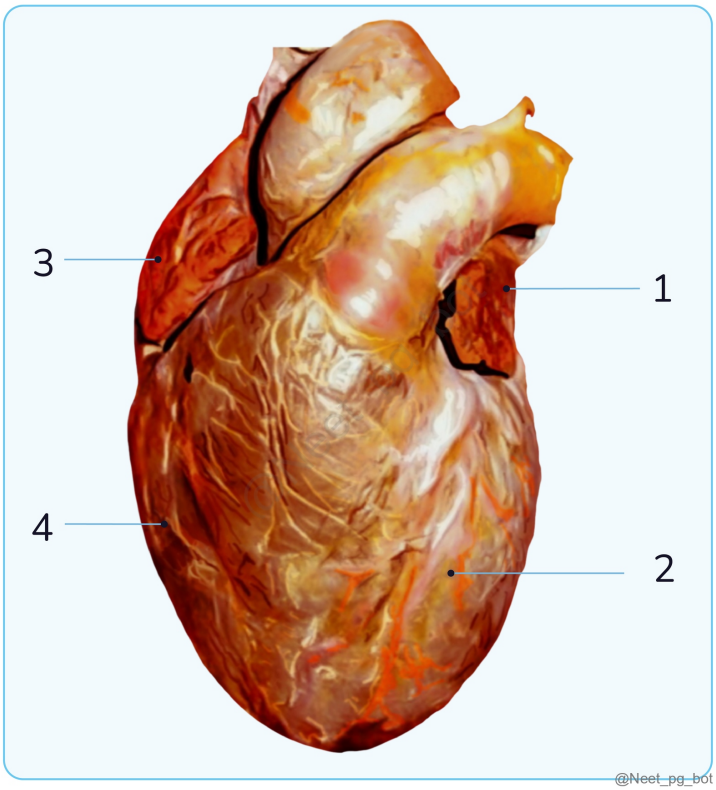
Q1: A chronic smoker presented with shortness of breath, bilateral pitting pedal edema, and abdominal distension. On examination, jugular venous pulse was found to be elevated and liver was palpable 8 cm below the costal margin. An abnormality in which of the following structures is responsible for the patient's symptoms? (Q856629)

A. 1

B. 2

C. 3

D. 4



See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 60-year-old male patient who is a known case of COPD presented with acute exacerbation and is admitted to the ICU. Which of the following statements is correct with regards to the initial management of this patient? (Q854995)

A. Non-invasive PPV should be given

B. Invasive PPV should be given

C. IV corticosteroids should be administered

D. Permissive hypercapnia is allowed

See Answer in Part B → Q2

@Neet_pg_bot

Q3: When you are posted as an intern in the emergency department, a 67 year old man with a known case of diabetic and CKD for 15 yrs is brought to you with complaints of persistent cough, shortness of breath, fever, fatigue, and chest pain. He has been tested positive for COVID 19. Which of the following features will prompt you to get this patient admitted to a dedicated COVID health center? A. Respiratory rate of 33/min B. SpO 2 88% C. Multiple comorbidities D. Chest pain E. Age (Q856965)

A. A & B only

B. A, B, C & E only

C. A, B, & C only

D. None of the above

See Answer in Part B → Q3

@Neet_pg_bot

Q4: High anion gap acidosis with low bicarbonate levels is seen in all of the following conditions except: (Q856957)

A. Renal tubular acidosis

B. Diabetic ketoacidosis

C. Lactic acidosis

D. Salicylate poisoning

See Answer in Part B → Q4

@Neet_pg_bot

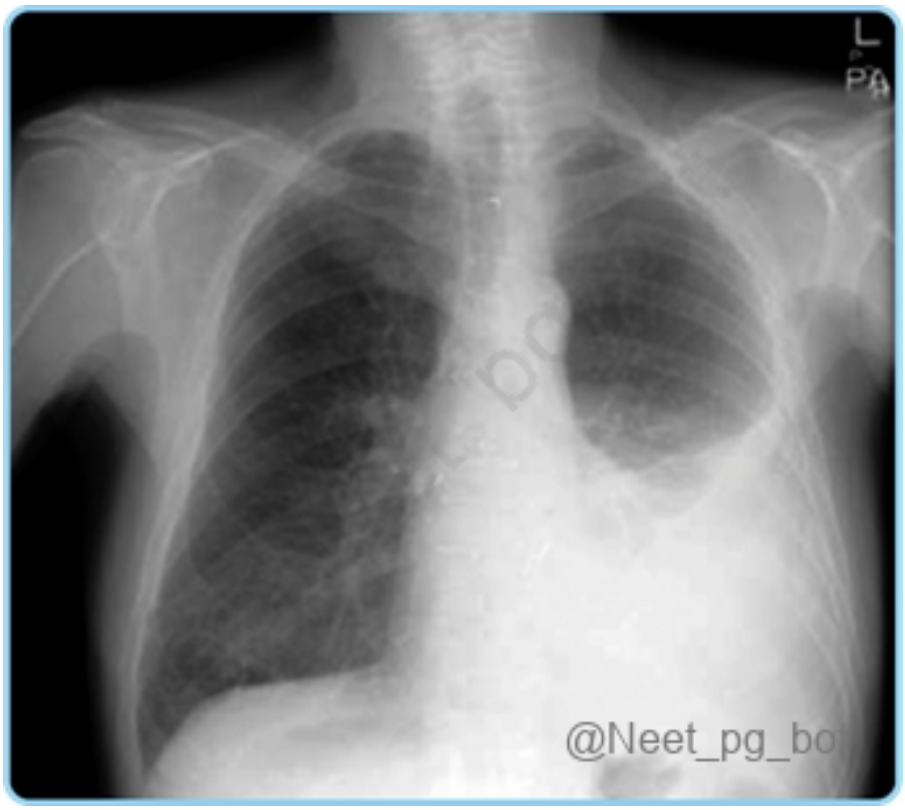
Q5: What should be your subsequent course of action for the patient, who has been intubated and his X-ray as depicted in the radiograph? (Q856937)

A. Suction

B. Chest physiotherapy

C. Start antibiotics and send and samples for culture

D. Ultrasound-guided aspiration



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 50-year-old individual who is a chronic smoker came with complaints of recurrent episodes of coughing up blood without any accompanying symptoms of fever or weight loss. On chest x-ray there were no abnormalities seen, and the sputum test is also negative for acid-fast bacilli (AFB). Which of the following options could be the next effective diagnostic test? (Q856926)

A. MRI

B. CT

C. Fiberoptic bronchoscopy

D. Bronchography

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 68-year-old man presents with a cough with yellowish sputum. Auscultation revealed bronchial breath sounds. He is hemodynamically stable and not confused. On examination, his respiratory rate is 20/min, and his blood pressure is 110/70 mmHg. Lab reports show urea levels of 44 mg/dL. What is the next best step in the management of this patient? (Q856194)

A. Given antibiotics and send the patient home

B. Admit to ICU without mechanical ventilation

C. Admit to ICU with invasive mechanical ventilation

D. Consider admission in a non-ICU setting

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A woman with hysteria who was hyperventilating developed carpo-pedal spasms. What could be the likely cause for this? (Q856163)

A. Respiratory acidosis

B. Metabolic acidosis

C. Respiratory alkalosis

D. Metabolic alkalosis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A diabetic woman presents with persistent vomiting after eating outside food. Her BP is 90/60 mmHg. ABG shows: pH: 7.52 HCO■■: 30 mEq/L PaCO■: 20 mmHg

Na■: 123 mEq/L K■: 3.2 mEq/L Cl■: 67 mEq/L What is the most likely cause of these ABG findings? (Q856157)

A. Isolated vomiting induced metabolic alkalosis

B. Diabetic ketoacidosis (DKA)

C. Septic shock

D. Mixed disorder: Vomiting + Early DKA

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A middle-aged man with chronic renal failure on dialysis presents with sudden collapse to the casualty with laboured breathing. ECG shows tall, tented T waves. What is the most likely acid-base imbalance that can be seen in this patient? (Q856141)

A. pH-7.14, pCO2-20 mmHg, HCO3- 5 mEq/L

B. pH-7.14, pCO2-20 mmHg, HCO3- 34 mEq/L

C. pH-7.54, pCO2- 34 mmHg, HCO3- 27 mEq/L

D. pH-7.4, pCO2- 40 mmHg, HCO3- 27 mEq/L

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 10-year-old child with AIDS presented with a fever and productive cough. On auscultation, bronchial breath sounds and crepitations were heard in the right infra-scapular region. Chest x-ray showed right lower lobe consolidation. The CD4 count was 55 cells/mm3. What is the most common causative organism for this condition? (Q856122)

A. Pneumocystis jirovecii

B. Streptococcus pneumonia

C. Staphylococcus aureus

D. Mycoplasma

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A patient presents with fever, nocturnal cough, breathlessness, and wheezing for 4 weeks. The absolute eosinophil count is >5000/µL. Chest x-ray shows a miliary pattern. What is the likely diagnosis? (Q856099)

A. Bronchial asthma

B. Miliary tuberculosis

C. Tropical pulmonary eosinophilia

D. Hypersensitivity pneumonitis

See Answer in Part B → Q12

@Neet_pg_bot

Q13: The arterial blood gas analysis findings of a patient are as follows: pH=7.30, HCO3=10 mEq/L, paCO2= 30 mmHg, which is suggestive of a partially compensated metabolic acidosis. What is the mechanism for the secondary disorder? (Q855004)

A. Hypoventilation causing decreased CO2 washout

B. Hyperventilation causing decreased CO2 washout

C. Increased tubular reabsorption of HCO3-

D. Increased excretion of H+

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Acid-base imbalance is suspected in a patient. Which of the following would you use to determine it? Arterial pH Venous pH Venous pO2 Venous pCO2 (Q856625)

A. 1,2

B. 1,2,3

C. 1,2,4

D. 1,2,3,4

See Answer in Part B → Q14

@Neet_pg_bot

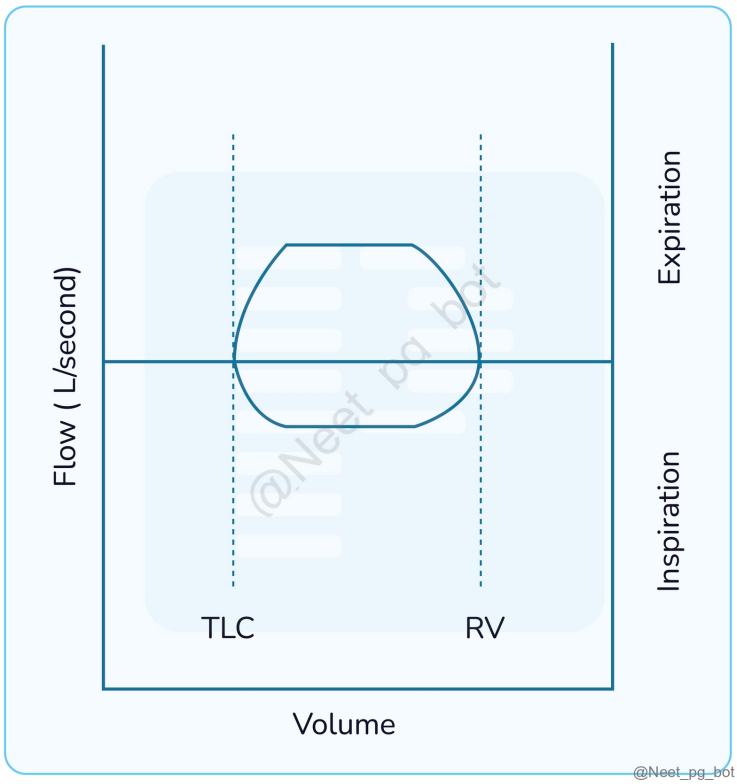
Q15: Identify the pathology from the given flow-volume loop: (Q856623)

A. Fixed distal airway obstruction

B. Fixed central airway obstruction

C. Variable intrathoracic obstruction

D. Variable extra thoracic obstruction



See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 35-year-old female patient with class II pulmonary hypertension presents with a negative vasoreactive test. Which of the following is used in the next step of management? (Q856608)

A. Iloprost

B. Ambrisentan

C. Nifedipine

D. Epoprostenol

See Answer in Part B → Q16

@Neet_pg_bot

Q17: During the discharge of a COVID patient who was treated with steroids and remdesivir, which of the following will you inform him about? Repeat RT-PCR after 7 days of discharge Watch for the persistence of Anosmia Watch for headache and nasal discharge Monitor glucose levels Watch for Sinusitis like symptoms (Q856591)

A. 1, 3 and 4

B. 2, 3 and 4

C. 3, 4 and 5

D. 1,2,3,4 and 5

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A patient came with hypoxemia and a normal alveolar-arterial oxygen gradient. What can be the cause? (Q855711)

A. Right-to-left shunt

B. Ventilation/perfusion mismatch

C. Hypoventilation

D. Alveolar membrane damage

See Answer in Part B → Q18

@Neet_pg_bot

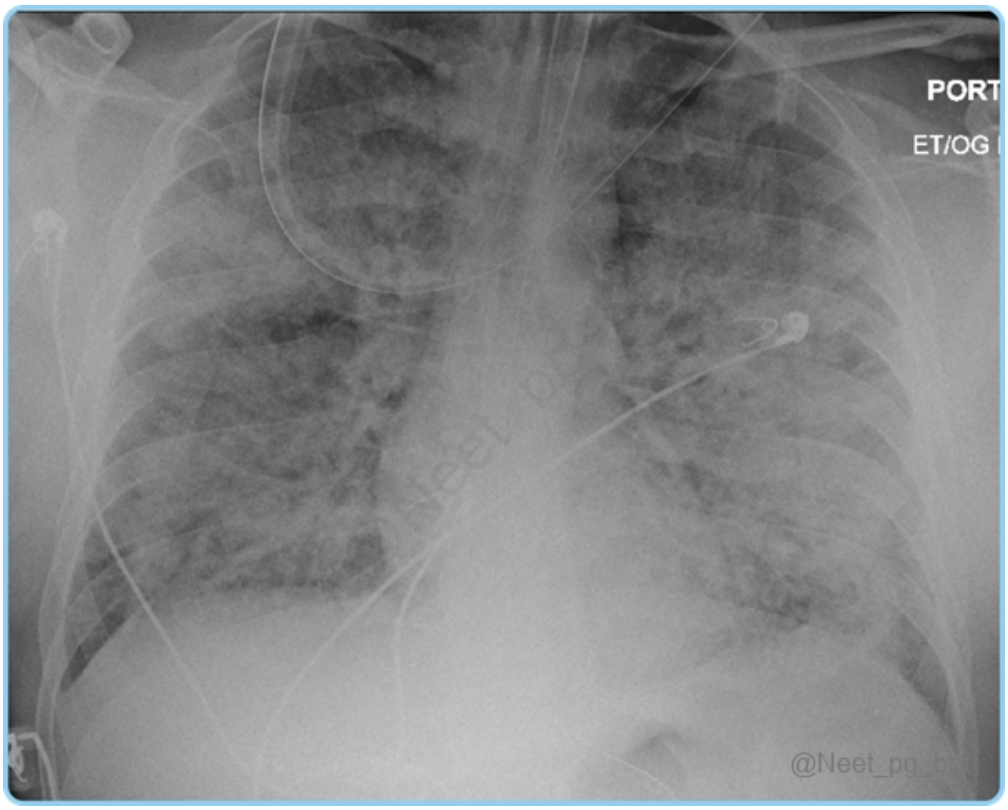
Q19: A patient with a history of fever for the past 4 days and sudden onset of breathlessness was admitted to ICU as he was deteriorating. He was unresponsive to the incremental flow rate of oxygen and his oxygen saturation was progressively decreasing. A chest x-ray was ordered and the findings are shown in the image below. What is the most likely diagnosis? (Q857678)

A. Atelectasis

B. Mediastinitis

C. Pulmonary fibrosis

D. ARDS



See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 45-year-old female presents to the emergency department with the following arterial blood gas (ABG) results: pH 7.55, PaCO 2 40 mmHg, HCO 3 - 32 mEq/L. Which of the following conditions is most likely responsible for these findings? (Q857651)

A. Metabolic acidosis

B. Metabolic alkalosis

C. Respiratory acidosis

D. Respiratory alkalosis

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following findings from a pleural fluid aspirate will suggest an exudative pleural effusion? Normal values Total S. Protein: 6-8 gm% S.LDH: 140-280 IU S. glucose: 140-200 (Q857644)

A. Pleural: Serum protein ratio > 0.5, pleural: Serum LDH ratio > 0.6 or pleural LDH > ■ of serum LDH

B. Pleural fluid protein = 4.5 gm% and glucose = 30 mg%

C. Pleural fluid LDH = 90IU and glucose = 30 mg%

D. Pleural fluid protein = 3.5gm% and glucose = 90 mg%

See Answer in Part B → Q21

@Neet_pg_bot

Q22: The following patient has presented after chest trauma. On examination, crepitus is felt. The clinical diagnosis is? (Q857053)

A. Subcutaneous emphysema

B. Gas gangrene

C. Acute tubular necrosis

D. SVC syndrome

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following imaging tests should be performed to confirm a diagnosis of pulmonary embolism in a patient? (Q857034)

A. Doppler echocardiography

B. CT pulmonary angiography

C. Ventilation perfusion scan of lungs

D. MR pulmonary angiography

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A male patient presents to the emergency department with the following arterial blood gas (ABG) values: pH: 7.2 pCO2: 81 mmHg HCO3: 40 mEq/L What is the most likely diagnosis? (Q856014)

A. Respiratory alkalosis

B. Metabolic acidosis

C. Respiratory acidosis

D. Metabolic alkalosis

See Answer in Part B → Q24

@Neet_pg_bot

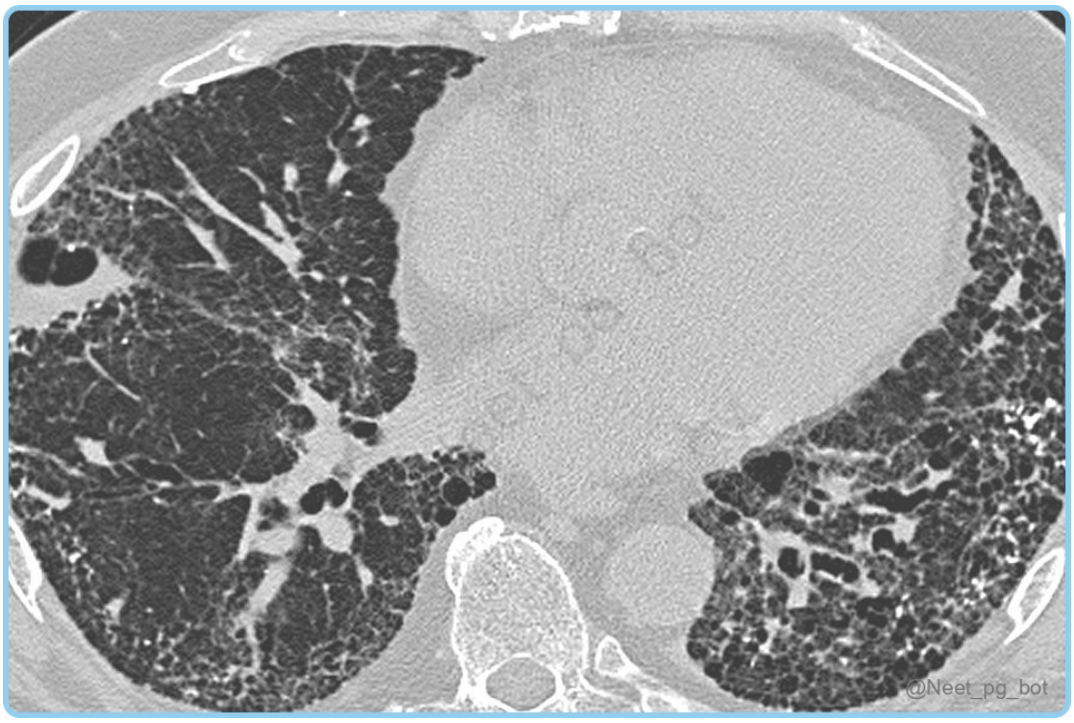
Q25: A 48-year-old woman presents with progressive shortness of breath and a dry cough for the past 6 months. HRCT chest is given below. All of the following are true about this condition except: (Q879457)

A. End inspiratory coarse crackles are heard

B. Honeycombing with reticular markings is visible on HRCT

C. Both pneumococcal and influenza vaccines are advised for such patients

D. Rheumatoid arthritis is associated with this condition



See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 58-year-old woman with rheumatoid arthritis, treated with methotrexate for 4 months, develops worsening shortness of breath and a nonproductive cough. Physical examination reveals bilateral fine crackles at the lung bases. Chest CT demonstrates bilateral ground-glass opacities consistent with interstitial lung involvement. What is the most likely diagnosis? (Q879212)

A. Methotrexate-induced pneumonitis

B. Bacterial pneumonia

C. Congestive heart failure

D. Sarcoidosis

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Which of the following risk factors is most likely to be associated with invasive pulmonary aspergillosis? (Q879209)

A. HIV patient with CD4+ count < 50

B. Febrile neutropenia

C. Patient on steroids

D. Diabetes mellitus

See Answer in Part B → Q27

@Neet_pg_bot

Q28: According to GOLD guidelines, what is the approximate cutoff value of FEV■ (% predicted) associated with clinically significant resting hypoxemia in chronic COPD patients? (Q879208)

A. 20%

B. 30%

C. 40%

D. 50%

See Answer in Part B → Q28

@Neet_pg_bot

Q29: According to GOLD COPD classification, which of the following is/are correct? Mild - FEV1/FVC < 0.7 and FEV1 >80% Moderate - FEV1/FVC < 0.7 and FEV1 >50 % but < 80% Severe - FEV1/FVC < 0.7 and FEV1 > 40% but < 50% Very severe - FEV1/FVC < 0.7 and FEV1 < 40% (Q879176)

A. 1

B. 1, 2

C. 1, 2, 3

D. 2, 3, 4

See Answer in Part B → Q29

@Neet_pg_bot

Q30: According to GOLD guidelines, which of the following are appropriate next steps in management of this acute COPD exacerbation in a smoker with RR 30/min, pulse 112/min, resting Sa02 87% room air and pCO2 60 mm Hg? a. Antibiotics b. Systemic corticosteroids c. Anti-virals d. Nebulized bronchodilators (Q879161)

A. a,c,d

B. a,b,d

C. b,c,d

D. a,b,c,d

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A 50-year-old male patient undergoing treatment for lung cancer complains of difficulty in breathing and dizziness. Upon examination, diminished breath sounds are noted over the left inferior-scapular region. What is the most probable diagnosis? (Q830830)

A. Constrictive pericarditis

B. Pleural effusion

C. Cardiac tamponade

D. Pneumothorax

See Answer in Part B → Q31

@Neet_pg_bot

Q32: In bronchial asthma, what is the minimum percentage increase in the FEV1/FVC ratio that indicates a reversible obstruction following the administration of bronchodilators? (Q830825)

A. >12%

B. >20%

C. >10%

D. >18%

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A male patient with infertility presents a disorder comprising the triad of situs inversus, chronic sinusitis, and bronchiectasis. Which of the following is the correct diagnosis? (Q860392)

A. Kartagener's syndrome

B. Cystic fibrosis

C. Mucovicidosis

D. Klinefelter syndrome

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A 55-year-old man presents with altered sensorium and deep labored breathing. ABG is given below. What is the most likely acid-base disorder? pH: 7.20 pCO■: 31 mmHg HCO■■:16 mEq/L Na■: 130 mEq/L Cl■: 84 mEq/L PaO■: 80 mmHg (Q866496)

A. Metabolic acidosis

B. Metabolic alkalosis

C. Respiratory acidosis

D. Respiratory alkalosis

See Answer in Part B → Q34

@Neet_pg_bot

Q35: Multidrug-resistant (MDR) tuberculosis shows resistance to which of the following drugs? (Q856022)

A. Isoniazid, rifampicin, and fluoroquinolone

B. Fluoroquinolones

C. Isoniazid and rifampicin

D. Isoniazid, rifampicin, and kanamycin

See Answer in Part B → Q35

@Neet_pg_bot

Q36: A patient was admitted to the ICU 48 hours after an accident in which he sustained a fracture of the femur. The oxygen saturation in the rebreathing unit was 100% but his SpO2 remained at 60%. The patient is in a state of confusion. Diffuse petechiae are noted on examination. Chest radiograph showed lung fields to be clear. What is the most likely diagnosis? (Q857033)

A. Pulmonary embolism

B. Fat embolism

C. ARDS

D. Occult pneumothorax

See Answer in Part B → Q36

@Neet_pg_bot

Q37: A 35-year-old female patient presents with fever, breathlessness, and cough with expectoration. A CT scan was done, which is shown below. What is the most likely diagnosis? (Q855908)

A. Consolidation with air bronchogram

B. Mediastinal mass

C. Pleural effusion

D. Diaphragmatic hernia

See Answer in Part B → Q37

@Neet_pg_bot

Q38: A patient presents with fever, night sweats, ptosis, and bilateral facial nerve palsy. Investigations show leukocytosis and bilateral hilar lymphadenopathy. Which of the following is the most likely diagnosis? (Q855905)

A. Sarcoidosis

B. Tuberculosis

C. Lymphoma

D. Hypersensitive pneumonitis

See Answer in Part B → Q38

@Neet_pg_bot

Q39: A 45-year patient working in a factory for the past 20 years presents with breathlessness. HRCT chest shows pleural thickening and fibrosis. Diagnosis is? (Q859808)

A. Asbestosis

B. Coal worker pneumoconiosis

C. Silicosis

D. Berylliosis

See Answer in Part B → Q39

@Neet_pg_bot

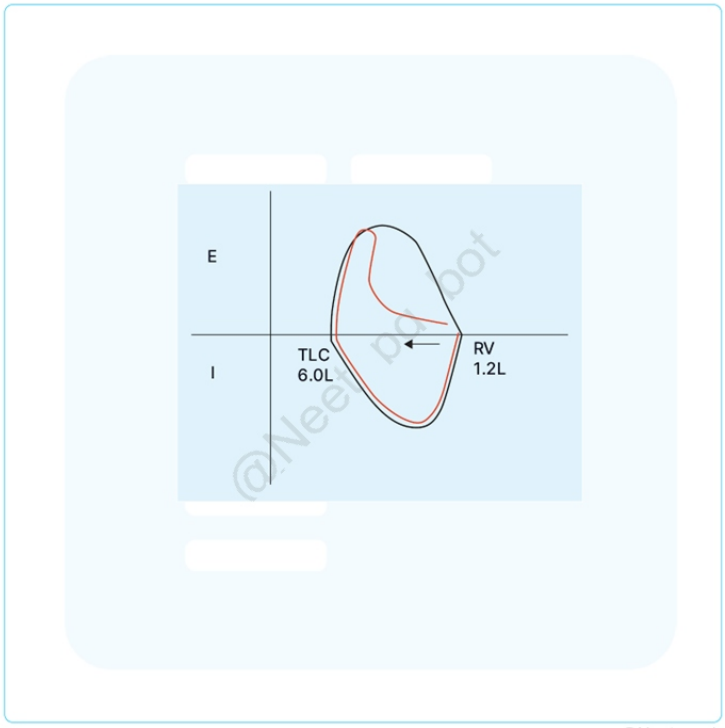
Q40: The flow-volume curve of a patient after spirometry is given below. The most likely diagnosis in this patient is: (Q859564)

A. Asbestosis

B. COPD

C. Myasthenia gravis

D. Vocal cord paralysis



@Neet_pg_bot

See Answer in Part B → Q40

@Neet_pg_bot

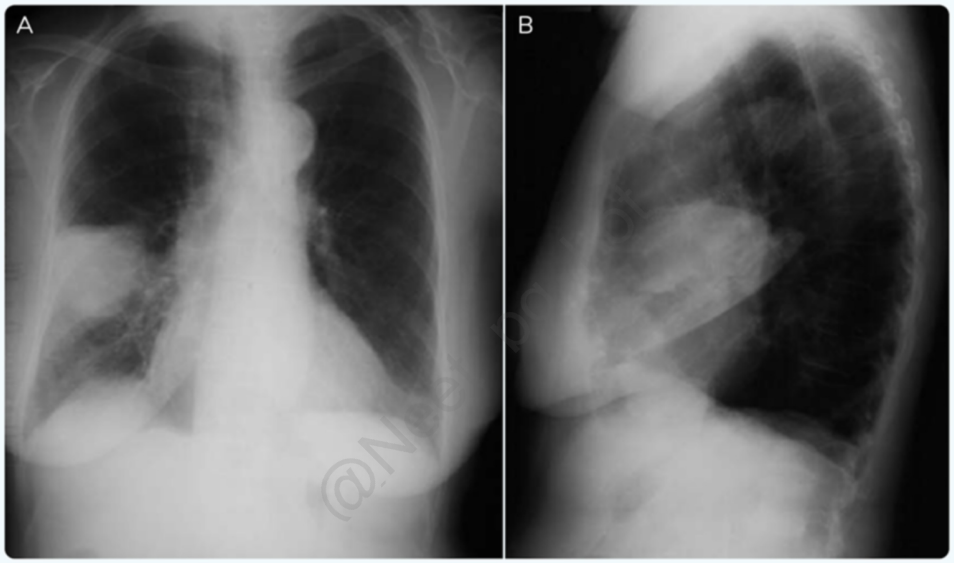
Q41: A 46-year-old chronic alcoholic male presents to the OPD with fever, headache, shortness of breath, chest pain, and productive cough with red currant jelly sputum for the last two days. On examination, there was bronchial breathing on the right side, increased vocal fremitus, increased vocal resonance, and a dull note on percussion. The patient's radiograph is shown below. Which is the most likely causative agent? (Q859561)

A. Streptococcus pneumoniae

B. Klebsiella pneumoniae

C. Pseudomonas aeruginosa

D. Haemophilus influenza



@Neet_pg_bot

See Answer in Part B → Q41

@Neet_pg_bot

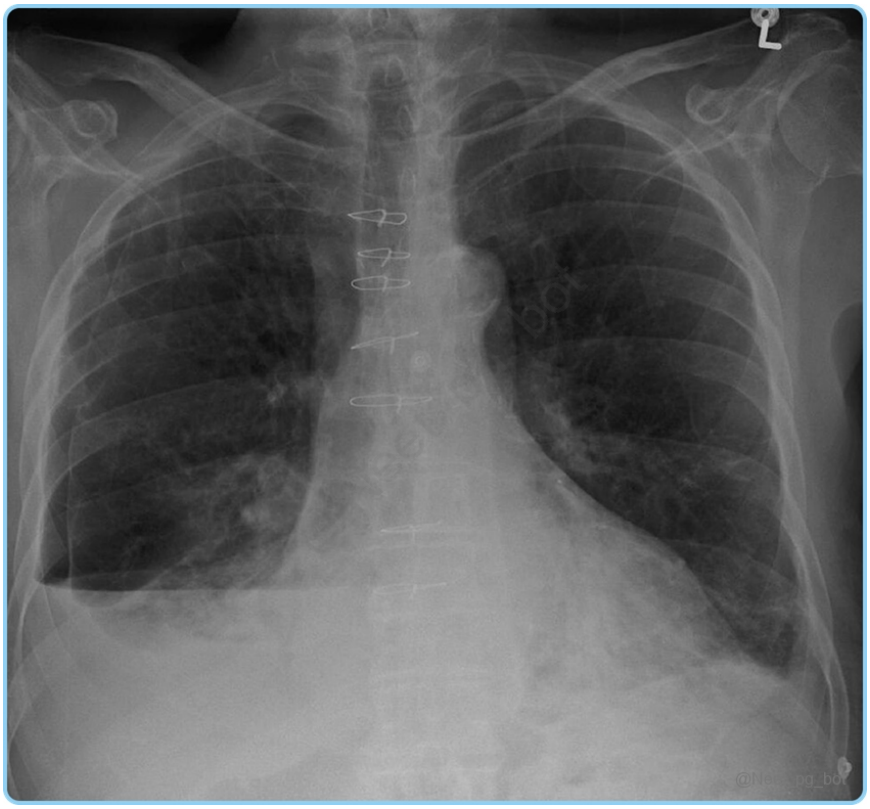
Q42: Identify the condition in the following X-ray. (Q859538)

A. Hydropneumothorax

B. Pleural effusion

C. Pericardial effusion

D. Pneumothorax



See Answer in Part B → Q42

@Neet_pg_bot

Q43: A 55-year-old patient presented with chronic projectile vomiting and weight loss. What is the expected metabolic abnormality to be seen here? (Q859530)

A. Hypokalemic hypochloremic metabolic alkalosis with hyponatremia

B. Hypokalemic hypochloremic metabolic alkalosis with hypernatremia

C. Hypokalemic hypochloremic metabolic alkalosis with hypercalcemia

D. Hypokalemic hypochloremic metabolic acidosis with hyponatremia

See Answer in Part B → Q43

@Neet_pg_bot

Q44: A 55-year-old male presented with tachypnea and mental confusion. His blood sugar is 350mg/dl, pH-7.2, HCO3-10, pCO2-30. What is the metabolic abnormality? (Q858450)

A. Metabolic alkalosis

B. Metabolic acidosis

C. Respiratory alkalosis

D. Respiratory acidosis

See Answer in Part B → Q44

@Neet_pg_bot

Q45: A 20-year-old man presents to the emergency department with respiratory distress and hypotension following a trauma. He has subcutaneous emphysema, and there is an absence of air entry into the right side of the lungs. What is the next best step? (Q858434)

A. Start IV fluids with a large bore cannula

B. Needle decompression into the 5 th intercostal space anterior to the midaxillary line

C. Take the patient to the ICU and intubate him

D. Start positive pressure ventilation

See Answer in Part B → Q45

@Neet_pg_bot

Q46: A 53-year-old woman underwent hip replacement surgery. A week after the surgery, the patient developed swelling of the legs associated with pain on palpation. Her heart rate is 70 beats per min. There is no history of hemoptysis or significant weight loss. There is no previous history of pulmonary embolism. What is the risk of developing pulmonary embolism in the patient based on Well's score? (Q855016)

A. Low

B. High

C. Moderate

D. Cannot comment without d-dimer values

See Answer in Part B → Q46

@Neet_pg_bot

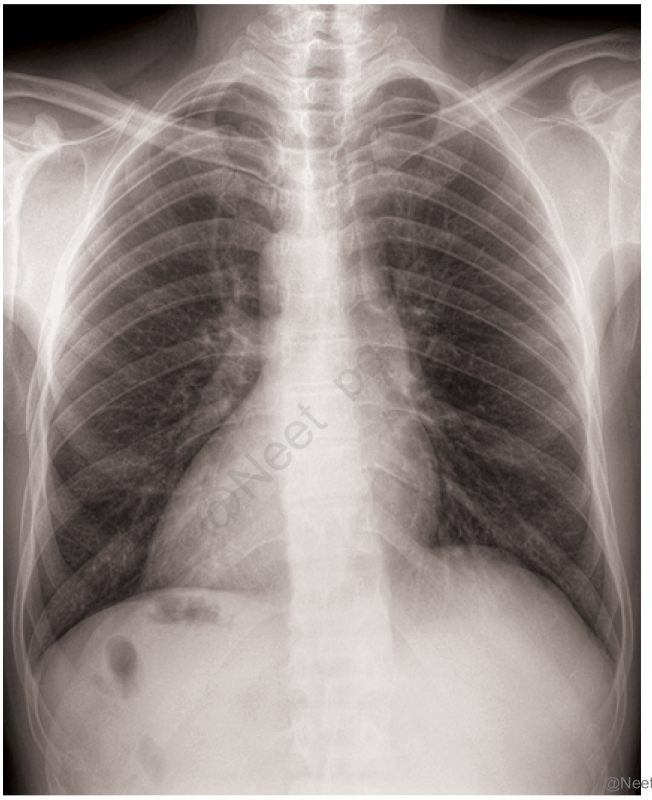
Q47: Patient presents with recurrent lung infections and CXR is given below. What is the most likely diagnosis? (Q844230)

A. Kartagener syndrome

B. Cystic fibrosis

C. Digeorge syndrome

D. Down syndrome



See Answer in Part B → Q47

@Neet_pg_bot

Q48: A 33-year-old woman is being evaluated for daytime sleepiness and memory loss which have been present for the past 1 year. Her BMI is 43, her BP is 170/98 mmHg. In an awake state, ABG shows pO2 70 mmHg, pCO2 53 mmHg, HCO3 33 mmol/L. What is the most likely diagnosis? (Q820347)

A. Obesity Hypoventilation Syndrome

B. Central Sleep Apnea

C. Narcolepsy

D. Obstructive sleep Apnea

See Answer in Part B → Q48

@Neet_pg_bot

Q49: A 40-year-old man presents with daytime sleepiness and impaired concentration and memory. On examination his BMI is 41 kg/m2, BP is 160/100 mm Hg. His awake ABG analysis is given: PaO 2 = 66mm Hg PaCO 2 = 50 mm Hg HCO 3 = 28 mEq/L What is the most likely diagnosis? (Q857285)

A. Obstructive sleep apnea

B. Narcolepsy

C. Obesity hypo-ventilation syndrome

D. Central sleep apnea

See Answer in Part B → Q49

@Neet_pg_bot

Q50: Match the following medical conditions with their corresponding descriptions: A Caplan syndrome 1 Initially observed in coal workers B Asbestosis 2 Presents with a characteristic "crazy pavement" appearance C Mesothelioma 3 Affects the pleura D

Sarcoidosis 4 Exhibits the presence of pleural effusion (Q857279)

A. A-1, B-4, C-3, D-2

B. A-4, B-2, C-3, D-1

C. A-3, B-4, C-2, D-1

D. A-2, B-4, C-3, D-1

See Answer in Part B → Q50

@Neet_pg_bot

Q51: Which membrane channel is mainly affected in Cystic fibrosis? (Q857260)

A. Sodium

B. Chloride

C. Calcium

D. Potassium

See Answer in Part B → Q51

@Neet_pg_bot

Q52: A 45-year-old woman with obstructive lung disease is currently using salmeterol and tiotropium but continues to experience breathlessness and frequent exacerbations. Given her current situation, which of the following treatments would be most appropriate? (Q860154)

A. Nebulization with LAMA-LABA

B. Long-Term Oxygen Therapy (LTOT)

C. Positive Pressure Ventilation (PPV)

D. Pneumococcal Vaccine

See Answer in Part B → Q52

@Neet_pg_bot

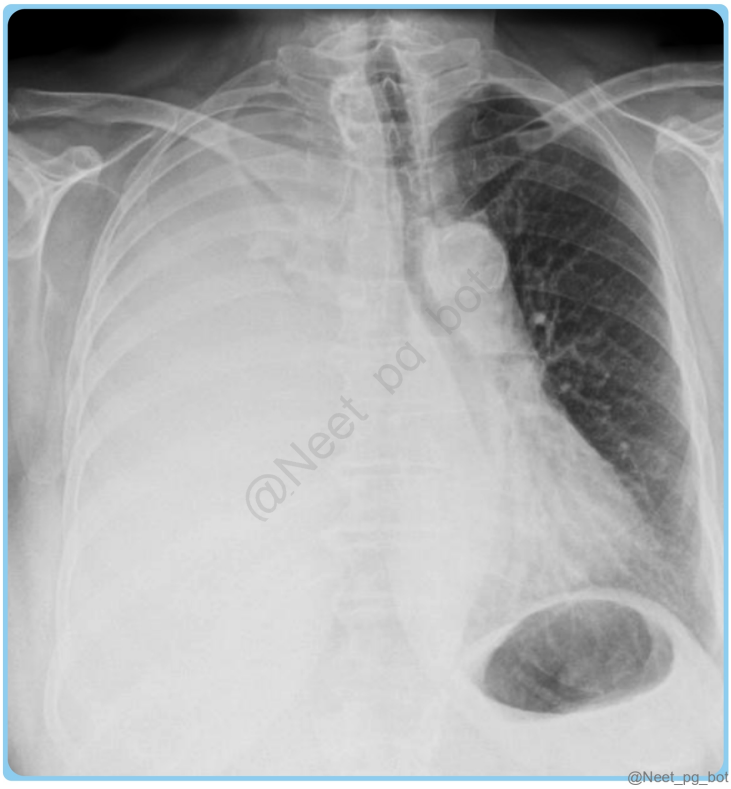
Q53: A 60-year-old man with chronic cough and weight loss presents with increasing breathlessness. Chest X-ray shown below. Which of the following is the most likely cause ? (Q860464)

A. Right-sided pneumothorax

B. Right lung consolidation

C. Right lung collapse

D. Massive pleural effusion due to pulmonary malignancy



See Answer in Part B → Q53

@Neet_pg_bot

Q54: Which of the following conditions will have an FEV■/FVC ratio < 0.7 and FEV■ < 80% of the predicted value along with wheezing in the morning hours and shortness

of breath? (Q860397)

A. Asthma

B. Interstitial Lung Disease

C. Idiopathic Pulmonary Fibrosis

D. Silicosis

See Answer in Part B → Q54

@Neet_pg_bot

Q55: Criterion that differentiates exudative from transudative pleural effusion? (Q860390)

A. Low protein in pleural fluid

B. High protein in pleural fluid

C. Low sugar in pleural fluid

D. High sugar in pleural fluid

See Answer in Part B → Q55

@Neet_pg_bot

Q56: Most common cause of death in idiopathic pulmonary fibrosis? (Q844287)

A. Respiratory failure

B. Pulmonary edema

C. Cancer

D. PAH

See Answer in Part B → Q56

@Neet_pg_bot

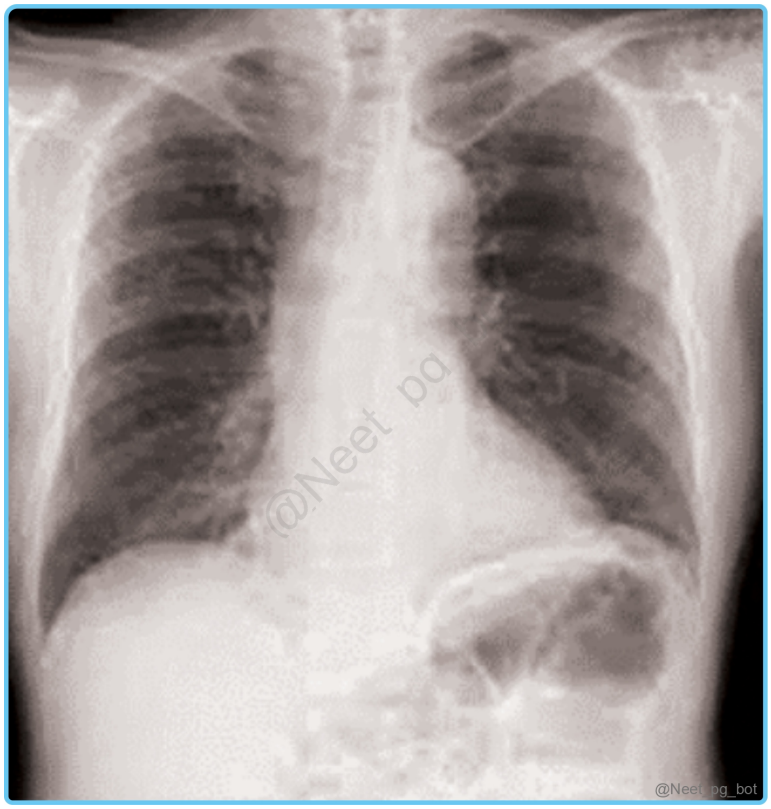
Q57: A patient presents with acute epigastric pain and an increase in serum lipase levels. Three days after stabilization, a chest X-ray is obtained. What is the most common pathology behind the chest X-ray findings? (Q844274)

A. Increased PCWP

B. Pulmonary thromboembolism

C. Non cardiogenic pulmonary edema

D. Aspiration pneumonitis



See Answer in Part B → Q57

@Neet_pg_bot

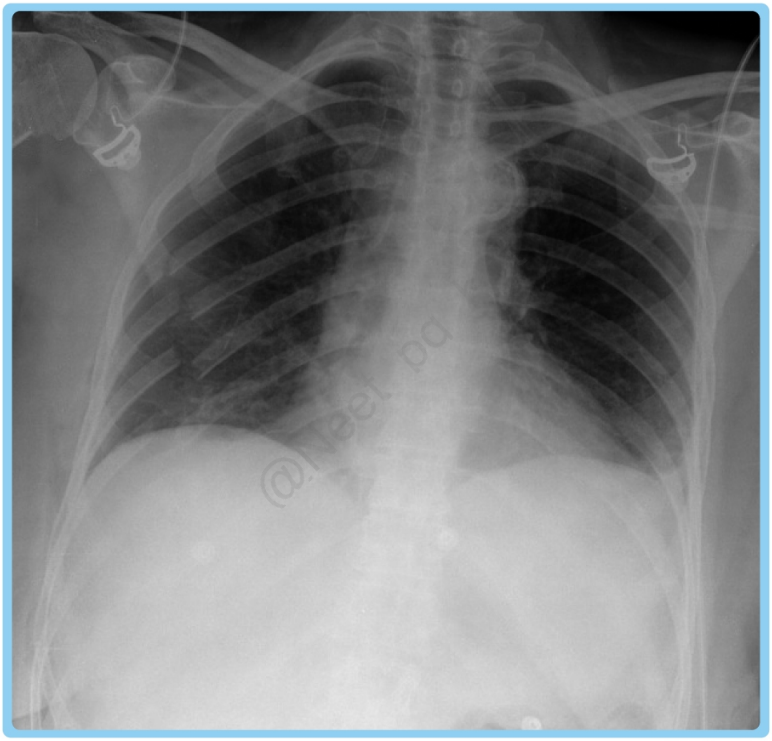
Q58: What is the expected finding in a patient with the following CXR? (Q844270)

A. Kussmaul breathing

B. Paradoxical breathing

C. Apneustic breathing

D. Bronchial breathing



See Answer in Part B → Q58

@Neet_pg_bot

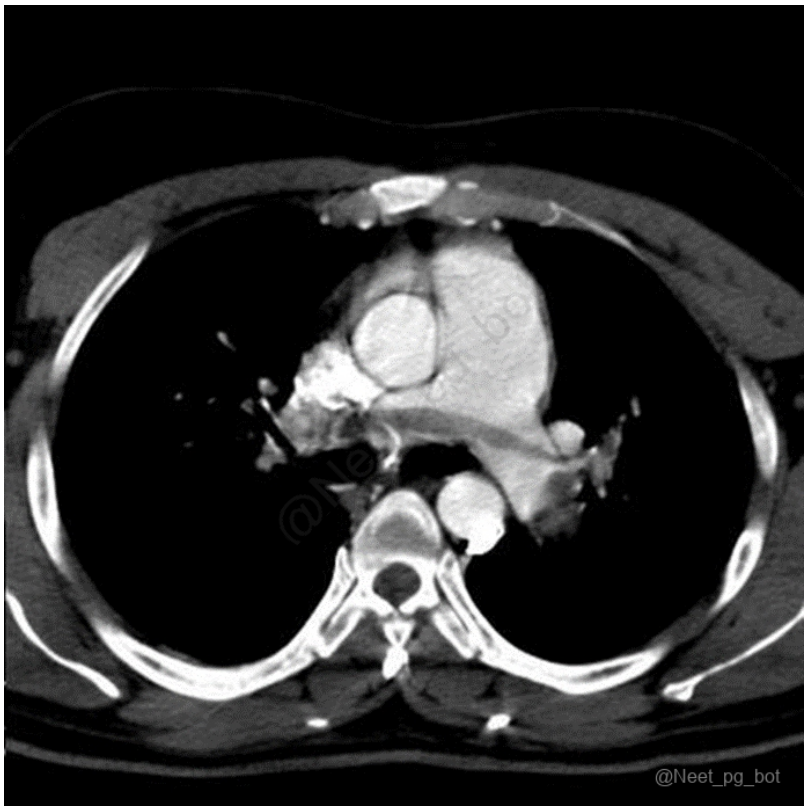
Q59: A 60-year-old bedridden patient develops sudden onset breathlessness and chest pain . CTPA was done. Which of the following non-invasive investigations will be useful to confirm the etiology of this presentation? (Q820451)

A. D dimer

B. MRI

C. Coagulogram

D. Doppler



See Answer in Part B → Q59

@Neet_pg_bot

Q60: A patient presents with wheezing that improves with as-needed use of albuterol. Spirometry shows FEV1 ranging from 70% to 83%, and the patient experiences nighttime chest tightening twice a week. What is the most appropriate treatment? (Q844179)

A. Continue with albuterol

B. Replace with salmeterol twice daily

C. Start Tab prednisolone

D. Add an inhaled corticosteroid

See Answer in Part B → Q60

@Neet_pg_bot

Q61: A 62-year-old woman with a history of chronic obstructive pulmonary disease (COPD) presents with increased breathlessness, cough, and sputum production over the last two days. She appears distressed and has a respiratory rate of 28 breaths per minute. Her oxygen saturation is 88% on room air. Which of the following management strategies is most appropriate for her immediate treatment? (Q852751)

A. Initiate high-flow oxygen therapy to maintain oxygen saturation above 95%

B. Start nebulised bronchodilator therapy with salbutamol and ipratropium

C. Begin intravenous glucocorticoids immediately

D. Order a chest X-ray before any treatment is provided

See Answer in Part B → Q61

@Neet_pg_bot

Q62: A patient with a history of pneumonia develops pleural effusion. What is the expected finding in the pleural analysis for parapneumonic effusion? (Q852740)

A. Pleural protein/plasma protein ratio less than 0.5

B. Pleural LDH less than 2/3rd of plasma LDH

C. Pleural pH less than 7.2

D. Pleural LDH less than 0.6 of plasma LDH

See Answer in Part B → Q62

@Neet_pg_bot

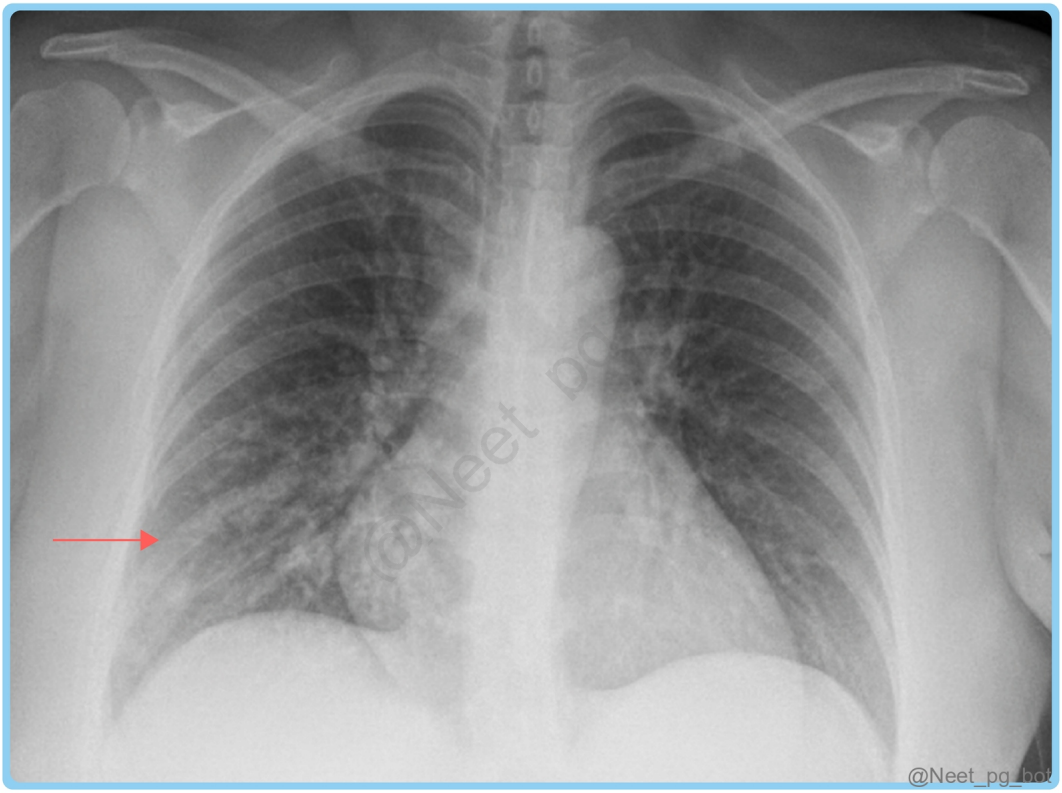
Q63: A 46-year-old diabetic patient presented with fever, malaise, and a productive cough. His chest X-ray is given below. Which of the following statements is incorrect? {{caption_text}} (Q853358)

A. Patchy infiltrates as seen in pyogenic pneumonia

B. Interstitial infiltrates as seen in Mycoplasma pneumonia

C. Hilar lymphadenopathy with infiltrates as seen in malignancy

D. Aspiration pneumonia is more common in the upper segment of the lower lobe and posterior segment of the upper lobe



See Answer in Part B → Q63

@Neet_pg_bot

Q64: Old man underwent joint replacement surgery 3 days ago. Today he develops SOB with chest pain. O/E : pulse 100/min, BP 100/70 mm Hg, RR28/min and sp02: 85% room air. D-dimer is elevated. Which is the next best test (Q866499)

A. V/Q scan

B. ECG

C. CXR

D. CTPA

See Answer in Part B → Q64

@Neet_pg_bot

Q65: A patient with COVID-19 pneumonia is admitted with severe respiratory distress and their PaO■/FiO■ is < 100. What is the most appropriate ventilatory strategy in this case? (Q866498)

A. Low PEEP, high tidal volume

B. High PEEP, low tidal volume

C. Low tidal volume, low PEEP

D. High tidal volume, high PEEP

See Answer in Part B → Q65

@Neet_pg_bot

Q66: A 45-year-old chronic smoker presents with complaints of dyspnea. Pulmonary function tests reveal an FEV1/FVC ratio of 65% and an RV/TLC ratio of 141%. Which of the following best describes the underlying pathophysiology? (Q865365)

A. Air trapping with hyperinflation of lungs

B. Decreased lung compliance

C. Restrictive lung disease

D. Increased lung compliance

See Answer in Part B → Q66

@Neet_pg_bot

Q67: A patient presents with progressive shortness of breath for the last 6 months, accompanied by dry cough. Auscultation reveals bilateral basal end-inspiratory crepitations. There is no history of fever, joint pain, or occupational exposure. What is the diagnosis? (Q866819)

A. Cor-pulmonale

B. Sarcoidosis

C. IPF

D. Hypersensitivity pneumonitis

See Answer in Part B → Q67

@Neet_pg_bot

Q68: A patient presents with SOB and fatigue. CXR was done. What is the diagnosis? (Q866818)

A. TB

B. Asbestosis

C. Silicosis

D. Byssinosis

See Answer in Part B → Q68

@Neet_pg_bot

Q69: A patient is in ICU and there is a failed attempt of subclavian catheterization. Shortly after, BP drops and the pulse rises. What is the diagnosis? (Q866813)

A. Pneumothorax

B. Displacement of endotracheal tube (ET)

C. Air embolism

D. Dislodgement of ET

See Answer in Part B → Q69

@Neet_pg_bot

Q70: A 45-year-old patient with a history of smoking a pack of cigarettes for the past 15 years presents with hemoptysis. Chest X-ray shows a 3cm upper lobe mass near the apex of the lung. What is the next best step for managing this patient? (Q858025)

A. Bronchoscopy

B. CT-guided biopsy

C. Sputum cytology

D. Sputum for AFB

See Answer in Part B → Q70

@Neet_pg_bot

Q71: Which of the following does not cause central cyanosis? (Q855700)

A. Methemoglobinemia

B. Pulmonary arteriovenous fistula

C. High altitude

D. Hypothermia

See Answer in Part B → Q71

@Neet_pg_bot

Q72: A chronic cigarette smoker has now joined a construction company. His pulmonary function test results are given below. What is the most likely diagnosis for this patient? Initial lung volumes were: FEV1-0.9L FVC-1.9L FEV1/FVC-0.4 After bronchodilation: FEV1-1.9L FVC-3.9L FEV1/FVC-0.4 (Q855598)

A. Vascular disease with bronchodilator reversibility

B. Restrictive lung disease with bronchodilator reversibility

C. Restrictive lung disease without bronchodilator reversibility

D. Obstructive disease with bronchodilator reversibility

See Answer in Part B → Q72

@Neet_pg_bot

Q73: A 65-year-old female patient weighing 60 kg is on mechanical ventilation for ARDS secondary to urosepsis. The respiratory parameters are as follows: tidal volume – 360 mL; frequency – 30 breaths/min; PEEP - 5 cm of H2O; and FiO2-90%. The arterial blood gas findings are as follows; paO2-50 mmHg; paCO2-38 mmHg; and pH-7.38. What is the next step? (Q855351)

A. Reduce FiO2

B. Increase tidal volume

C. Increase respiratory rate

D. Increase PEEP

See Answer in Part B → Q73

@Neet_pg_bot

Q74: A 72-year-old man presented with weight loss, decreased appetite, and iron deficiency anemia. Chest x-ray was done and given below. What is the diagnosis? (Q856976)

A. Lung metastasis

B. Bronchogenic carcinoma

C. Miliary tuberculosis

D. Mesothelioma

See Answer in Part B → Q74

@Neet_pg_bot

Q75: A 55 year old shipbuilding worker presents with dyspnea. He has been working in this industry for the past 25 years. Which is the most specific malignancy that we can expect in this patient? (Q856984)

A. Bronchogenic carcinoma

B. Malignant mesothelioma

C. Small cell carcinoma of lung

D. Squamous cell carcinoma of lung

See Answer in Part B → Q75

@Neet_pg_bot

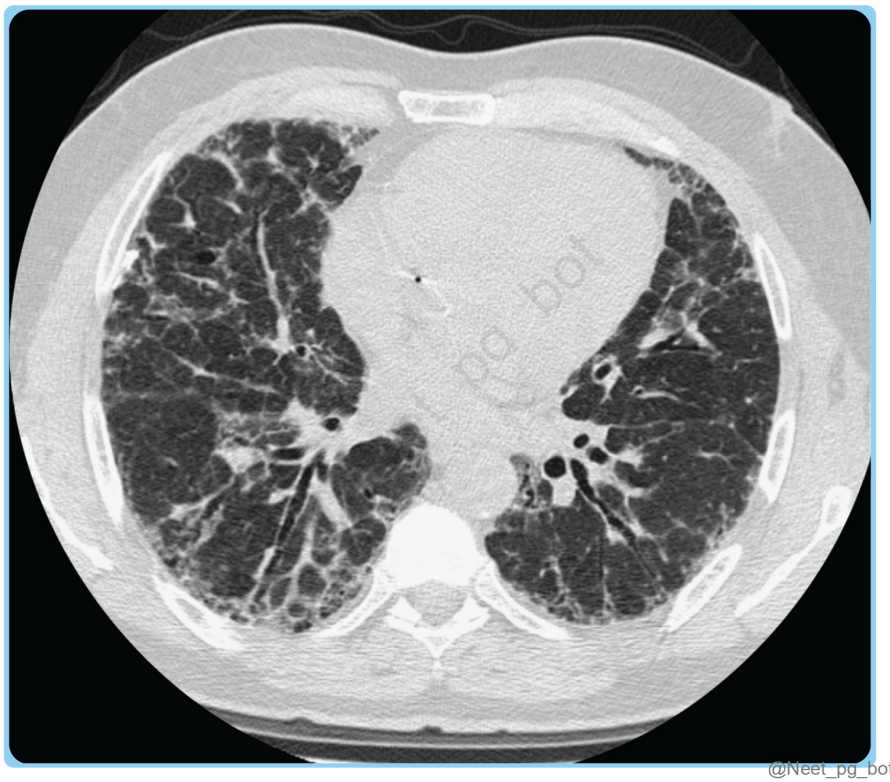
Q76: A 60-year-old male patient comes to your clinic with an 8-month history of shortness of breath and non-productive cough. He has smoked half a pack of cigarettes for the past 30 years. On physical examination, clubbing is seen and fine crackles are heard on both sides during inspiration. You perform pulmonary function tests and it shows an FEV1/FVC ratio of 92%. The CT scan of the chest is shown below. What is the most probable diagnosis? (Q856989)

A. Bronchial asthma

B. Pulmonary fibrosis

C. Pulmonary tuberculosis

D. Chronic obstructive pulmonary disease



See Answer in Part B → Q76

@Neet_pg_bot

Q77: On examination, a person has distended neck veins, absent breath sounds, hyperresonance, and a shift of the trachea. What is the management? (Q866805)

A. Bedside CXR in casualty followed by chest tube insertion

B. Wide bore needle in 2 nd ICS

C. Pericardiocentesis

D. Pleurodesis with doxycycline

See Answer in Part B → Q77

@Neet_pg_bot

Q78: A 5-year-old child presented with recurrent respiratory infections with thickened sputum. Chest X-ray showed bronchial wall thickening. He has been suffering from steatorrhea since birth. Which of the following is the first differential diagnosis? (Q858033)

A. Hyaline membrane disease

B. Cystic fibrosis

C. Alpha 1 anti-trypsin deficiency

D. Malabsorption syndrome

See Answer in Part B → Q78

@Neet_pg_bot

Q79: Which of the following is a cause of exudative pleural effusion? (Q858016)

A. Heart failure

B. Rheumatic arthritis

C. Dressler syndrome

D. Nephrotic syndrome

See Answer in Part B → Q79

@Neet_pg_bot

Q80: In which medical condition is a ground-glass appearance observed on high-resolution computed tomography (HRCT)? (Q858009)

A. Asbestosis

B. Silicosis

C. Anthracosis

D. Bagassosis

See Answer in Part B → Q80

@Neet_pg_bot

Q81: A 65-year-old chronic smoker came to the medicine outpatient department with complaints of upper chest discomfort and drooping of an eyelid. He also complained of pain radiating to the upper arm and a tingling sensation in the 4th and 5th digits of his right hand. The chest X-ray is given below. Which of the following is the most likely diagnosis? (Q855501)

A. Pancoast tumor

B. Superior vena cava obstruction

C. Upper lobe pneumonia

D. Aspergilloma

See Answer in Part B → Q81

@Neet_pg_bot

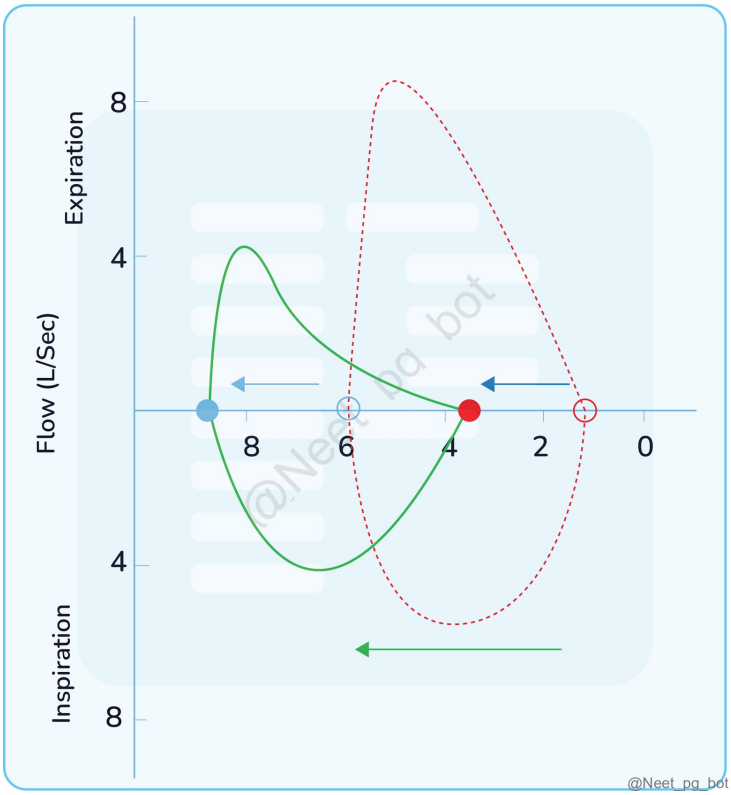
Q82: Comment on the lung disease? (Q854721)

A. Hypersensitivity pneumonitis

B. Sarcoidosis

C. Acute respiratory distress syndrome

D. Bronchiectasis



See Answer in Part B → Q82

@Neet_pg_bot

Q83: A male patient who is a known case of COPD presents to the emergency department with dyspnea. The arterial blood gas report is as follows: pH: 7.28 pCO 2 : 60 mmHg HCO 3 : 28 meq/L Which of the following is the most likely diagnosis? (Q854712)

A. Inadequately compensated respiratory acidosis

B. Fully compensated respiratory acidosis

C. Fully compensated respiratory alkalosis

D. Inadequately compensated metabolic alkalosis

See Answer in Part B → Q83

@Neet_pg_bot

Q84: A 70-year-old diabetic man presents after a fall. He is having a high fever, cough and breathing difficulty and appears confused. CXR shows lobar consolidation. Labs show elevated BUN and creatinine. Which is the most appropriate management? (Q854678)

A. Inpatient management with levofloxacin

B. Inpatient management with ceftriaxone

C. Discharge home on Amoxicillin with Clavulanic acid

D. Discharge home on Azithromycin

See Answer in Part B → Q84

@Neet_pg_bot

Q85: A 30-year-old man came with complaints of fever and cough for 3 days. On examination, creatinine is 1.5 and BUN is 45. Chest-x ray shows infiltrates in the right lung and patchy infiltrates in the left lung. A nasopharyngeal swab shows only Rhinovirus. The patient is shifted to the ICU. Which antibiotics are suitable for this patient? (Q854657)

A. Amoxicillin + Clavulanic acid

B. Azithromycin

C. Ceftriaxone + Azithromycin

D. Piptaz + Ciprofloxacin

See Answer in Part B → Q85

@Neet_pg_bot

Q86: In patients affected by COVID-19, which of the following patterns is frequently observed in chest CT scans? (Q856993)

A. Interlobular septal thickening

B. Air bronchograms

C. Ground glass opacity

D. Crazy paving pattern

See Answer in Part B → Q86

@Neet_pg_bot

Q87: A male patient with a history of chronic smoking presents with the complaint of dysphagia . Out of the following, which type of lung cancer is most likely to be found in this patient? (Q793827)

A. Squamous cell carcinoma

B. Adenocarcinoma

C. Large cell carcinoma

D. Bronchogenic carcinoma

See Answer in Part B → Q87

@Neet_pg_bot

Q88: What is the diagnosis based on the image given below ? (Q793956)

A. Pulmonary tuberculosis

B. Chronic obstructive pulmonary disease

C. Bronchial asthma

D. Bronchiectasis

See Answer in Part B → Q88

@Neet_pg_bot

Q89: A young man presents with a sudden onset of severe headache, dizziness, breathlessness, and blurring of vision while trekking on a mountain at an altitude of 5000 meters . He is unable to climb any further. Which of the following develops at high-altitude? (Q793881)

A. Metabolic alkalosis

B. Respiratory alkalosis

C. Respiratory acidosis

D. Metabolic acidosis

See Answer in Part B → Q89

@Neet_pg_bot

Q90: A patient presents with chronic complaints of a productive cough in the morning . The expectoration is yellow, foul smelling and increases on turning from left to right side. Which of the following lung diseases is likely to be present ? (Q793834)

A. Lung cancer

B. Bronchiectasis

C. Bronchial asthma

D. Pulmonary embolism

See Answer in Part B → Q90

@Neet_pg_bot

Q91: Kartagener syndrome is associated with defects in which of the following structures? (Q820676)

A. Microvilli

B. Microtubules

C. Cilia

D. Microfilaments

See Answer in Part B → Q91

@Neet_pg_bot

Q1: Relative bradycardia is seen in which of the following infections? (Q850949)

A. Brucellosis

B. Influenza

C. Streptococcal Pharyngitis

D. Tuberculosis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 28-year-old male presents with a history of fever, malaise, and abdominal discomfort for last one week. Physical examination reveals coated tongue, relative bradycardia and a hepatomegaly. NS-1 antigen is negative. What is the most likely fever pattern seen in this case? (Q850950)

A. Intermittent fever

B. Remittent fever

C. Saddle back fever

D. Sustained fever

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Quotidian fever is seen with which of the following species of Plasmodium? (Q850951)

A. Falciparum

B. Malariae

C. Ovale

D. Vivax

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old male presents with a fever of 38.5°C (101.3°F) that has persisted for three weeks. He reports significant weight loss, night sweats, and fatigue. His medical history is unremarkable. On physical examination, he has splenomegaly and cervical lymphadenopathy. Which investigation would be the most appropriate next step in this patient's management? (Q850952)

A. Chest X-ray

B. Blood culture

C. CT scan of the abdomen and pelvis

D. HIV test

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is not considered an autoinflammatory syndrome? (Q850953)

A. Familial Mediterranean fever

B. Adult-onset Still's disease

C. Rheumatoid arthritis

D. Cryopyrin-associated periodic syndromes

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 30-year-old female presents with a fever of 39°C that has persisted for the past five days. She reports severe muscle pain, nausea, and retroorbital pain. On examination, she has mild dehydration and a negative tourniquet test. Which of the following investigations would be most appropriate to confirm the diagnosis? (Q850954)

A. Hematocrit

B. NS-1 Antigen test

C. MAC ELISA for Dengue virus antibody

D. Platelet count

See Answer in Part B → Q6

@Neet_pg_bot

Q7: What is the most common neurological complication during the course of dengue fever illness? (Q850955)

A. Encephalopathy

B. Guillain-Barré Syndrome

C. Stroke

D. Encephalitis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 30-year-old farmer presents with high-grade fever, retro-orbital pain, and severe calf muscle tenderness for the past 3 days. What is the most likely diagnosis? (Q850956)

A. Dengue fever

B. Leptospirosis

C. Zika virus

D. Typhoid / Enteric fever

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Following a sudden outbreak of mystery fever in a South Indian village, several individuals from the same locality developed fever, headache, altered sensorium, and seizures. Which of the following is not true regarding this likely condition? (Q850957)

A. The disease has been linked to Pteropus species as natural reservoirs

B. The condition often presents as rapidly progressive viral encephalitis

C. Case fatality rate below 10%

D. Human-to-human transmission has been documented in prior outbreaks

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 28-year-old woman presents with fever, conjunctivitis, and a maculopapular rash after returning from a trip to Central America. Local health authorities comfirm antibodies to Zika virus infection. Which of the following is correct about this infection? (Q850958)

A. Transmitted only through infected bodily fluids.

B. Incubation period is 4 weeks

C. Complications include microcephaly and Guillain–Barré syndrome.

D. Reliable diagnosis via serology in the first week.

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 32-year-old male presents with progressive bilateral lower limb weakness over the past 10 days after recovery from zika virus infection. On examination, he has flaccid paralysis and absent deep tendon reflexes in the affected limbs. CSF analysis shows cytoalbuminological dissociation. NCV test confirms a demyelinating pattern. Which diagnostic criteria are used to diagnose this presentation? (Q850959)

A. Brighton

B. Macdonald

C. Hakim's

D. Adam and Victor

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 40-year-old HIV-positive patient presents with fever, dry cough, and progressive shortness of breath. His CD4+ count is 150 cells/mm³. Chest X-ray shows bilateral interstitial infiltrates. Which of the following is the most likely mechanism of infection in this patient? (Q850960)

A. Primary infection acquired from a contaminated water source

B. Airborne transmission from an infected individual

C. Ingestion of fungal spores from environmental reservoirs

D. Reactivation of a previously dormant infection acquired during childhood

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 45-year-old male with HIV presents with low-grade fever, nonproductive cough, and progressive shortness of breath over the past month. His HRCT shows bilateral ground-glass opacities. Which of the following is not correct about the suspected oppurtunisitic infection? (Q850961)

A. Increased Alveolar arteriolar gradient

B. Use of steroids during treatment of this oppurtunistic infection

C. Crushed ping pong ball appearance on Gomori methamine stain

D. Cultured on Sabaroud dextrose agar

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following diagnostic methods provides the highest sensitivity for confirming the presence of Pneumocystis jirovecii ? (Q850962)

A. Induced sputum and staining with gomori methamine stain

B. Sputum immunofluuroscence

C. Polymerase Chain Reaction

D. β-D-glucan assay

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 35 year old truck driver with AIDS is having CD4 count of 150 cells/ cu.mm. He has sulfa drug allergy. Which of the following drugs can be used in this patient by nebulization route for prevention of this opportunisticinfection? (Q850963)

A. Pentamidine

B. Trimethoprim and Sulfamethoxazole

C. Atovaquone

D. Clindamycin with Primaquine

See Answer in Part B → Q15

Q1: A 42-year-old HIV-positive male with a history of disseminated Mycobacterium avium complex (MAC) infection presents for a routine check-up. He is compliant with antiretroviral therapy (ART) and has a CD4+ count of 46 cells/μL. Which prophylactic therapy is recommended in this patient to prevent Mycobacterium avium complex? (Q850974)

A. Monotherapy with azithromycin

B. Trimethoprim-sulfamethoxazole

C. Clarithromycin + ethambutol

D. Isoniazid + pyridoxine

See Answer in Part B → Q1

@Neet_pg_bot

Q2: An HIV positive patient presented with a whitish plaque in the mouth and esophagus as shown in the image below. Most likely diagnosis is: (Q882169)

A. Oral leukoplokia

B. Hairy cell leukemia

C. Oral candidiasis

D. Oral cancer

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55-year-old man with triple vessel disease presents with a persistent cough, fever, and shortness of breath. On admission he has respiratory rate 26 /minute and an sp02 92% on room air. His RT-PCR for SARS-COV2 is positive. What is the preferred oxygen delivery device for this patient? (Q850983)

A. Non invasive ventilation with tight fitting face mask

B. Nasal cannula and flow rate of 6L/min

C. CPAP mask

D. Non-rebreathing face mask

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 60-year-old woman with obesity and hypertension presents with a cough, fever and shortness of breath for the past four days. Her SpO2 is 90% on room air and her respiratory rate is 34/min. Her RT-PCR for SARS COV2 is positive. Which of the following is correct about laboratory findings seen in this case? (Q850982)

A. Reduced D-dimer

B. Reduced IL-6

C. Elevated platelet count

D. Elevated NLR

See Answer in Part B → Q4

@Neet_pg_bot

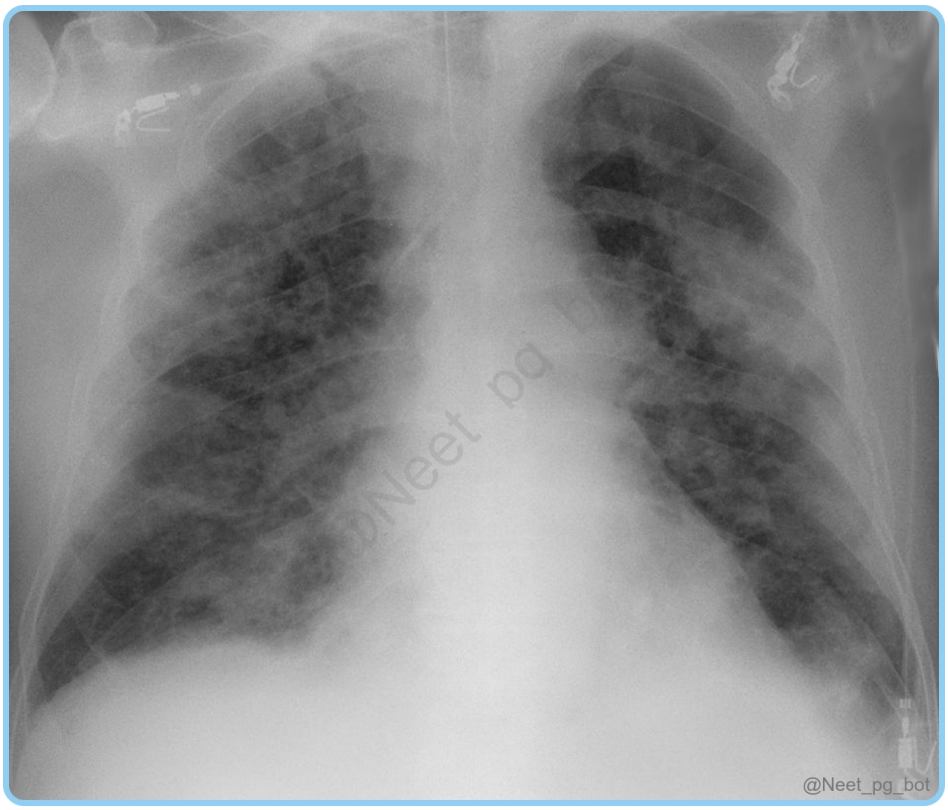
Q5: A 55-year-old man with a history of asthma presents with a persistent cough, fever, and shortness of breath that started three days ago after attending a family gathering. His examination shows a SpO 2 of 92% on room air and a respiratory rate of 26 breaths per minute, with the accompanying X-ray. What is the investigation of choice for this condition? (Q850981)

A. HRCT chest

B. C-reactive protein

C. RT-PCR

D. Rapid antigen test



See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 35-year-old HIV-positive man with a CD4 count of 80 cells/mm³ presents with chronic watery diarrhea and significant weight loss. Stool examination reveals oval-shaped oocysts measuring 20–30 microns, which appear pink to red on modified Kinyoun stain, showing a characteristic sporoblast. Which of the following is the best treatment? (Q850980)

A. Metronidazole

B. Nitazoxanide

C. TMP-SMX

D. Albendazole

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 36-year-old man with AIDS with CD4 count of 74 cells/μL presents with acute onset of odynophagia and retrosternal chest pain. Upper GI endoscopy reveals well-circumscribed, "volcano-like" ulcers in the mid-esophagus. Which of the following is the most likely diagnosis? (Q850979)

A. Cytomegalovirus esophagitis

B. Herpes simplex virus esophagitis

C. Candida esophagitis

D. ART induced esophagitis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A medical intern sustains a needle-stick injury from a known HIV-positive patient. What is the ideal time frame to initiate post-exposure prophylaxis for maximum efficacy? (Q850978)

A. Within 2 hours

B. Within 24 hours

C. Within 48 hours

D. After 72 hours

See Answer in Part B → Q8

@Neet_pg_bot

Q9: You have started fluconazole for secondary prevention of cryptococcus neoformans meningitis. Which of the following is correct statement about it? (Q850977)

A. Continue till CD4 count > 100 cells for one year and HIV RNA suppressed for >3 months

B. Continue till CD4 count > 200 cells for one year and HIV RNA suppressed for > 3 months

C. Continue till CD4 count < 200 cells for one year and HIV RNA suppressed for < 3 months

D. Continue till CD4 count > 200 cells and HIV RNA < 5000 copies/ ml

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following drugs is effective against both HIV and hepatitis B? (Q850976)

A. Efavirenz

B. Tenofovir

C. Abacavir

D. Ritonavir

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 38 -year-old man is newly diagnosed with HIV. He is asymptomatic with a CD4 count of 650 cells/mm^3. Based on WHO recommendations, which of the following combinations would be best suited for treatment of this case? (Q850975)

A. Zidovudine + Lamivudine + Raltegravir

B. Abacavir + Lamivudine + Lopinavir

C. Tenofovir + Lamivudine + Efavirenz

D. Tenofovir + Lamivudine + Dolutegravir

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 55-year-old immunocompromised patient presents with fever, cough, and respiratory distress. CT chest is perfomed. Which of the following investigations would be most specific to confirm the diagnosis? (Q850930)

A. Lung histology shows fungal septate hyphae with branching at 45 degrees

B. BACTEC MGIT 960

C. Galactomannan antigen on sputum

D. Beta 1,3 D- glucan test

See Answer in Part B → Q12

@Neet_pg_bot

Q13: AIDS Patient is having a CD4 count of 200 cells/cu.mm. He has had fever, cough and shortness of breath for the past week. Auscultation reveals scattered bronchial breathing in the left infra-axillary and infrascapular areas. CXR reveals air bronchograms in the left lower lobe. Which opportunistic infection is present in this patient? (Q850973)

A. Pneumococcus

B. Mycobacterium avium intracellulare

C. Mycobacterium tuberculosis

D. Pneumocystis jirovecii

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A truck driver with AIDS is brought in with fever and altered mental status. His family reports a week-long history of worsening headache, fever, projectile vomiting, and confusion. Neuroimaging shows a soapy bubble appearance, and CSF shows 50 lymphocytes/cu.mm with low sugar and a mild increase in protein. Which of the following is the most accurate test for confirmation of the diagnosis of this condition? (Q850972)

A. CSF Lateral flow assay

B. CSF gram staining

C. CSF India ink preparation

D. CSF staining with mucicarmine

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 3-week-old infant born to an HIV-positive mother is brought to OPD. The baby was delivered vaginally and was not breastfed. The mother has been on antiretroviral therapy throughout pregnancy. Which of the following is the most appropriate test to diagnose HIV infection in this neonate? (Q850971)

A. PCR HIV RNA

B. PCR HIV DNA

C. Serum ELISA for HIV

D. p24 antigen

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 28-year-old lab technician presents 10 days after sustaining a needle-stick injury while drawing blood from an HIV-positive patient. He did not receive post-exposure prophylaxis He is currently asymptomatic and anxious about possible seroconversion. Which of the following test will help in early detection of possible transmission of infection? (Q850970)

A. HIV PCR RNA

B. Western Blot

C. HIV PCR DNA

D. ELISA for HIV-1 and HIV-2

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which is correct about definiton of AIDS? (Q850969)

A. ELISA positive for HIV plus any WHO clinical stage 4 condition that includes AIDS-defining illnesses

B. ELISA positive for HIV plus CD4 count less than 350 cells /cu.mm

C. ELISA positive for HIV plus CD4 count less than 500 cells /cu.mm

D. ELISA positive for HIV plus persistent generalized lymphadenopathy involving > 2 groups

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 53-year-old man visits the clinic with recurring respiratory infections and oral candidiasis. Lab tests show a CD4 count of 150 cells/mm³, raising suspicion for HIV. Which structure allows the HIV virus to attach to CD4 cells initially? (Q850934)

A. CCR5

B. gp41

C. p17

D. gp120

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 31-year-old woman diagnosed with HIV is in her third trimester of pregnancy. Which of the following statements is not true regarding vertical transmission of HIV? (Q850933)

A. ART greatly lowers the risk of vertical transmission.

B. Transmission can occur through breast milk.

C. Prolonged membrane rupture increases transmission risk.

D. Viral transmission does not occur in the first trimester.

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 30-year-old asthmatic patient presents with worsening respiratory symptoms and is diagnosed with Allergic Bronchopulmonary Aspergillosis . Which of the following is the most appropriate initial treatment strategy? (Q850932)

A. Voriconazole

B. Itraconazole with low-dose corticosteroids

C. Fluconazole with corticosteroids

D. Posaconazole

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following findings is not seen with allergic bronchopulmonary aspergillosis? (Q850931)

A. Elevated total serum IgE

B. Central bronchiectasis on HRCT

C. Presence of hyper-attenuated mucus on imaging

D. Halo sign on HRCT chest

See Answer in Part B → Q21

@Neet_pg_bot

Q1: The blood investigation of a patient is given below. What is the probable diagnosis? HBsAg- Nonreactive HBeAg- Nonreactive IgG anti-HbcAg – Reactive IgM anti-HbcAg – Nonreactive (Q855717)

A. Acute hepatitis B

B. Chronic hepatitis B

C. Remote infection of hepatitis B

D. Core window period

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A patient arrives at the hospital with symptoms of fever and chills. A fever profile test is conducted, which rules out malaria and dengue as the cause. However, the rK39 test comes back positive. What is the preferred treatment for this condition? (Q855608)

A. Amphotericin B

B. Griseofulvin

C. Dapsone

D. Hydroxychloroquine

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A patient, who is a known case of HIV with a CD4 count of 200 cells/cu.mm, presents with 5 days of cough and high-grade fever without chills and rigors. There is no history of diarrhoea, vomiting, or nuchal rigidity. The chest x-ray is normal. What treatment will you give? (Q855704)

A. Amoxicillin-clavulanic acid + Azithromycin

B. Amphotericin B

C. Co-trimoxazole only

D. Antitubercular treatment

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is NOT a potential complication in a 40-year-old man who presents with a 15-day history of fever and a 1-day history of altered sensorium and is diagnosed with Plasmodium falciparum through a rapid diagnostic test? (Q855326)

A. Blood glucose <40 mg/dL

B. Arterial pH >7.2

C. Serum creatinine -5.2

D. Unarousable coma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 25-year-old immunocompromised man presents with fever, headache, and altered sensorium. Examination shows neck rigidity and positive Kernig's sign. CSF reveals lymphocytic predominance, high protein, low glucose, and encapsulated yeast cells on India ink staining. What is the most appropriate treatment regimen for this patient? (Q855355)

A. Piperacillin + Tazobactam

B. Vancomycin + Ceftriaxone

C. Amphotericin B + Flucytosine

D. Ceftriaxone + Ampicillin

See Answer in Part B → Q5

@Neet_pg_bot

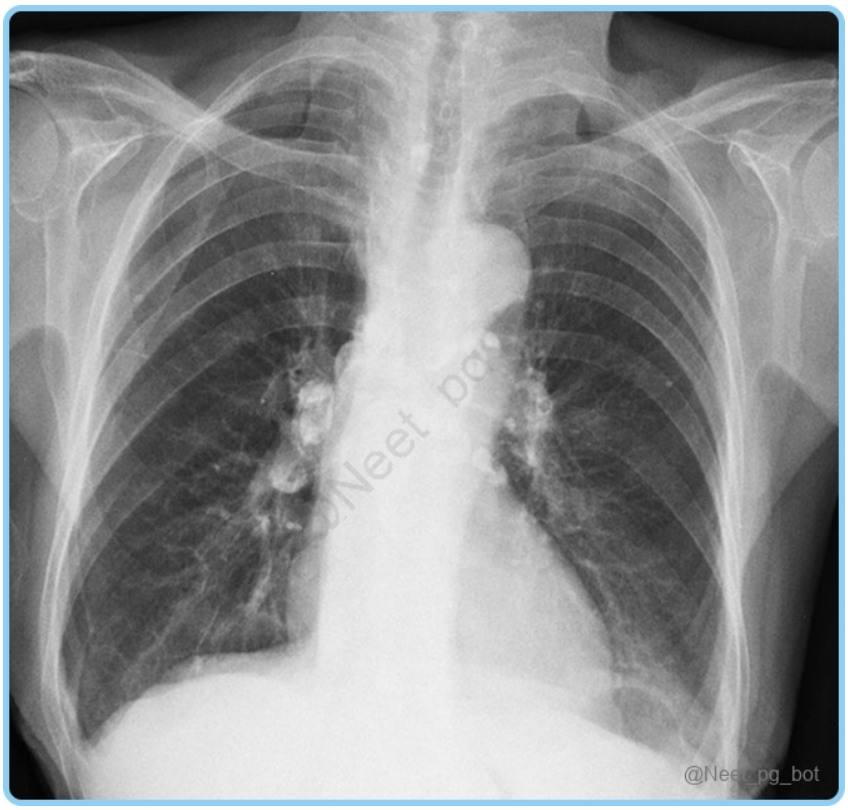
Q6: A patient presents with cough, cold, fever and malaise associated with weight loss and ascites. A radiograph of the chest is shown below. Ascitic fluid analysis showed elevated adenosine deaminase. Which of the following is the next step in management? (Q855357)

A. Biopsy

B. Start ATT after laparotomy stricture removal

C. Start anti-tubercular therapy

D. Symptomatic management



See Answer in Part B → Q6

@Neet_pg_bot

Q7: What is the association of Rhino-cerebral Mucor mycosis? (Q857049)

A. Diabetic ketoacidosis

B. Pregnancy

C. Antibiotics

D. Inhaled steroids

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 7-year-old boy presents with fever, painful swelling in front of both ears, and difficulty chewing or talking. On examination, he also complains of mild testicular

pain. What is the most likely diagnosis? (Q857613)

A. Cervical tuberculosis

B. Diphtheria

C. Mumps

D. Lymphoma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A newly diagnosed HIV patient presented with fever, cough and haemoptysis. His sputum sample showed acid-fast bacilli. What is the appropriate management for this patient? (Q855702)

A. Start ART if CD4<200

B. Start ART and then ATT after 2 weeks

C. Start ATT and then ART after 2 weeks

D. Start ATT and ART simultaneously

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A patient presents with fever and altered sensorium. Peripheral smear shows multiple ring stages. Best treatment is? (Q866815)

A. Primaquine

B. Quinine

C. Chloroquine

D. Artesunate

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Identify the correct ‘organism-drug to which it is intrinsically resistant’ pair: (Q856588)

A. Aspergillus niger - Voriconazole

B. Aspergillus fumigatus - Micafungin

C. Candida albicans - Amphotericin B

D. Candida Krusei - Fluconazole

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 23-year-old medical student with fever had developed epistaxis which had resolved on its own and on evaluation his platelet counts are 14,000/µL and BP is 110/70 mmHg and there is a 28% rise in haematocrit. Then he has been afebrile for the last 24 hours now, what should be the next steps of management of this patient? Give 4 units of platelets Give plenty of oral fluids Give IV fluids Keep under observation Discharge the patient (Q856966)

A. 1 and 2

B. 1,2 and 4

C. 2,3 and 4

D. 2 and 5

See Answer in Part B → Q12

@Neet_pg_bot

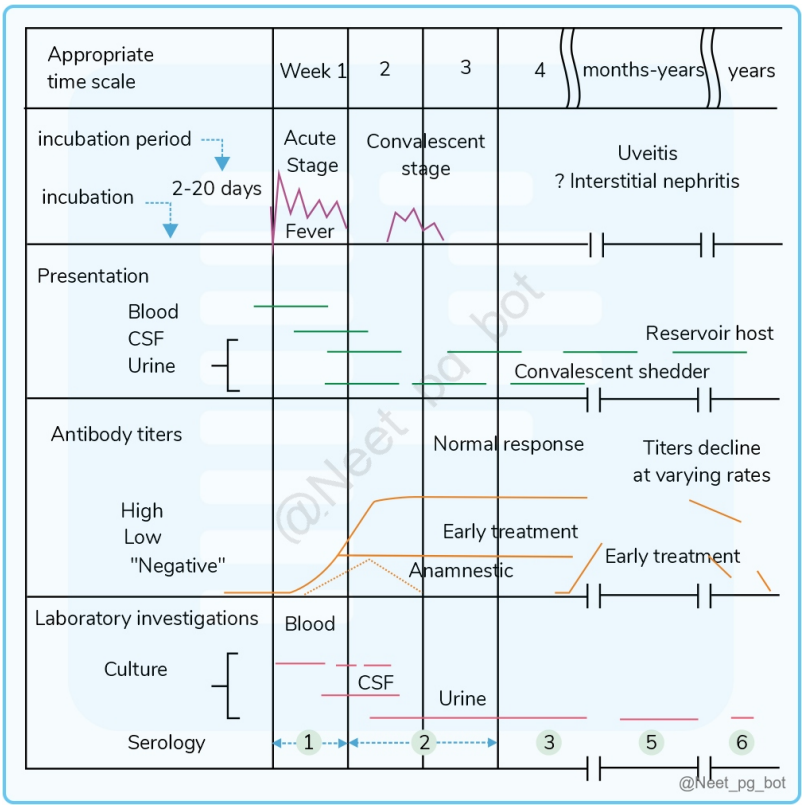
Q13: Following is a graphic representation of a patient admitted in the medicine ward with a fever. What could be the possible diagnosis? (Q856270)

A. Cerebral malaria

B. Brucellosis

C. Leptospirosis

D. Typhoid



See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following is false about Mycoplasma pneumoniae? (Q856293)

A. Responds well to Amoxiclav

B. Antibodies are useful in diagnosis

C. Chest X-ray shows bilateral infiltrates

D. Can be cultured in a cell-free medium

See Answer in Part B → Q14

@Neet_pg_bot

Q15: An HIV-positive patient presents with the following finding. What is the diagnosis & WHO clinical stage of HIV? (Q859754)

A. Oral candidiasis & WHO stage 2

B. Oral hairy leukoplakia & WHO Stage 3

C. Oral candidiasis & WHO stage 3

D. Oral hairy leukoplakia & WHO stage 2

See Answer in Part B → Q15

@Neet_pg_bot

Q16: As seen below, a 49-year-old man presents with flu-like symptoms and a palmoplantar rash. On examination, he has epitrochlear lymphadenopathy. Which of the following is the likely diagnosis? (Q859759)

A. Primary syphilis

B. Secondary syphilis

C. Pyoderma gangrenosum

D. Steven Johnson syndrome

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A patient diagnosed to be retro-positive was started on highly active antiretroviral therapy (HAART). Which of the following can be used to monitor treatment efficacy? (Q855853)

A. CD4+ T cell count

B. Viral load

C. p24 antigen

D. Viral serotype

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A patient presents with a fever for 4 days. There are no bleeding manifestations, and vitals are stable. Workup shows Hb = 9 g/dl, platelet count - 20,000/mm³. What is the next appropriate step in management in 1st hour PCM Antibiotic Platelets transfusion Steroids (Q879177)

A. 1,2,3,4

B. 1,2,3

C. 1,2

D. 1

See Answer in Part B → Q18

@Neet_pg_bot

Q19: What immunological abnormality is observed due to the absence of CD40 in B cells? (Q857281)

A. Total lack of NK cells

B. Lack of CD8-mediated cytotoxicity

C. Decreased IgG and increase in IgM

D. Inability of neutrophils to act against infections

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A HIV-positive patient presents with chronic diarrhoea for 4 weeks. Stool microscopy shows oval/ elliptical cysts measuring 16 X 20 µm. Diagnosis is? (Q866800)

A. Cryptosporidium

B. Cryptococcus

C. Cyclospora

D. Cystoisospora

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 35-year-old farmer presents with intermittent fever, profuse sweating, fatigue, and arthralgia for 3 weeks. He reports handling livestock and consuming unpasteurized dairy products. Mild hepatosplenomegaly is noted. Blood cultures reveal Brucella species. Which of the following is the most appropriate antimicrobial therapy? (Q866824)

A. Doxycycline alone

B. Doxycycline plus rifampicin

C. Doxycycline with azithromycin

D. Doxycycline plus ceftriaxone

See Answer in Part B → Q21

@Neet_pg_bot

Q22: 30 year old man presents with severe headache, fever for one day with altered sensorium. Nuchal rigidity is absent. Guarded LP was done and CSF shows 50 cells with 20% neutrophils and 80% lymphocytes with CSF sugar of 70 mg and RBS 100 mg/dl with protein= 90 mg/dl. Diagnosis is? (Q866829)

A. Viral encephalitis

B. Acute bacterial meningitis

C. Tubercular Meningitis

D. Viral meningitis

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A patient underwent cardiac surgery and was admitted to the ICU. He later developed ventilator-associated pneumonia (VAP) and was started on empirical antibiotics. A few hours later, the patient developed acute kidney injury (AKI). Serum procalcitonin was sent. Which of the following statements regarding procalcitonin is correct? (Q865372)

A. It helps in determining the duration of antibiotic therapy

B. It helps in identifying which empirical antibiotics to be given

C. It can be used to confirm source of infection

D. It is used to differentiate bacterial from fungal cause

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 38-year-old male presents with a one-week history of fever, headache, retro-orbital pain, and myalgia. Skin examination reveals multiple purpura and petechiae on the left shoulder, trunk, and legs. Similar cases have been reported linked to increased incidence of mosquito breeding. What is the most common neurological complication associated with this condition? (Q852755)

A. Encephalopathy

B. Guillain-Barré Syndrome

C. Stroke

D. Encephalitis

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A patient has pleural fluid with an LDH level greater than 0.6 times the serum LDH and protein greater than 0.5 times the serum protein. What is the most likely diagnosis? (Q844266)

A. Tuberculosis (TB)

B. Heart failure

C. Hepatic failure

D. Renal failure

See Answer in Part B → Q25

@Neet_pg_bot

Q26: What is the investigation of choice for detecting enteric fever in the first week? (Q860128)

A. Blood culture

B. Urine culture

C. Stool culture

D. Antibody detection

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Which of the microorganisms listed below will exhibit intrinsic resistance to meropenem and aminoglycosides, but have sensitivity to cotrimoxazole? (Q857273)

A. Burkholderia cepacia

B. Acinetobacter

C. Pseudomonas

D. Stenotrophomonas

See Answer in Part B → Q27

@Neet_pg_bot

Q28: In a patient with HIV, the incorrect statement regarding prophylaxis for various organisms is: (PCP-Pneumocystis pneumonia, MAC-Mycobacterium avium complex) (Q854659)

A. Prophylaxis for PCP is indicated when CD4 count is <200 cells/µL

B. Stop prophylaxis for Coccidioides if CD4 count is >250 cells/µL for 6 months

C. Prophylaxis for MAC is indicated when CD4 count is <50 cells /µL

D. Prophylaxis for cryptococcus is indicated when the CD4 count is >150 cells/µL

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 30-year-old HIV-positive man presents with neck rigidity and papilledema. His CSF sample showed a capsulated organism positive for India ink staining. Which of the following statements is true? (Q854680)

A. Intracranial pressure remains normal

B. Delay antiretroviral therapy by 4-6 weeks after the initiation of antifungal treatment

C. Initiate treatment with oral fluconazole

D. Brain imaging shows changes in > 80 % of patients

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 30-year-old farmer from Tamil Nadu presented with fever, myalgia, headache and cough. On physical examination, a lesion is seen on the chest. Lung auscultation shows extensive bilateral rales. Blood investigation showed positive IgM for scrub

typhus. What would be the appropriate treatment? (Q854699)

A. Doxycycline

B. Doxycycline with Ceftriaxone

C. Ceftriaxone with Azithromycin

D. Doxycycline with Azithromycin

See Answer in Part B → Q30

@Neet_pg_bot

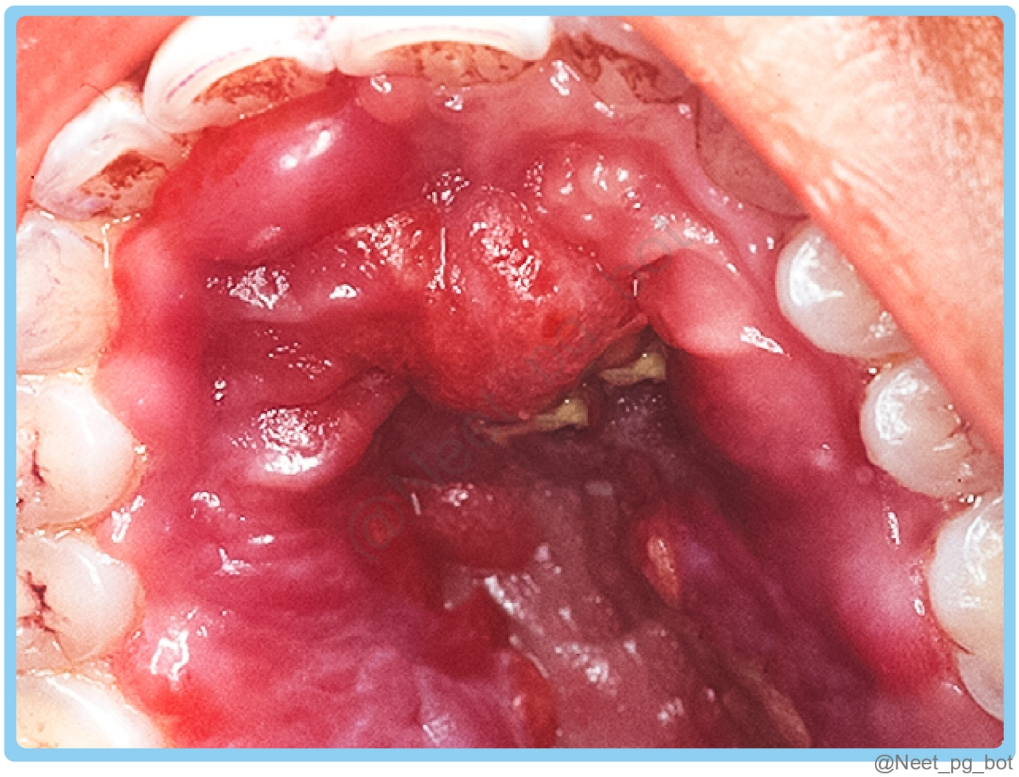
Q31: A 50-year-old HIV patient presented with a painful lesion, as shown in the image. What is the most likely diagnosis? (Q855448)

A. Basal cell carcinoma

B. Kaposi sarcoma

C. Malignant melanoma

D. Squamous cell carcinoma



See Answer in Part B → Q31

@Neet_pg_bot

Q32: A 45-year-old HIV-positive male came with complaints of persistent cough and weight loss. He has skin lesions that appear as umbilicated papules and nodules predominantly on the face, trunk, and upper extremities. Chest x-ray showed multiple bilateral nodular infiltrates. His sputum CBNAAT for tuberculosis was negative and he has a low CD4 count. What is the probable diagnosis? (Q855461)

A. HIV with disseminated histoplasmosis

B. HIV with disseminated cryptococcosis

C. HIV with molluscum contagiosum

D. HIV with tuberculosis

See Answer in Part B → Q32

@Neet_pg_bot

Q33: An HIV-positive man presents with a high-grade fever. Examination reveals a positive Kernig's sign. CSF shows reduced glucose, increased protein, and increased leukocytes. A diagnosis of cryptococcal meningitis is made. What is the appropriate management for this patient? (Q858018)

A. Vancomycin

B. High dose fluconazole with flucytosine

C. Voriconazole

D. Liposomal amphotericin B

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A 70-year-old patient with a smoking history presents with high-grade fever, cough, confusion, and diarrhea. Chest X-ray shows bilateral infiltrates in bilateral lower lung fields. On sputum gram stain, no organisms were detected. Laboratory results reveal Na: 126mEq/L, AST:62, ALT:56, RBS:112 mg/dl, serum bilirubin of 0.8mg%, and a positive HIV test. Which of the following organisms is responsible? (Q858022)

A. Streptococcus

B. Legionella

C. Pneumocystis jiroveci

D. Klebsiella

See Answer in Part B → Q34

@Neet_pg_bot

Q35: A 65-year-old male presented with unexplained fever and prolonged respiratory distress despite appropriate treatment. A diagnosis of cryptic tuberculosis was made. Which of the following is the correct statement related to this condition? (Q858030)

A. Positive skin tuberculin test and negative chest X-ray

B. Positive skin tuberculin test and positive chest X-ray

C. Negative skin tuberculin test and negative chest X-ray

D. Negative skin tuberculin test and positive chest X-ray

See Answer in Part B → Q35

@Neet_pg_bot

Q36: What is the drug of choice for Legionnaire's disease? (Q793967)

A. Vancomycin

B. Azithromycin

C. Streptomycin

D. Erythromycin

See Answer in Part B → Q36

Q1: A 52-year-old male presents with worsening shortness of breath and fatigue. An echocardiogram shows left ventricular dilation and significant aortic regurgitation. Which of the following are the possible conditions causing Aortic regurgitation? Ankylosing Spondylitis Aortic Dissection Marfan's Syndrome Syphilis (Q850418)

A. 1,2,3

B. 2,3,4

C. 1,3,4

D. 1,2,3,4

Correct Answer: D. 1,2,3,4

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: All of the above are potential causes of aortic regurgitation but through different mechanisms. Aortic Regurgitation Aetiology Conditions affecting the valve structure and its functions Conditions causing valve root dilatation Bicuspid Aortic valve (Congenital) Infective Endocarditis Rheumatic fever Myxomatous prolapse of the valve Scarring of the valve by Syphilis (statement 4) Ankylosing spondylitis (statement 1) Radiation Trauma Aortic Dissection (statement 2) Aortitis (Takayasu arteritis or GCA) Hypertension Marfan syndrome (statement 3) Medial Degeneration Nonsyndromic familial aneurysm Pathophysiology Clinical symptoms Usually, it starts appearing only after 10 to 15 years. Symptoms specific to AR : Palpitations (more in the supine position) Head pounding sensation Other symptoms: Paroxysmal Nocturnal dyspnea(sometimes the early one to appear) Angina on rest or exertion & breathlessness on exertion Orthopnea and diaphoresis Peripheral edema

@Neet_pg_bot

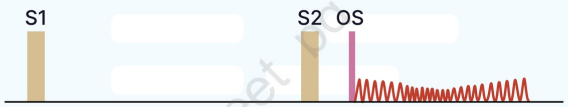
Q2: Match the following murmurs with the respective conditions. S.No Murmur Condition 1) a) Mitral Stenosis 2) b) Aortic Stenosis 3) c) Mitral Regurgitation 4) d) Aortic Regurgitation (Q850444)

A. 1-a, 2-b, 3-c, 4-d

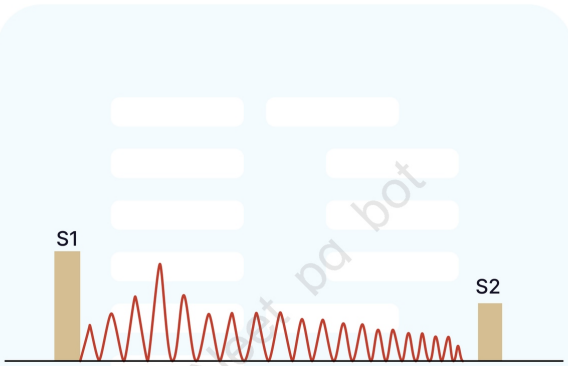
B. 1-c, 2-a, 3-d, 4-b

C. 1-a, 2-c, 3-b, 4-d

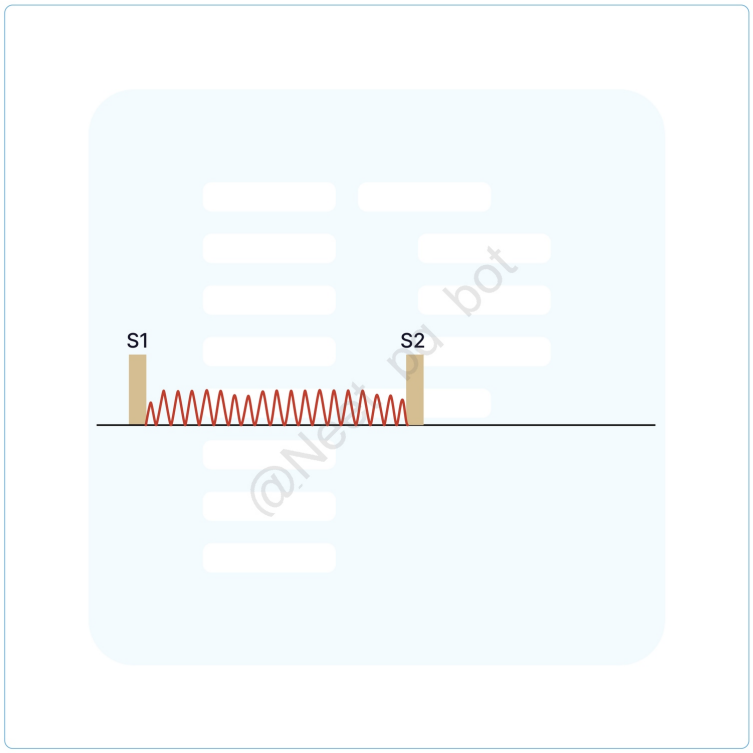
D. 1-d, 2-b, 3-c, 4-a



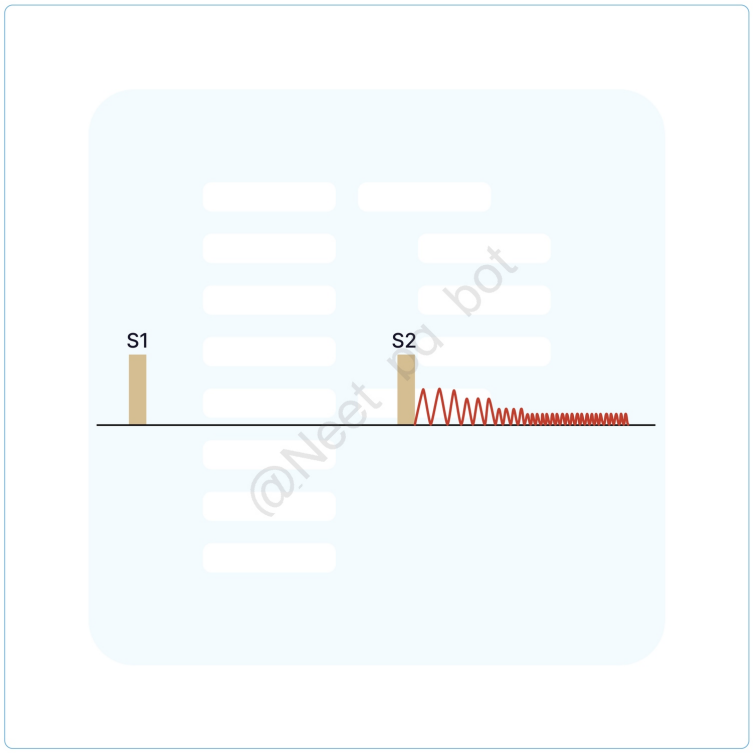
@Neet_pg_bot



@Neet_pg_bot



@Neet_pg_bot



@Neet_pg_bot

Correct Answer: A. 1-a, 2-b, 3-c, 4-d

Explanation: Aortic Stenosis: Crescendo-decrescendo ejection murmur Mitral/Tricuspid Regurgitation: Holosystolic, high-pitched “blowing” murmur Aortic Regurgitation: Early diastolic, decrescendo, high-pitched “blowing” murmur Mitral Stenosis: Delayed rumbling mid-to-late diastolic murmur with opening snap Mitral valve prolapse: Late crescendo murmur with mid systolic click (MC) that occurs after carotid pulse Ventricular septal defect: Holosystolic, harsh-sounding murmur

Harrison's Principles of Internal Medicine, 22nd Edition, Page 283, 286-289. Davidson’s Principles and Practice of Medicine, 24th Edition, Page 460

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 25 year old woman diagnosed with scleroderma presents with exertional dyspnea. You auscultate a high-pitched, decrescendo diastolic murmur at the second left intercostal space, radiating along the left sternal border that increases with inspiration. Which of the following is correct about this case? (Q850440)

A. Graham Steell murmur

B. Austin Flint murmur

C. Carey-Coombs murmur

D. Gibson’s murmur

Correct Answer: A. Graham Steell murmur

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This clinical scenario indicates a Graham steel murmur. Graham Steel Murmur Features: High-pitched, decrescendo diastolic murmur is best heard at the second left intercostal space and radiates along the left sternal border. Occurs due to pulmonary regurgitation due to pulmonary artery hypertension . It can become louder with inspiration Causes of pulmonary regurgitation: Pulmonary artery hypertension Severe PAH - annular dilatation of pulmonic valve Tetralogy of Fallot repair Over correction of sub-pulmonic stenosis Post balloon valvotomy Over correction of pulmonic stenosis Marfan syndrome Fibrillin gene defect on chromosome 15 Austin Flint Murmur (Option B): Low-pitched mid-to-late diastolic murmur from severe aortic regurgitation. Carey-Coombs Murmur (Option C): Mid-diastolic murmur of acute rheumatic fever due to inflamed mitral valve. Gibson murmur (Option D): Continuous machine-like murmur of PDA , not a diastolic murmur.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2049.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 65-year-old male presents to the clinic with complaints of left arm pain and intermittent dizziness. O/E, you find a notable difference in blood pressure readings: 150/90 mmHg in the right arm and 100/60 mmHg in the left arm. Which condition is least likely to cause this variation? (Q850438)

A. Coarctation of the aorta

B. Aortic dissection

C. Supravalvular aortic stenosis

D. Takayasu arteritis

Correct Answer: C. Supravalvular aortic stenosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Supravalvular aortic stenosis is at sinotubular junction , meaning just before the aortic arch branches. Hence blood supply to both right brachiocephalic trunk and left common carotid artery will be reduced equally. Supravalvular aortic stenosis occurs above the aortic valve and affects blood flow from the root , not the branches. It does NOT typically cause a large difference between right and left arm blood pressures , because both subclavian arteries receive blood after the narrowed segment without asymmetrical involvement. Coarctation of the Aorta (CoA) (Option A) typically causes lower blood pressure in the lower extremities compared to the upper extremities, but can also lead to differences between arms due to collateral circulation. Aortic Dissection (Option

B) can cause differences in blood pressure between arms if the dissection extends into the subclavian arteries or affects the branches that supply the arms. Takayasu Arteritis (Option D) is an inflammatory condition that often affects the aorta and its branches and may cause stenosis or occlusion leading to differences in blood pressure between the arms.

@Neet_pg_bot

Q5: Match the following cardiac valvular disorders with their specific murmur type: Valvular defect Murmur 1. Aortic stenosis a. Pansystolic murmur increasing with inspiration 2. Mitral regurgitation b. Mid-diastolic rumble with opening snap 3. Mitral stenosis c. Harsh systolic murmur radiating to the carotids 4. Tricuspid regurgitation d. Holosystolic murmur radiating to the axilla (Q850436)

A. 1-b, 2-a, 3-d, 4-c

B. 1-c, 2-b, 3-a, 4-d

C. 1-c, 2-d, 3-b, 4-a

D. 1-d, 2-a, 3-c, 4-b

Correct Answer: C. 1-c, 2-d, 3-b, 4-a

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Valvular disease Type of murmur Mitral regurgitation Holosystolic murmur radiating to the axilla. Mitral stenosis Mid-diastolic rumble with an opening snap. Tricuspid stenosis Mid-diastolic murmur Tricuspid regurgitation Blowing holosystolic murmur Aortic regurgitation Decrescendo diastolic murmur Aortic stenosis Crescendo-decrescendo ejection murmur . Pulmonary regurgitation End–diastolic murmur (Graham Steel murmur) Pulmonary stenosis Systolic ejection murmur

@Neet_pg_bot

Q6: A 6-year-old girl with a history of Tetralogy of Fallot repair 12 months ago presents with abdominal swelling and pedal oedema. Cardiac auscultation reveals an early diastolic murmur, and ECG shows right ventricular and atrial enlargement. Considering the suspicion of pulmonary regurgitation, which investigation is most appropriate for further evaluation? (Q850433)

A. Transthoracic echocardiography

B. Cardiac magnetic resonance imaging

C. Transesophageal echocardiography

D. Cardiac catheterisation

Correct Answer: B. Cardiac magnetic resonance imaging

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Cardiac MRI is the investigation of choice to diagnose pulmonary regurgitation , especially in patients with repaired congenital heart defects , as it provides more anatomical details and helps precisely access the Right ventricular volume and function. PULMONARY REGURGITATION Investigations Chest X-ray: Enlarged right atrium and ventricular shadow Cardiac MRI: Investigation of choice, especially in patients with repaired congenital heart defects. Echocardiography (transthoracic): It helps assess pulmonary valve morphology and the direction of blood flow. (Option A and C) Cardiac catheterisation is not usually done but can be done during transcatheter pulmonary valve procedures. (Option D) In a patient with pulmonary regurgitation, the MRI specifically identifies: Regurgitant Fraction (RF): It directly measures the volume of blood leaking back into the right ventricle (RV). An RF >30-40% is typically considered severe. RV Volumes and Function: It is the most accurate way to measure Right Ventricular End-Diastolic Volume (RVEDV) and End-Systolic Volume (RVESV) . This helps clinicians decide if the RV is becoming dangerously dilated. Flow Quantification: Using "phase-contrast" imaging, it calculates the net forward flow versus the backward flow across the pulmonary valve. Myocardial Fibrosis: Through Late Gadolinium Enhancement (LGE), MRI can identify scarring in the RV muscle, which is a predictor of arrhythmias and poor outcomes.

@Neet_pg_bot

Q7: A 10-year-old girl presents with exercise intolerance and occasional chest pain. Examination reveals a systolic ejection murmur at the left upper sternal border and

elevated jugular venous pressure. An echocardiogram shows a peak systolic gradient of 70 mmHg across the pulmonary valve, raising suspicion for pulmonary valve stenosis. Which of the following set of statements is true regarding this condition? Pulmonic stenosis is always congenital. Dysplastic valves leading to pulmonary stenosis are seen in Noonan syndrome. Severe PS is defined by peak systolic gradient across the PV>64 mmHg Percutaneous balloon valvuloplasty is indicated for all patients. Pulmonic stenosis usually leads to right ventricular hypertrophy. (Q850431)

A. 2 and 5

B. 3 and 4

C. 2,3 and 5

D. 1,2 and 5

Correct Answer: C. 2,3 and 5

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Pulmonary stenosis can involve dysplastic valves in Noonan syndrome. It is considered severe when the peak systolic gradient exceeds 64 mmHg and typically leads to right ventricular hypertrophy due to pressure overload. PULMONARY STENOSIS Aetiology It is essentially a congenital disease, but it may be acquired (Statement 1 ruled out) Noonan syndrome (dysplastic pulmonary valve) (Statement 2) Tetralogy of Fallot Carcinoids Bulky vegetation or tumours Pathophysiology Pulmonary stenosis obstructs blood flow from the right ventricle, resulting in increased chamber pressure and subsequent right ventricular hypertrophy. (Statement 5) Right ventricular dysfunction occurs early and at lower pressures due to its reduced adaptability to hemodynamic burden compared to the left ventricle. Severity Defined by the systolic pressure gradient between the RV and PA Severe: Peak systolic gradient >64 mm hg (Statement 3) Moderate: Peak systolic gradient 36-64 mm hg Mild: Peak systolic gradient <36 hh mg Management Medical: Diuretics for symptoms of right-sided heart failure Surgical: Percutaneous pulmonary balloon valvuloplasty (Statement 4 ruled out) is done when Symptomatic patients with moderate to severe PS Asymptomatic patients with peak gradient >64 mmHg or mean gradient > 35 mmHg.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2063.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 75-year-old male with a history of long-standing hypertension and atrial fibrillation presents with progressive fatigue & bilateral leg swelling. O/E, the patient

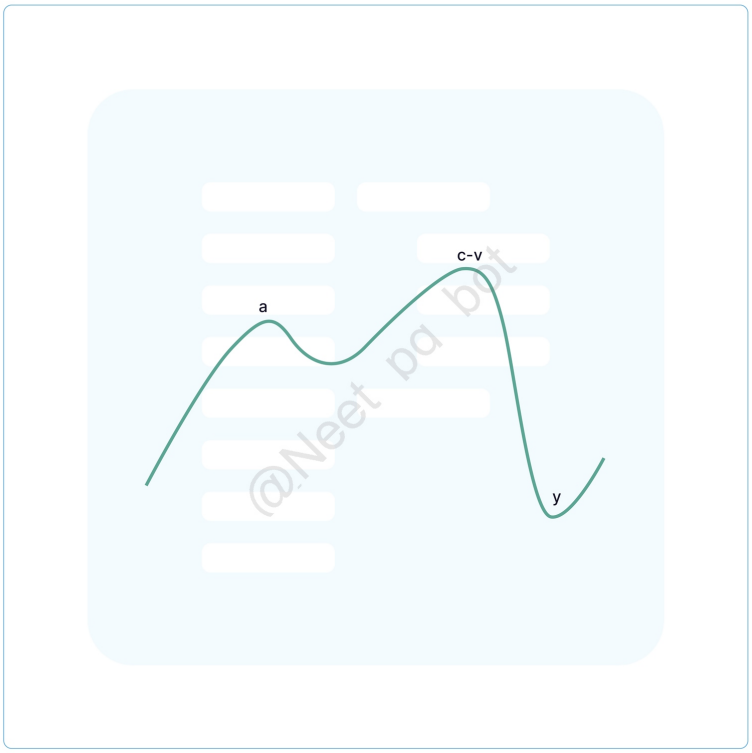
has distended neck veins with the following waveform with a blowing holosystolic murmur that increases with inspiration and radiating to epigastrium. What is the most likely diagnosis? (Q850429)

A. Pulmonary hypertension

B. Tricuspid regurgitation

C. Pulmonary stenosis

D. Mitral regurgitation



Correct Answer: B. Tricuspid regurgitation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This is likely tricuspid regurgitation , as the patient presents with jugular venous distension (prominent C-V waves, rapid Y descent) , ascites, and hepatomegaly. The characteristic finding is a blowing holosystolic murmur at the lower left sternal border, which increases with inspiration. Carvallo’s Sign): The murmur intensifies with inspiration . This occurs because the drop in intrathoracic pressure increases venous return to the right heart, increasing the regurgitant volume. Pulmonary hypertension (Option A): While pulmonary hypertension can eventually lead to right-sided heart failure and secondary TR, it has distinct clinical markers: It features a loud P2 (forceful pulmonary valve closure) rather than a holosystolic murmur. In the JVP, PH is more likely to show a giant "a" wave due to the right atrium contracting against a stiff, non-compliant right ventricle.

Pulmonary Stenosis (PS) (Option C): Pulmonary stenosis involves an obstruction of blood flow from the right ventricle to the pulmonary artery. PS presents with an ejection systolic murmur (crescendo-decrescendo) heard best over the pulmonic area (left upper sternal border), not a holosystolic murmur. Unlike TR, this murmur does not typically intensify with inspiration. Characterized by a prominent "a" wave due to right ventricular hypertrophy. Mitral Regurgitation (MR) (Option D): Mitral regurgitation is a left-sided heart pathology that differs in location and physiology: It causes a holosystolic murmur best heard at the apex with radiation to the axilla . As a left-sided murmur, it does not intensify with inspiration (blood pools in the lungs, reducing left-sided flow). JVP findings are usually normal in isolated MR, as the JVP reflects right-sided pressures.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2060-2062.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 66-year-old female presents with fatigue, abdominal discomfort, and swelling in her legs. On examination, she has jugular venous distention with giant ‘a’ waves, hepatomegaly, and ascites. Auscultation reveals a diastolic murmur at the lower left sternal border, which increases in intensity with inspiration. What’s the most likely diagnosis? (Q850426)

A. Mitral stenosis

B. Tricuspid stenosis

C. Constrictive pericarditis

D. Aortic stenosis

Correct Answer: B. Tricuspid stenosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Tricuspid stenosis Explantion: The diastolic murmur at the lower left sternal border that increases with inspiration, along with jugular venous distention with giant ‘a’ waves , hepatomegaly , and ascites, is suggestive of Tricuspid stenosis. This condition is characterised by restricted blood flow from the right atrium to the right ventricle, often leading to right-sided heart failure symptoms like swelling in the legs, abdominal discomfort, and hepatomegaly. The presence of a diastolic murmur at the lower left sternal border further supports the diagnosis. Primary Causes: Rheumatic Heart Disease: Most common cause Carcinoid Syndrome Infective Endocarditis Congenital: Rare Mitral stenosis (MS) (Option A) causes left atrial pressure overload , leading to pulmonary congestion and dyspnea, often with orthopnea and paroxysmal nocturnal dyspnea . This patient’s presentation is dominated by right-sided heart failure symptoms (ascites, hepatomegaly, oedema) without the significant pulmonary congestion typically seen in MS. Primary Causes: Rheumatic Fever Congenital: "Parachute"

mitral valve. Severe Mitral Annular Calcification Constrictive pericarditis (Option C) causes a thickened, non-compliant pericardium, limiting diastolic filling and leading to systemic venous congestion (jugular venous distension, hepatomegaly, ascites). Heart sounds may be muffled, and a pericardial knock can be present. Unlike tricuspid stenosis, constrictive pericarditis lacks a diastolic murmur. Primary Causes: Idiopathic/Viral: Following an undiagnosed pericarditis. Post-Surgical: Common after cardiac surgery (scarring). Radiation Therapy Tuberculosis Aortic stenosis (Option D) causes left ventricular outflow obstruction, leading to exertional dyspnea, angina, and syncope, with a systolic ejection murmur radiating to the carotids. This patient's right-sided heart failure and diastolic murmur are more consistent with tricuspid stenosis, not aortic stenosis. Primary Causes: Age-related Calcification Bicuspid Aortic Valve Rheumatic Heart Disease:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2059.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 69-year-old man presents with severe aortic regurgitation. He reports increasing fatigue, breathlessness, and episodes of dizziness. On auscultation, a diastolic murmur is heard along with a water-hammer pulse, and an echocardiogram shows significant left ventricular dilation and an ejection fraction of 55%. What is the most appropriate management for this patient? (Q850425)

A. Medical management

B. Transcatheter aortic valve implantation

C. Intra-aortic balloon counterpulsation

D. Aortic valve replacement

Correct Answer: D. Aortic valve replacement

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Aortic valve replacement is the ideal management for severe aortic regurgitation patients who are symptomatic, irrespective of their LV function. In asymptomatic progressive aortic regurgitation , AVR is advisable if LV dysfunction is evident. Regular non-invasive follow-up, once in 6-12 months, is necessary to monitor the development of myocardial dysfunction , as surgery delayed long after its development has minimal chances of completing LV recovery. Management Type Acute AR Chronic AR Medical (Option A) IV Diuretics (Furosemide) and Vasodilators (Sodium Nitroprusside) are used to stabilise the patient. Beta Blockers are contraindicated as they worsen the symptoms and reduce the cardiac output. Diuretics and Vasodilators like ACEi, CCB, Hydralazine, ARBs (can be used in chronic AR) to manage HTN; Target SBP <140 mm/Hg. For Angina: Nitrates For Syphilis: Benzathine Penicillin, 2.4 million units IM, three doses given with one week gap. Surgical

Aortic valve replacement (AVR) is the treatment of choice, usually within 24 hours of diagnosis. Intra-Aortic Balloon pum p is contraindicated as it worsens the regurgitant flow. (Option C) AVR is indicated when developing LV dysfunction or symptoms . Transcatheter aortic valve implantation (Option B) is not suggeste d due to its limited success in chronic conditions.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2044-2045.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 72-year-old male presents with complaints of worsening dyspnea, angina and orthopnea. Physical examination reveals a loud diastolic murmur at the left sternal border and a widened pulse pressure. An echocardiogram indicates significant left ventricular dilation. What is the likely estimated regurgitant volume in this condition to label as severe valvular dysfunction? (Q850419)

A. < 35 ml/beat

B. > 35 ml/beat

C. < 60 ml/beat

D. > 60 ml/beat

Correct Answer: D. > 60 ml/beat

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Widened pulse pressure with diastolic murmur with the given symptom profile points to Aortic regurgitation. The regurgitant volume in a patient with severe aortic regurgitation exceeds 60 mL per beat. Aortic regurgitation severity: Degree of regurgitant Regurgitant volume Regurgitant fraction Mild <30 ml/beat <30 % Moderate 30-59 ml/beat 30-50 % Severe ≥60 ml/beat >50 %

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2044-2045.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 32-year-old female presents with palpitations, chest discomfort, and fatigue. A mid-systolic click and late systolic murmur are heard at the apex. Echocardiography shows mitral valve leaflets billowing into the left atrium during systole. Which of the following is leading cause of this presentation? (Q850397)

A. Inflammation of the mitral valve due to rheumatic fever

B. Fibrotic changes affecting the mitral valves

C. Rupture of the tendinae of the mitral valve

D. Myxomatous degeneration of mitral valve apparatus.

Correct Answer: D. Myxomatous degeneration of mitral valve apparatus.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Myxomatous degeneration of the mitral valve apparatus leads to mitral valve leaflets billowing into the left atrium during systole, thus causing Mitral valve prolapse. Inflammation of the mitral valve due to rheumatic fever (Option A) occurs in Rheumatic heart disease, which can result in fibrotic changes in the mitral valve (Option B), leading to mitral stenosis, which produces a low-pitched diastolic rumble. Rupture of the tendinae of the mitral valve (Option C) leads to acute severe mitral regurgitation, which can be a complication of mitral valve prolapse but is not the cause.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2057.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 65-year-old woman reports experiencing mild chest pain and shortness of breath on exertion. On examination, harsh ejection- systolic murmur is noted, best heard at the right second intercostal space and radiating to the carotids. An Echocardiogram shows an aortic valve area of 0.9 cm^2. Which stage of aortic stenosis is present and what is the ideal management? (Q850417)

A. Stage B and TAVR

B. Stage D and Statins

C. Stage B and Statins

D. Stage D and TAVR

Correct Answer: D. Stage D and TAVR

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Aortic Valve area of < 1 cm^2 (Severe Stenosis) along with symptoms are categorized into Stage D and is managed by Transcatheter Aortic Valve Replacement (TAVR). Stage Aortic Valve area

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2039.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 72-year-old patient presents with angina and shortness of breath on exertion. Physical examination reveals a slow-rising carotid pulse and a systolic ejection murmur. Which of the following is most likely to be observed in this patient? (Q850415)

A. Triple vessel disease

B. Right atrial enlargement

C. Medial displacement of heaving apex

D. Junctional Tacycardia

Correct Answer: A. Triple vessel disease

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Aortic stenosis has slow rising anacortic pulse with ejection systolic murmur. It is seen in geriatric population and hence these patients have co-existent triple vessel disease. Left atrial hypertrophy causing double apical impulse will be seen in these patients. Note that hypertrophy causes lateral displacement of apex beat and not medial.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2037-2038.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 65-year-old patient presents to the clinic with increasing fatigue and shortness of breath on exertion. O/E a harsh, systolic crescendo-decrescendo ejection murmur is noted at the right second intercostal space. Which of the following is not seen in this condition ? (Q850413)

A. Left axis deviation

B. Angina pectoris

C. Syncope on exertion

D. Water Hammer pulse

Correct Answer: D. Water Hammer pulse

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical scenario described indicates case of Aortic stenosis, characterized by a harsh systolic crescendo-decrescendo ejection murmur typically heard at the right second intercostal space. Water hammer pulse is seen in Aortic regurgitation while Aortic stenosis has anacrotic pulse. Left axis deviation is seen in AS due to concentric left ventricular hypertrophy.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2037-2038.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 72-year-old woman presents with fatigue and progressive shortness of breath, particularly when climbing stairs. During the physical examination, a harsh, systolic ejection murmur is heard at the right second intercostal space, radiating to the carotids. Which of the following factors is least likely to be associated with the development of the condition? (Q850412)

A. Mediastinal irradiation

B. Mutation in NOTCH1

C. Prior rheumatic inflammation

D. Systemic lupus erythematosus

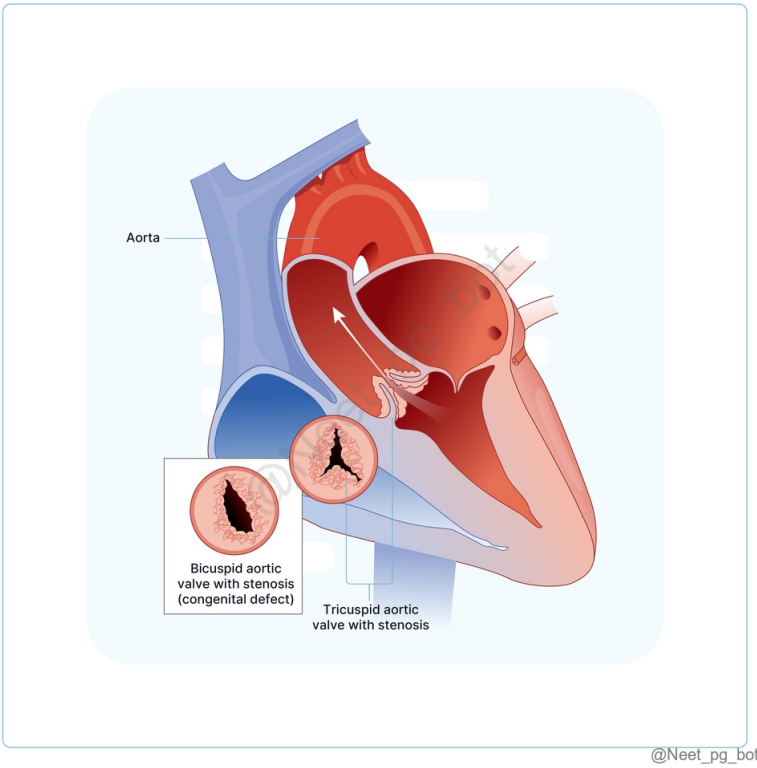
Correct Answer: D. Systemic lupus erythematosus

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario with systolic ejection murmur heard at the right second intercostal space radiating to the carotids suggests Aortic Stenosis . While mediastinal irradiation, mutation in NOTCH1, and prior rheumatic inflammation are all factors associated with aortic valve dysfunction. Systemic lupus erythematosus is less directly linked to the development of Aortic Stenosis. Etiology of Aortic stenosis (AS): Degenerative Calcification The primary cause of aortic stenosis (AS) in adults, often due to: Congenital Bicuspid Aortic Valve

(BAV) : Approximately 53% of cases. Trileaflet Valve Deterioration Previous Rheumatic Fever (Option C ruled out) : Inflammation can lead to scarring and calcification. Mediastinal Radiation (Option A ruled out) Cause late scarring and calcification of the aortic leaflets. Bicuspid Aortic Valve Disease Most common congenital heart valve defect, with a male predominance (2–4:1) . Genetic Factors : Mutations in NOTCH1 (Option B ruled out) , GATA5 , and GATA4 have been noted



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2035-2037.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 65-year-old male presents with recurrent syncopal episodes. Auscultation reveals an ejection systolic murmur heard at the right 2 nd intercostal space and radiates to the carotids. The murmur also becomes higher-pitched when heard at the apex. ECG shows left axis deviation with a normal sinus rhythm. Which condition is most likely in this patient? (Q850410)

A. Sick Sinus syndrome

B. Aortic stenosis

C. Complete heart block

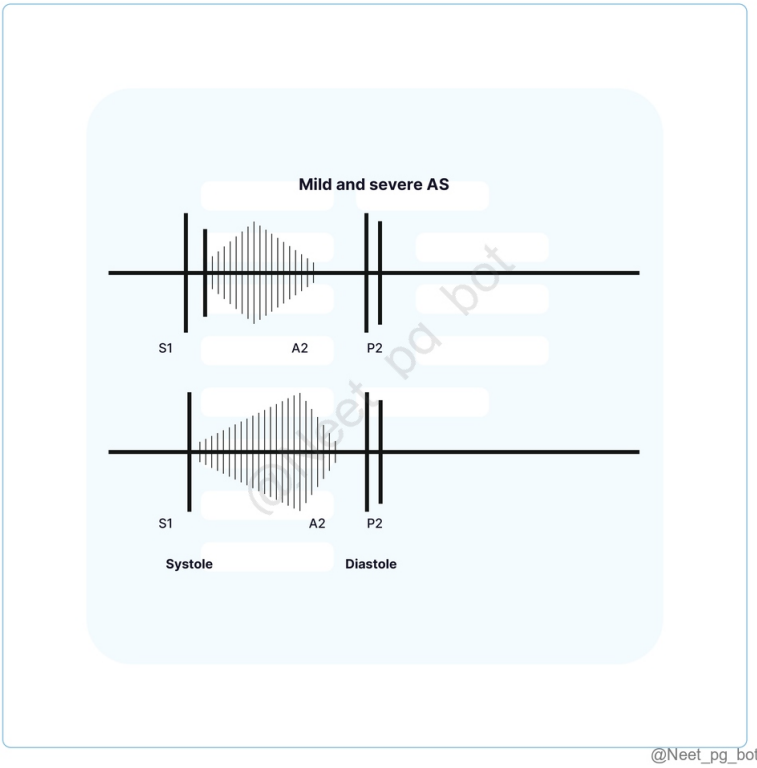
D. Pulmonary stenosis

Correct Answer: B. Aortic stenosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Aortic Stenosis Explantion : The given clinical presentation of Syncopal episodes with an Ejection systolic murmur in the geriatric age group points to valvular aortic stenosis. The ejection systolic murmur of aortic stenosis has two components: Low-frequency, harsh component – heard at right upper sternal border High-frequency musical component – transmitted to the apex = Gallavardin phenomenon/effect Gallavardin Effect: It refers to the phenomenon where a murmur of aortic stenosis (AS) becomes higher-pitched and more acoustically pure when auscultated at the apex of the heart despite originating from the aortic region. The ejection (mid) systolic (Crescendo-decrescendo) murmur of AS typically starts shortly after S1, increases in intensity, peaks during ejection, and ends just before aortic valve closure. Sick Sinus Syndrome (Option A): Causes bradycardia and syncope but no systolic murmur . Complete Heart Block (Option C): Syncope with AV dissociation , not normal sinus rhythm; no AS-type murmur . Pulmonary Stenosis (Option D): Murmur at left upper sternal border, no carotid radiation , no Gallavardin effect.



@Neet_pg_bot

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2037.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 50-year-old female patient presents with exertional dyspnea and a history of rheumatic fever. Echocardiogram shows severe mitral stenosis with calcification. Which of the following is the most appropriate management strategy for her condition? (Q850408)

A. Initiate warfarin therapy

B. Percutaneous mitral balloon commissurotomy (PMBC)

C. Schedule for mitral valve replacement

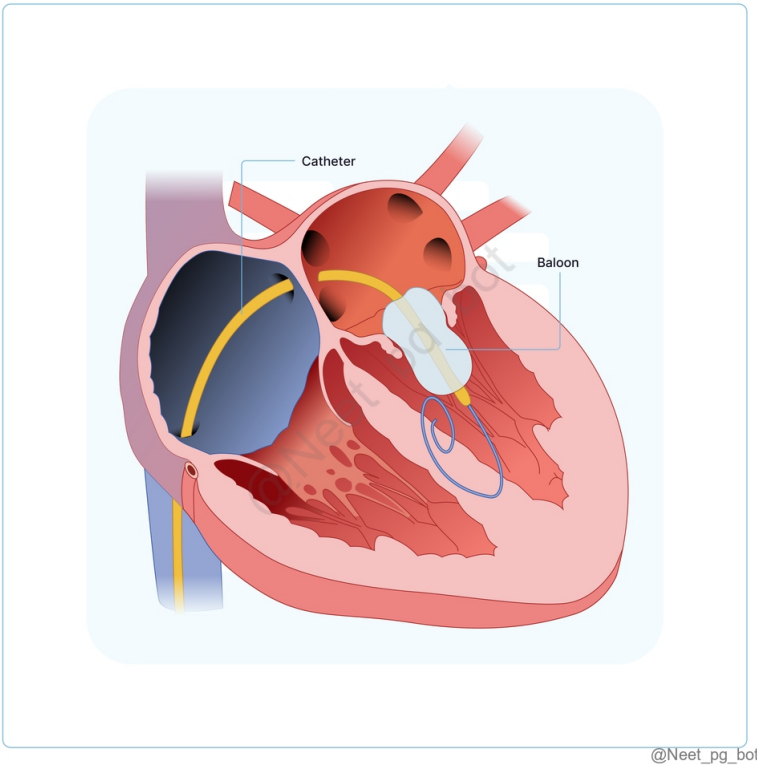
D. Start beta-blockers and diuretics

Correct Answer: C. Schedule for mitral valve replacement

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Mitral valve replacement is indicated for significant symptoms in patients with calcified severe mitral stenosis, particularly when heavy calcification makes the valve unsuitable for balloon valvuloplasty. Management of Mitral Stenosis: Medical Management: Patients with mild symptoms may be managed medically. Penicillin Prophylaxis : Essential for preventing rheumatic fever in risk patients. Symptomatic Relief : Sodium restriction, diuretics, beta-blockers (Option D ruled out), and Calcium channel blockers help manage symptoms and control heart rate in atrial fibrillation (AF). Anticoagulation : Warfarin for patients with AF, history of thromboembolism, or left atrial thrombus; INR target 2–3. (Option A ruled out) Cardioversion : For recent-onset AF, ensure anticoagulation for at least three weeks. Infective Endocarditis Prophylaxis : Routine antibiotic prophylaxis is no longer recommended. Interventional: Considered if patients remain symptomatic despite medical management or if pulmonary hypertension develops/Severe MS (<1.5 cm^2) Balloon valvuloplasty Mitral valvotomy/Mitral valve replacement Procedure Indications / Requirements Mitral Balloon Valvuloplasty (PMBC) (Option B ruled out) Significant symptoms present Isolated mitral stenosis (no or trivial mitral regurgitation) Mobile, non-calcified valve/sub valve apparatus on echocardiogram Left atrium free of thrombus Mitral Valve Replacement (Option C) Substantial mitral regurgitation Rigid and calcified valve Presence of thrombus formation Mitral Balloon Valvuloplasty/Percutaneous Mitral Balloon Commissurotomy:



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2051-2052.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A 48-year-old female presents with worsening exertional dyspnea and fatigue. She has a history of rheumatic fever during her childhood. Examination shows diastolic murmur at the cardiac apex with pronounced opening snap. Which of the following findings is least likely to be present in this case? (Q850406)

A. Left atrial enlargement

B. Reduced mitral valve area

C. Right ventricular hypertrophy

D. Heaving apex beat

Correct Answer: D. Heaving apex beat

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The presentation is classic for rheumatic mitral stenosis (diastolic murmur at apex with opening snap, history of rheumatic fever). MS leads to reduced mitral valve area , left atrial enlargement , and, in advanced disease, pulmonary hypertension with right ventricular hypertrophy . A heaving apex beat suggests left ventricular pressure overload (e.g., aortic stenosis), which is not typical of isolated mitral stenosis , where the apex is usually tapping or normal. Left atrial enlargement (Option A) is expected due to chronic pressure overload from obstructed mitral inflow. Reduced mitral valve area (Option B) is the hallmark anatomical change in mitral stenosis. Right ventricular hypertrophy (Option C) can occur secondary to pulmonary hypertension from long-standing mitral stenosis.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2049

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 40-year-old female with a history of rheumatic heart disease comes to the OPD for a regular follow-up. Echocardiography confirmed the presence of severe mitral regurgitation . When considering her treatment options, which of the following interventions should not be included in her management plan? (Q850404)

A. Use of Apixaban if her CHA2DS2-VASc score ≥2

B. Cardiac resynchronization therapy, when indicated

C. Mitral valve repair if EF < 60%

D. Vitamin K antagonists

Correct Answer: A. Use of Apixaban if her CHA2DS2-VASc score ≥2

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In patients with rheumatic heart disease (RHD) and mitral valve involvement —especially rheumatic mitral stenosis or regurgitation with atrial fibrillation —the recommended anticoagulant is a Vitamin K antagonist (Warfarin) . NOACs (e.g., Apixaban) are not recommended because major trials excluded patients with significant rheumatic valvular disease, and their safety/effectiveness is not established in this group. Cardiac resynchronization therap y (Option B): Appropriate if standard CRT criteria are met (EF ≤ 35%, LBBB). RHD is not a contraindication , so this should be included. Mitral valve repair if EF < 60% (Option C): Correct recommendation in severe chronic MR; EF < 60% indicates early LV dysfunction. Vitamin K antagonists (Option D): Preferred anticoagulants in rheumatic mitral valve disease, especially with AF; should be included.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3450.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: A 65-year-old female presents to the clinic with complaints of fatigue, shortness of breath on exertion, and palpitations. On physical examination, a systolic thrill is palpable at the cardiac apex. Echocardiography showed severe backflow of blood from the left ventricle to the left atrium during ventricular systole. What kind of murmur is most likely to be heard during cardiac auscultation of this patient? (Q850401)

A. Continuous murmur

B. An opening snap followed by a diastolic murmur

C. Holosystolic murmur, best heard at the apex

D. Crescendo decrescendo systolic murmur best heard at the base

Correct Answer: C. Holosystolic murmur, best heard at the apex

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation and echocardiography show features of severe mitral regurgitation , so on cardiac auscultation, a holosystolic murmur will most likely be heard at the cardiac apex. Continuous murmurs (Option A) occur during both systole and diastole, which is not characteristic of mitral regurgitation. They are typically associated with conditions that involve persistent blood flow between high- and low-pressure areas, such as in patent ductus arteriosus (PDA), where there is a constant flow of blood between the aorta and pulmonary artery. An opening snap followed by a diastolic murmur (Option B) is heard in mitral stenosis . It occurs due to the narrowed mitral valve opening during diastole, resulting in an opening snap followed by a low-pitched diastolic rumble. Crescendo-decrescendo systolic murmur (Option C) is typical of aortic stenosis . It is heard best at the base of the heart and radiates to the carotids. This murmur reflects the turbulent flow of blood through the narrowing of the aortic valve.

Harrison’s Principle of Internal Medicine, 22nd Edition, Page 2053.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: Which of the following is not a cause of primary chronic mitral regurgitation? (Q850400)

A. Ischemic cardiomyopathy

B. Rheumatic fever

C. Infective endocarditis

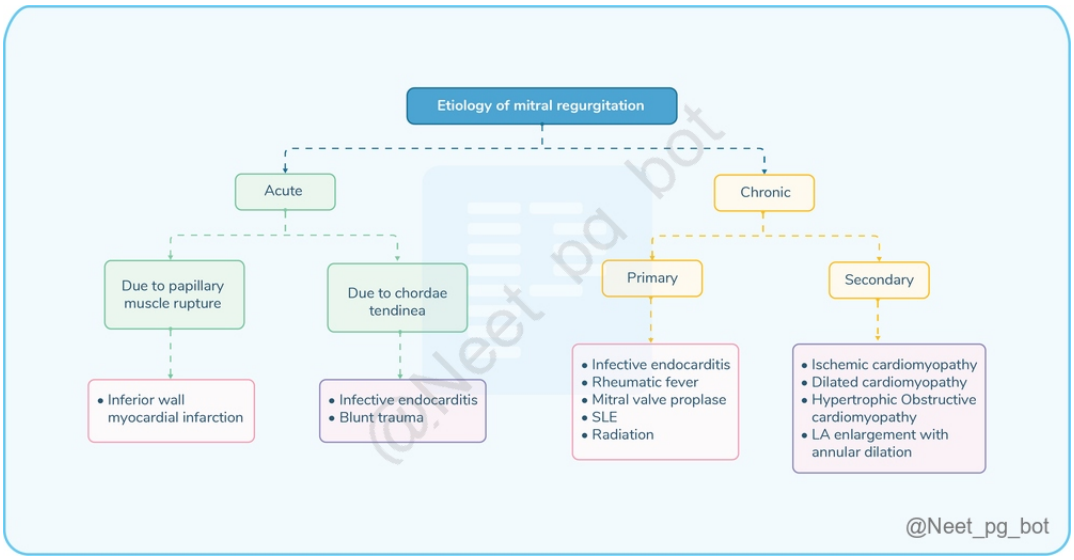
D. Radiation

Correct Answer: A. Ischemic cardiomyopathy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Ischemic cardiomyopathy causes secondary (functional) MR due to LV dilation or papillary muscle displacement , leading to poor leaflet coaptation. Primary MR occurs due to intrinsic structural abnormalities of the mitral valve (leaflets, chordae, papillary muscles). Rheumatic fever , infective endocarditis , and radiation (Option B,C & D) : all directly damage the mitral valve apparatus , making them causes of primary MR.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2052.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: A 65-year-old diabetic male with mitral valve prolapse presents with palpitations. Pulse 130/min irregular, BP on admission is 160/100 mmHg. He also has a history of infective endocarditis. Which of the following statements regarding his management is not true? (Q850398)

A. Anticoagulation therapy should be avoided due to low CHADS2Vasc score

B. Beta-blockers should be initiated for his palpitations

C. Mitral valve repair is preferred over mitral valve replacement

D. Prophylactic antibiotics should be initiated

Correct Answer: A. Anticoagulation therapy should be avoided due to low CHADS2Vasc score

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: As the patient has a CHA2DS2-VASc score of 3. (Age, DM and HTN) anticoagulation therapy should be initiated to reduce the risk of cerebrovascular accident . Prophylactic Antibiotics are given if patient has previous history of infective endocarditis. (Option D) Beta blockers will be useful for palpitations and patient should be scheduled for mitral valve prolapse repair to prevent further damage to left atria. (Option B) Repair

preserves the native valve, improves outcomes, and decreases postoperative complications. (Option C)

[01_Cardiology] 002 Heart Sounds And Murmurs — Quick Jump

Q1 (p. 1104)	*Q2 (p. 1105)*	*Q3 (p. 1106)*	*Q4 (p. 1107)*	*Q5 (p. 1107)*	*Q6 (p. 1108)*
Q7 (p. 1109)	*Q8 (p. 1110)*	*Q9 (p. 1111)*	*Q10 (p. 1113)*	*Q11 (p. 1114)*	*Q12 (p. 1115)*
Q13 (p. 1116)	*Q14 (p. 1118)*	*Q15 (p. 1119)*	*Q16 (p. 1120)*	*Q17 (p. 1121)*	*Q18 (p. 1122)*
Q19 (p. 1123)	*Q20 (p. 1124)*	*Q21 (p. 1125)*	*Q22 (p. 1125)*	*Q23 (p. 1126)*	*Q24 (p. 1127)*
Q25 (p. 1128)					

Q1: A 55-year-old man presents with gradually worsening shortness of breath and fatigue. He has a history of tuberculosis treated 10 years ago. Physical examination reveals elevated jugular venous pressure (JVP) that rises paradoxically with inspiration. Which of the following is the most likely diagnosis? (Q850497)

A. Pulmonary embolism

B. Restrictive cardiomyopathy

C. TB pericardial effusion

D. Constrictive pericarditis

Correct Answer: D. Constrictive pericarditis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A history of tuberculosis with progressive dyspnea , elevated JVP, and Kussmaul’s sign (JVP rising with inspiration) strongly suggests constrictive pericarditis . TB is a leading cause of constrictive pericarditis in endemic regions. Rigid, calcified pericardium restricts ventricular filling → right-sided heart failure signs + Kussmaul’s sign. Pulmonary embolism (Option A) Does not cause Kussmaul’s sign; presents with acute dyspnea, chest pain, and tachycardia. Restrictive cardiomyopathy (Option B) May mimic constriction but Kussmaul’s sign is less prominent , and TB history more strongly favors constrictive pericarditis. TB pericardial effusion (Option C) Tamponade physiology shows pulsus paradoxus , not Kussmaul’s sign; JVP falls on inspiration.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1906, 2081.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which of the following statements is correct about grades of murmurs? (Q850755)

A. Grade 1 murmur is very loud and audible even without a stethoscope

B. Grade 2 murmur is faint but audible with a stethoscope

C. Grade 4 murmur has a loud intensity without thrill

D. Grade 6 murmur is very faint and heard with difficulty

Correct Answer: B. Grade 2 murmur is faint but audible with a stethoscope

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Grading of Heart Murmurs - Levine scale (commonly used scale): Grade 1 Very faint, heard only with difficulty. Grade 2 Faint but audible with a stethoscope. Grade 3 Moderately loud, easily audible. Grade 4 Loud, with a palpable thrill. Grade 5 Very loud, with a palpable thrill, heard with the edge of the stethoscope. Grade 6 Extremely loud, audible without a stethoscope, with a palpable thrill.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 283.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Match the following murmurs to their characteristics Murmurs Characteristics 1. Mitral Stenosis A. High-pitched, crescendo-decrescendo murmur best heard at the right upper sternal border. 2. Aortic Stenosis B. Holosystolic murmur radiating to the axilla, often with a displaced apical impulse. 3. Patent Ductus Arteriosus C. Early diastolic decrescendo murmur best heard along the left sternal border. 4. Hypertrophic Cardiomyopathy D. "Machine-like" continuous murmur heard best at the left infraclavicular area. 5. Mitral Regurgitation E. Loud S1, opening snap, and low-pitched diastolic murmur heard best at the apex. 6. Aortic Regurgitation F. Systolic ejection murmur, often with a crescendo-decrescendo pattern, best heard at the right upper sternal border, radiating to the carotids. (Q850756)

A. 1 - E, 2 - F, 3 - D, 4 - A, 5 - B, 6 - C

B. 1 - E, 2 - F, 3 - A, 4 - D, 5 - C, 6 - B

C. 1 - F, 2 - E, 3 - D, 4 - A, 5 - C, 6 - B

D. 1 - F, 2 - E, 3 - A, 4 - D, 5 - B, 6 - C

Correct Answer: A. 1 - E, 2 - F, 3 - D, 4 - A, 5 - B, 6 - C

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Mitral Stenosis Low-pitched diastolic murmur with opening snap, best at the apex. Accentuated by exercise or Valsalva's maneuver. Aortic Stenosis Systolic ejection murmur, crescendo-decrescendo pattern, radiating to carotids Patent Ductus Arteriosus A continuous, machine-like murmur, heard at the left infraclavicular area Hypertrophic Cardiomyopathy Harsh systolic murmur, crescendo-decrescendo pattern Mitral Regurgitation Holosystolic murmur radiating to the axilla Aortic Regurgitation Early diastolic decrescendo murmur, best heard at the left sternal border Graham Steell Murmur Early diastolic decrescendo murmur due to pulmonary regurgitation, heard best at the left upper sternal border. Austin Flint Murmur Low-pitched, rumbling diastolic

murmur due to severe aortic regurgitation causing turbulent flow in the left ventricle.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 285, 2037-2038, 2044, 2049, 2053, 2072.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 35-year-old male presents with exertional chest pain and dyspnea. On physical examination, you note a harsh mid systolic murmur that is loudest at the left sternal border and increases in intensity with the Valsalva maneuver. Which of the following is the most likely cause? (Q850752)

A. Hypertrophic Cardiomyopathy

B. Aortic Stenosis

C. Pulmonary Stenosis

D. Atrial Septal Defect

Correct Answer: A. Hypertrophic Cardiomyopathy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypertrophic cardiomyopathy causes a harsh mid-systolic murmur at the left sternal border that increases with Valsalva due to dynamic left ventricular outflow tract obstruction becoming more pronounced as preload decreases. Aortic and pulmonary stenosis (Option B and C) have ejection systolic murmurs that will decrease with Valsalva. Atrial Septal Defect (Option D) does not have shunt murmur.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2006-2007.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 45-year-old male presents shortness of breath on exertion. Examination reveals a pansystolic murmur heard best at the apex of the heart, radiating to the axilla. The intensity of the murmur does not change with inspiration. Which of the following is

the most likely diagnosis? (Q850753)

A. Chronic Mitral Regurgitation

B. Chronic Tricuspid Regurgitation

C. Aortic Stenosis

D. Acute Mitral Regurgitation

Correct Answer: A. Chronic Mitral Regurgitation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Mitral Regurgitation (MR) is characterized by a high-pitched holosystolic murmur that is best heard at the apex of the heart and radiates to the axilla. It does not change with inspiration. Causes of Chronic Mitral Regurgitation: Primary Secondary (Annulus dilatation: Mitral valve prolapse Rheumatic fever (children) Infective endocarditis Atrial septal defect (Ostium primum) Ostium primum - cleft mitral valve Dilated cardiomyopathy Cause - Alcohol Hypertrophic cardiomyopathy Systolic anterior movement of mitral valve → leakage of blood Long standing Atrial fibrillation with left atrial enlargement On Auscultation in Chronic Mitral Regurgitation: Pansystolic murmur (Uniform intensity throughout systole) Flow murmur (mid-diastolic murmur) S3 is heard in chronic mitral regurgitation. Treatment of Chronic Mitral Regurgitation: MVRP (Mitral Valve Repair) MVR (Mitral Valve Replacement) Transcatheter based approach - Mitra-clip: Removes redundant/damaged mitral valve tissue Mitra-clip squeeze valve → valve leaflets function appropriately → leakage of blood minimized Chronic tricuspid regurgitation (Option B) becomes louder on inspiration. Best heard in the lower left sternal edge. Aortic Stenosis (Option C) presents with ejection systolic murmur. Best heard in the right second intercostal space, may radiate to the carotid arteries. Acute mitral Regurgitation (Option D) causes early murmur due to rapid rise in left atrial pressure. Best heard in the apex, may radiate to the axilla.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2053-2054.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 7-year-old child is brought to the clinic for evaluation of high blood pressure detected during a routine check-up. On physical examination, the blood pressure is higher in the arms compared to the legs. A continuous murmur is heard over the back, near the left scapula. Which of the following is the most likely diagnosis? (Q850754)

A. Takayau Arteritis

B. Coarctation of the Aorta

C. Atrial Septal Defect

D. Aortic Dissection

Correct Answer: B. Coarctation of the Aorta

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Coarctation of the aorta is the narrowing of the aortic arch, typically distal to the left subclavian artery, leading to higher blood pressure in the arms than in the legs and a continuous murmur over the back. Clinical features: Can cause cardiac failure in newborns but may be asymptomatic in older children or adults. Hypertension above narrowing may cause headaches; reduced blood flow below may lead to leg cramps or weakness. Radio-femoral delay. A continuous murmur is typically heard over the back near the left scapula. Additional sound (ejection click) may be heard in the aortic area if a bicuspid aortic valve is present. Collateral circulation develops through periscapular, internal mammary, and intercostal arteries, sometimes causing localized bruits. Takayasu arteritis (Option A) is a large-vessel vasculitis that can cause pulse discrepancies and limb claudication, and does not typically present with a continuous murmur or blood pressure gradient between limbs. Atrial septal defect (Option C) causes a fixed split of the second heart sound and a systolic murmur due to increased flow across the pulmonary valve, but it does not cause blood pressure differences between the arms and legs. Aortic dissection (Option D presents with sudden, severe chest or back pain and may cause unequal blood pressures in the arms and not associated with a continuous murmur.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2076-2077.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: In aortic regurgitation, capillary pulsations can be seen in the nail beds. What is this sign called? (Q850751)

A. Quincke’s sign

B. Duroziez’s sign

C. de Musset’s sign

D. Hill sign

Correct Answer: A. Quincke’s sign

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Quincke’s sign is capillary pulsation visible in the nail beds and is a classic peripheral sign of aortic regurgitation due to wide pulse pressure . Other signs of Aortic Regurgitation: deMusset's sign (Option C ruled out) A head bob occurring with each cardiac cycle Duroziez's sign (Option B ruled out) A systolic and diastolic bruit heard when the femoral artery is partially compressed. Hill's sign (option D) Popliteal cuff systolic pressure exceeds brachial pressure by more than 20 mmHg. Rosenbach's sign Systolic pulsations of the liver. Gerhard's sign Systolic pulsations of the spleen. Mueller's sign Systolic pulsations of the uvula. Becker's sign Visible pulsations of the retinal arteries and pupils. Quincke's pulses Visible Capillary pulsations in the nailbeds after holding the tip of the nail. Traube's sign A pistol shot murmur (systolic and diastolic sounds) heard over the femoral arteries. Mayne's sign More than a 15 mmHg decrease in DBP with arm elevation from the value obtained with the arm in the standard position.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2044-2045.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: From the list of ECG findings given below which will not be seen in mitral stenosis? (Q850749)

A. Tall R waves in V1-V3

B. Bifid P wave

C. Atrial fibrillation

D. Tall tented T-waves

Correct Answer: D. Tall tented T-waves

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Tall tented T waves are seen in Hyperkalemia and not in mitral stenosis. Tall R waves in V1–V3 (Option A) can be seen in mitral stenosis due to right ventricular hypertrophy secondary to pulmonary hypertension. Bifid P wave (Option B) (also called P mitrale) is a classic sign of left atrial enlargement, commonly seen in mitral stenosis. Atrial fibrillation (Option C) frequently occurs in mitral stenosis due to left atrial dilation and increased pressure.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2049.

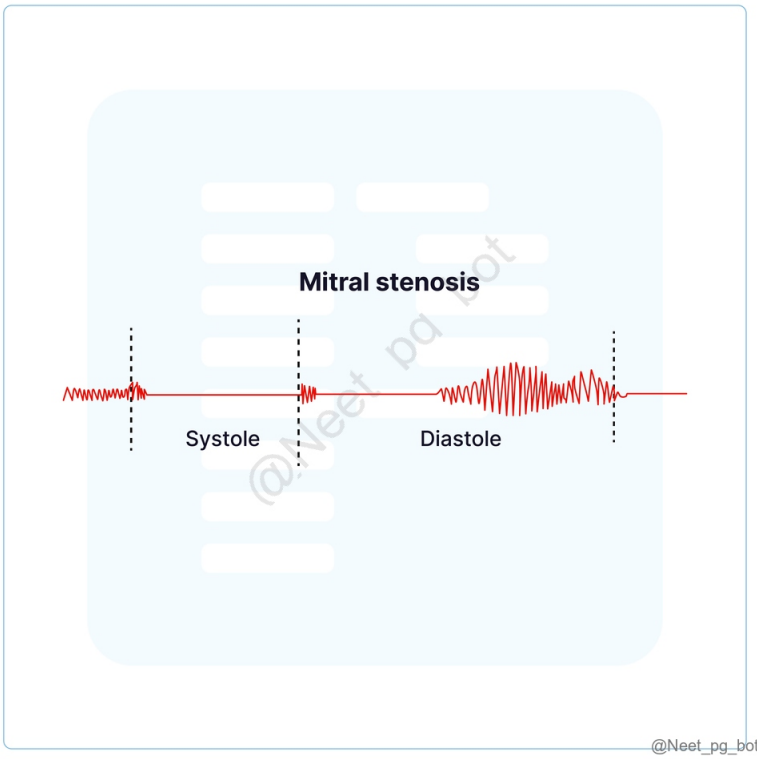
↑ *Back to this question in Part A*

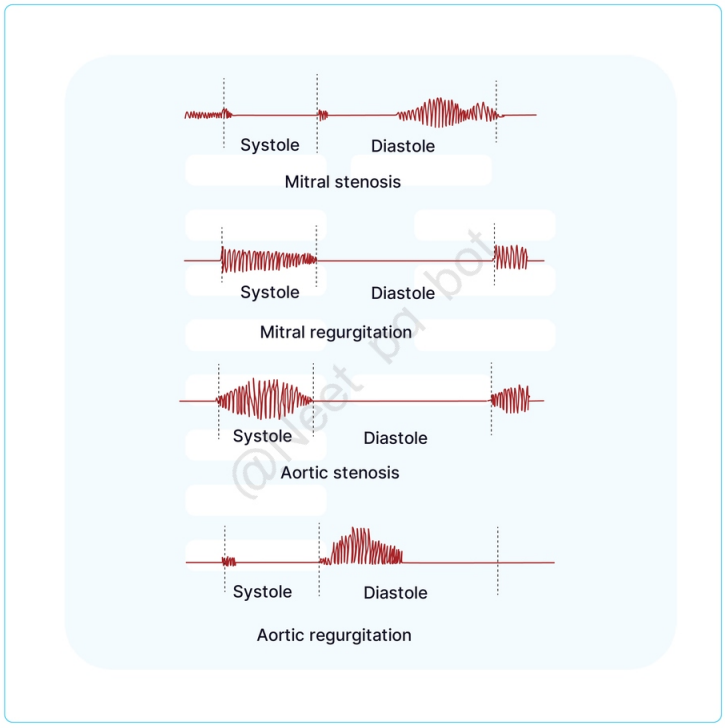
Q9: Which of the following schematic represents murmur of mitral stenosis? (Q850748)

Correct Answer: Unknown

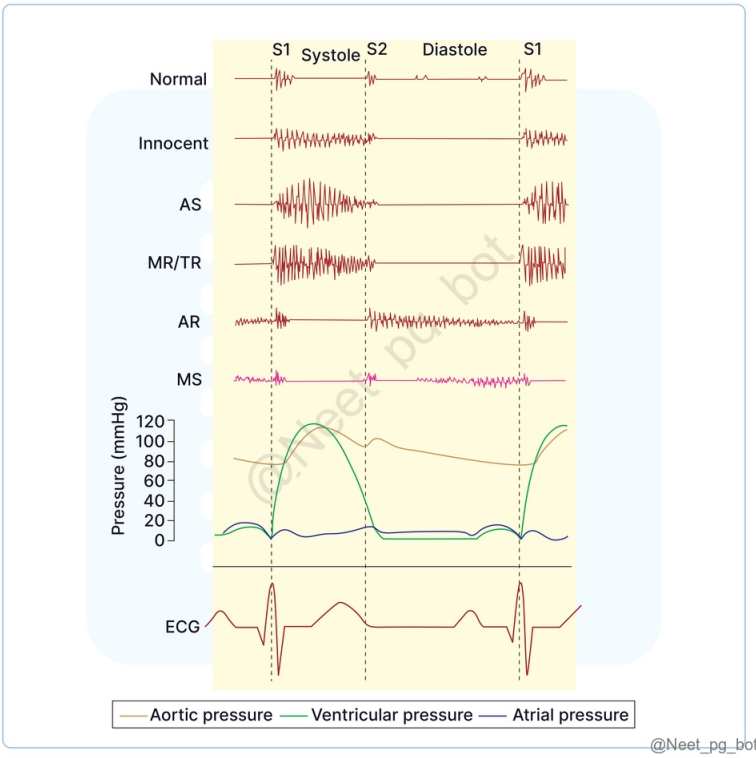
- *Listen (English)*
- *Listen (Hindi)*

Explanation: Mitral stenosis presents with a mid-diastolic murmur with presystolic accentuation.





@Neet_pg_bot



@Neet_pg_bot

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2048-2049.

↑ *Back to this question in Part A*

@Neet_pg_bot

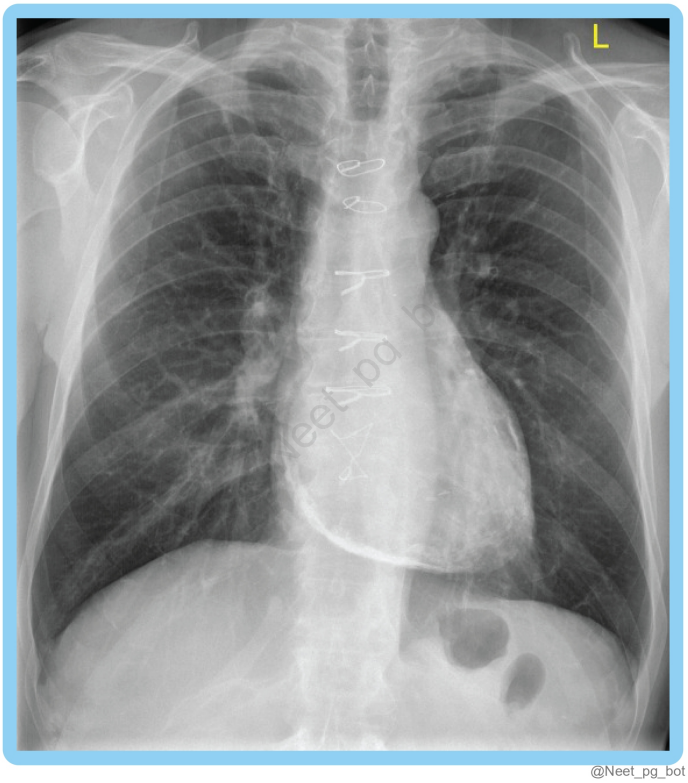
Q10: A 60-year-old male with presents with shortness of breath and pedal edema. Auscultation reveals a loud diastolic sound. Chest X-ray is given below. What is the treatment? (Q850746)

A. Diuretics

B. Pericardiocentesis

C. Beta-blockers

D. Glyceryl trinitrate



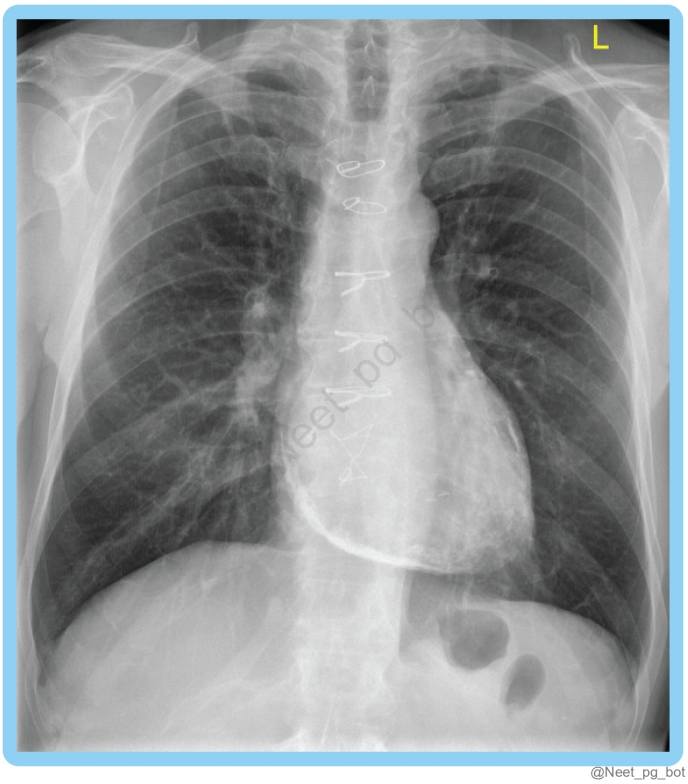
Correct Answer: A. Diuretics

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The X-ray shows diffuse pericardial calcification along the left lateral and inferior wall of the heart. Loud pericardial sound indicates pericardial shudder. Diagnosis is constrictive pericarditis , and loop diuretics and

aldosterone antagonists are used for treatment. {{caption_text}} Pericardiocentesis (Option B) is indicated for pericardial effusion or cardiac tamponade , not for constrictive pericarditis where the pericardium is thickened and fibrotic rather than fluid-filled. Beta-blockers (Option C) are generally not helpful in constrictive pericarditis and may worsen symptoms by reducing heart rate and cardiac output. Glyceryl trinitrate (Option D) (nitroglycerin) is a vasodilator used in angina and heart failure but can worsen hypotension in constrictive pericarditis without improving the mechanical constraint.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2083-2084.

↑ *Back to this question in Part A*

@Neet_pg_bot

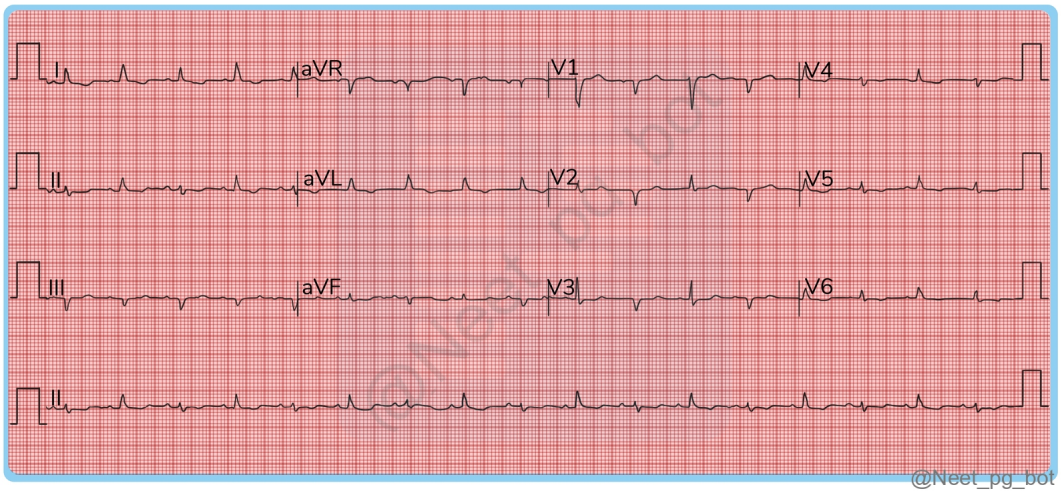
Q11: A 45-year-old woman recently diagnosed with adenocarcinoma lung presents with sudden dyspnoea, tachycardia, and hypotension. Examination reveals elevated JVP and an abnormal drop of 15mm Hg in systolic blood pressure during inspiration. An ECG was performed and is given below. What is the most appropriate next step in management? (Q850745)

A. Intravenous diuretics

B. Pericardiocentesis

C. Start vasopressors

D. Schedule elective cardiac surgery



Correct Answer: B. Pericardiocentesis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Patient shows signs of cardiac tamponade, including hypotension , elevated JVP and pulsus paradoxus (drop in systolic BP >10–15 mmHg on inspiration). ECG shows electrical alternans. Urgent drainage of the pericardial fluid is required to relieve pressure on the cardiac chambers and restore cardiac output. Intravenous diuretics (Option A) are not helpful in tamponade, as reducing preload can worsen hypotension and cardiac output. Start vasopressors (Option C) may temporarily support blood pressure, but do not address the underlying mechanical compression , and delaying definitive treatment can be fatal. Schedule elective cardiac surgery (Option D) is inappropriate for an emergency like tamponade; pericardiocentesis is the immediate life-saving measure.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2082.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 60-year-old man with a history of heart failure presents with worsening edema and jugular venous distention. You observe a steep x and steep y descent in the jugular venous waveform. Which of the following conditions is most likely responsible for these findings? (Q850500)

A. Constrictive pericarditis

B. Tricuspid regurgitation

C. Pericardial tamponade

D. Acute Pericarditis

Correct Answer: A. Constrictive pericarditis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Constrictive pericarditis typically causes a steep y descent to maximise ventricular filling before the calcified pericardial sac limits the diastole. Steep x is explained by atrial dilatation because of having to work against the resistance of stiff ventricles. Causes: Post-Viral/Infectious: Often follows a bout of acute pericarditis. Tuberculosis Cardiac Surgery Radiation Therapy: Particularly in patients treated for chest malignancies (like Hodgkin lymphoma or breast cancer). Connective Tissue Disorders: Conditions like Rheumatoid Arthritis or SLE (Lupus). Clinical signs: Kussmaul's Sign Pericardial Knock Right-Sided Heart Failure Symptoms: Ascites Peripheral edema Hepatomegaly Pulsus Paradoxus Management: Medical Management Diuretics to reduce fluid overload and NSAIDs/Colchicine if there is active inflammation. Pericardiectomy The definitive "cure." This is the surgical removal of the scarred pericardium. It's a major surgery but releases the heart from its cage. Addressing Underlyings Treating TB with antitubercular therapy or managing autoimmune flares.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1906, 2081.

↑ *Back to this question in Part A*

@Neet_pg_bot

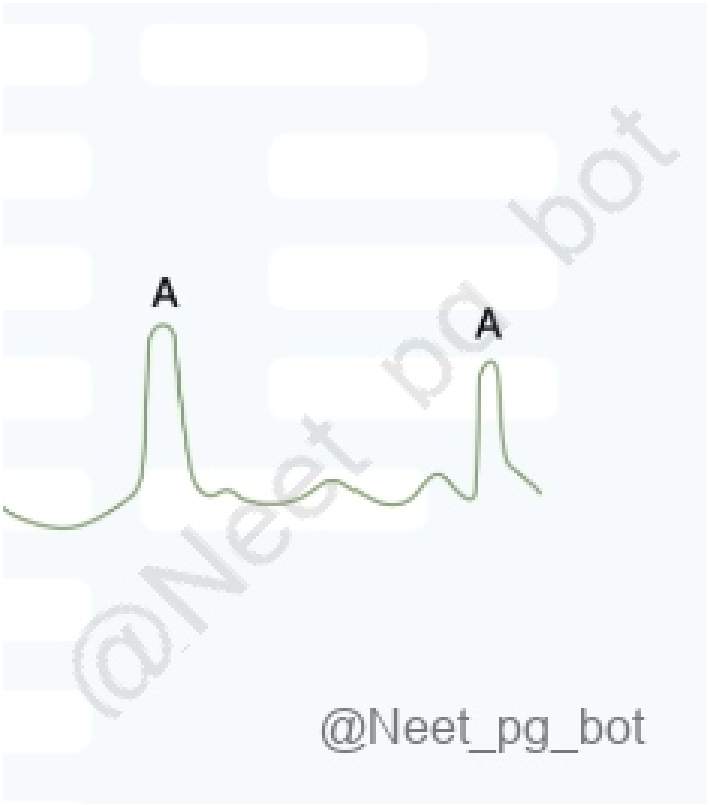
Q13: A 65-year-old man presents with palpitations and lightheadedness. His ECG shows an unequal number of P waves and R waves and his jugular venous pressure tracing is shown below. Which of the following conditions is responsible for this finding? (Q850498)

A. Atrial fibrillation

B. Complete heart block

C. Tricuspid stenosis

D. Electromechanical dissociation

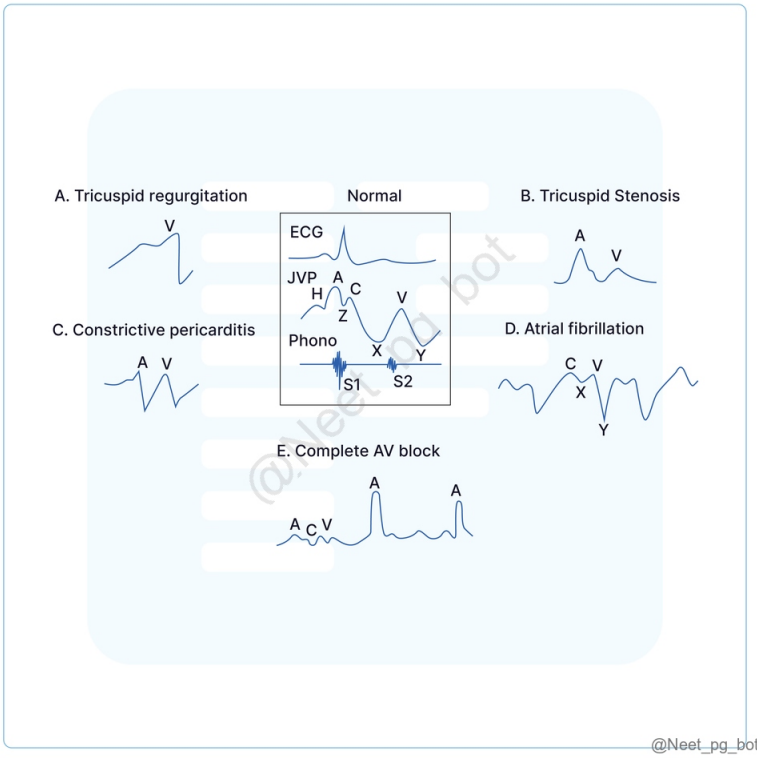


@Neet_pg_bot

Correct Answer: B. Complete heart block

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Unequal R waves and P waves indicate AV dissociation. Cannon "a" waves occur when the atria contract against a closed tricuspid valve. Diagnosis is complete heart block. Atrial fibrillation (Option A) will have absent waves. Tricuspid stenosis (Option C) will cause large ‘a’ waves in JVP. Electromechanical dissociation (Option D) occurs after transmural MI causes the ventricular chamber to rupture.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1925-1926.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: Loud first heart sound (S1) in mitral stenosis indicates? (Q850476)

A. Reduced LV compliance

B. Increased left atrial pressure

C. Severe calcified mitral stenosis

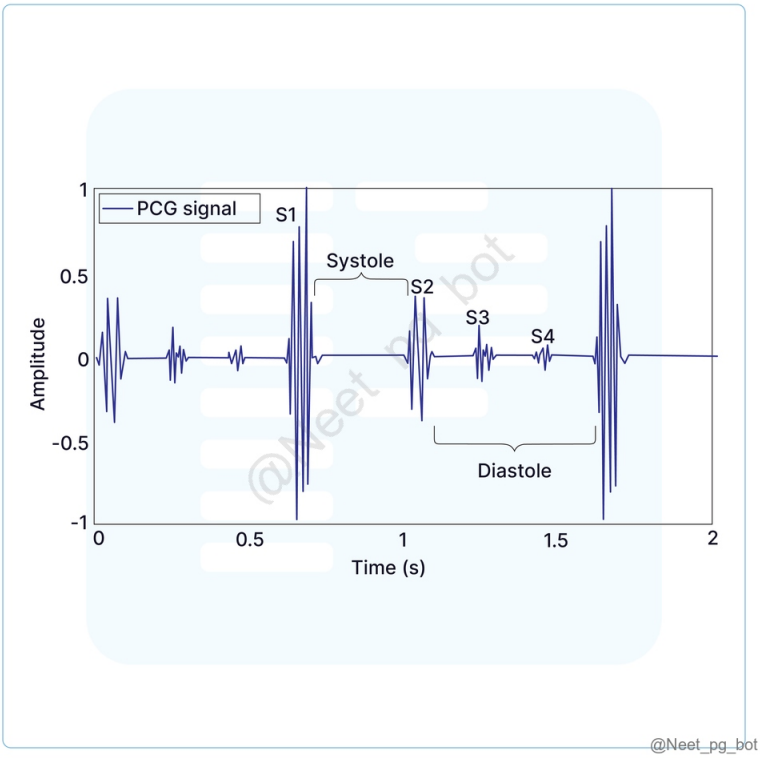
D. Hypertrophy of the right ventricle

Correct Answer: B. Increased left atrial pressure

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Loud S1 is indicative of increased left atrial pressure, causing faster, abrupt closure of AV valves and, hence, a loud first heart sound. First heart sound (S1): The first heart sound is due to the closing of the AV valves. It occurs at the beginning of the isovolumetric contraction as lub sound. The intensity of S1 is determined by the distance over which the anterior leaflet of the mitral valve must travel to return to its annular plane, leaflet mobility, LV contractility, and PR interval. S1 is loud in rheumatic MS, hyperkinetic circulatory states and short PR interval. Severe calcified mitral stenosis (Option C) leads to immobile, stiff valve leaflets , which reduce the intensity of S1, making it soft or absent , not loud. Reduced LV compliance (Option A) typically affects diastolic filling but does not directly cause a loud S1; it may even reduce it in some conditions. Hypertrophy of the right ventricle (Option D) may be a consequence of pulmonary hypertension due to mitral stenosis, but it does not directly affect the loudness of S1 .



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1864, 2049.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 70-year-old woman with a history of ischemic cardiomyopathy, hypertension, and diabetes presents with worsening shortness of breath and fatigue. On physical examination, you hear both an S3 and an S4 heart sound. Which of the following best explains the presence of both heart sounds in this patient? (Q850495)

A. Atrial fibrillation with mitral stenosis

B. Acute mitral regurgitation

C. Combined systolic and diastolic heart failure

D. Severe aortic stenosis

Correct Answer: C. Combined systolic and diastolic heart failure

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The presence of both S3 and S4 heart sounds strongly suggests that this patient has combined systolic and diastolic dysfunction , which is common in elderly patients with long-standing hypertension, diabetes, and ischemic cardiomyopathy. S3 (ventricular gallop): Marker of Systolic Dysfunction S3 occurs just after S2 during rapid passive filling of the ventricle. It is produced when the ventricle is dilated and has reduced contractility. This patient has ischemic cardiomyopathy, which leads to a weak, dilated LV, causing an S3. S3 is strongly associated with reduced ejection fraction (HFrEF). S4 (atrial gallop): Marker of Diastolic Dysfunction S4 occurs just before S1, when the atria contract against a stiff ventricle. Long-standing hypertension and diabetes cause LV hypertrophy, making the ventricle non-compliant, resulting in S4. S4 is associated with HFpEF, diastolic dysfunction, and stiff ventricles. Together The coexistence of S3 and S4 implies: A dilated, poorly contracting ventricle (S3) A stiff, hypertrophied, non-compliant ventricle (S4) This combination occurs most commonly in advanced mixed heart failure , especially in older patients with multiple comorbidities—exactly the profile in this case. Atrial fibrillation with mitral stenosis (Option A) : An S4 is absent in atrial fibrillation because atrial contraction is ineffective. Mitral stenosis typically causes a loud S1 and an opening snap, not an S3 or S4. Acute mitral regurgitation (Option B): Acute mitral regurgitation can cause an S3 due to rapid ventricular filling, but an S4 would be uncommon unless there is concurrent diastolic dysfunction, which is less likely in an acute setting. Severe aortic stenosis (Option D): Aortic stenosis can cause an S4 due to the stiff left ventricle. However, an S3 is less likely unless there is concurrent left ventricular failure. Isolated aortic stenosis would not explain both sounds.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 270, 1984.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 35-year-old woman presents with palpitations. On examination, hyperdynamic precordium is noted with soft S1 and pansystolic murmur. Which of the following is the most likely cause? (Q850494)

A. Hyperthyroidism

B. Mitral stenosis

C. Mitral regurgitation

D. Myxedema heart

Correct Answer: C. Mitral regurgitation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A pansystolic (holosystolic) murmur with a soft S1 and a hyperdynamic precordium is classic for mitral regurgitation: the mitral leaflets fail to coapt, producing a continuous systolic leak (murmur) and a soft/absent S1. The hyperdynamic impulse reflects increased volume load on the left ventricle. The closest option of Hyperthyroidism is ruled out as it has a loud S1 with ejection systolic murmur with hyperdynamic precordium. Hyperthyroidism (Option A): Produces a hyperdynamic circulation and systolic flow murmurs, but not a pansystolic murmur with soft S1. Mitral stenosis (Option B): Gives a loud, tapping S1 and a diastolic rumbling murmur with opening snap — opposite to findings here. Myxedema (hypothyroidism) (Option D): Associated with a low-output, sluggish precordium and bradycardia, not a hyperdynamic impulse or pansystolic murmur.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2053.

↑ *Back to this question in Part A*

@Neet_pg_bot

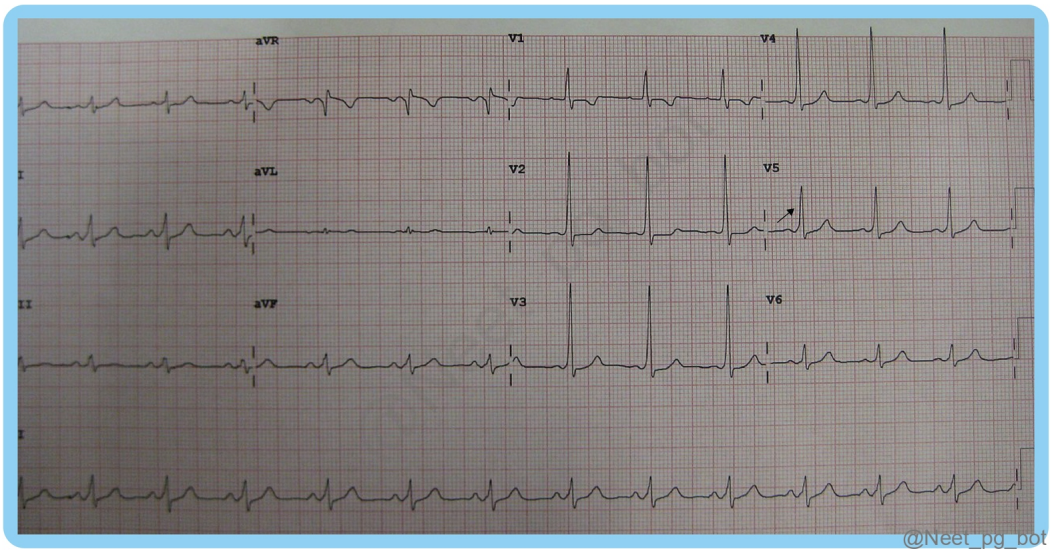
Q17: A 25-year-old man presents to the ER with recurrent episodes of palpitations, dizziness, and occasional chest discomfort. Auscultation shows loud S1 and normal split S2. An ECG of the condition is given below. What is the most likely diagnosis for this patient's condition? (Q850491)

A. Atrial Fibrillation

B. Wolff-Parkinson-White (WPW) Syndrome

C. Myocardial Infarction

D. Brugada syndrome

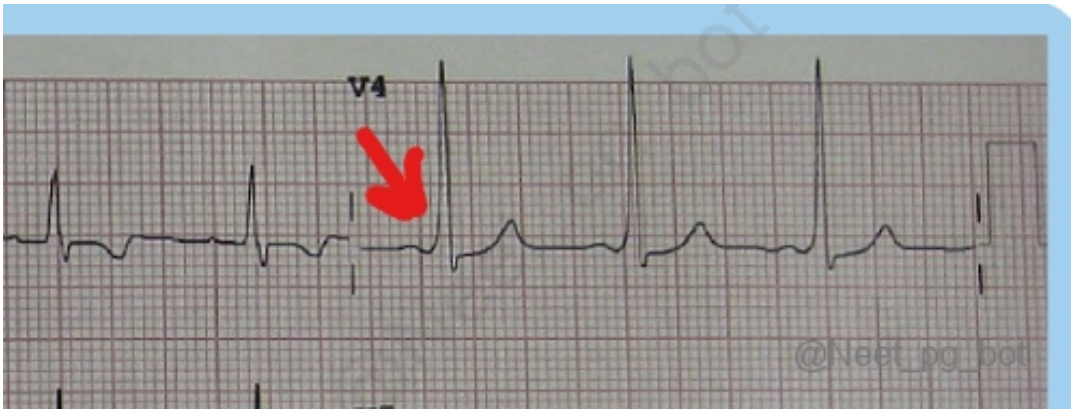


Correct Answer: B. Wolff-Parkinson-White (WPW) Syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ECG shows short PR interval, delta wave (red marking) , and wide QRS complex, diagnostic of Wolff-Parkinson-White (WPW) Syndrome. Loud S1 is explained by tachycardia due to fast conduction via the bundle of kent. Atrial Fibrillation (Option A): AF can occur in WPW but does not cause a delta wave and presents with irregular rhythm rather than the specific findings in WPW. Myocardial Infarction (Option C): rMI causes ischemic changes on ECG, such as ST elevation or Q waves, but not the delta wave or short PR interval seen in WPW. Brugada syndrome (Option D) has coved or saddleback ST segment elevation.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1940-1941

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 6-year-old boy is brought my mother as he gets very breathless during physical activities and had hospitalization for recurrent pneumonia episodes. Inspection shows a right parasternal heave, no cyanosis and auscultation reveals a systolic ejection murmur. Which is correct auscultatory finding seen in this case? (Q850488)

A. Narrow split S2

B. Paradoxical split S2

C. Wide split fixed S2

D. Wide split variable S2

Correct Answer: C. Wide split fixed S2

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A 6-year-old with exertional breathlessness, recurrent respiratory infections, right parasternal heave (RV hypertrophy), and a systolic ejection murmur suggests Atrial Septal Defect (ASD – ostium secundum type) . The classic auscultatory finding in ASD is a wide, fixed split S2 due to constant increased RV stroke volume and delayed pulmonic valve closure. Narrow split S2 (Option A): Occurs with conditions causing early P2, not seen in ASD. Paradoxical split S2 (Option B): Occurs when A2 is delayed (e.g., LBBB, aortic stenosis), opposite of ASD physiology. Wide split variable S2 (Option D): Seen in right bundle branch block or pulmonary stenosis, but variable , not fixed like in ASD.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1864.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 3-year-old girl presents to the clinic with a history of recurrent respiratory infections and exercise intolerance. On physical examination, a holosystolic murmur is noted at the left lower sternal border. Which of the following is correct about heart sound finding in this case? (Q850487)

A. Wide Fixed split S2

B. Paradoxical split S2

C. Narrow split S2

D. Wide split variable S2

Correct Answer: D. Wide split variable S2

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical features are of Ventricular Septal Defect (VSD) which presents with a wide split variable S2. Wide Fixed split S2 (Option A) occurs in conditions like atrial septal defect (ASD), where the split remains constant during respiration due to continuous right heart volume overload, which is not seen in VSD. Paradoxical split S2 (Option B) happens when A2 occurs after P2, often due to conditions like HOCM with severe LV obstruction or severe aortic stenosis. It is not typical for VSD. Narrow split S2 (Option C) indicates a delayed closure of the aortic valve but is not characteristic of VSD, where increased right-sided volume typically causes a wider split.

References:

www.ncbi.nlm.nih.gov/books/NBK341/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A 45-year-old man presents with progressive dyspnea and occasional dizziness. On auscultation, a harsh crescendo-decrescendo systolic murmur is noted at the left sternal border, which increases with the Valsalva maneuver. There is also evidence of a jerky carotid pulse. Which of the following will be heard on auscultation in this case? (Q850485)

A. Wide split S2

B. Fixed split S2

C. Paradoxical split S2

D. Physiological split S2

Correct Answer: C. Paradoxical split S2

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical features suggest Hypertrophic Obstructive Cardiomyopathy (HOCM) with severe left ventricular outflow tract obstruction. It can delay the closure of the aortic valve (A2). This leads to the paradoxical splitting of S2, where A2 occurs after P2, causing the split to be heard during expiration. Wide split S2 (Option A):

This occurs when there is a delayed closure of the pulmonic valve (P2), causing an exaggerated split that increases during inspiration. Common in conditions like right bundle branch block (RBBB) or pulmonic stenosis. Fixed split S2 (Option B): The split remains constant throughout the respiratory cycle, typically seen in atrial septal defect (ASD), due to continuous right heart volume overload. Physiological split S2 (Option D): A normal finding where the split between A2 and P2 increases during inspiration and disappears during expiration due to increased venous return delaying P2.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1864.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: Narrow split S2 heart sound is heard in which of the following conditions? (Q850484)

A. Mitral regurgitation

B. Aortic stenosis

C. Atrial septal defect

D. Pulmonary hypertension

Correct Answer: B. Aortic stenosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Narrow split S2 occurs in aortic stenosis because delayed closure of the aortic valve brings the A2 (aortic component) closer to P2 (pulmonic component). Mitral regurgitation (Option A): In mitral regurgitation, the S2 sound is typically unaffected. However, an S3 sound (due to volume overload) may be heard. Atrial septal defect (ASD) (Option C): In ASD, a wide and fixed split S2 is heard due to increased right-sided volume, which delays the closure of the pulmonic valve (P2). Pulmonary hypertension (Option D): This can lead to a delayed P2, causing a wide split S2, not a narrow split.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1864, 2037.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: Match the following Heart sound Condition seen 1) Wide Split S2 a) RBBB 2) Paradoxical Splitting S2 b) Mitral regurgitation 3) Fixed Splitting S2 c) LBBB 4) Narrow Split S2 d) Hypertrophic cardiomyopathy e) ASD (Q850482)

A. 1-b, 2-c, 3-e, 4-d

B. 1-a, 2-e, 3-b, 4-c

C. 1-b, 2-d, 3-b, 4-e

D. 1-c, 2-a, 3-b, 4-e

Correct Answer: A. 1-b, 2-c, 3-e, 4-d

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Condition Type of Split Wide split Mitral regurgitation due to early A2 Paradoxical split LBBB due to delayed closure of A2 Fixed Splitting ASD Narrow splitting Dynamic out flow tract obstruction will cause more time for blood to exit from left side. This causes delayed closure of A2 causing narrow split S2

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1864.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A 28-year-old woman comes with a history of fever, chest pain, weight loss, and night sweats. During cardiac auscultation, the physician notes a characteristic sound that persists on breath holding. ECG shows global ST segment elevation with concavity upwards. What is this finding called on auscultation known as? (Q850481)

A. Opening snap

B. Pericardial friction rub

C. Pericardial knock

D. Pleural rub

Correct Answer: B. Pericardial friction rub

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Auscultatory finding is pericardial friction rub as it persists on breath holding that differentiates it from pleural rub. ECG finding of global ST segment elevation indicates acute pericarditis. Possible etiology is Tuberculosis that will require more workup. Tuberculous pericarditis is a form of extrapulmonary tuberculosis . There is a serofibrinous exudate outside the heart which causes inflammation and irritation of the phrenic nerve, causing pain to radiate to the shoulders. Presents with chest pain at rest. On examination: Pericardial friction rub (scratchy sound on auscultation) present even when patient holds his breath. Investigation of choice: CBNAAT or Gene Expert testing of pericardial fluid. Treatment: ATT for 6 months. Opening snap (Option A) is a high pitch sound heard in cases of mitral stenosis, follows S2, occurring in early diastole. Pericardial knock (Option C) also known as pericardial shudder is seen in cases of calcification around the heart in patients after treatment with ATT. Pleural rub(Option D) is best heard in the phase of deep inspiration and disappears on breath holding.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1389, 1867.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: Which of the following features would raise suspicion for a diagnosis of Carney complex? (Q850480)

A. Association with tuberous sclerosis

B. Presence of skin pigmentation abnormalities

C. Restrictive cardiomyopathy

D. A-V nodal block

Correct Answer: B. Presence of skin pigmentation abnormalities

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Carney complex is familial cause of Atrial myxomas + skin lesions (pigmentation) + Endocrine abnormalities like Cushing syndrome, acromegaly, multinodular goiter and precocious puberty. Atrial Myxomas: Introduction Most common primary cardiac tumors in adults. Location Often found in the left atrium. Types Sporadic. Familial: Carney Complex (Myxomas + skin lesions + Endocrinopathies). Association with tuberous sclerosis (Option A): Not related; tuberous sclerosis is a separate genetic syndrome. Restrictive cardiomyopathy (Option C): Cardiac involvement is usually myxomas , not restrictive cardiomyopathy. A-V nodal block (Option D): Conduction defects are not a typical feature .

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2085, 3004.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: During the cardiac cycle, the closing of the aortic valve takes place at ? (Q850478)

A. End of isovolumetric contraction

B. End of rapid filling phase

C. Start of isovolumetric relaxation

D. Start of ejection

Correct Answer: C. Start of isovolumetric relaxation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The aortic valve closes when the left ventricular pressure falls below aortic pressure — this marks the end of ejection and the beginning of isovolumetric relaxation . This event produces the second heart sound (S2) . End of isovolumetric contraction (Option A): This is when the aortic valve opens , not closes. End of rapid filling phase (Option B): This is a diastolic filling event , unrelated to aortic valve closure. Start of ejection (Option D): The aortic valve opens at the start of ejection, not closes.

Q31 (p. 1156)					

Q1: A 78 year old man, three months after undergoing transcatheter aortic valve replacement presents with high grade fever with chills and rigors. What is the most common causative organism in TAVR-associated infective endocarditis? (Q850454)

A. Streptococcus viridans

B. Enterococcus spp

C. Staphylococcus aureus

D. Candida spp.

Correct Answer: B. Enterococcus spp

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Enterococcus spp. is the most common causative organism associated with TAVR-related infective endocarditis, followed by S. Aureus. Streptococcus viridans (Option A) is for community-acquired native valve -IE. For C.I.E.D. (Cardiac implantable electronic devices, such as pacemakers), the infective endocarditis leading organism is C.O.N.S.> Staph. Aureus

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1037.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which of the following is a minor criterion for diagnosing infective endocarditis based on 2023 Duke-ISCVID criteria? (Q850473)

A. Two negative blood cultures

B. Echocardiogram showing valve perforation

C. PCR from a sterile body site identifying a typical pathogen

D. Two positive blood cultures

Correct Answer: C. PCR from a sterile body site identifying a typical pathogen

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Positive Blood culture is a major criteria. (Option D ruled out) Echo showing valve perforation is a major criteria (Option B ruled out) Negative blood culture would not be considered for diagnosis.. (Option A ruled out) PCR, amplicon or metagenomic sequencing of typical pathogens from sterile sites other than cardiac tissue is now a minor criterion. The 2023 Duke-International Society for Cardiovascular Infectious Diseases (ISCVID) Criteria for Infective Endocarditis - Minor Criteria Updates Predisposing Conditions Expanded to include transcatheter valve procedures, endovascular leads of cardiac implantable devices, and a history of IE. Vascular Phenomenon Includes splenic and cerebral abscesses. Immunological Phenomena Clarifies immune complex-mediated glomerulonephritis, with a practical definition involving unexplained acute kidney injury, hematuria, proteinuria, or a renal biopsy showing immune complex disease. Microbiological Evidence PCR, amplicon or metagenomic sequencing of typical pathogens from sterile sites other than cardiac tissue is now a minor criterion Imaging Abnormal metabolic activity as detected by [18F]FDG PET/CT within 3 mo of implantation of prosthetic valve, ascending aortic graft (with concomitant evidence of valve involvement), intracardiac device leads or other prosthetic material Physical Exam A new regurgitant murmur on auscultation is considered a minor criterion when echocardiography is unavailable.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1040. www.iscvid.org/wp-content/uploads/2023/07/2023-The-2023-Duke-ISCVID-Criteria-for-Infective-Endocarditis-Fowler-CID-May-4-2023-Final.pdf

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which of the following is a typical organism causing infective endocarditis based on 2023 Duke-ISCVID criteria? (Q850472)

A. Enterococcus faecalis

B. Streptococcus pneumoniae

C. Pseudomonas aeruginosa

D. Streptococcus pyogenes

Correct Answer: A. Enterococcus faecalis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: 2023 Duke-ISCVID criteria for infective endocarditis (IE) - Typical and Non-typical Organisms Typical Non-Typical For General cases: Staphylococcus aureus, Staphylococcus lugdunensis Enterococcus faecalis (Option A) All streptococci (except Streptococcus pneumoniae and Streptococcus pyogenes) Granulicatella, Abiotrophia, Gemella species HACEK group (e.g., Haemophilus, Aggregatibacter, Cardiobacterium, Eikenella, Kingella) For cases involving intracardiac prosthetic material , additional typical organisms include: Coagulase-negative staphylococci Corynebacterium striatum, Corynebacterium jeikeium Serratia marcescens, Cutibacterium acnes Pseudomonas aeruginosa (Option C ruled out) Non-tuberculous mycobacteria (e.g., Mycobacterium chimaera) Candida species Organisms classified as non-typical are less frequently associated with IE and require three or more positive blood cultures for diagnosis. Streptococcus pneumoniae (Option B ruled out) Streptococcus pyogenes (Option D ruled out) Non-faecalis enterococci

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1040.

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 529.

The 2023 Duke-ISVD Criteria

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 70 year old man with a prosthetic aortic valve has a fever, positive blood cultures for Enterococcus faecalis, valve vegetations visualized on echocardiography. Cardiac Computed Tomography shows a valve abscess. Which finding is a new major criterion for infective endocarditis in the 2023 Duke-ISCVID criteria? (Q850471)

A. Direct visual evidence of vegetations during surgery

B. Echocardiogram revealing vegetation

C. Positive blood cultures with Enterococcus faecalis

D. Development of a new onset murmur

Correct Answer: A. Direct visual evidence of vegetations during surgery

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Findings like valvular vegetation, perforation, aneurysm, intracardiac fistula or abscesses on CCT are now considered major criteria according to the updated 2023 Duke-International Society for Cardiovascular Infectious Diseases (ISCVID) Criteria for Infective Endocarditis. The 2023 Duke-International Society for Cardiovascular Infectious Diseases (ISCVID) Criteria for Infective Endocarditis - Major Criteria Updates Microbiological Criteria Expanded "Typical" Pathogens : The list now includes Staphylococcus lugdunensis, Enterococcus faecalis, and other streptococci, excluding S. pneumoniae and S. pyogenes. Additionally, Granulicatella, Abiotrophia, and Gemella species are now recognised as typical IE pathogens. Prosthetic Material-Associated Pathogens : In intracardiac prosthetic devices, certain bacteria like coagulase-negative staphylococci and Corynebacterium species, as well as Pseudomonas aeruginosa, are considered typical. Simplified Blood Culture Protocol : Timing and separate venipuncture rules have been removed, though separate draws are still ideal. Fastidious Pathogens : New criteria account for hard-to-culture organisms like Coxiella burnetii, Bartonella, and Tropheryma whipplei, diagnosed via PCR or specific serology. Imaging Criteria Cardiac CT (CCT): Findings like valvular vegetation, perforation, aneurysm, intracardiac fistula or abscesses on CCT are now considered major criteria. (Option A) [18F]FDG PET/CT : Abnormal metabolic activity involving a native or prosthetic valve, ascending aortic graft (with concomitant evidence of valve involvement), intracardiac device leads or other prosthetic material. Surgical Evidence Intraoperative Findings : Direct visual evidence of IE during surgery, such as vegetations or abscesses, qualifies as a major criterion in cases without other definitive findings.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1040.

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 529

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 65 year old male patient with a history of rheumatic heart disease presents to the dental clinic for a tooth extraction. He has a prosthetic heart valve placed two years ago and reports a penicillin allergy. Which of the following prophylactic antibiotic regimens should be administered to this patient before his dental procedure to prevent infective endocarditis? (Q850470)

A. Amoxicillin 2g orally 1 hour before the procedure

B. Ampicillin 2g IV or IM within 1 hour before the procedure

C. Clarithromycin 500 mg orally 1 hour before the procedure

D. Cefazolin 1g IV or IM 30 minutes before the procedure

Correct Answer: C. Clarithromycin 500 mg orally 1 hour before the procedure

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Clarithromycin is a suitable alternative for patients with penicillin allergies and is indicated for prophylaxis in patients with prosthetic heart valves. High-risk cardiac Lesions for endocarditis prophylaxis before dental procedures Prophylactic Antibiotic Regimens for endocarditis in adults with high-risk cardiac lesions Prosthetic heart valves or material Left ventricular assist devices. Prior endocarditis. Unrepaired cyanotic congenital heart disease, including palliative shunts or conduits. Completely repaired congenital heart defects during the 6 months after repair. Repaired congenital heart disease with residual defects adjacent to the prosthetic material. Surgical or transcatheter pulmonary artery valve or conduit placement Valvulopathy developed after cardiac transplantation. Standard oral regimen (Option A ruled out) Amoxicillin: 2g oral 1hr before procedure Inability to take oral medication (Option B ruled out) Ampicillin: 2g IV or IM within 1hr before procedure Penicillin allergy Clarithromycin or Azithromycin: 500 mg PO 1hr before procedure. Cephalexin: 2g oral 1hr before procedure (avoid if immediate hypersensitivity to penicillin). Doxycycline: 100 mg oral 1hr before procedure. Penicillin allergy, inability to take oral medication (Option D ruled out) Cefazolin or Ceftriaxone: 1g IV or IM 30 mins before the procedure.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1048.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 55 year old man with a history of prosthetic valve deployment presents with fever, chills, and fatigue. Blood cultures reveal methicillin-resistant Staphylococcus aureus. The patient has a prosthetic valve and shows evidence of vegetation on echocardiography. What is the appropriate antibiotic regimen for managing this patient’s infection? (Q850469)

A. Vancomycin + Gentamicin + Rifampin

B. Vancomycin + Daptomycin

C. Nafcillin + Gentamicin + Rifampin

D. Ampicillin + Gentamicin

Correct Answer: A. Vancomycin + Gentamicin + Rifampin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has MRSA prosthetic valve endocarditis (PVE). The appropriate treatment includes Vancomycin + Rifampin and Gentamicin . Rifampin is crucial for targeting bacteria in biofilms which are formed on prosthetic valves. Treatment of Infective Endocarditis Based on Pathogen and Valve Type Methicillin-resistant Staphylococcus aureus (MRSA) NVE: Vancomycin or Daptomycin for 6 weeks. (Option B ruled out) PVE: Vancomycin + Rifampin+ Gentamicin Methicillin-sensitive Staphylococcus aureus (MSSA) PVE: Nafcillin + Rifampin (both for 6-8 weeks) + Gentamicin(for 2 weeks) (Option C ruled out)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1041-1044.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following is a minor criterion under the Modified Duke's Criteria for infective endocarditis? (Q850468)

A. Positive echocardiographic findings of vegetation

B. Two positive blood cultures with a typical organism

C. Presence of a prosthetic valve

D. Abscess formation on echocardiogram

Correct Answer: C. Presence of a prosthetic valve

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Positive echocardiographic findings of vegetation (Option A), Two positive blood cultures with a typical organism (Option B), Abscess formation on echocardiogram (Option D): All the given conditions form the major criteria for Infective Endocarditis in Modified Duke's criteria. Modified Duke's Criteria - Minor criteria Predisposing heart condition Any pre-existing valvular or cardiac abnormality, such as valvular disease, congenital heart defects, or prosthetic valves. (Option C) Intravenous drug use Recognised as a significant risk factor for IE. Fever ≥ 38°C Commonly seen in patients with IE. Vascular phenomena Such as embolic events (stroke, septic pulmonary infarcts), mycotic aneurysms, intracranial haemorrhages and Janeway lesions. Immunological phenomena Rheumatoid factor, Osler's nodes, Roth's spots or glomerulonephritis. Positive blood culture not meeting major criteria Isolation of organisms typical of IE in a single culture or other non-major findings. Suggestive echocardiography Abnormal findings that raise suspicion but do not meet the criteria for a major criterion. (D529)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1040. Davidson’s Principles and Practice of Medicine, 24th Edition, Page 529

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 60 year-old man with a mechanical aortic valve presents with 2 weeks of fever, fatigue, and shortness of breath. He has a history of a dental procedure done 3 weeks back. Blood cultures are negative. FDG-PET/CT shows abnormal uptake around the valve. Which major criterion from the Modified Duke’s Criteria does this patient meet? (Q850467)

A. Negative blood culture for a typical organism

B. Evidence of endocardial involvement by FDG-PET/CT

C. Osler nodes and Janeway lesions

D. Recent history of dental procedure

Correct Answer: B. Evidence of endocardial involvement by FDG-PET/CT

■ *Listen to Audio 1*

Explanation: The FDG-PET/CT scan revealed abnormal uptake around the prosthetic valve, which is considered a major criterion under the Modified Duke’s Criteria. FDG-PET/CT is useful in cases involving prosthetic valves where traditional blood cultures might be negative, helping to detect inflammation around the valve, consistent with endocardial involvement. Modified Duke’s Criteria - Major criteria Positive blood cultures Identification of a typical organism from two cultures, or persistent positive cultures drawn more than 12 hours apart. Three or more positive cultures that have been taken over at least one hour apart. A single positive blood culture for Coxiella burnetii or a phase I IgG antibody titre > 1:800. Evidence of endocardial involvement Positive echocardiographic findings such as vegetations, abscesses, or new valvular regurgitation. Oscillating intracardiac masses or partial dehiscence of a prosthetic valve. Additional diagnostic tools like FDG-PET/CT or EKG-gated cardiac CT angiograms also meet major criteria for prosthetic valve endocarditis. (Added by the European Society of Cardiology)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1040.

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 529

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 30 year old woman who is known case of rheumatic heart disease and mitral regurgitation presents with complaints of fever for past 2 weeks.Echo showed vegetations on both surfaces of mitral valve.Blood cultures grew staphylococcus aureus. Which of the following would be immunological phenomenon seen in these patient? (Q850464)

A. Janeway lesions and Osler's nodes

B. Roth spots and Osler nodes

C. Carditis and Arthritis

D. Splinter hemorrhages in nails and clubbing

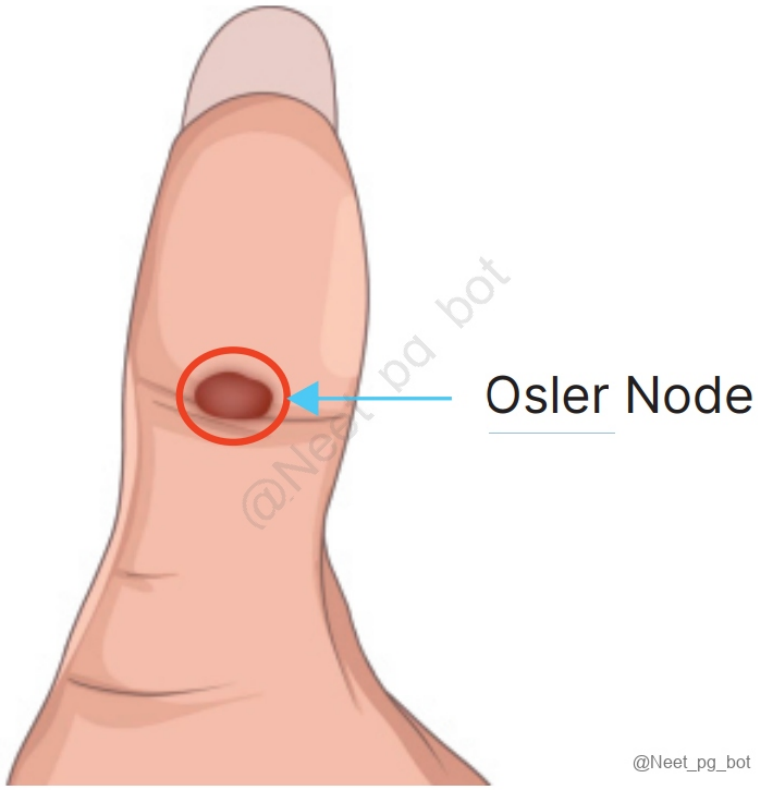
Correct Answer: B. Roth spots and Osler nodes

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Immunological phenomena are ROG : R oth spots on fundus examination R A factor is positive (Suggests chronic immune activation) O sler nodes (Pea-shaped nodules in tips of fingers and occur due to immune complex deposition in dermal vessels) and G lomerulonephritis. Janeway lesions and Osler's nodes (Option A) is for vascular phenomenon seen in these patients. Carditis and Arthritis (Option C) is for rheumatic fever Manifestations: Cardiac manifestations: Perforation: Contributing to new onset murmur Paravalvular abscess Ring abscess Heart block CHF (Congestive Heart Failure) Intracardiac fistula Coronary embolization of vegetations Non-Cardiac manifestations: Janeway lesions Painless, erythematous macules on palms and soles. Related to septic microembolization Osler’s nodes Small painful pea-shaped nodules located at the tips of fingers and toes (Immune complex mediated). Subungual haemorrhages/Splinter haemorrhages More common in acute S. aureus IE. Haemorrhages below nails- multiple linear lesions, initially red then turning brown or black. Roth spots Pale-centred retinal haemorrhages that are seen in the fundus examination

@Neet_pg_bot



Osler Node
@Neet_pg_bot

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1040.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: In the context of infective endocarditis, what role do MSCRAMMs play in the disease process? (Q850463)

A. They enhance the immune response against pathogens during bacteremia.

B. They facilitate bacterial adherence to nonbacterial thrombotic endocarditis (NBTE) or injured endothelium.

C. They are responsible for the formation of emboli that lead to tissue infarction.

D. They promote the breakdown of vegetation formed in the heart.

Correct Answer: B. They facilitate bacterial adherence to nonbacterial thrombotic endocarditis (NBTE) or injured endothelium.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: MSCRAMMs (Microbial Surface Components Recognising Adhesive Matrix Molecules) are adhesion proteins expressed by organisms like Staphylococcus aureus and Staphylococcus epidermidis . They allow bacteria to stick to exposed extracellular matrix and the sterile platelet–fibrin thrombus (NBTE), initiating vegetation formation in infective endocarditis. Enhance immune response (Option A): Incorrect; MSCRAMMs help bacteria evade immunity, not enhance it. Formation of emboli (Option C): Emboli occur due to friable vegetations, not MSCRAMMs. Breakdown of vegetation (Option D): MSCRAMMs promote adhesion, not degradation.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1038.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 65 year old male with ischemic cardiomyopathy and a history of benign prostatic hyperplasia presents with fever, malaise, and a new heart murmur. He recently underwent a urinary catheterisation for urinary retention. Blood cultures are positive for gram-positive cocci. What is the most likely causative organism of his infective endocarditis? (Q850461)

A. Staphylococcus aureus

B. Streptococcus gallolyticus

C. Enterococcus faecalis

D. Haemophilus species

Correct Answer: C. Enterococcus faecalis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Enterococcus faecalis is a gram-positive cocci and is frequently linked to infective endocarditis following genitourinary procedures, such as catheterization. Portals of entry Oral cavity: The entry point for viridans streptococci. Skin: Common entry point for staphylococci and S.epidermidis. Upper respiratory tract: Source for HACEK organisms (Haemophilus, Aggregatibacter, Cardiobacterium hominis, Eikenella corrodens, Kingella). (Option D ruled out) Gastrointestinal tract: Streptococcus gallolyticus (formerly S. bovis) is associated with colonic polyps and tumours. (Option B ruled out) Genitourinary tract and GI tract procedures (catheterization, colonoscopy): Source for enterococci. Nosocomial (hospital-acquired) sources: S. aureus, coagulase-negative staphylococci (CoNS), and enterococci are often linked to healthcare-associated infective endocarditis. (Option A ruled out) Prosthetic valve infections (PVE): Intraoperative contamination or postoperative infection, especially with S. aureus, CoNS, and gram-negative bacilli. Intravenous drug use: Primary portal for S. aureus infections, especially in tricuspid valve involvement. (Option A ruled out)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1038.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 68 year old farmer with a prosthetic valve presents with fever, night sweats, and fatigue 6 months post-surgery. Blood cultures are negative. He has goats and cows on his farm . Which organism is most likely responsible for his prosthetic valve endocarditis? (Q850460)

A. Staphylococcus epidermidis

B. Coxiella burnetii

C. Mycobacterium chimaera

D. Enterococcus faecalis

Correct Answer: B. Coxiella burnetii

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Culture-Negative Infective Endocarditis (IE) Coxiella burnetii, and Bartonella species are due to exposure to animals. Common Cause : One-third to one-half of culture-negative cases are due to prior antibiotic exposure. Fastidious Organisms : Streptococci, Granulicatella, and Abiotrophia species. HACEK organisms - Haemophilus, Aggregatibacter, Cardiobacterium, Eikenella, and Kingella

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1354.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 3 year girl with a history of patent ductus arteriosus presents with high grade fever. Her recent echocardiogram shows vegetations along the inner lining of her aorta. Which of the following conditions is the most likely diagnosis for this patient based on her symptoms and history? (Q850459)

A. Acute bacterial endocarditis

B. Subacute bacterial endocarditis

C. Infective endarteritis

D. Fungal endocarditis

Correct Answer: C. Infective endarteritis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The key-words are vegetations along the wall of the aorta in case of patent ductus arteriosus, which point more towards infective endarteritis. Infective endarteritis is an infection of the inner layer of arteries, often affecting shunts (arteriovenous, arterio-arterial like PDA) or coarctation of the aorta. Acute bacterial endocarditis (Option A): Involves rapid infection of normal valves, usually by Staphylococcus aureus , not arterial walls. Subacute bacterial endocarditis (Option B): Affects abnormal valves with slower progression, not the aorta. Fungal endocarditis (Option D): Involves large friable vegetations on valves, typically in immunocompromised or IV drug users.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1036.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 72 year female with a history of mitral valve prolapse presents with a fever and fatigue for last > 2 weeks. Physical examination reveals a new heart murmur and petechiae on her extremities. Blood cultures are sent. What is the leading organism

associated with this patient's probable condition? (Q850458)

A. Staphylococcus aureus

B. Streptococcus viridans

C. Enterococcus faecalis

D. HACEK organisms

Correct Answer: B. Streptococcus viridans

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's symptoms have persisted for > 2weeks aligning with the gradual onset characteristic of subacute bacterial endocarditis. Additionally, her history of mitral valve prolapse suggests a predisposing condition for the development of endocarditis. Streptococcus viridans is the most common organism associated with subacute bacterial endocarditis. Acute Bacterial Endocarditis Subacute Bacterial Endocarditis -Presentation as Fever, fatigue, and malaise within <2 weeks of infection Slow progression compared to Acute endocarditis. Signs : Changing heart murmur , Janeway lesions (hemorrhagic macules on palms/soles), petechiae, Roth's spots, splinter haemorrhages Signs : Gradual onset presentation over weeks to months (>2 weeks) but can be life-threatening if untreated Causative organisms : S. aureus Causative organism: Streptococcus viridans (Most common cause)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1206, 2417.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: Which of the following lists the valves in order of frequency of involvement in infective endocarditis, from most to least commonly affected? (Q850456)

A. Mitral valve > Aortic valve > Tricuspid valve > Pulmonic valve

B. Aortic valve > Mitral valve > Pulmonic valve > Tricuspid valve

C. Tricuspid valve > Mitral valve > Aortic valve > Pulmonic valve

D. Pulmonic valve > Aortic valve > Tricuspid valve > Mitral valve

Correct Answer: A. Mitral valve > Aortic valve > Tricuspid valve > Pulmonic valve

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Rationale is that mitral valve operates at the highest pressure gradient in the heart followed by the aortic valve. On the right side it is tricuspid followed by the pulmonic valve.

@Neet_pg_bot

Q16: Which of the following statements is false regarding right-sided infective endocarditis (IE)? (Q850455)

A. Right-sided infective endocarditis is more commonly associated with enterococci than left-sided infective endocarditis.

B. Staphylococcus aureus is the most common pathogen in right-sided infective endocarditis

C. Injecting particles are more likely to reach the right-sided valves compared to the left-sided valves

D. Right-sided infective endocarditis has a better long-term prognosis compared to left-sided infective endocarditis

Correct Answer: A. Right-sided infective endocarditis is more commonly associated with enterococci than left-sided infective endocarditis.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Enterococci are more common in left-sided infective endocarditis than in right-sided IE. Staphylococcus aureus is responsible for IE in IVDU due to poor injection hygiene. (Option B) Injected particles damage right-sided valves. (Option C) Right-sided infective endocarditis has a better long-term prognosis (Option D)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1037.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 72 year old woman presents with severe chest pain and shortness of breath after the death of her husband. She has no history of heart disease. ECG shows STE of 2 mm in lead I , aVL, V2-V4. Bedside echocardiogram shows left ventricular ballooning and cardiac biomarkers are elevated. What is the most likely diagnosis? (Q850403)

A. Anterior wall MI

B. Takotsubo Cardiomyopathy

C. Inferior wall MI

D. Pulmonary Embolism

Correct Answer: B. Takotsubo Cardiomyopathy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Takotsubo cardiomyopathy, also known as broken heart syndrome, is characterized by left ventricular dysfunction often triggered by emotional stress. The patient's recent stressful event, ballooning of the left ventricle, and elevation of cardiac enzymes align perfectly with this diagnosis Anterior wall MI (Option A): Presents with similar ECG changes but has obstructive LAD lesion on angiography. Inferior wall MI (Option C): Causes ST elevation in leads II, III, and aVF, not V2–V4. Pulmonary embolism (Option D): Shows sinus tachycardia or S1Q3T3 pattern, not diffuse ST elevation.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2019, 3164.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: Which of the following is the most common echocardiographic finding associated with rheumatic carditis in children? (Q850453)

A. Aortic regurgitation

B. Mitral regurgitation

C. Aortic stenosis

D. Mitral stenosis

Correct Answer: B. Mitral regurgitation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The most common valvular lesion seen in Rheumatic carditis in children is mitral regurgitation. The same patient, after 18 years of age will have Mitral stenosis (predominant lesion) with mitral regurgitation.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2855.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 12 year old girl presents with involuntary, jerky movements in her hands and feet, worsening with stress or purposeful tasks and does not interferes with eating. Her mother tells that for 3 months she had developed arthritis that caused her to limp for a week with swelling of knee and ankle joints. Work up shows increased PR interval, What is the most appropriate initial treatment? (Q850451)

A. Penicillin prophylaxis

B. Haloperidol

C. Intravenous immunoglobulin (IVIG)

D. Carbamazepine

Correct Answer: A. Penicillin prophylaxis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has Sydenham's chorea , a delayed complication of acute rheumatic fever following untreated streptococcal pharyngitis. Penicillin prophylaxis is the initial step to prevent further streptococcal infection and recurrent episodes of rheumatic fever, even if no active infection is present. Clinical features of Sydenham's chorea: Darting tongue / Harlequin tongue Pronator sign Hung up reflexes Emotional lability Signs seen in Sydenham's chorea: Tongue fasciculations (" Bag of worms ") Motor impersistence, for example, the "Milkmaid sign" (grip strength fluctuates, as if hand milking a cow), Inability to sustain tongue protrusion (called Jack-in-the-box tongue or Serpentine tongue , as the tongue slides in and out of the mouth) Treatment for Sydenham’s Chorea: Moderate to severe chorea Category Medications Purpose Initial Antibiotic Prophylaxis Benzathine penicillin G Prevent the recurrence of rheumatic fever Additional Treatment Neuroleptics : Pimozide, haloperidol, risperidone, olanzapine (Option B ruled out) Control chorea symptoms Anticonvulsants : Valproate, carbamazepine (Option D ruled out) Off-label use for symptom management Immunomodulatory Therapy

Corticosteroids, Intravenous immunoglobulin (IVIG), Plasma exchange (Option C ruled out) For severe/persistent symptoms Mild chorea does not need any treatment

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2858.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A 25 year woman presents with a history of exertional dyspnea, palpitations, and episodes of syncope. She recalls experiencing multiple episodes of sore throat as a child, followed by joint pains, for which she received no definitive treatment. On auscultation, there is a diastolic murmur at the apex and a loud S1. An echocardiogram reveals mitral valve orifice < 1.5 cm 2 with left atrial enlargement. What is the next most appropriate step in management? (Q850450)

A. Mitral balloon valvotomy

B. Mitral valve repair

C. ACE Inhibitors and rate control drugs

D. Immediate mitral valve replacement

Correct Answer: A. Mitral balloon valvotomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has rheumatic mitral stenosis secondary to untreated rheumatic fever in childhood, leading to significant narrowing of the mitral valve and left atrial enlargement. Mitral balloon valvotomy is the treatment of choice for symptomatic patients with mitral stenosis who do not have significant mitral regurgitation or left atrial thrombus. It is a minimally invasive procedure that can significantly improve valve function and relieve symptoms. Mitral valve repair (Option B): It is standard for regurgitation but rarely first line for mitral stenosis. In MS, thickened leaflets and fused commissures make repair harder than valvotomy. ACE Inhibitors and rate control drugs (Option C): Medical therapy eases symptoms but does not relieve the mechanical obstruction. ACE inhibitors help HFrEF, not MS, where the problem is filling; rate-control drugs can lengthen diastole but are not the next step once the patient has syncope and already needs mechanical intervention. Immediate mitral valve replacement (Option D): It is an invasive open-heart surgery using a prosthetic valve. It is reserved for patients unsuitable for balloon valvotomy (heavy calcification, major MR, or atrial thrombus); in a young adult, we prefer valve preservation to avoid lifelong anticoagulation or early prosthetic failure.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1893, 2050. Davidson’s Principles and Practice of Medicine, 24th Edition, Page 465, 467, 517, 519, 521, 524, 525

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 35-year-old woman presents with progressive exertional dyspnea, fatigue, and occasional palpitations. O/E, she has an irregular pulse, a loud S1, an opening snap, and a low-pitched diastolic rumble at the apex. She recalls a childhood illness with fever and joint pain requiring hospitalization. Which of the following investigations is NOT primarily used in diagnosing her condition? (Q850449)

A. Echocardiography

B. Electrocardiogram

C. Blood cultures

D. Chest X-ray

Correct Answer: C. Blood cultures

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The hallmark auscultatory findings of mitral stenosis is loud S1, opening snap, and diastolic rumble. Echo will tell you about the severity of Mitral stenosis. ECG will inform about cardiac chamber enlargement and PR interval prolongation which is a minor diagnostic criteria. Blood cultures are primarily used in diagnosing infective endocarditis, not for diagnosing RHD itself. They help identify pathogens when infection is suspected, particularly in patients with fever and valvular vegetation. Diagnosis of RHD: Blood Tests Leukocytosis, ESR, CRP Indicators of systemic illness. Raised ESR and CRP are common inflammatory markers. Throat Swab Culture Used to identify group A β-haemolytic streptococci . Cultures may also be taken from family members and contacts to confirm the source of infection. Antistreptolysin O (ASO) titres Elevated ASO levels (> 200 U in adults, > 300 U in children) or rising titres support the diagnosis of acute rheumatic fever. Normal ASO titres do not rule out the disease. Investigations Electrocardiogram (ECG) (Option B ruled out) Shows first-degree, and rarely, second-degree atrioventricular block. Pericarditis features. T-wave inversion. QRS voltage reduction. Chest X-ray (Option D ruled out) Identifies cardiomegaly and pulmonary congestion. Echocardiography (Option A ruled out) Reveals cardiac dilatation. Detects valve abnormalities: Commonly mitral regurgitation with mitral annulus dilatation and anterior mitral leaflet prolapse. Shows aortic regurgitation. Identifies pericardial effusion.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2857. Davidson’s Principles and Practice of Medicine, 24th Edition, Page 488, 517, 530, 536, 538, 542, 620

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: Which of the following is not a part of the major criteria for a low-risk population? (Q850445)

A. Carditis

B. Polyarthritis

C. Chorea

D. Polyarthralgia

Correct Answer: D. Polyarthralgia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Polyarthralgia is not part of the major criteria; it is a minor criterion for low-risk populations but is a major criterion for high-risk populations. Carditis, Polyarthritis and Chorea (Option A,B and C): Major Jones criteria in both low- and high-risk populations. Modified Jones Criteria for Rheumatic Fever: Criteria Low-Risk Population High-Risk Population Major Criteria Carditis (clinical or subclinical) (Option A ruled out) Polyarthritis (Option B ruled out) Chorea (Option C ruled out) Erythema marginatum Subcutaneous nodules Carditis (clinical or subclinical) Monoarthritis or Polyarthritis Chorea Erythema marginatum Subcutaneous nodules Polyarthralgia (Option D) Minor Criteria Polyarthralgia (Option D) Hyperpyrexia (≥ 38.5ºC) ESR ≥ 60 mm/h and/or CRP ≥ 3.0 mg/dl Prolonged PR interval (if no there is no carditis in major criterion) Monoarthralgia Hyperpyrexia (≥ 38.0ºC) ESR ≥ 30 mm/h and/or CRP ≥ 3.0 mg/dl Prolonged PR interval (if no there is no carditis in major criterion)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: Which of the following is correct about St Vitus's dance? (Q850443)

A. It is an early manifestation of rheumatic fever

B. It occurs in all patients with rheumatic fever

C. It is associated with emotional lability

D. It is a minor diagnostic criteria

Correct Answer: C. It is associated with emotional lability

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: St Vitus's dance is another name for Sydenham's chorea. Sydenham's chorea is characterized by involuntary, purposeless movements, and significant emotional instability , often presenting as mood swings and obsessive-compulsive traits. It is more common in females. These features highlight its distinctive neurological profile as a complication of rheumatic fever.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2856.

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 516

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: A 5 year old boy presents with fever and migratory joint pain. On auscultation, a soft mid-diastolic murmur is heard at the apex. Echocardiography reveals mitral valve inflammation. Which of the following is most likely present in this patient? (Q850442)

A. Mitral stenosis murmur

B. Austin Flint murmur

C. Carey Coombs murmur

D. Graham Steele Murmur

Correct Answer: C. Carey Coombs murmur

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Characterstic murmur of RHD is Carey Coombs murmur. It is a soft mid-diastolic apical murmur due to inflammation of the mitral valve leaflets (valvulitis) in acute rheumatic fever (ARF). It is a Flow murmur that occurs due to increased blood flow across thickened leaflets of mitral valve. This is specifically associated with ARF and reflects early mitral valve involvement. Mitral stenosis murmur (Option A): Mitral stenosis is seen after 18 years of age in RHD. It does not have valvulitis but has commisural fusion. Austin Flint (Option B) is seen in

Severe AR Graham Steel (Option D) is seen in PAH causing mild pulmonic regurgitation.

@Neet_pg_bot

Q25: Which of the following clinical features is most commonly associated with Acute Rheumatic fever in the Indian population? (Q850437)

A. Polyarthritis

B. Erythema Marginatum

C. Subcutaneous Nodules

D. Pulmonary Hypertension

Correct Answer: A. Polyarthritis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Polyarthritis is the most common symptom in ARF , seen in 60-75% of cases. In India, polyarthritis remains a prominent early manifestation of ARF. India has a high incidence of rheumatic heart disease, ranging from 13 to 150 cases per 100,000 population annually.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2855-2856. Davidson’s Principles and Practice of Medicine, 24th Edition, Page 515

↑ *Back to this question in Part A*

@Neet_pg_bot

Q26: A 10 y/o boy presents with fever, joint pain, and a recent history of sore throat. Examination reveals a heart murmur suggestive of mitral regurgitation. Laboratory tests show elevated antistreptolysin O titers. Which of the following best explains the pathogenesis of his condition? (Q850435)

A. Direct invasion of heart valves by Streptococcus bacteria

B. Immune response triggered by molecular mimicry between bacterial antigens and heart tissue

C. Autoimmune destruction of heart valves due to viral infection

D. Genetic mutations in heart muscle proteins

Correct Answer: B. Immune response triggered by molecular mimicry between bacterial antigens and heart tissue

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: RF is an autoimmune process with ASO antibody causing damage to self cardiac tissues. It is an example of type 2 hypersensitivity/ molecular mimicry.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2854-2855.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q27: A 11 year boy with a history of acute rheumatic fever without carditis presents for follow-up. Based on the AHA guidelines, what is the recommended duration for continuing secondary prophylaxis in this patient? (Q850432)

A. Continue prophylaxis for 1 more year

B. Continue prophylaxis until the age of 25

C. Continue prophylaxis on lifelong basis

D. Continue prophylaxis until the age of 21

Correct Answer: D. Continue prophylaxis until the age of 21

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Secondary Prevention in Acute Rheumatic Fever Duration of Prophylaxis Determined by the presence and severity of carditis, age, and time since the last ARF episode No Carditis 5 years or until 21 years of age, whichever is longer. Carditis without Valvular Disease 10 years or until 21 years of age, whichever is longer. Persistent Valvular Disease 10 years or until 40 years of age, whichever is longer. Lifelong prophylaxis may be needed in severe cases.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2858.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q28: Which of the following is not an indication for ICD implantation? (Q850430)

A. Chagas disease

B. Wolff-Parkinson-White syndrome

C. Hypertrophic cardiomyopathy

D. Long QT syndrome

Correct Answer: B. Wolff-Parkinson-White syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: While Wolff-Parkinson-White syndrome can lead to arrhythmias, it is typically amenable to catheter ablation, making ICD implantation unnecessary in the absence of other risk factors. Indication for ICD implantation Ischemic, Non-ischemic, Hypertrophic (Option C ruled out) , and Familial cardiomyopathy Arrhythmogenic right ventricular dysplasia Cardiac sarcoidosis Brugada syndrome Long-QT syndrome (Option D ruled out) Catecholaminergic polymorphic VT (CPVT) LV noncompaction Chagas disease (dilated cardiomyopathy due to infection) (Option A ruled out)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2339-2340.

↑ *Back to this question in Part A*

@Neet_pg_bot

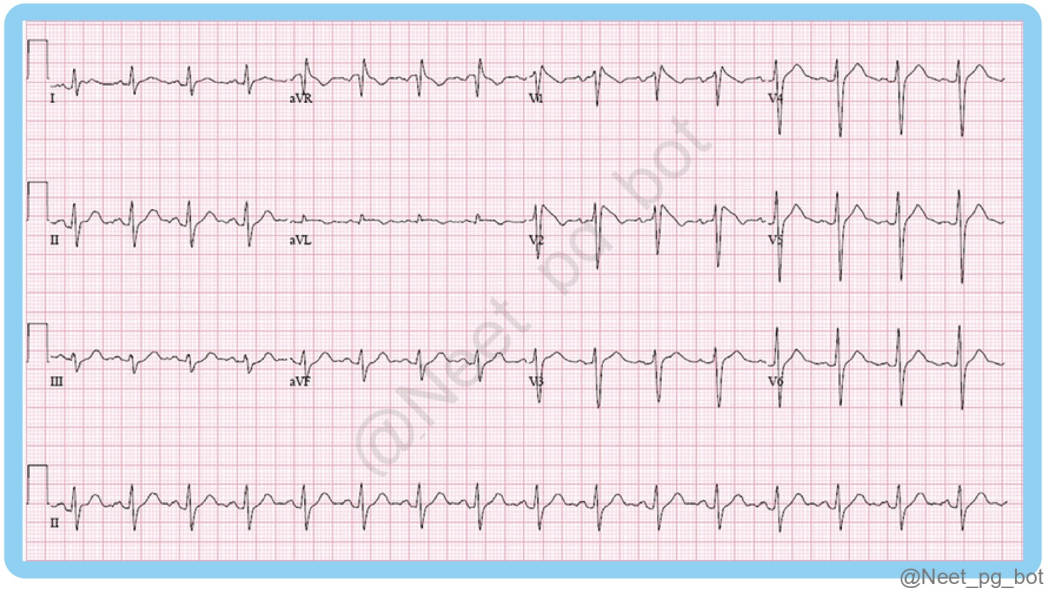
Q29: A 13 year old male is brought to ER by his father who noticed agonal breathing at 5 am in morning. He is the only child in family. Urgent ECG is done. What finding is noted? (Q850423)

A. Delta waves

B. Deep Q waves

C. Coved ST elevation

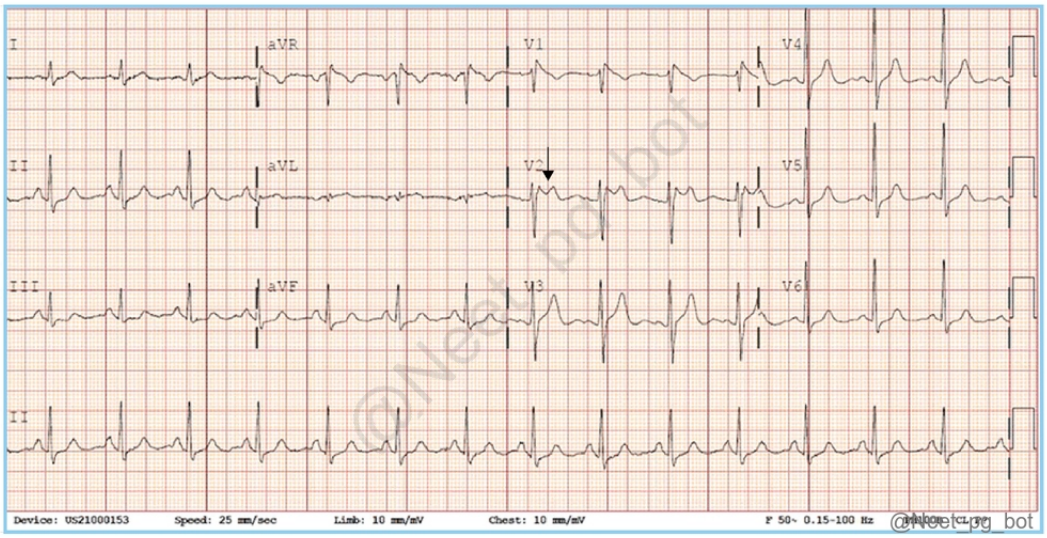
D. Epsilon waves



Correct Answer: C. Coved ST elevation

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Notice the Coved ST elevation in V1-V3 which is seen in Brugada syndrome. It is a SCN5A defect and causes sudden nocturnal death in South east asian males. Epsilon waves are seen in ARVD and Deep Q waves in Hypertrophic cardiomyopathy and MI. Saddleback ST elevation (check out the arrow drawn at lead V2) is seen in Type 2 Brugada syndrome



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1970.

↑ *Back to this question in Part A*

@Neet_pg_bot

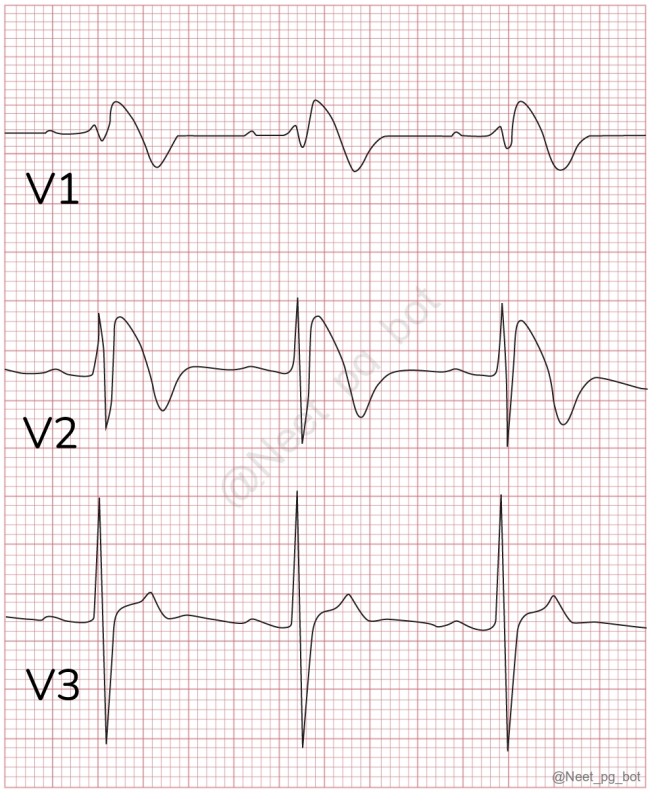
Q30: A 15-year-old male presents to the ED after experiencing a brief episode of syncope. He reports occasional palpitations and dizziness. His family history is significant for sudden cardiac death at a young age. An ECG of leads V1-V3 is given below. Which of the following management options is most appropriate for this patient, given the findings? (Q850411)

A. Prescribe a beta-blocker and advise lifestyle modifications

B. Perform Troponin I levels

C. It is also called Broken heart syndrome

D. Deploy implantable cardioverter-defibrillator.



Correct Answer: D. Deploy implantable cardioverter-defibrillator.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ECG shows coved-type ST elevation >2 mm in V1–V3, characteristic of Brugada syndrome , which carries a high risk of sudden cardiac death. An ICD is the definitive management to prevent fatal arrhythmias. Prescribe a beta-blocker and advise lifestyle modifications (Option A): Beta-blockers are not effective and may worsen arrhythmias. Perform Troponin I levels (Option B): This is used for myocardial infarction, not Brugada syndrome. It is also called Broken heart syndrome (Option C): Refers to Takotsubo cardiomyopathy, not Brugada.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1970.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q31: A 68 year old postmenopausal woman presents to the emergency department with chest pain and dyspnea after a recent stressful event. Her ECG shows ST-segment elevation and cardiac biomarkers are elevated. What is the most appropriate next step in management of this patient? (Q850407)

A. Administer intravenous anticoagulation therapy

B. Implant an implantable cardioverter-defibrillator.

C. Initiate inotropic support immediately.

D. Perform coronary angiography

Correct Answer: D. Perform coronary angiography

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's symptoms, ST-segment elevation on ECG, and troponin elevation suggest Takotsubo cardiomyopathy, especially given her postmenopausal status and recent stress. The initial management focuses on ruling out obstructive coronary disease through coronary angiography while addressing acute symptoms. Administer intravenous anticoagulation therapy (Option A): Indicated for true MI or thromboembolism, not diagnostic here. Implant an implantable cardioverter-defibrillator (Option B): Not needed in transient, reversible stress cardiomyopathy. Initiate inotropic support immediately (Option C): Can worsen LV outflow obstruction; supportive care is preferred.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2019

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 541

↑ *Back to this question in Part A*

Q7 (p. 1165)	*Q8 (p. 1165)*	*Q9 (p. 1167)*	*Q10 (p. 1168)*	*Q11 (p. 1169)*	*Q12 (p. 1170)*
Q13 (p. 1171)	*Q14 (p. 1173)*	*Q15 (p. 1174)*	*Q16 (p. 1176)*	*Q17 (p. 1177)*	*Q18 (p. 1179)*
Q19 (p. 1180)	*Q20 (p. 1181)*	*Q21 (p. 1182)*			

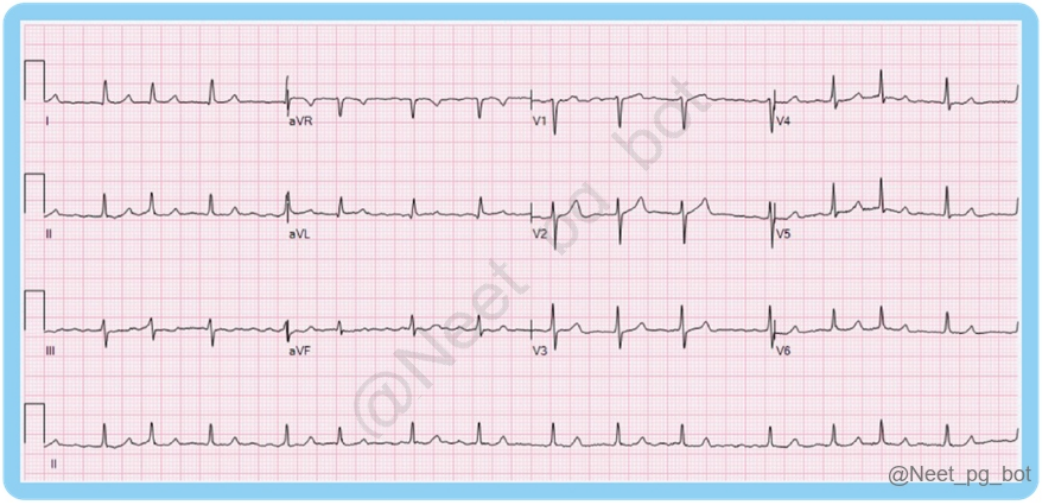
Q1: A 68-year-old smoker man with a history of hypertension presents to the ER with complaints of palpitations and shortness of breath for the past 2 hours. On examination, his pulse is irregularly irregular with a rate of 140 beats per minute. An ECG of the patient is given below. He has poorly controlled COPD. Which of the following statements about his condition is incorrect? (Q850694)

A. Multiple ectopic foci due to structural damage to heart

B. Start beta blockers followed by warfarin

C. CHADS2VASc score is used to decide the need for anticoagulation

D. Amiodarone is used for chemical cardioversion



Correct Answer: B. Start beta blockers followed by warfarin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's clinical presentation of irregularly irregular pulse and ECG findings indicate atrial fibrillation. Beta blockers are contraindicated in asthma /COPD patients. For anticoagulation in non valvular causes start apixaban or dabigatran. Warfarin is used for RHD with mitral stenosis causing atrial fibrillation. CHA2DS2-VASc stroke risk scoring system for AF Points Parameters Score C Congestive heart failure 1 H Hypertension history 1 A2 Age (≥75 years) 2 D Diabetes mellitus 1 S2 Previous stroke or transient ischemic attack (TIA) 2 V Vascular disease 1 A Age (65-74 years) 1 Sc Sex category (female) 1 Maximum total score 9 points Management option for AF as per CHA2DS2-VASc score 0: need not anticoagulate 1: Give aspirin >=2: Warfarin/Dabigatran/Rivaroxaban

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1949-1951 Davidson’s Principles and Practice of Medicine, 24th Edition, Page 470, 471, 472

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 68-year-old male patient with a history of hypertension presents to the emergency department in acute distress. He is diaphoretic, tachycardic, and complains of severe chest pain. BP is 90/60 mm Hg. His ECG is given below. Given the patient's condition, what is the most appropriate immediate management for this patient? (Q850728)

A. Amiodarone

B. Radiofrequency catheter ablation

C. Digoxin

D. Synchronized cardioversion

Correct Answer: D. Synchronized cardioversion

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's clinical presentation of acute distress, diaphoresis, tachycardia, and severe chest pain, along with the ECG showing saw-tooth flutter waves indicative of atrial flutter , suggests he is hemodynamically unstable. This necessitates immediate synchronized cardioversion to restore normal sinus rhythm and stabilize his condition. Atrial Flutter Management 1. Rhythm Control: Acute Management: Hemodynamically Unstable Patients: Synchronized cardioversion. Stable Patients: Electrical cardioversion (if no intracardiac thrombus). Pharmacological cardioversion: Antiarrhythmic drugs: Amiodarone Class IA: Procainamide, Quinidine, Disopyramide Class IC: Flecainide, Propafenone Calcium Channel Blockers: Verapamil, Diltiazem Beta-Blockers: Metoprolol, Carvedilol, Esmolol Long-Term Management: Radiofrequency catheter ablation of the cavotricuspid isthmus. 2. Rate Control: First-Line Agents: Calcium Channel Blockers (e.g., Verapamil, Diltiazem) Beta-Blockers (e.g., Metoprolol, Carvedilol, Esmolol) Digoxin (use cautiously due to toxicity). Goal: Heart rate < 110 beats per minute. 3. Anticoagulation: Assess stroke risk using the CHADS2-VASC score: Anticoagulation Recommendations: 2 or more points: Strong recommendation for anticoagulation. 1 point: Consider either aspirin or full anticoagulation.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1944-1946.

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 470

↑ *Back to this question in Part A*

@Neet_pg_bot

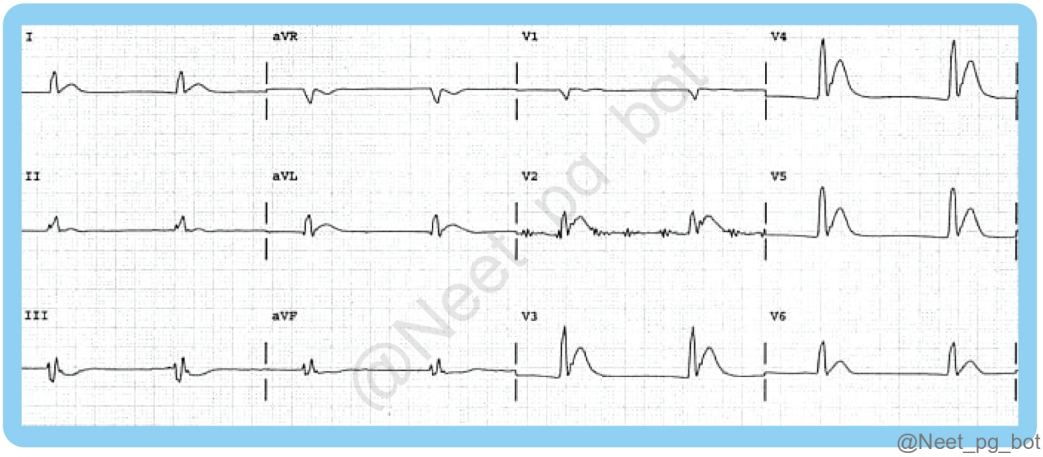
Q3: A 42-year-old woman diagnosed with stage IV breast cancer presents to the emergency department with confusion and breathing difficulty. BP on admission is 80/60 mm Hg. The ECG is attached below. Which of the following would be the most likely diagnosis in this patient? (Q850726)

A. Malignant pericardial effusion

B. Cardiac tamponade

C. Acute pericarditis

D. Constrictive pericarditis



Correct Answer: B. Cardiac tamponade

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ECG shows low voltage with electrical alternans in V3–V6, II, III, aVF. BP is low, indicating cardiac tamponade. Precordial leads show J point elevation / Osborn waves that can be explained by hypercalcemia caused by breast carcinoma. All the remaining options will have normal to low BP, but hemodynamic instability favours the diagnosis as cardiac tamponade.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1905-1906.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 45-year-old man is brought to the emergency department with confusion and muscle weakness. His laboratory results show a serum potassium level of 7.2 mEq/L.Which of the following T-wave morphologies is most likely to be seen on this patient's ECG? (Q850722)

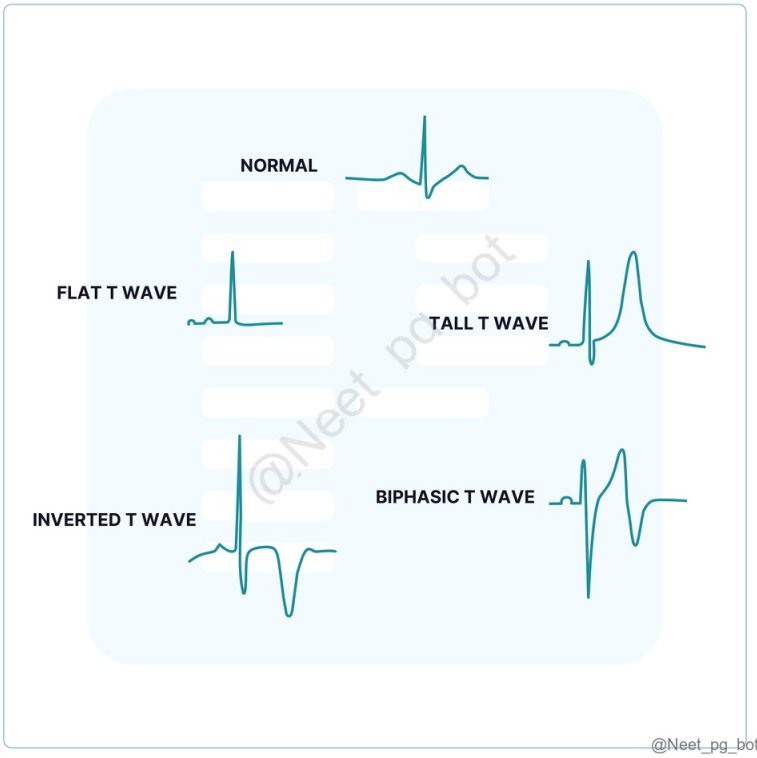
Correct Answer: Unknown

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In the setting of severe hyperkalemia (serum potassium > 7.0 mEq/L), the ECG typically shows peaked/tall T-waves, which is represented in Option C. T-wave abnormalities: {{caption_text}} T-wave Abnormality Associated Conditions and Characteristics Peaked T-waves Hyperkalemia: Narrow, pointed, called tall tented T-waves Myocardial infarction: Broad-based, asymmetric T-waves Left ventricular hypertrophy: Tall

T-waves in precordial leads Prinzmetal angina: Tall, pointed T-waves during chest pain Inverted T-waves Myocardial ischemia: Symmetrically inverted T-waves Wellens syndrome Cerebrovascular injury: cerebral T-waves Hypertrophic cardiomyopathy Pulmonary embolism in S1Q3T3



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 359, 1874.

↑ *Back to this question in Part A*

@Neet_pg_bot

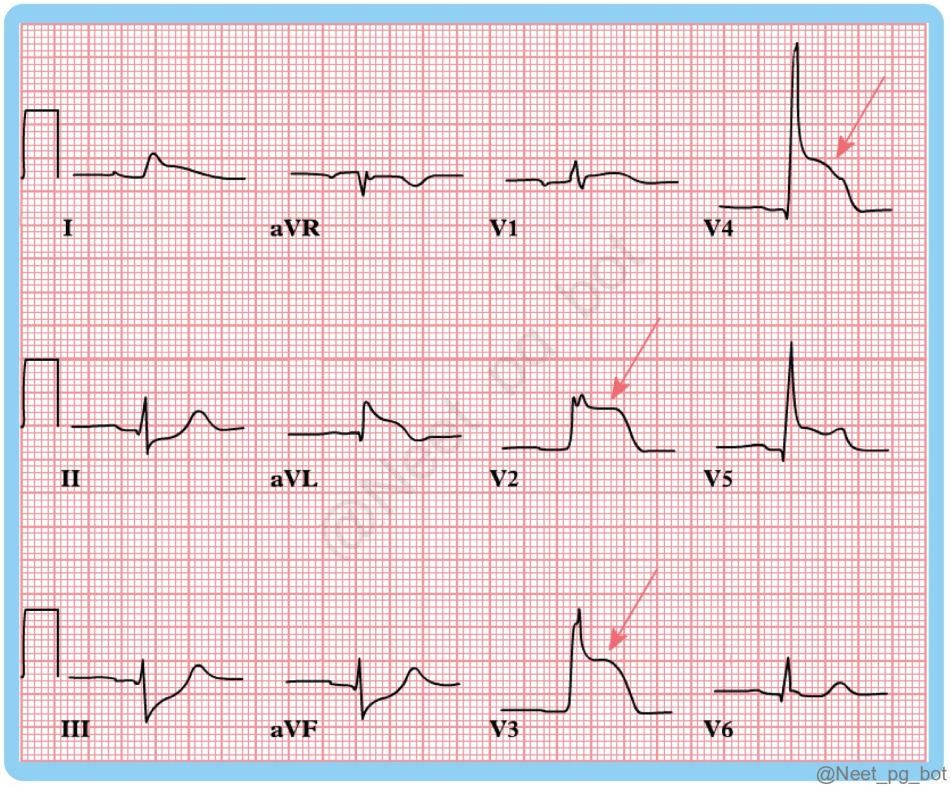
Q5: A 55-year-old alcoholic presents to the emergency department with sweating and palpitations. He is a known case of T2DM on metformin and Glipizide. Labs show plasma glucose 65 mg/dl, serum creatinine 2.0 mg/dl, BUN 70 mg/dl and serum potassium of 5.8 meq/dl. ECG is shown below. What is the next best step in the management of this patient? (Q850714)

A. Call nephrology for urgent hemodialysis

B. Stop metformin

C. Give IV dextrose with thiamine

D. Send to cath lab



Correct Answer: D. Send to cath lab

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The ECG shows ST elevation in leads I, AVL, and V2-V5 & reciprocal depressions in the inferior leads (II, III, AVF). This is a case of anterior wall STEMI, and PCI should be done within 90 minutes of arrival at the hospital. Call nephrology for urgent hemodialysis (Option A): Because: K■ 5.8 mEq/L is elevated but not at dialysis threshold, and STEMI management takes priority. Stop metformin (Option B): Metformin should be stopped in AKI, but this is not the immediate step in a STEMI emergency. Give IV dextrose with thiamine (Option D): Patient has no features of Wernicke encephalopathy and mild hypoglycemia can be corrected after stabilizing STEMI; not the first step.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2119.

↑ *Back to this question in Part A*

@Neet_pg_bot

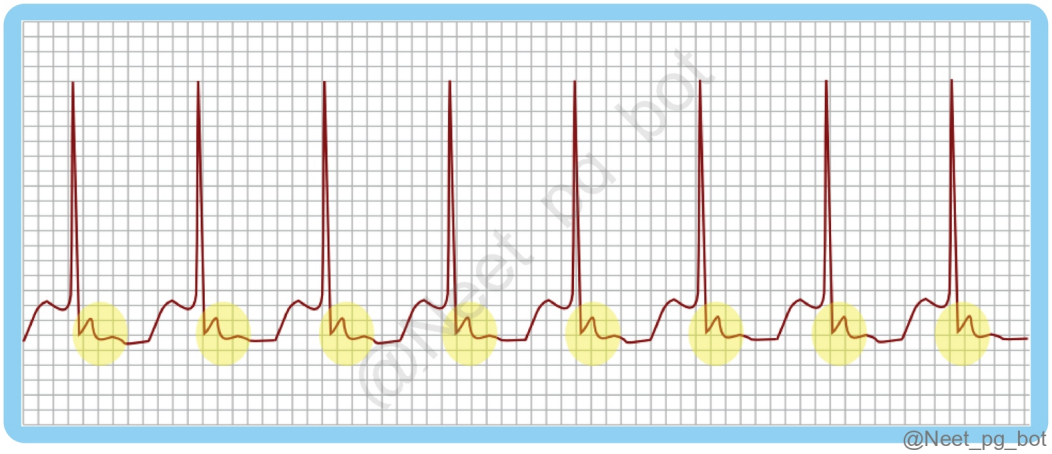
Q6: A 62-year-old man presents to the emergency department with palpitations and lightheadedness. His ECG shows a rapid, regular rhythm with a rate of 150 beats per minute, as shown below Which of the following conditions is most likely to be associated with this ECG finding? (Q850708)

A. Ventricular tachycardia

B. AV nodal re-entrant tachycardia

C. Wolf-Parkinson-White syndrome

D. Hypothermia



Correct Answer: B. AV nodal re-entrant tachycardia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The ECG shows a narrow qRS complex tachycardia seen in PSVT / AV nodal re-entrant tachycardia. The highlighted section in the ECG shows ST depression with P waves occurring after the RS complex. Rationale would be activation of atria after ventricles due to re-entry current. In most cases, these P waves may also not be seen. Ventricular tachycardia (Option A) will have broad QRS tachycardia. Wolf-Parkinson-White syndrome (Option C) has delta waves. Hypothermia (Option D) has osborn waves. Types of QRS Complex Abnormalities: Type of QRS Complex Associated Conditions Narrow QRS complex Tachycardia AV nodal re-entrant tachycardia, AV reentrant tachycardia (Orthodromic) Broad QRS complex Tachycardia Ventricular tachycardia, Torsades de Pointes Delta Wave Wolf-Parkinson-White syndrome J wave/Osbourne wave Hypothermia Epsilon wave Arrhythmogenic right ventricular dysplasia

@Neet_pg_bot

Q7: Match the following tachyarrhythmias with their respective pharmacological interventions Tachyarrhythmia Treatment 1. Atrial Fibrillation in Hypertension A. Adenosine 2. Stable Monomorphic Ventricular Tachycardia B. Esmolol followed by Anticoagulation 3. Torsades de Pointes C. Magnesium Sulfate 4. AV nodal re-entrant tachycardia D. Amiodarone (Q850706)

A. 1-B, 2-D, 3-C, 4-A

B. 1-B, 2-A, 3-D, 4-C

C. 1-D, 2-B, 3-A, 4-C

D. 1-A, 2-C, 3-B, 4-D

Correct Answer: A. 1-B, 2-D, 3-C, 4-A

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: 1 → B. Esmolol followed by Anticoagulation (Atrial fibrillation with hypertension → rate control with a β-blocker such as esmolol) 2 → D. Amiodarone (Stable monomorphic VT → amiodarone is the preferred antiarrhythmic) 3 → C. Magnesium sulfate (Torsades de pointes → first-line therapy is IV magnesium) 4 → A. Adenosine (AVNRT → adenosine is the drug of choice for acute termination)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1938, 1942-1943, 1974. Goldberger’s Clinical Electrocardiography, A Simplified Approach, 9th Edition, Page. 139, 154, 167.

↑ *Back to this question in Part A*

@Neet_pg_bot

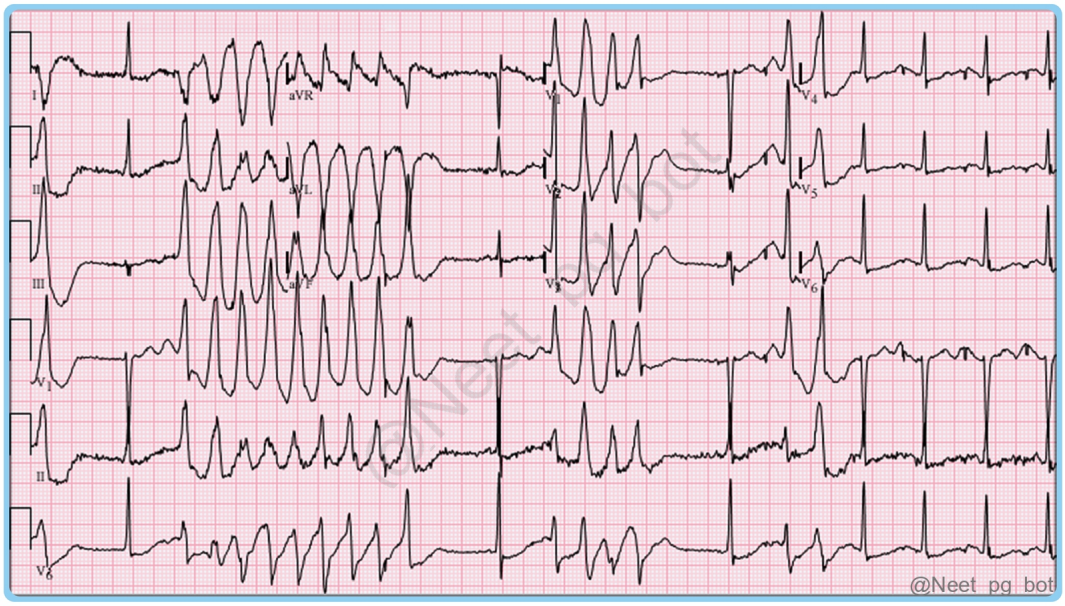
Q8: A 62-year-old woman presents to the ER with palpitations and lightheadedness. She is on azithromycin and cough syrup by her GP. BP on admission is 100/60 mm Hg. Her ECG is given below: Which of the following is the most appropriate immediate management for this patient? (Q850703)

A. Administer intravenous amiodarone

B. Perform immediate electrical cardioversion

C. Administer intravenous magnesium sulfate

D. Start oral beta-blocker therapy



Correct Answer: C. Administer intravenous magnesium sulfate

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The ECG is suggestive of Torsades de Pointes (TdP) , a specific form of polymorphic ventricular tachycardia occurring in the setting of QT interval prolongation. Key trigger is macrolides with over the counter cough syrups that may contain anti-histaminics like astemizole or terfenadine. This combination causes QT prolongation and triggers polymorphic ventricular tachycardia. Intravenous magnesium sulfate is the first-line treatment for TdP, as it helps suppress the triggering PVCs and can shorten the QT interval. Spindle-shaped pattern: The QRS complexes form a twisting or spindle-shaped "envelope." {{caption_text}} Treatment : Immediate management: Intravenous magnesium sulfate (even if serum magnesium is normal) Discontinue potential QT-prolonging medications Correct electrolyte abnormalities, especially hypokalemia Consider temporary pacing or isoproterenol infusion to increase heart rate and shorten QT interval Amiodarone (Option A) should be avoided as it can further prolong the QT interval. Immediate electrical cardioversion (Option B) is usually reserved for hemodynamically unstable patients. Oral beta-blockers (Option D) are not the immediate management, although they may be considered later in the treatment course.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1974-1975. Goldberger's Clinical Electrocardiography, A Simplified Approach, 9th Edition, Page. 166, 167.

↑ *Back to this question in Part A*

@Neet_pg_bot

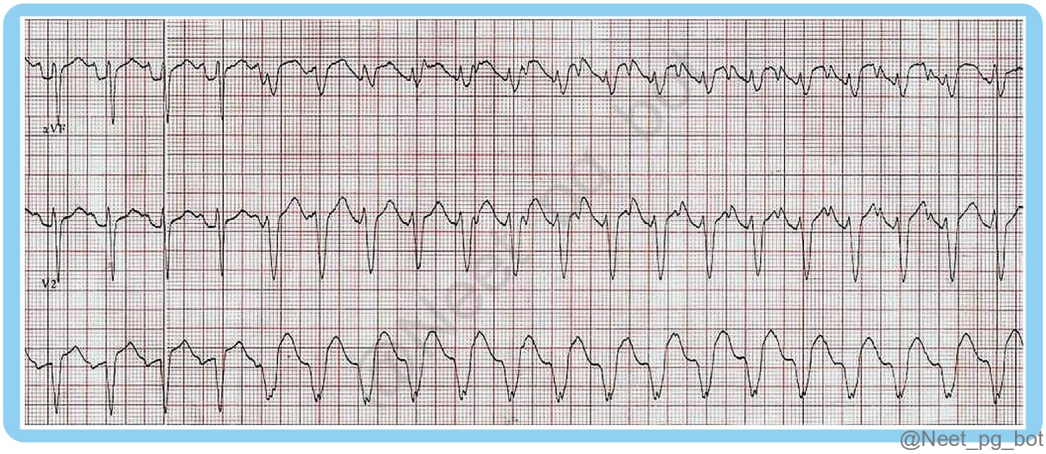
Q9: A 65-year-old male with a history of prior myocardial infarction presents to the emergency department with severe palpitations, dizziness, and chest pain. He suddenly becomes pulseless and BP is unrecordable. An ECG shows wide QRS complexes, a regular rhythm, and a ventricular rate of 160 bpm. What is the most appropriate initial treatment for this patient? (Q850701)

A. Intravenous Adenosine

B. Intravenous Magnesium Sulfate

C. Defibrillation

D. Intravenous Procainamide



Correct Answer: C. Defibrillation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient has pulseless/ unstable monomorphic ventricular tachycardia (VT) as indicated by the wide QRS complexes, regular rhythm, and associated symptoms (hypotension, chest pain, altered mental status). Hemodynamic instability in VT requ ires immediate defibrillation. Treatment: Stable Monomorphic VT : Intravenous procainamide or amiodarone can be used. (Options A & D ruled out) Unstable Monomorphic VT : Immediate synchronized cardioversion is required. (Option C) Polymorphic VT (Torsades de Pointes) : IV magnesium sulfate and correction of underlying electrolyte abnormalities (e.g., hypokalemia) are crucial, along

with discontinuation of QT-prolonging drugs. (Option B ruled out)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1964. Goldberger’s Clinical Electrocardiography, A Simplified Approach, 9th Edition, Page 167.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Which of the following is correct about Wolff-Parkinson-White syndrome? Accessory pathway between the atria and ventricles that lacks the decremental property Prolonged PR interval, delta waves, and narrow QRS complexes. Short PJ interval The drug of choice for an acute episode of palpitations is procainamide (Q850699)

A. 1 and 4 only

B. 2 and 3 only

C. 4 only

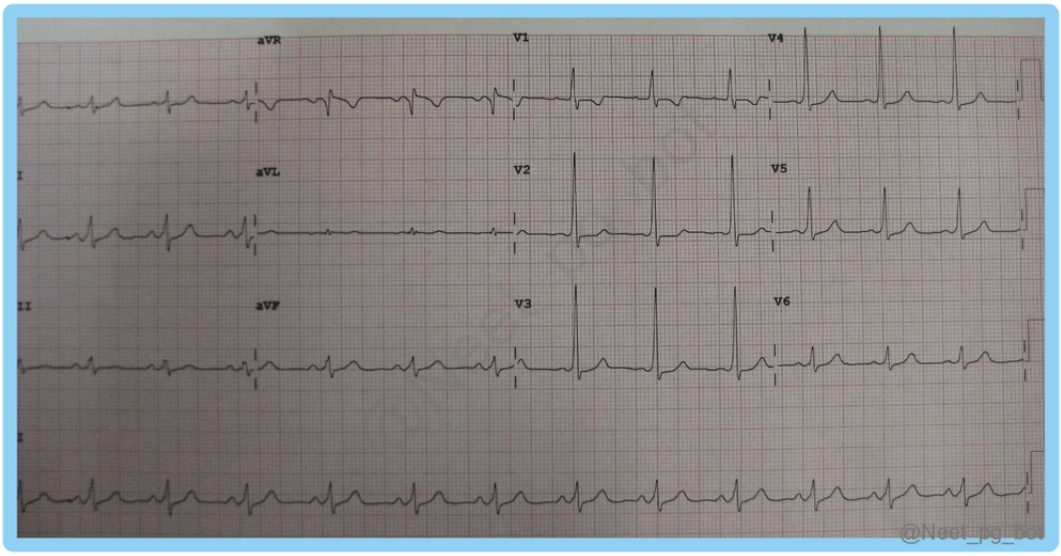
D. 1, 2, 3, and 4

Correct Answer: A. 1 and 4 only

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Wolff-Parkinson-White (WPW) syndrome has an accessory electrical pathway between the atria and ventricles, bypassing the AV node. This accessory pathway, also known as the Bundle of Kent. PR interval is short (Option B is ruled out) PJ interval is normal (O ption C is ruled out) Procainamide is used for acute management of WPW ECG features of WPW Short PR interval (<120 ms) due to rapid conduction through the accessory pathway Delta wave: a slurred upstroke of the QRS complex Widened QRS complex (>110 ms) due to the fusion of early (preexcited) and normal ventricular activation The PJ interval is normal {{caption_text}} Fig: ECG in WPW Syndrome



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1940-1941. Davidson’s Principles and Practice of Medicine 24 th Edition, Page 473, 474.

↑ *Back to this question in Part A*

@Neet_pg_bot

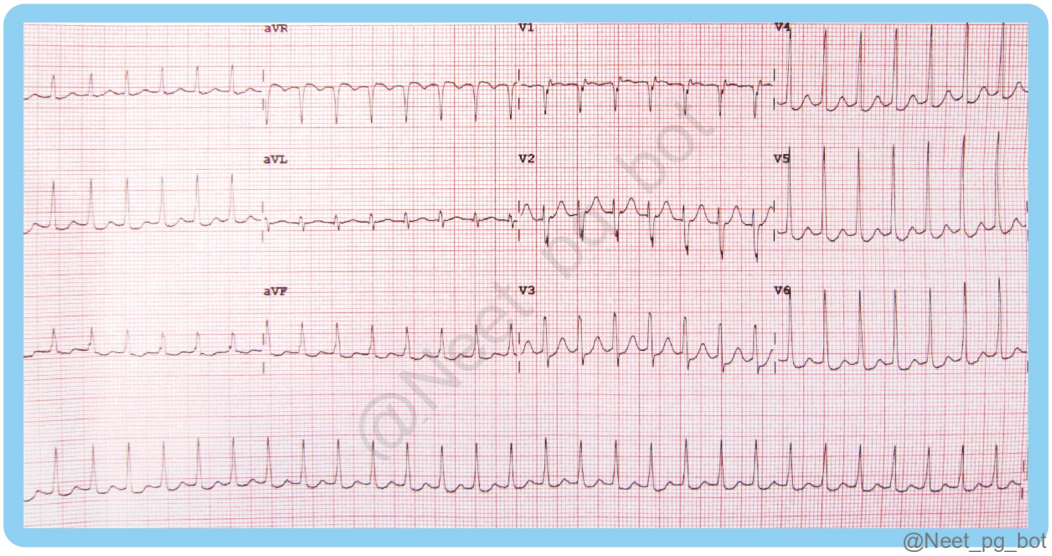
Q11: A 25-year-old female presents with sudden onset palpitations. ECG is shown below. You successfully terminated the arrhythmia using the Valsalva maneuver. Which of the following best describes the primary mechanism by which this maneuver terminates the arrhythmia? (Q850697)

A. Vagus induced decreased firing of the sinoatrial node

B. Vagus induced an increased sympathetic tone to the heart

C. Transient block in AV node conduction

D. Mechanical disruption of accessory pathways



Correct Answer: C. Transient block in AV node conduction

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Valsalva maneuver transiently increases intrathoracic pressure. This leads to a reflex increase in vagal tone (parasympathetic activity). Increased vagal tone affects the AV node, potentially causing a transient block in conduction of re-entry current responsible for PSVT. Effect on the arrhythmia: Many supraventricular tachycardias involve a reentry circuit that includes the AV node. A transient block in AV node conduction can disrupt this circuit. This disruption can terminate the tachyarrhythmia, often restoring normal sinus rhythm. Management: Acute termination: Vagal maneuvers (e.g., Valsalva, carotid sinus massage) If vagal maneuvers fail, IV adenosine is the first-line pharmacological treatment: 6 mg - 12mg fast iv push. Alternative drugs: verapamil, diltiazem, or beta-blockers Synchronized cardioversion for hemodynamically unstable patients Long-term management: Catheter ablation: Often curative, especially for AVNRT and AVRT Pharmacological therapy: Beta-blockers or calcium channel blockers for prevention Class IC or III antiarrhythmic drugs in selected cases Patient education on performing vagal maneuvers Lifestyle modifications: Avoid triggers (e.g., caffeine, alcohol, stress) Regular exercise Adequate sleep Direct stimulation of the sinoatrial node (Option A): Vagal maneuvers actually slow the SA node; they do not stimulate it to terminate re-entry. Increased sympathetic tone of the heart (Option B): Sympathetic tone increases heart rate and would worsen the tachycardia. Vagal maneuvers aim for the opposite (parasympathetic). Mechanical disruption of accessory pathways (Option D): Accessory pathways are physical structures of heart tissue; they cannot be mechanically disrupted by a breathing maneuver.

@Neet_pg_bot

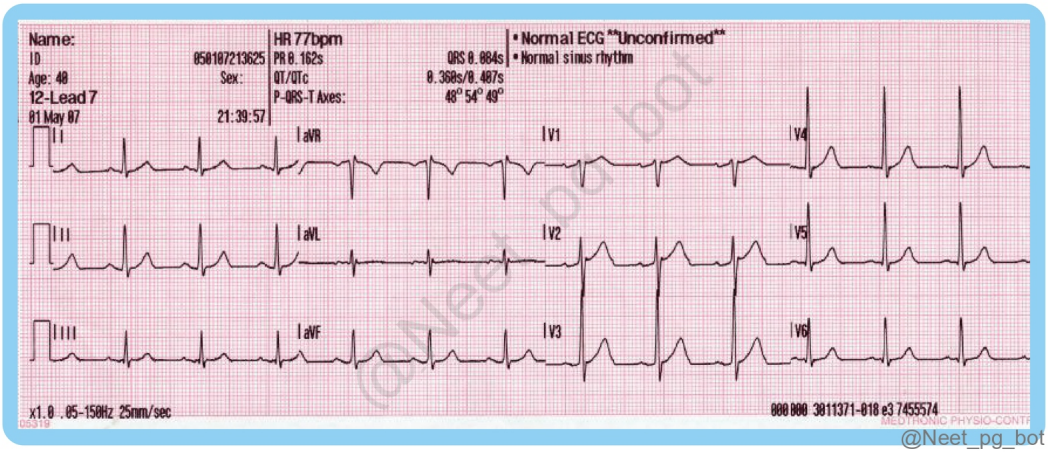
Q12: A 50-year-old man comes to your clinic for a annual medical check-up. He has Hypertension and takes Ramipril and Amlodipine. Office BP recording is 124/ 80 mm Hg. What is the ECG findings shown below? What is the most likely finding based on this ECG? (Q850534)

A. Left ventricular hypertrophy

B. Normal sinus rhythm

C. Second-degree AV block

D. Right bundle branch block



Correct Answer: B. Normal sinus rhythm

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: LVH requires SV1 + RV5 > 35 mm which is not present. (Option A) Second degree AV block has missed beats which are not present. (Option C) RBBB has rSR pattern in lead V1 which is not seen. (Option D) The interpretation by exclusion is normal sinus rhythm.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1935. Goldberger’s Clinical Electrocardiography, A Simplified Approach, 9th Edition, Page. 11-20.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 70-year-old patient is diagnosed with stokes adam syndrome. Which is correct about management of this patient? (Q850692)

A. Dual chamber pacemaker

B. Triple chamber pacemaker

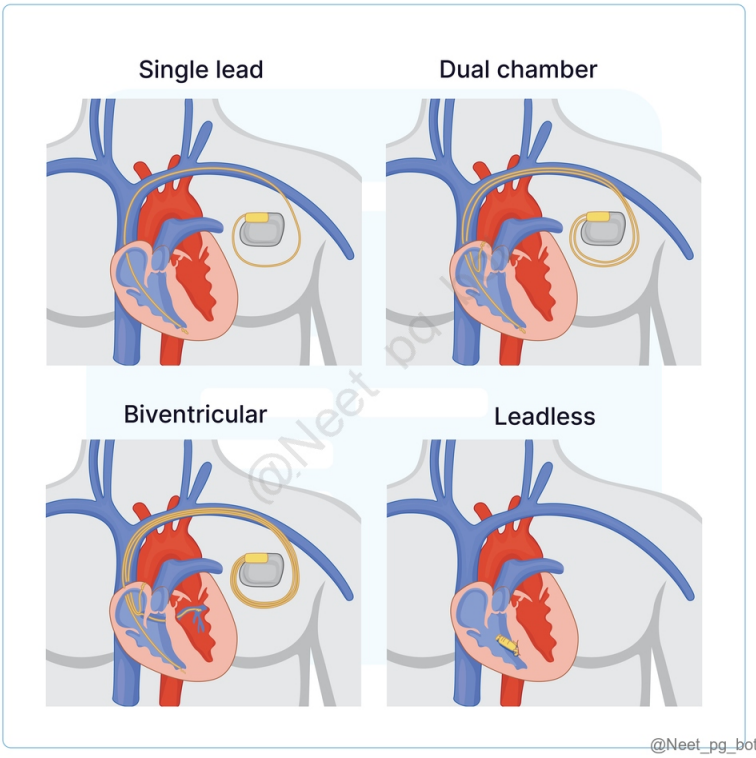
C. Transcutaneous pacemaker

D. Transvenous pacemaker

Correct Answer: A. Dual chamber pacemaker

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Stokes-Adams syndrome has AV dissociation that leads to low cardiac output and increased risk of sudden cardiac death. Dual-chamber pacemaker will restore AV synchrony and improve cardiac output. It will ensure atrial contraction is followed by ventricular contraction to ensure normal hemodynamics. Management: 1. Definitive/Long-term Management: Dual Chamber Pacemaker: It coordinates the contraction of both the atria and the ventricles, maintaining the "atrial kick" and improving cardiac output. The triple chamber pacemaker (Option B) is called CRT (cardiac resynchronization therapy) and are specifically used for heart failure with a reduced ejection fraction and bundle branch blocks to synchronize the two ventricles. It is not the standard first-line for isolated Stokes-Adams. 2. Acute/Emergency Management: If the patient is currently unstable or in active distress, the "step-up" approach for pacing is used: Atropine: Often the first medication tried, though frequently ineffective in high-degree blocks. Transcutaneous Pacing (Option C): This is an emergency, temporary measure using external pads (Zoll pads). It is painful and not a long-term solution. Transvenous Pacing (Option D): An interim step where a wire is threaded through a vein into the heart. This is used to stabilize the patient while they wait for the "permanent" pacemaker to be surgically implanted. {{caption_text}}



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1931. Davidson’s Principles and Practice of Medicine, 24th Edition, Page 482, 483

↑ *Back to this question in Part A*

@Neet_pg_bot

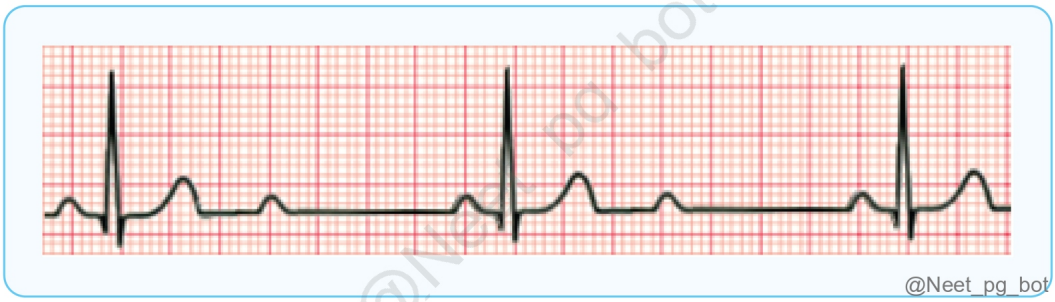
Q14: A 74-year-old patient comes to the emergency department with complaints of intermittent dizziness and lightheadedness. An electrocardiogram (ECG) is performed, as shown below. Based on the ECG findings and the clinical scenario, what type of atrioventricular block is most likely present in this patient? (Q850687)

A. Mobitz Type I - Wenckebach

B. Infranodal conduction defect

C. First-degree AV block

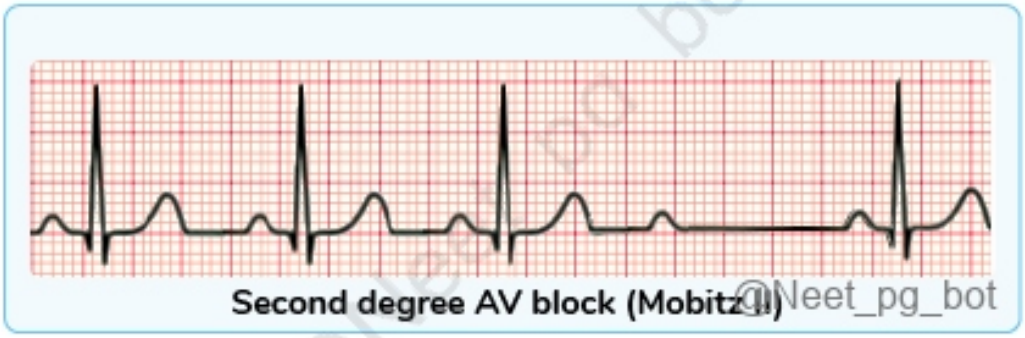
D. Third-degree AV block



Correct Answer: B. Infranodal conduction defect

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Notice a dropped beat after the second qRS complex. The P wave prior to it is visible, but QRS is missing. Now measure the PR interval after and before the missed beat, which is equal, and this indicates infranodal conduction defect. Also notice that each alternate P wave is not conducted down to ventricles indicating 2:1 block Mobitz I heart block (Option A) shows serial prolongation of PR interval. Third-degree AV Block (Option D) shows complete dissociation between P waves and QRS complexes, with no correlation between the two. First-degree heart block (Option C) has a PR interval > 200 msec



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1927.

↑ *Back to this question in Part A*

@Neet_pg_bot

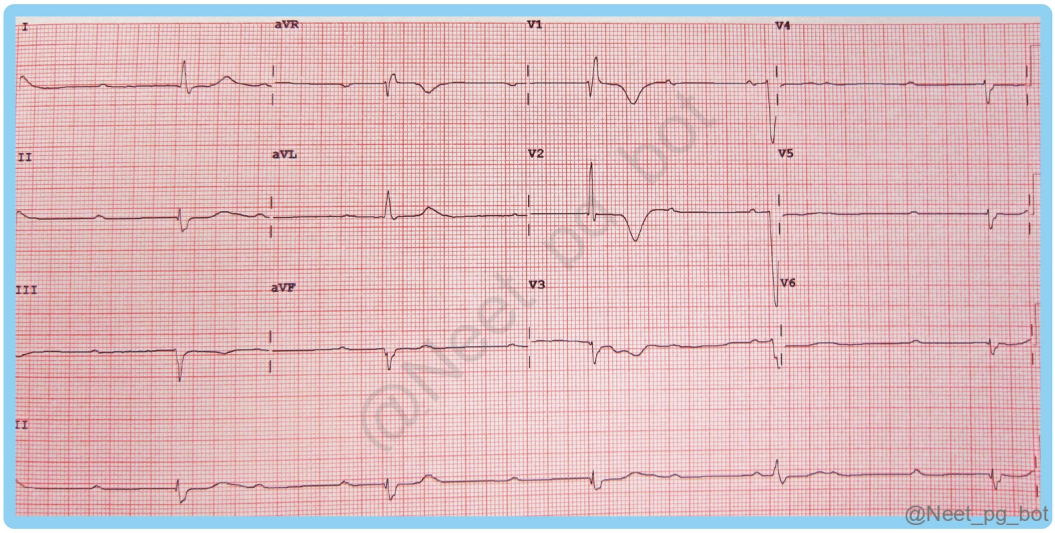
Q15: A 72-year-old man is brought to the ER due to sudden onset syncope in the bathroom. His medical history includes hypertension and a prior myocardial infarction. ECG of the patient is given below. What is the most appropriate initial management for this patient? (Q850685)

A. Oral beta-blockers

B. Temporary pacing

C. Permanent pacemaker placement

D. IV atropine 0.4 mg

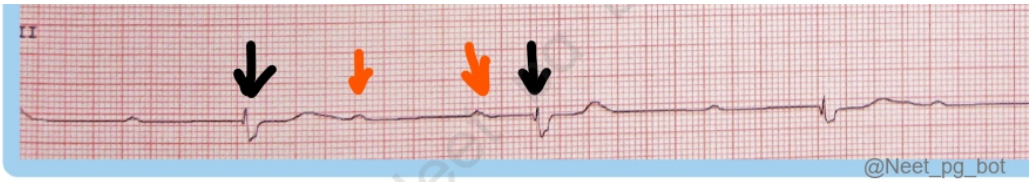


Correct Answer: B. Temporary pacing

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The ECG shows third-degree (complete) AV block, where the atria and ventricles beat independently, causing slow heart rate and syncope. The initial management for symptomatic bradycardia is Atropine. But atropine does not work if the lesion is below the level of the AV node. So temporary pacing is the initial treatment to be started. ECG shows a huge difference between RR interval (black arrows) and PP interval (orange arrows). Ventricular rate is < 30 per min. There is complete dissociation between P waves and QRS complexes and the diagnosis is a third-degree atrioventricular block. Why Atropine Fails: Atropine speeds up the top chamber but can't fix a block deep in the wiring system below the AV node. It might even make things worse by speeding atria without helping ventricles. Best Treatment Steps: Start temporary pacing right away for stability in ER. Later, consider permanent pacemaker if block persists.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1925-1926.

↑ *Back to this question in Part A*

Q16: A 68-year-old male patient presents to the ER with complaints of fatigue and occasional lightheadedness. He has a history of hypertension and coronary artery disease. During the examination, he describes episodes of near-syncope. The physician performs an ECG to evaluate his symptoms. What is the most likely diagnosis based on the ECG findings? (Q850668)

A. First-degree heart block

B. Mobitz Type I

C. Mobitz Type II

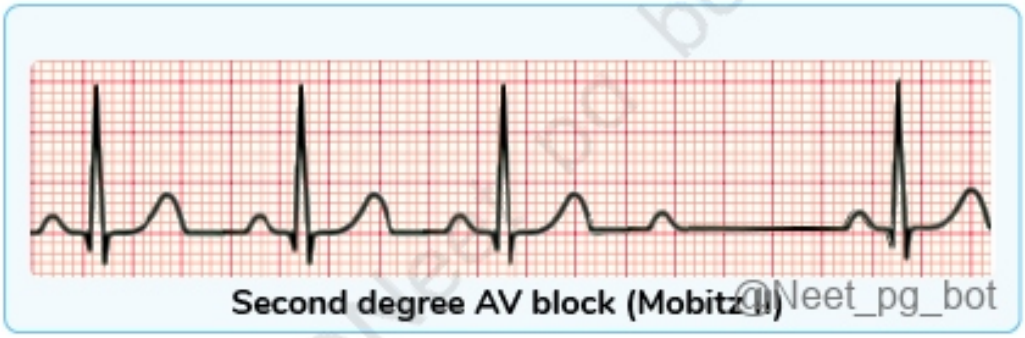
D. Complete heart block

Correct Answer: C. Mobitz Type II

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ECG shows a normal PR interval followed by a non-conducted P wave, leading to dropped beats. This type is often associated with structural heart disease and can progress to complete heart block, which aligns with the patient's symptoms and history. First-degree heart block (Option A): PR interval is prolonged but every P is followed by a QRS . Mobitz Type I – Wenckebach (Option B): Progressive PR lengthening until a beat drops. Complete heart block (Option D): No relation between P waves and QRS complexes (AV dissociation).



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1929.

↑ *Back to this question in Part A*

@Neet_pg_bot

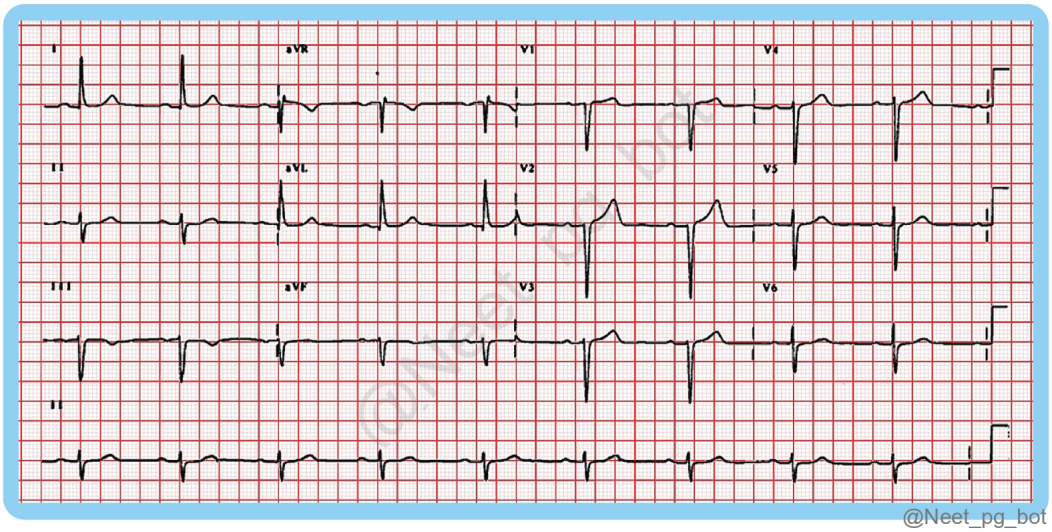
Q17: A 58-year-old woman comes to the clinic for an annual medical check up. She has a history of mild hypertension, which is well-controlled with medication. She reports no symptoms such as palpitations, dizziness, or chest pain. An ECG of the patient is given below. What is the most likely diagnosis based on the ECG findings? (Q850631)

A. Second-Degree AV Block

B. First-Degree AV Block

C. Third-Degree AV Block

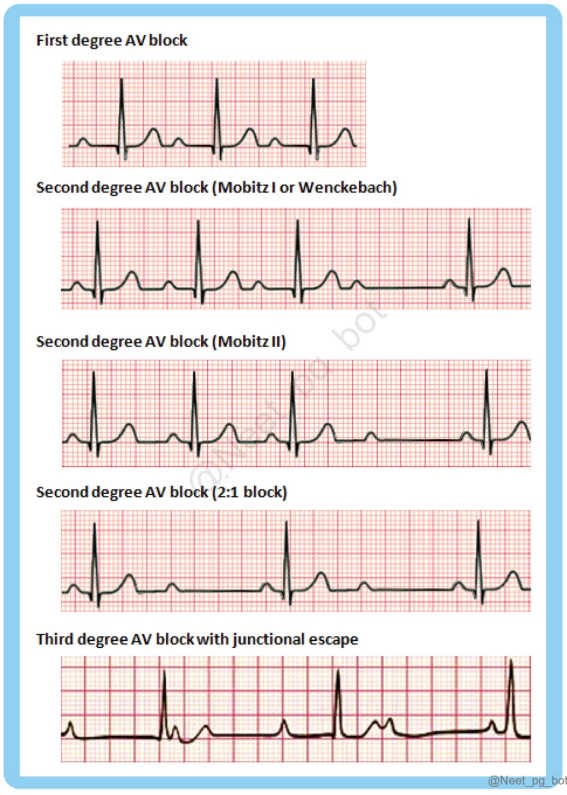
D. Bundle Branch Block



Correct Answer: B. First-Degree AV Block

- *Listen (English)*
- *Listen (Hindi)*

Explanation: There are no dropped beats, so a second-degree heart block is ruled out. Number of P waves is equal to the number of R waves, so a third-degree heart block is ruled out. BBB will have broad qRS complexes and ST segment changes that are not seen. So the answer is first-degree heart block that can be physiological. The PR interval in this ECG is 6 small squares, making it 240 msec. {{caption_text}}



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1925.

↑ *Back to this question in Part A*

@Neet_pg_bot

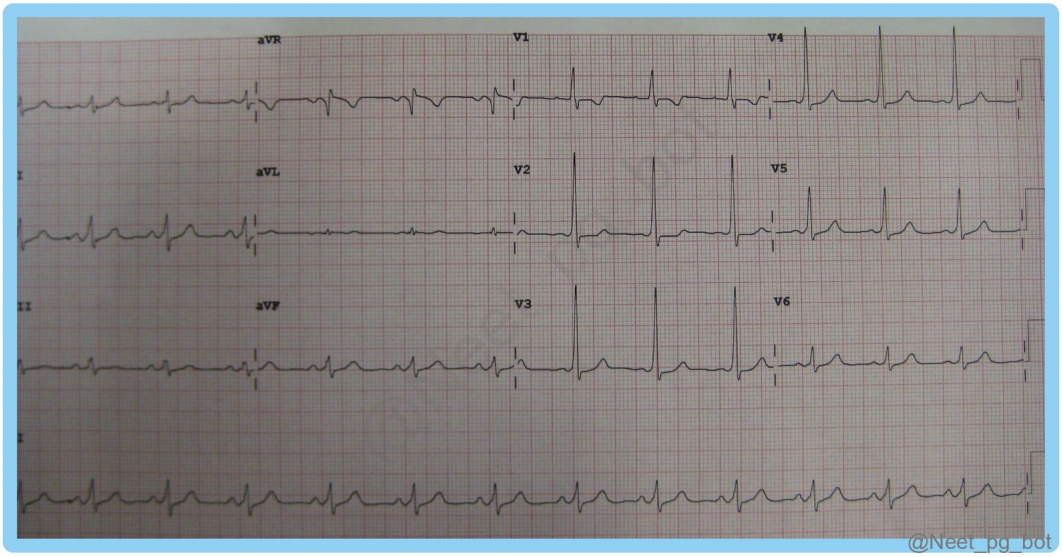
Q18: A 25-year-old male presents with recurrent palpitations and dizziness. An ECG of the patient is given below. Which of the following statements is true regarding this patient's diagnosis? (Q850625)

A. He is at risk for pre-excited atrial fibrillation leading to dangerously fast ventricular rates

B. The accessory pathway is the Bundle of James, facilitating rapid conduction.

C. ECG shows prolonged PR interval with delta waves

D. Adenosine is drug of choice for this condition



Correct Answer: A. He is at risk for pre-excited atrial fibrillation leading to dangerously fast ventricular rates

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The ECG shows short PR interval + delta wave → Wolff–Parkinson–White (WPW) syndrome . In WPW, the accessory pathway (Bundle of Kent) can conduct impulses very rapidly , especially during atrial fibrillation , causing extremely fast ventricular rates and risk of ventricular fibrillation —a medical emergency. The accessory pathway is the Bundle of James, facilitating rapid conduction(Option B): Bundle of James is seen in

Lown–Ganong–Levine (LGL) syndrome , not WPW. ECG shows prolonged PR interval with delta waves(Option C): WPW has a short , not prolonged, PR interval. ■■■■■■■Adenosine is drug of choice for this condition■■■■■■■(Option D): Adenosine is contraindicated in WPW because AV nodal blockade can worsen conduction through the accessory pathway. Procainamide is preferred in acute episodes; flecainide for prevention.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1941. Davidson’s Principles and Practice of Medicine, 24th Edition, Page 473, 474

↑ *Back to this question in Part A*

@Neet_pg_bot

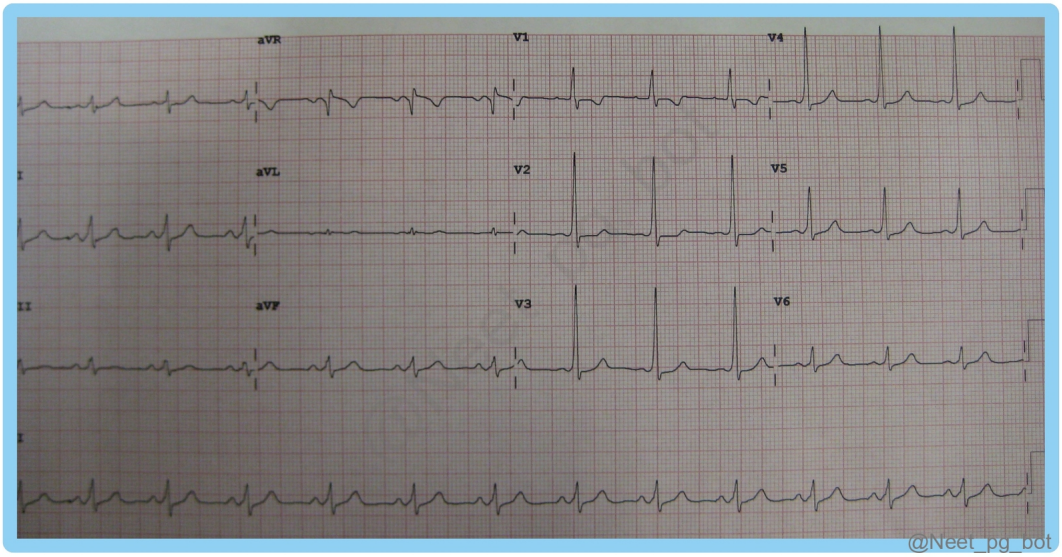
Q19: A 28-year-old male presents to the emergency department with palpitations and lightheadedness. He has no significant past medical history and is otherwise healthy. After a thorough examination, an ECG is obtained. Based on the patient’s presentation and the findings of the ECG, what is the most likely diagnosis? (Q850619)

A. Atrial Fibrillation

B. Wolff-Parkinson-White (WPW) Syndrome

C. First-degree AV Block

D. Second degree heart block

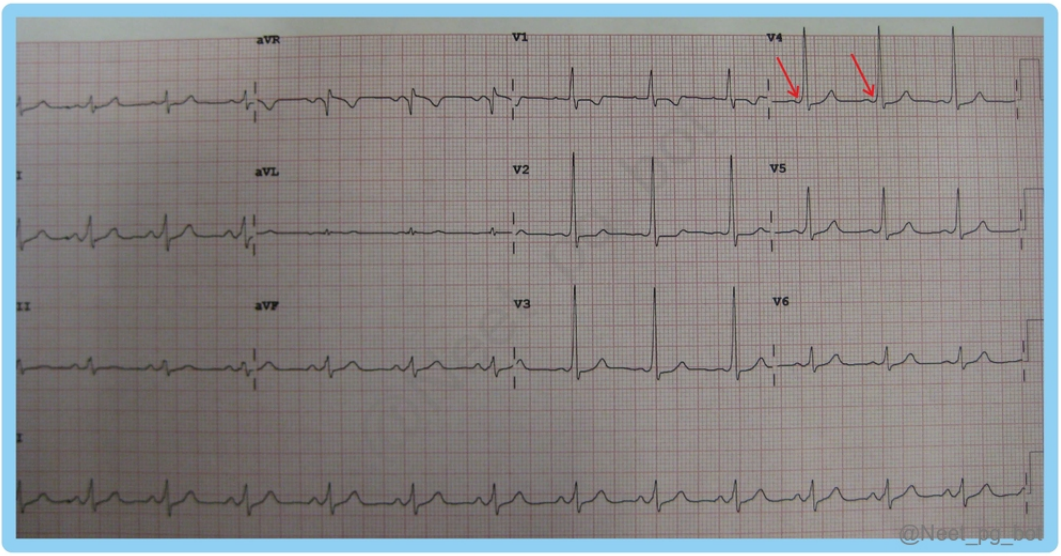


Correct Answer: B. Wolff-Parkinson-White (WPW) Syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The PR interval is short (0.12 seconds). A delta wave (marked in the red arrows) is present in all leads, but it is particularly well seen in leads I, II, and V1-V6. Total QRS duration is prolonged (0.14 seconds). There is a tall R wave in the right-sided precordial leads, and non-specific ST segment/T wave changes accompany this. First-degree AV Block and second-degree heart block (Option C and D) cause bradycardia and are ruled out. Presence of P waves rules out atrial fibrillation (Option A) .



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1941. Goldberger’s Clinical Electrocardiography, A Simplified Approach, 9th Edition, Page. 242.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A 2-year-old child is referred to your hospital for a suspected congenital heart condition due to central cyanosis. On examination, there is a prominent jugular venous pulsation and a pansystolic murmur at the left lower sternal border. ECG shows Himalayan P waves. Which condition will you suspect? (Q850611)

A. Ebstein’s Anomaly

B. Atrial septal defect

C. Ventricular septal defect

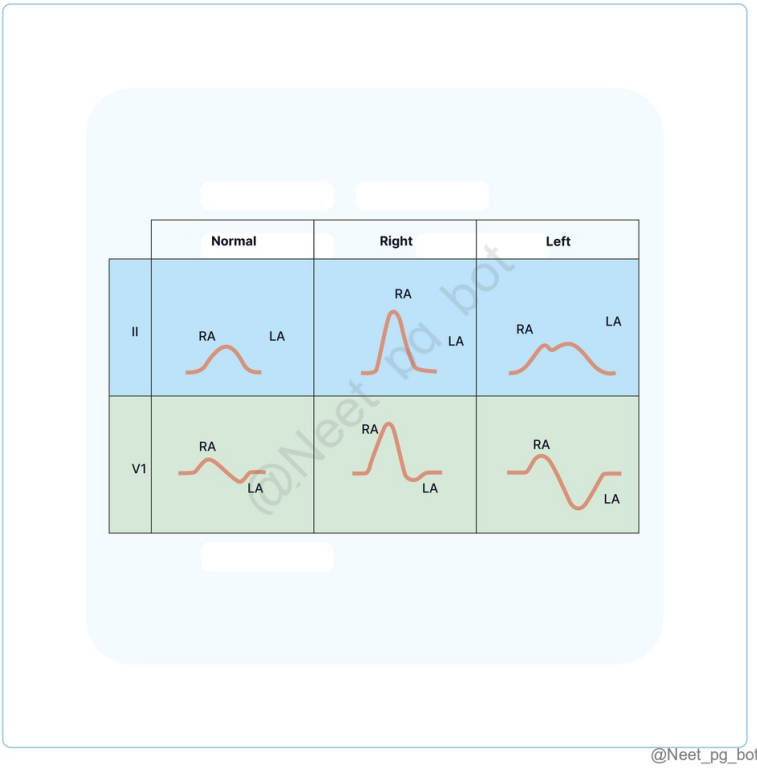
D. Tetralogy of Fallot

Correct Answer: A. Ebstein’s Anomaly

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Key word is himalayan P waves/ Peaked P waves that indicate Right atrial enlargement. The presence of pansystolic murmur indicates regurgitation across the tricuspid valve. This is seen in Ebstein anomaly which has an inferior displacement of the tricuspid valve. The cyanosis is explained by R to L shunting across ASD or patent foramen ovale.. Atrial septal defect (Option B): Usually acyanotic with fixed split S2; does not produce Himalayan P waves or pansystolic murmur. Ventricular septal defect (Option C): Causes a pansystolic murmur but no prominent JVP and no giant P waves ; cyanosis only in late Eisenmenger stage. Tetralogy of Fallot (Option D): Cyanosis and murmur, but murmur is ejection systolic , not pansystolic; JVP and Himalayan P waves are not features.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2062. Goldberger’s Clinical Electrocardiography, A Simplified Approach, 9th Edition, Page. 50-53.

↑ *Back to this question in Part A*

@Neet_pg_bot

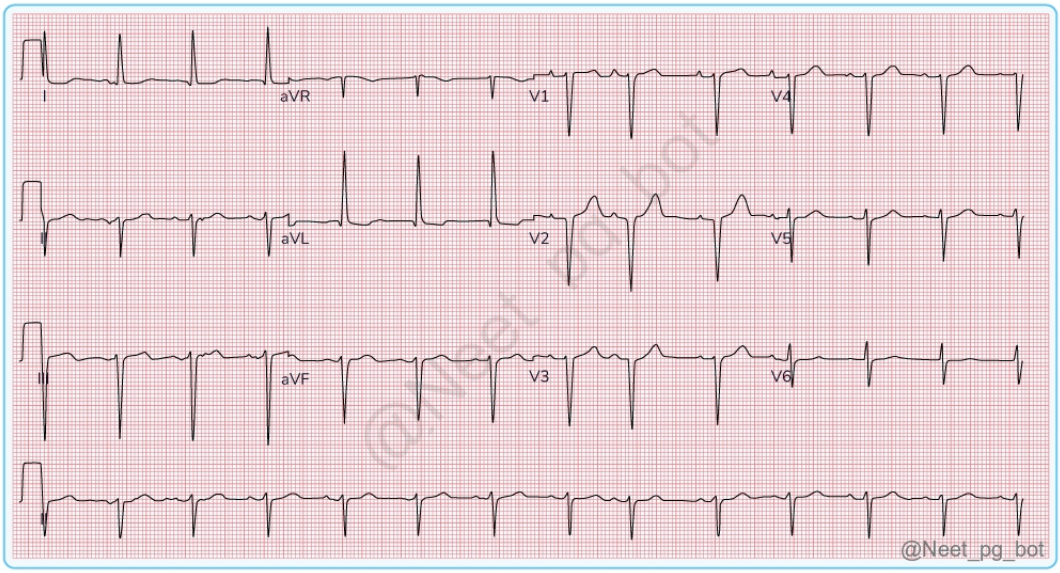
Q21: A 60-year-old woman with a history of hypertension and diabetes presents with a one-month history of mild exertional dyspnea. She denies chest pain but has noticed some occasional palpitations. Physical examination reveals a blood pressure of 140/90 mmHg and regular heart sounds. You order an ECG, which is shown below. What is the most likely diagnosis based on this ECG? (Q850602)

A. Normal axis

B. Right axis deviation

C. Left axis deviation

D. Extreme axis deviation



Correct Answer: C. Left axis deviation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The ECG in question shows left axis deviation when the vectors are plotted for the following data: QRS is POSITIVE (dominant R wave) in Lead I QRS is NEGATIVE (dominant S wave) in leads II, III and aVF Normal Axis : QRS axis between -30° and +90°, points downward and slightly left. Abnormal Axis Deviations: Left Axis Deviation : QRS axis less than -30°. Right Axis Deviation : QRS axis greater than +90°. Extreme Axis Deviation : QRS axis between -90° and 180°.

	Normal Axis 0 to 90	Left Axis Physiological 0 to -30	Left Axis Pathological -30 to -90	Right Axis 90 to 180	Extreme Axis -90 to -180	Indeterminate Axis ?
Lead I						
Lead II						
Lead III

Q1: A 35-year-old woman comes at 8 am to the ER with chest pain that started last evening and has progressively worsened. She describes the pain as a burning sensation accompanied by a sour taste in her mouth, which began shortly after dinner. She has had similar experiences previously. This morning she passed a black stool. ECG and Echocardiography shows normal results. What is next investigation to be performed in this patient? (Q850457)

A. 24 hour pH monitoring

B. Endoscopy

C. hs-CTn

D. Coronary CT angiography

Correct Answer: B. Endoscopy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient is having chest pain due to reflux esophagitis . The first investigation to be done will be an Upper GI endoscopy, which will show mucosal erythema and friability. Passage of black stool is a red flag, and endoscopy will help in determining whether it is bleeding due to mucosal erosions or peptic ulceration that has caused this presentation. 24-hour pH monitoring (Option A) is the gold standard investigation and may not be available readily. hs-CTn (Option C) is a high-sensitivity troponin assay that would be done if presentation was of acute coronary syndrome. Coronary CT angiography (Option D) is done for ch ronic stable angina.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 103, 2504.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 70-year-old male presents with an acute onset of severe dyspnea and shock 5 days after receiving fibrinolysis for STEMI. On examination, an early systolic murmur is heard at the apex. Echocardiography reveals valvular dysfunction. What is the most likely cause of his condition? (Q850499)

A. Ventricular septal rupture

B. Papillary muscle rupture

C. Ventricular aneurysm

D. Ventricular rupture

Correct Answer: B. Papillary muscle rupture

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The buzzword in question is the Echo report of valvular dysfunction, implying Papillary muscle rupture . This occurs after a STEMI due to ischemia of the papillary muscles, leading to acute mitral valve insufficiency. Auscultation finding of acute MR is an early systolic murmur. VSD (Option A) will cause a pansystolic murmur. LV aneurysm (Option C) will cause clot formation and increased risk of stroke. Ventricular rupture (Option D) will cause cardiac tamponade.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2122.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 65-year-old male patient presents 6 weeks after experiencing an ST-elevation myocardial infarction . He reports malaise, fever, and chest discomfort that worsens with deep breathing. On examination, a pericardial friction rub is heard. Laboratory tests reveal leukocytosis and an elevated ESR. What is the most appropriate initial treatment for this condition? (Q850496)

A. Glucocorticosteroids

B. Aspirin

C. Colchicine

D. Rescue PCI

Correct Answer: B. Aspirin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The scenario indicates Dressler syndrome due to fever, malaise, and pericardial effusion occurring 6 weeks post-myocardial infarction, reflecting a delayed inflammatory response . Elevated inflammatory markers confirm this autoimmune reaction to myocardial injury. Aspirin (650 mg every 4 hours) is the initial treatment as it reduces inflammation and relieves symptoms without risking complications associated with NSAIDs or glucocorticoids, which can impair healing after an MI. Glucocorticoids and NSAIDs should be avoided within 4 weeks of STEMI due to risks of impaired infarct healing, ventricular rupture. (Option A & C) Rescue PCI (Option D) is done in case of failure of Fibrinolysis.

References:

Robbins & Cotran's Pathologic Basis of Diseases, 10th Edition, Page 552.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 60-year-old female with a history of hypertension and hyperlipidemia presents with severe chest pain for 3 hours. She has a blood pressure of 180/110 mmHg and a history of active peptic ulcer disease. Her ECG shows ST-elevation in leads V2-V4. What is the most appropriate treatment option for this patient? (Q850493)

A. Streptokinase

B. Tissue plasminogen activator

C. Coronary artery bypass surgery

D. Percutaneous coronary intervention

Correct Answer: D. Percutaneous coronary intervention

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Percutaneous coronary intervention (PCI): This patient has an acute anterior wall STEMI (ST elevation in V2–V4) presenting within 3 hours. She has active peptic ulcer disease, which is an absolute

contraindication to thrombolytic therapy due to the high risk of life-threatening bleeding. In such patients, primary PCI is the treatment of choice, as it achieves rapid reperfusion without systemic fibrinolysis. Fibrinolysis: Absolute contraindications: History of cerebrovascular hemorrhage. Nonhemorrhagic stroke or cerebrovascular event in the past year. Marked hypertension (>180/110 mmHg) at presentation. Suspected aortic dissection. Active internal bleeding (excluding menses). Relative contraindications: Use of anticoagulants (INR >2). Recent (<2 weeks) invasive procedure or prolonged (>10 min) CPR. Bleeding diathesis Pregnancy Hemorrhagic ophthalmic conditions (e.g., hemorrhagic diabetic retinopathy) Active peptic ulcer disease. Streptokinase and Allergy Risk: Patients should not receive streptokinase if they have already received it within the preceding 5 days to 2 years due to the risk of allergic reactions. Streptokinase (Option A): Streptokinase is contraindicated in patients with active internal bleeding, including peptic ulcer disease, due to high hemorrhagic risk. Tissue plasminogen activator (tPA) (Option B): tPA is also a fibrinolytic agent and shares the same absolute contraindication in active peptic ulcer disease. Coronary artery bypass surgery (CABG) (Option C): CABG is not the first-line emergency reperfusion strategy in acute STEMI unless PCI fails or there is a mechanical complication.

Harrison's Principles of Internal Medicine, 22nd Edition, Page2129-2130.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 60-year-old male with a history of hypertension and hyperlipidemia presents with chest pain lasting 45 minutes. His ECG shows STE in lead I, avL, V5, V6. Which of the following statements about his management is correct? (Q850490)

A. Beta blockers should be avoided in all patients with STEMI.

B. First line drug for the management of STEMI is Streptokinase

C. LMWH provides more reliable anticoagulation than UFH.

D. Leading cause of death after 24 hours of hospitalization is cardiac rupture

Correct Answer: C. LMWH provides more reliable anticoagulation than UFH.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: LMWH provides a more predictable and reliable anticoagulant effect than unfractionated heparin (UFH) with fewer bleeding complications and no need for frequent monitoring, making it preferred in STEMI management. Low-Molecular-Weight Heparins (LMWH): Advantages: Higher bioavailability Subcutaneous administration Reliable anticoagulation without monitoring Geater anti-Xa:IIa activity Enoxaparin reduces death/nonfatal reinfarction and urgent revascularization compared with unfractionated heparin (UFH), but has higher bleeding rates. Beta blockers should be avoided in all patients with STEMI (Option A): Beta blockers reduce the size of the infarct by reducing oxygen consumption of the heart. So they are given to all patients unless

some contraindication, like acute pulmonary edema or bradycardia, is present. First-line drug for the management of STEMI is Streptokinase (Option B): The first drug given to patients with STEMI is aspirin chewable 325mg with Ticagrelor. The leading cause of death after 24 hours of hospitalization is cardiac rupture (Option D): The leading cause of death after 24 hours of hospitalization is Cardiogenic shock or pump failure.

@Neet_pg_bot

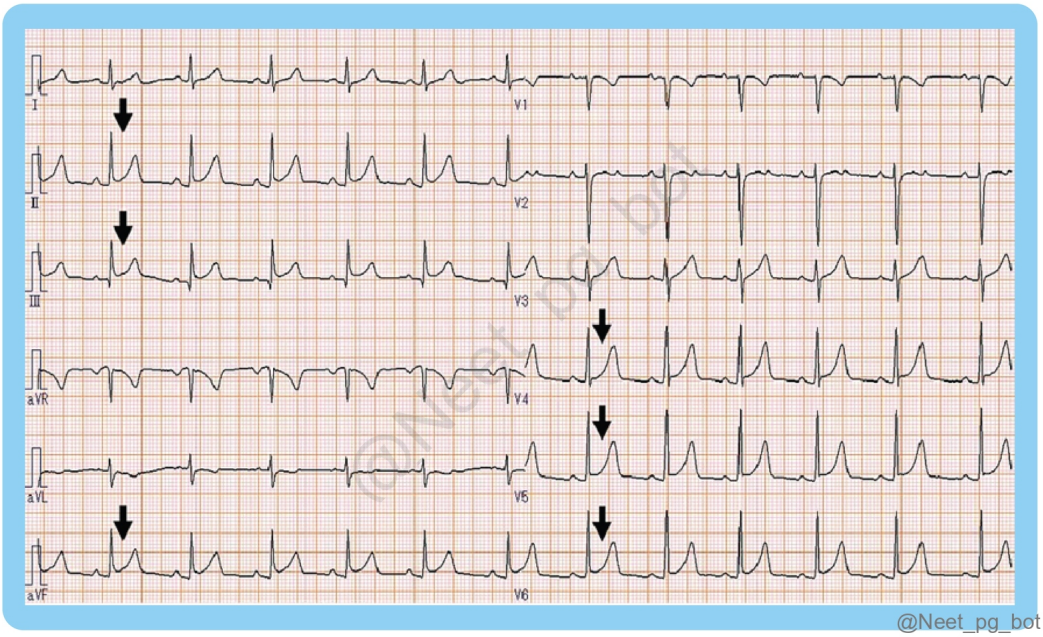
Q6: A 65-year-old male presents with central chest pain for the last 3 hours radiating to the left shoulder. On admission, blood pressure is 150/100 mmHg, and his oxygen saturation is 95% on room air. Which of the following drugs should be avoided in this patient? (Q850486)

A. Administer morphine IV for pain relief

B. Administer nifedipine to relieve chest pain

C. Administer clopidogrel loading dose for platelet inhibition

D. Administer sublingual nitroglycerin (0.4 mg) to reduce myocardial oxygen demand



Correct Answer: B. Administer nifedipine to relieve chest pain

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ECG shows ST elevations in leads II, III, aVF, V4-V6, indicating infero-lateral MI. Calcium channel blockers, particularly short-acting dihydropyridines like nifedipine, will cause reflex tachycardia and increase myocardial oxygen demand. This can worsen the patient, and hence is the wrong statement Morphine IV for pain relief (Option A) is appropriate for pain control and reducing sympathetic stress. Clopidogrel loading dose for platelet inhibition (Option C) is indicated to reduce thrombus formation in ACS. Sublingual nitroglycerin (0.4 mg) to reduce myocardial oxygen demand (Option D) is safe and effective for symptom relief.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2102.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following would provide the least accurate diagnosis of Myocardial infarction? (Q850483)

A. Echocardiography

B. Coronary angiography

C. High sensitivity Troponin I

D. Radionuclide ventriculography

Correct Answer: D. Radionuclide ventriculography

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Radionuclide ventriculography primarily assesses ventricular function and wall motion but is not specific for diagnosing myocardial infarction. Echocardiography (Option A): This provides functional evidence . It identifies Regional Wall Motion Abnormalities (RWMA) that occur almost instantly when a coronary artery is blocked, making it a highly accurate bedside tool. Coronary angiography (Option B): This is the anatomic gold standard . It uses fluoroscopy to directly visualize the "culprit" vessel occlusion, allowing for immediate therapeutic intervention (stenting). High sensitivity Troponin I (Option C): This is the biochemical gold standard . These assays detect minute amounts of myocardial necrosis within 1–3 hours of injury with near-perfect specificity for cardiac tissue.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2106, 2098.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 58-year-old male smoker was managed with primary PCI for STEMI 4 days ago. On the day of planned discharge he again develops central chest pain. Which of the following should be done in this patient to identify a reinfarction? (Q850479)

A. Troponin T

B. Creatine Kinase-MB

C. Lactate Dehydrogenase

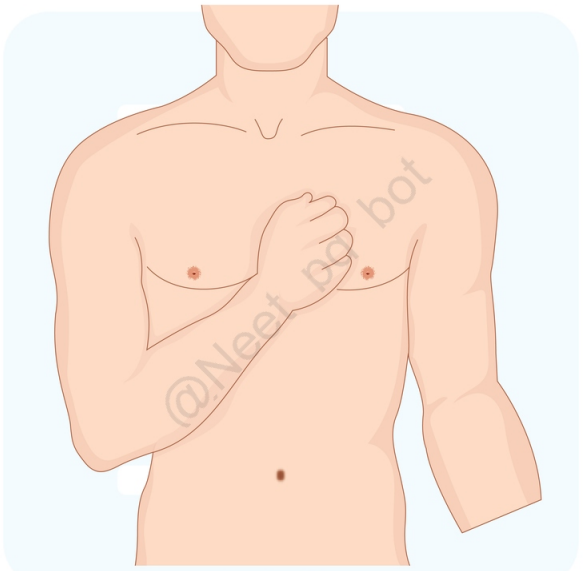
D. Heart fatty acid-binding Protein

Correct Answer: B. Creatine Kinase-MB

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In this scenario, CK-MB is the most useful marker for confirming reinfarction, as its levels normalize within 72 hours after an initial infarction. Troponin T (Option A) remains elevated for 7–10 days after the initial MI, so it is not reliable for detecting reinfarction. Lactate Dehydrogenase (Option C) rises late and is nonspecific for reinfarction. Heart fatty acid-binding protein (Option D) is sensitive but less commonly used in routine clinical practice for reinfarction detection. {{caption_text}} Cardiac Biomarkers for Acute Myocardial Infarction (AMI): {{caption_text}}



Levine Sign

@Neet_pg_bot

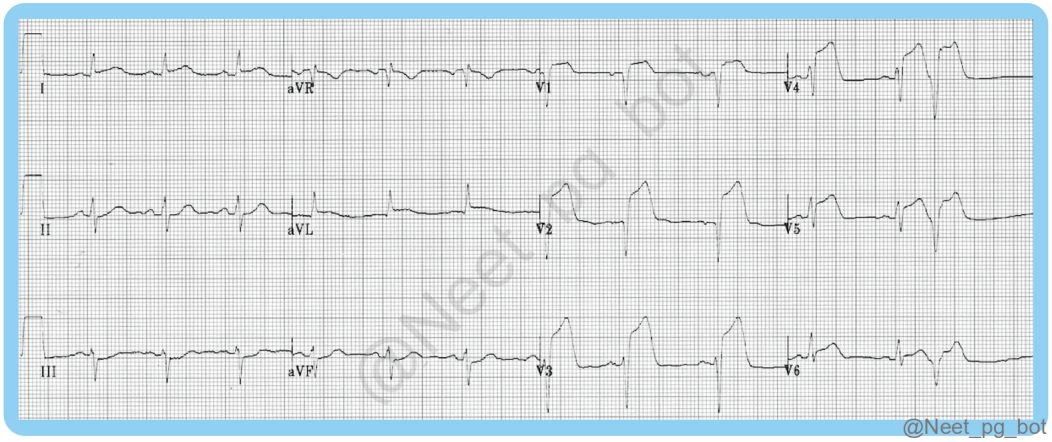
Q9: A 58-year-old male presents with chest pain, and an ECG reveals the following changes Based on these findings, which coronary artery is most likely affected? (Q850477)

A. Left Circumflex Artery

B. Right Coronary Artery

C. Anterior Interventricular Artery

D. Posterior Descending Artery



Correct Answer: C. Anterior Interventricular Artery

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ECG shows ST elevation in leads V1–V6, I, and aVL, implying anterolateral MI. The blood vessel involved is the proximal LAD, also called the anterior interventricular artery. Left Circumflex Artery (Option A) will cause lateral wall MI Right Coronary Artery (Option B) will cause inferior wall MI Posterior Descending Artery (Option D) will cause posterior wall MI.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1873.

↑ *Back to this question in Part A*

@Neet_pg_bot

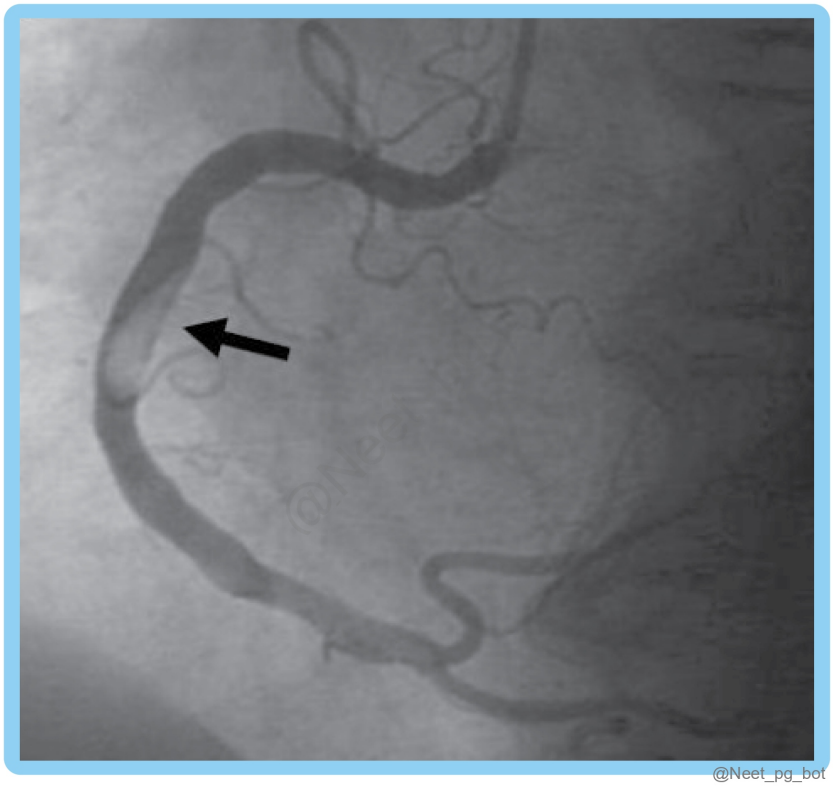
Q10: A 65-year-old male patient with a history of coronary artery disease undergoes angiography, which reveals a thrombus in the right coronary artery (RCA). Based on this finding, which area of the heart is most likely to be affected by an infarct? (Q850475)

A. Anterior wall

B. Lateral wall

C. Inferior wall

D. Septal wall



Correct Answer: C. Inferior wall

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In a patient with a thrombus in the right coronary artery, the area of the heart to be affected by an infarct is the inferior wall. Coronary Artery Affected Location of Infarct Left Coronary Artery (LCA) Extensive Anterior Wall MI Left Circumflex Artery (LCX) Lateral Wall MI Left Anterior Descending (LAD) Anterior Wall MI Right Coronary Artery (RCA) Inferior Wall MI Posterior Descending Artery (PDA) Posterior Wall MI Coronary Circulation: {{caption_text}}

@Neet_pg_bot

Q11: Which of the following is correct placement for Lead II on the ECG? (Q850474)

A. Left arm (+) to Left arm (–)

B. Right arm (+) to Left arm (–)

C. Left arm (–) to Left leg (+)

D. Right arm (–) to Left leg (+)

Correct Answer: D. Right arm (–) to Left leg (+)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In an ECG, the correct configuration for Lead II involves placing the positive electrode on the Left Leg (LL) and the negative electrode on the Right Arm (RA). This configuration allows the ECG to capture the electrical activity of the heart as it flows from the right atrium to the left ventricle. 12-Lead ECG System for Cardiac Monitoring Limb Leads forming einthoven's Triangle The concept of Einthoven's triangle is crucial for understanding lead placement in ECGs. It is an imaginary triangle formed by connecting the three limb electrodes (Right Arm, Left Arm, and Left Leg). The triangle represents the standard limb leads, which are as follows: Lead I: Left Arm (+) to Right Arm (–) Lead II: Left Leg (+) to Right Arm (–) Lead III: Left Leg (+) to Left Arm (–)

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1869.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 56-year-old smoker male presented to the emergency department with chest pain radiating to interscapular area. On examination unequal radial artery pulse is palpated with BP of 180/110 mm Hg. Clinical diagnosis is: (Q850466)

A. Aortic dissection

B. Preductal coarctation of aorta

C. Aortic transection

D. Postductal coarctation of aorta

Correct Answer: A. Aortic dissection

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Correct Option A - Aortic dissection: This patient presents with sudden severe chest pain radiating to the interscapular region, severe hypertension, and unequal radial pulses, which are classic features of acute aortic dissection. Smoking and hypertension are major risk factors. Pulse deficit and differential blood pressure between limbs are hallmark clinical signs. Preductal coarctation of aorta (Option B): Preductal coarctation presents in infancy or childhood with heart failure and differential cyanosis. It does not present acutely in a 56-year-old. Aortic transection (Option C): Aortic transection is usually due to severe blunt trauma (e.g., road traffic accident) and presents with shock, not isolated hypertension. Postductal coarctation of aorta (Option D): Postductal coarctation presents in younger patients with upper limb hypertension and weak femoral pulses, not acute tearing chest pain.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1872, 2115.

↑ *Back to this question in Part A*

@Neet_pg_bot

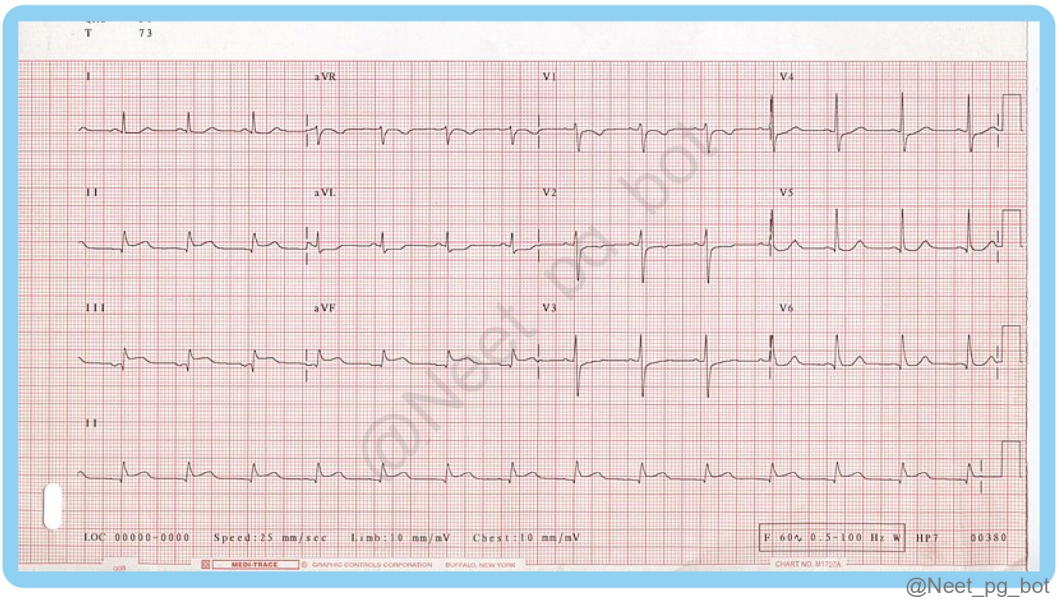
Q13: A 60-year-old male presents with a sudden onset of severe chest pain that radiates to his left arm. This pain started about 60 minutes ago while he was having his breakfast. His medical history includes hypertension and hyperlipidemia. An ECG has been performed and cardiac biomarkers are significantly elevated. What is the most likely cause of his presentation? (Q850465)

A. Coronary artery spasm

B. Coronary artery embolism

C. Spontaneous coronary artery dissection

D. Plaque rupture



Correct Answer: D. Plaque rupture

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The 12-lead ECG reveals ST-segment elevation in leads II, III, and aVF, accompanied by reciprocal ST-segment depression in leads I and aVL, indicating an inferior wall ST-segment elevation myocardial infarction. The primary underlying cause of this STEMI is often the rupture of an atherosclerotic plaque, which results in thrombus formation and subsequent myocardial ischemia. Coronary artery spasm (Prinzmetal's angina) (Option A): This causes transient ST-segment elevation due to vasospasm but does not typically lead to the same pattern of ischemia or cardiac marker elevation seen in this patient. Coronary artery embolism (Option B): Although a possible cause of myocardial infarction, it is much rarer compared to plaque rupture. Coronary emboli can result from conditions like atrial fibrillation or endocarditis but generally present differently. Spontaneous coronary artery dissection (Option C): SCAD is a rare cause of myocardial infarction, seen mostly in younger women and often associated with pregnancy or connective tissue disorders. The presentation may differ from classic STEMI.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2113-2116.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 72-year-old man underwent PCI with drug-eluting stents for double vessel disease yesterday. Today he develops chest pain with ECG showing ST-segment depression and cTn levels rising to five times the 99th percentile of the upper limit. What type of MI is seen in this case? (Q850462)

A. Type 1

B. Type 2

C. Type 3

D. Type 4

Correct Answer: D. Type 4

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Post PCI myocardial infarction is classified as Type 4a MI. It has Troponin I values rising to 5x or more of normal. Types of MI Type 1 MI Occurs due to Plaque rupture/ Ulceration/ coronary dissection with thrombus Type 2 MI Occurs due to supply demand mismatch Fixed coronary atherosclerosis Coronary spasm or Coronary embolism Coronary artery dissection without thrombus Sustained tachyarrhythmia, Severe bradyarrhythmia Severe anemia or hypotension Type 3 MI When sudden cardiac death occurs due to MI before biomarkers values could be drawn and sent to lab Type 4a MI related to percutaneous coronary intervention Requires a fivefold increase in cTn values if initial values are normal. If initial cTn values are above the 99th percentile URL, a 20% rise is needed, with final values exceeding five times the 99th percentile. Type 4b MI This is associated with a stent thrombosis. Type 4c MI Associated with focal or diffuse restenosis after PCI Type 5 MI related to coronary artery bypass grafting Requires a tenfold increase in cTn values if initial values are normal. If initial cTn values are above the 99th percentile URL, a 20% rise is needed, with final values exceeding ten times the 99th percentile.

@Neet_pg_bot

Q15: Which of the following is correct about predisposition to atherosclerosis in these vessels? (Q850396)

A. Popliteal arteries > Coronary arteries > Circle of Willis > Abdominal aorta

B. Coronary arteries > Abdominal aorta > Circle of Willis > Popliteal arteries

C. Abdominal aorta > Coronary arteries > Popliteal arteries > Circle of Willis

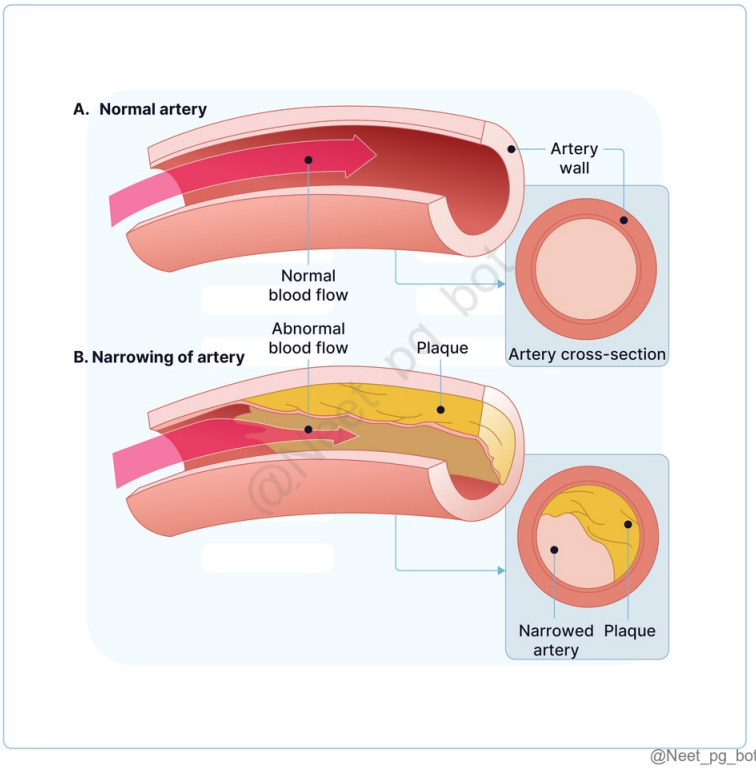
D. Coronary arteries > Circle of Willis > Abdominal aorta > Popliteal arteries

Correct Answer: C. Abdominal aorta > Coronary arteries > Popliteal arteries > Circle of Willis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Arteries Involved in Atherosclerosis in decreasing order of involvement (mnemonic: ACP-Willis) A bdominal Aorta: Formation of an abdominal aortic aneurysm in infrarenal abdominal aorta C oronary Arteries ST-Elevation Myocardial Infarction Non-ST Elevation Myocardial Infarction / Unstable Angina P opliteal Arteries: Atherosclerosis in these arteries leads to peripheral artery disease (PAD), causing intermittent claudication Circle of Willis : Atherosclerotic plaques in the cerebral arteries can result in transient ischemic attacks (TIA) or strokes. {{caption_text}}



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2170.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 58-year-old man presents with chest pain at rest for the past 4 hours. He has a history of hypertension and hyperlipidemia. ECG shows ST-segment depression in lead II, III, aVF and his cardiac troponin levels are elevated. What is the most appropriate next step in managing this patient's condition? (Q850452)

A. Immediate coronary artery bypass grafting

B. Thrombolysis

C. High-intensity Atorvastatin and ACEI

D. Aspirin and Ticagrelor

Correct Answer: D. Aspirin and Ticagrelor

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has NSTEMI (ST depression and elevated troponins)- inferior wall MI. The initial management includes dual antiplatelet therapy with aspirin and a P2Y12 inhibitor (e.g., ticagrelor) along with anticoagulation and risk stratification. Immediate coronary artery bypass grafting (Option A) is not first-line; CABG is reserved for high-risk anatomy or failed PCI. Thrombolysis (Option B) is used for STEMI, not NSTEMI. High-intensity Atorvastatin and ACEI (Option C) are part of secondary prevention, not immediate acute management.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2110.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 59-year-old woman with T2DM presents to ER with chest discomfort at rest radiationg to jaw and nausea for past 2 hours. ECG shows T wave inversion and ST depression in lead II, III, aVF. Trop I value is greater than 99th centile of upper reference limit. Which of the following is the most likely diagnosis? (Q850448)

A. Stable angina

B. Unstable angina

C. Non-ST elevation MI

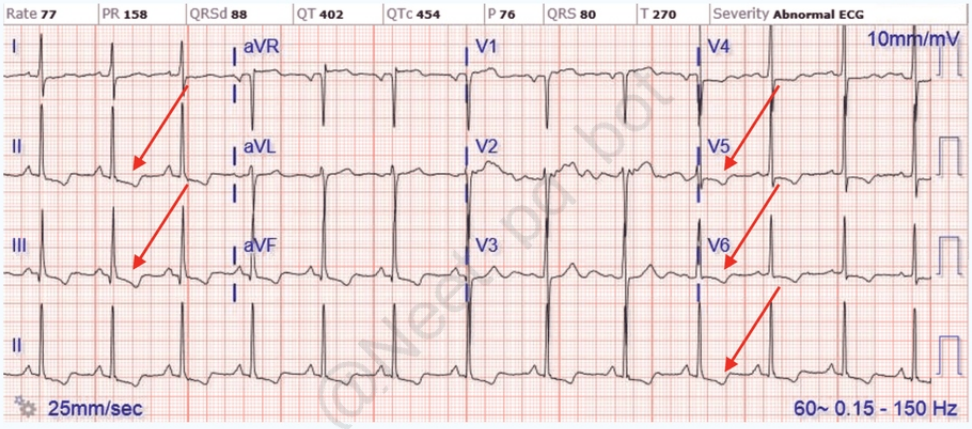
D. ST elevation MI

Correct Answer: C. Non-ST elevation MI

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The scenario here points to NSTEMI which is diagnosed by raised serum troponin levels, ECG changes of T-wave inversion, and clinical symptoms of chest pain. {{caption_text}} Stable angina (Option A) is a type of ischemic heart disease that occurs when the heart muscle does not receive adequate oxygen due to reduced blood flow through the coronary arteries, especially during physical exertion or emotional stress and presents with chest pain that lasts 2-10 minutes and is relieved on rest . Unstable angina (Option B) is ruled out as it has normal biomarkers. ST-Elevation MI (Option D) is caused by prolonged obstruction of blood supply to a part of the heart muscle, leading to tissue damage or necrosis, and has significant ST elevation in the ECG.



ECG of initial NSTEMI showing T wave inversion in leads II, III, aVF, and V4-6.
ECG, electrocardiogram : NSTEMI, non-ST segment elevation myocardial infraction

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1873-1874.

↑ *Back to this question in Part A*

@Neet_pg_bot

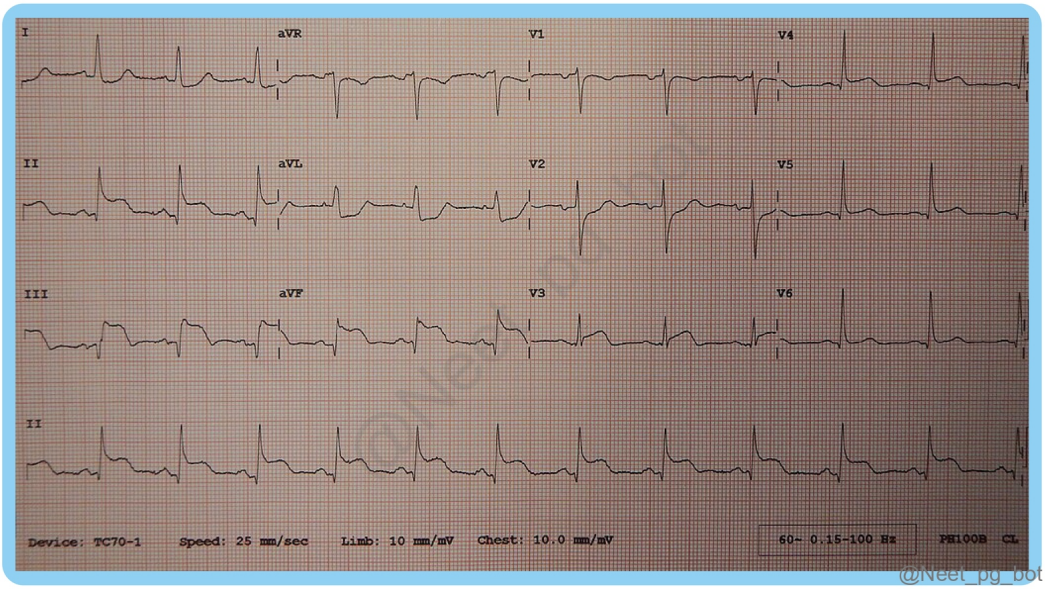
Q19: A 65-year-old woman presents to the ER with early morning episode of chest pain lasting 15 minutes which is relieved by sublingual nitroglycerin. She has had similiar episodes in past and her husband says that metoprolol was started which worsend her chest pain episodes so they stopped the medication. Past medical history is significant for Raynaud phenomenon. ECG is given below. There is no elevation of cardiac markers on serial evaluation. Which of the following is the most likely diagnosis? (Q850434)

A. Stable angina

B. Unstable angina

C. Prinzmetal angina

D. Myocardial infarction



@Neet_pg_bot

Correct Answer: C. Prinzmetal angina

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Based on the given scenario, the diagnosis is consistent with Prinzmetal angina, which is characterized by episodes of chest pain at rest, often relieved by nitroglycerin, and associated with transient ST-segment elevations on ECG. It is caused by coronary artery spasm rather than obstructive coronary artery

disease, and cardiac markers remain normal during these episodes. Stable angina (Option A): This type of angina is typically triggered by physical exertion or emotional stress and is characterized by predictable episodes of chest pain. It does not usually occur at rest and does not show transient ST-segment elevations during rest episodes. Unstable angina (Option B): This condition involves chest pain that occurs at rest, is more severe, and may last longer than stable angina. Myocardial infarction (Option D): MI typically presents with prolonged chest pain, elevated cardiac markers, and more significant ECG changes such as ST-segment elevation or depression that do not resolve with nitroglycerin.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2112.

↑ *Back to this question in Part A*

@Neet_pg_bot

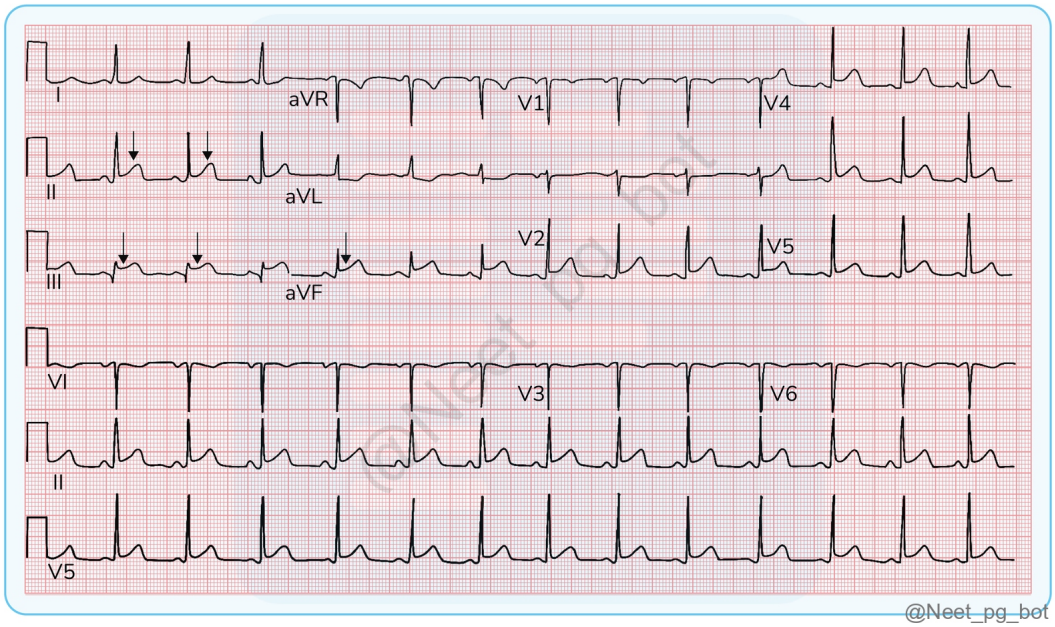
Q20: A 62-year-old male presents to ER central chest pain at rest and shortness of breath for last one hour. His medical history includes hypertension and hyperlipidemia. Troponin I is elevated. Which of the following is the most appropriate initial management for this patient's condition? (Q850428)

A. Send for PCI

B. Chewable Aspirin and Atorvastatin

C. Enoxaparin and Eptifibatide

D. IV atropine followed by temporary pacing



Correct Answer: B. Chewable Aspirin and Atorvastatin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This ECG shows inferior STEMI with ST elevation in leads II, III, aVF and reciprocal ST-depression in aVL . The most appropriate initial management step in the ER is to give: Chewable Aspirin (162–325 mg) for immediate platelet inhibition High-intensity Atorvastatin (80 mg) to stabilize plaque After these first-line measures, the patient should be sent for urgent PCI (door-to-balloon <90 min). Send for PCI (Option A) is not the initial step in NSTEMI; it is considered after risk stratification. Enoxaparin and Eptifibatide (Option C) are anticoagulant and GP IIb/IIIa inhibitors, used adjunctively, not as the very first action. IV atropine followed by temporary pacing (Option D) is for bradyarrhythmias, not ACS management.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2117-2118.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 65-year-old woman is known case of chronic stable angina and has undergone PCI with stenting last year. Today morning, she presents to the ER with a 60-minute episode of chest discomfort that occurred while she was watching television. She describes the pain as a tightness in his chest, radiating to her left arm. She has a history of T2DM and has deranged lipid profile. An ECG reveals inverted T-waves. Which of the following is the best next step in the management of this patient?

(Q850422)

A. Cardiac biomarkers

B. Send to Cath lab for PCI

C. Treadmill test

D. Myocardial perfusion imaging

Correct Answer: A. Cardiac biomarkers

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient is known case of chronic stable angina and has already undergone a revascularization procedure. Due to T2DM and deranged lipids , atherosclerosis process is still ongoing and has today caused her to develop Acute coronary syndrome. Since ECG shows T wave inversion she is either is having unstable angina or NSTEMI. To differentiate between the two, Cardiac biomarkers must be done initially Send to Cath lab for PCI (Option B) is indicated after confirming NSTEMI or high-risk features, not immediately without biomarkers. Treadmill test (Option C) is not appropriate during acute chest pain. Myocardial perfusion imaging (Option D) is used for elective ischemia assessment, not in acute evaluation.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2113.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: What is the revascularization procedure of choice for two different cases, Patient A with triple vessel disease and Patient B with left anterior descending artery blockage with EF < 40%? (Q850420)

A. A: CABG; B: PCI with stenting

B. CABG for both A and B

C. A: PCI with stenting; B: CABG

D. A: PCI with Bare metal stenting ; B: PCI with drug eluting stenting

Correct Answer: B. CABG for both A and B

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Coronary revascularization can be achieved either by Percutaneous Coronary Intervention (PCI) or Coronary Artery Bypass Grafting (CABG). The choice depends on the number of vessels involved, the location of the lesion, the complexity of coronary artery disease, and left ventricular function. Patient A: Triple Vessel Disease Patient B: LAD Blockage with EF < 40% In patients with triple-vessel coronary artery disease, CABG is the preferred revascularization strategy because it: Provides better long-term survival Achieves more complete revascularization Reduces the need for repeat revascularization procedures Therefore, CABG is the treatment of choice for triple-vessel disease, especially when there is associated left ventricular dysfunction or diabetes mellitus. In patients with significant LAD disease and reduced left ventricular ejection fraction (<40%), CABG is preferred over PCI because of surgical revascularization: Improves myocardial perfusion Provides better survival benefit in patients with LV dysfunction Reduces long-term mortality and major cardiac events Thus, CABG is the preferred revascularization strategy in patients with significant coronary artery disease associated with reduced ejection fraction.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2103, 2105

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A 65-year-old male with chronic stable angina presents with chest pain during routine activities. His current medications include aspirin, metoprolol, isosorbide mononitrate and atorvastatin, but his symptoms persist. Coronary angiography reveals 90% stenosis of the right coronary artery. and 70% in LCX. What is the most appropriate intervention? (Q850416)

A. Increase the dose of beta-blockers

B. Increase the dose of Long acting nitrates

C. PCI with drug-eluting stenting

D. Refer for coronary artery bypass grafting

Correct Answer: C. PCI with drug-eluting stenting

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In a patient with chronic stable angina who remains symptomatic despite optimal medical therapy and has significant coronary stenosis (>70%) on angiography, PCI with drug-eluting stent placement is the appropriate next step to improve symptoms and prognosis. Increasing the dose of beta-blockers (Option A) may reduce heart rate and myocardial oxygen demand but will not correct the underlying mechanical obstruction.

Increasing the dose of long-acting nitrates (Option B) provides temporary symptomatic relief but is not definitive therapy once critical stenosis is documented. Coronary artery bypass grafting (Option D) is indicated in left main disease, triple-vessel disease, or diabetics with multivessel involvement — not in isolated RCA and LCX stenosis.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2103.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: A 60-year-old man with a history of CAD presents with recurrent syncope. Considering his intermediate to high risk for CAD, which imaging modality would be most appropriate for further evaluation? (Q850414)

A. Myocardial Perfusion Imaging

B. Stress Echocardiography

C. Multigated Acquisition (MUGA) Scanning

D. Treadmill test

Correct Answer: A. Myocardial Perfusion Imaging

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Myocardial perfusion imaging is ideal for evaluating ischemia in patients with intermediate to high CAD risk, like this patient with a history of CAD and syncope . Thallium-201 imaging effectively detects areas of reduced blood flow , helping identify underlying ischemic disease. It's preferred when structural heart disease has been ruled out, as in this case, where echocardiography showed no abnormalities. Stress echocardiography (Option B) is useful but less sensitive than MPI in patients with known CAD and baseline ECG abnormalities. Multigated Acquisition (MUGA) scanning (Option C) assesses left ventricular ejection fraction but does not evaluate myocardial ischemia. Treadmill test (Option D) is contraindicated in high-risk CAD patients and may be unreliable or unsafe in those with recurrent syncope.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1885-1886.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: A 60-year-old male smoker presents with chest pain on climbing stairs. He is started on low-dose aspirin, statins and metoprolol by his GP. His symptoms have worsened despite medical therapy. What is the next best step in diagnosing the extent of his coronary artery disease? (Q850409)

A. Stress echocardiography

B. Myocardial perfusion imaging

C. Coronary angiography

D. Coronary computed tomography angiography

Correct Answer: D. Coronary computed tomography angiography

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Coronary CT angiography (CCTA) is the next best step to evaluate the extent and severity of coronary artery disease in a stable patient whose symptoms have worsened despite optimal medical therapy. It is a non-invasive imaging modality that provides detailed visualization of coronary anatomy and plaque burden before considering invasive procedures. Stress echocardiography (Option A) is mainly used for initial diagnosis in stable angina, not for further evaluation when symptoms worsen despite therapy. Myocardial perfusion imaging (Option B) detects reversible ischemia but does not define coronary anatomy precisely. Coronary angiography (Option C) is invasive and reserved for patients with high-risk findings or those being considered for revascularization after non-invasive assessment.

@Neet_pg_bot

Q26: A 60-year-old male undergoes a treadmill ECG stress test and develops 2 mm of horizontal ST-segment depression after 12 minutes of exercise. He reports non-limiting chest pain (angina index = 1). What is his Duke Treadmill Score (DTS) and his risk category? (Q850405)

A. DTS = 0; Intermediate risk

B. DTS = 5; Low risk

C. DTS = -2; Intermediate risk

D. DTS = -8; High risk

Correct Answer: C. DTS = -2; Intermediate risk

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Duke Treadmill Score (DTS) is calculated using the formula: DTS = Exercise time (in minutes) – (5× ST-segment deviation (in mm)) – (4 × angina index) The patient exercised for 12 minutes . There was 2 mm of horizontal ST-segment depression, so multiply by 5 . 5×2=10 The patient reported non-limiting chest pain, so the angina index = 1 (non-limiting angina). 4×1=4 Therefore, the DTS calculation: DTS = 12 –10 – 4= –2DTS This places the patient in the intermediate-risk category . Risk Interpretation: Risk DTS Interpretation Low Risk ≥ 5 No need for further coronary angiography. Intermediate Risk (Option C) +4 to –10 May need further tests, such as myocardial perfusion scanning or coronary angiography. High Risk < –10 Requires further investigation with coronary angiography.

pmc.ncbi.nlm.nih.gov/articles/PMC1123951/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q27: An elderly male with a history of cigarette smoking and hypertension develops chest pain after an evening walk. The pain is relieved after lying down for a few minutes. A treadmill stress test reveals ST-segment depression. What is the most likely cause attributed to this clinical presentation? (Q850402)

A. Hypertrophic Cardiomyopathy

B. Prinzmetal Angina

C. Non-ST-Elevation Myocardial Infarction (NSTEMI)

D. Chronic Stable Angina

Correct Answer: D. Chronic Stable Angina

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Chronic stable angina, or exertional angina, is a type of ischemic heart disease that occurs when the heart muscle does not receive adequate oxygen due to reduced blood flow through the coronary arteries, especially during physical exertion or emotional stress. Usually lasts 5-10 minutes and resolves with rest or with the use of sublingual nitroglycerin within a few minutes. ECG Findings: Symptomatic Phase (During Angina): ST-segment

depression (hallmark finding), indicating subendocardial ischemia due to insufficient blood flow to the inner layer of the heart muscle. Hypertrophic Cardiomyopathy (Option A): While this condition may cause ischemia, it is not typically associated with ST-segment depression on a treadmill test. Prinzmetal Angina (Option B): This type of angina typically occurs at rest, often during nighttime or early morning, and is associated with transient ST-segment elevation rather than depression. Non-ST-Elevation Myocardial Infarction (NSTEMI) (Option C): While NSTEMI can present with ST-segment depression, the chest pain is more persistent and not typically relieved by rest.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2094-2097.

↑ *Back to this question in Part A*

@Neet_pg_bot

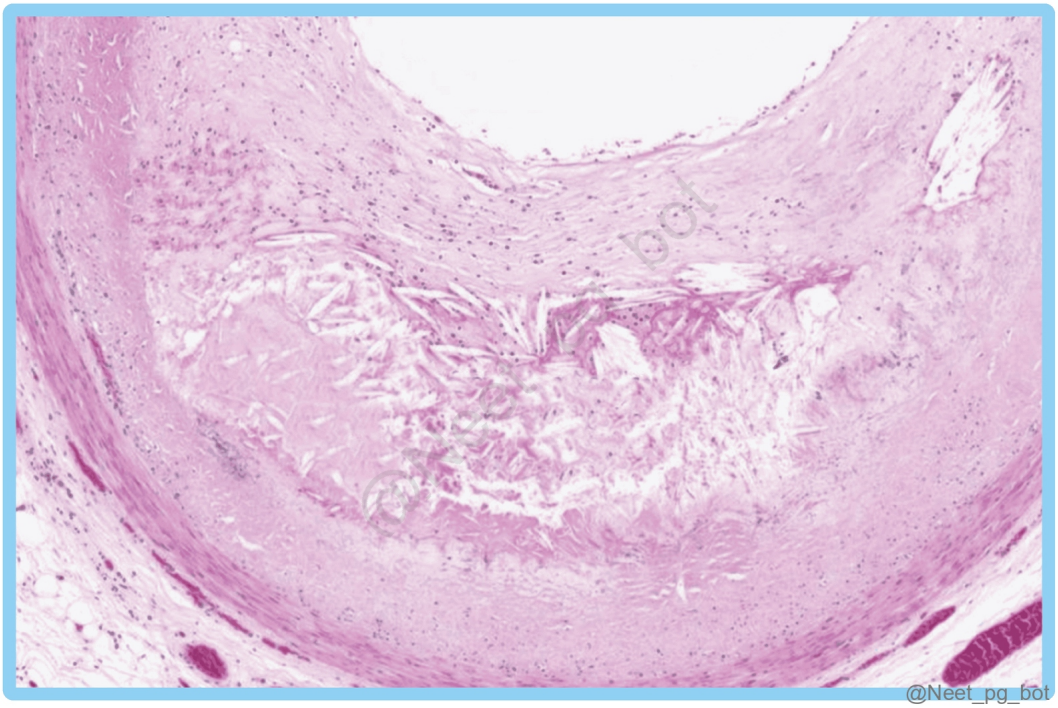
Q28: Arrange the following structures of an atherosclerotic plaque inside a blood vessel from the innermost to the outermost layer: Fibrous cap Necrotic core Foam cell layer Media (Q850399)

A. Fibrous cap → Foam cell layer→ Necrotic core → Media

B. Necrotic core → Media → Foam cell layer → Fibrous cap

C. Foam cell layer → Fibrous cap → Media→ Necrotic core

D. Foam cell layer → Necrotic core → Fibrous cap → Media



Correct Answer: A. Fibrous cap → Foam cell layer→ Necrotic core → Media

Explanation: Sequence of Atherosclerosis Development Endothelium (injury from HTN, hyperlipidemia, smoking) → LDL accumulation & macrophage engulfment → Foamy cell layer (fatty streaks) → Foam cell death → Necrotic core (dead cells + cholesterol) → Smooth muscle migration → Fibrous cap formation → Media thinning & weakening → Plaque formation and vulnerability {{caption_text}} {{caption_text}}

« Back to Folder Directory

[01_Cardiology] 006 Systemic Htn Pulmonary Htn — Quick Jump

Q1 (p. 1216) *Q2 (p. 1216)* *Q3 (p. 1217)* *Q4 (p. 1218)* *Q5 (p. 1219)* *Q6 (p. 1220)*
Q7 (p. 1221) *Q8 (p. 1221)* *Q9 (p. 1222)* *Q10 (p. 1223)*

Q1: A 55-year-old male presented to the clinic for a routine check-up last week. Automated Office Blood Pressure (AoBP) readings of 142/94, 138/86, and 138/90 mmHg. Ambulatory blood pressure monitoring (ABPM) was advised and the average 24-hour blood pressure is 138/86 mmHg. According to the ACC/AHA hypertension classification, what category does his blood pressure fall into? (Q850501)

A. Normal blood pressure

B. Elevated blood pressure

C. Stage 1 hypertension

D. Stage 2 hypertension

Correct Answer: C. Stage 1 hypertension

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Stage 1 hypertension is a systolic blood pressure between 130-139 mmHg or diastolic blood pressure between 80-89 mmHg. The patient’s ABPM shows systolic readings between 138-142 mmHg and diastolic values between 86-90 mmHg. Hypertension category based on the American College of Cardiology (ACC) Blood pressure category Systolic (mm Hg) Diastolic (mm Hg) Normal < 120 < 80 Elevated 120-129 <80 Stage 1 hypertension 130 – 139 80 – 89 Stage 2 hypertension ≥140 ≥90 Hypertensive crisis >180 >120

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2134.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 60-year-old male with a BMI of 30 presents with frequent headaches and dizziness. His office blood pressure is recorded as 126/74 mmHg, but home readings range between 150/94 mmHg and 156/90 mmHg. Ambulatory blood pressure monitoring confirms these findings with higher readings outside the office. Which of the following is the most appropriate management plan for this patient? (Q850503)

A. Lifestyle modifications alone is sufficient

B. Initiate antihypertensive therapy

C. Increase clinic visit frequency to monitor blood pressure

D. Diagnosis to be reconfirmed in 3 to 6 months

Correct Answer: B. Initiate antihypertensive therapy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The person in question most likely has masked hypertension. Lifestyle measures plus antihypertensive drug therapy are recommended. ACC/AHA White coat hypertension Masked hypertension Definition Elevated clinic or office BP and normal out-of-office BP (on ABPM or HBPM) in individuals not receiving antihypertensive therapy Normal BP on clinic or office BP readings and elevated out-of-office BP readings in individuals not receiving antihypertensive therapy Diagnosis Cutoff for Office Blood Pressure: ≥130/80 mmHg Cutoff for Out-of-Office Blood Pressure (Daytime ABPM or HBPM): <130/80 mmHg Cutoff for Office Blood Pressure: 120–129/<80 mmHg Cutoff for Out-of-Office Blood Pressure (Daytime ABPM or HBPM): ≥130/80 mmHg Management Lifestyle measures Diagnosis to be reconfirmed in 3 to 6 months (Option D ruled out) Yearly follow-ups with ABPM to detect progression to sustained hypertension Antihypertensive treatment: Estimated 10-year atherosclerotic cardiovascular disease risk of ≥10% Hypertension-related target organ damage Lifestyle measures + antihypertensive drug therapy recommended (Option B)(Option A ruled out) Long-term out-of-office BP monitoring (Option C ruled out) Abbreviations: HBPM - Home BP monitoring ABPM - Ambulatory BP monitoring

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1862, 2135.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: During a lecture on cardiovascular physiology, a professor explained that conditions causing unequal arm blood pressure often involve branches of the aortic arch. Which of the following conditions is not likely to cause a difference in blood pressure between the arms? (Q850504)

A. Aortic dissection involving the ascending aorta

B. Coarctation of the aorta distal to the left subclavian artery

C. Takayasu arteritis affecting the aortic arch

D. Subclavian artery stenosis

Correct Answer: B. Coarctation of the aorta distal to the left subclavian artery

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Coarctation of the aorta that occurs distal to the left subclavian artery does not cause a difference in blood pressure between the arms because the left subclavian and right brachiocephalic artery originates from the aorta before the point of coarctation. As a result, blood flow to the arms remains relatively equal. It will rather cause unequal BP between upper limbs and lower limbs. Conditions causing unequal left and right arm blood pressures Pathophysiology Aortic Dissection (Option A) Dissection occurring at the site of arterial branching from the aorta Subclavian Artery Stenosis (Option D ruled out) Atherosclerosis or other causes of stenosis (Thoracic Outlet Syndrome) in the subclavian artery reduce blood flow to the affected arm Takayasu Arteritis (Option C) Chronic vasculitis that affects large arteries, particularly the aorta and its branches

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1862.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 28-year-old male with a history of resistant hypertension and periodic muscle cramps is being investigated. Lab tests show hypokalemia, low plasma renin activity, and low aldosterone levels. Genetic testing reveals a mutation in the epithelial sodium channel (ENaC). What is the most likely diagnosis? (Q850505)

A. Gordan syndrome

B. Liddle syndrome

C. Congenital adrenal hyperplasia (CAH)

D. Pheochromocytoma

Correct Answer: B. Liddle syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Liddle syndrome is characterized by a mutation in the ENaC , leading to increased sodium reabsorption, volume expansion, and hypertension. The presence of hypokalemia, low renin, and low aldosterone levels is consistent with this diagnosis. Mendelian causes of HTN Disease Mode of inheritance Pathophysiology Key Features Gordon syndrome (Pseudohypoaldosteronism type II) (Option A ruled out) Autosomal dominant Mutations in regulatory proteins for the NCC (sodium chloride cotransporter) channel allow for unchecked activity, causing subsequent electrolyte and fluid overabsorption Hyperkalemia Normal glomerular filtration rate Pheochromocytoma (Option D ruled out) Autosomal dominant Neoplasia of the adrenal medulla generates heightened levels of norepinephrine and epinephrine Associated with MEN-2A (Sipple syndrome) MEN-2B VHL syndrome NF-1 Congenital Adrenal Hyperplasia (CAH) (Option C ruled out) Autosomal recessive Defects in steroid synthesis lead to buildup of intermediate metabolites with mineralocorticoid receptor activity 17-α hydroxylase deficiency: ↑ in aldosterone and thus HTN 11-β hydroxylase deficiency: ↑ in deoxycortisol which stimulates ENaC and causes HTN

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 355.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 65-year-old man with a long-standing history of hypertension presents with occasional episodes of dizziness and transient visual disturbances. Neurological examination and fundoscopy are normal. A carotid doppler is performed to visualize the carotid arteries. Which of the following findings is not expected to be seen in this patient? (Q850507)

A. Increased peak systolic velocity

B. Normal intima-media thickness

C. String sign

D. Turbulent blood flow in the carotid arteries

Correct Answer: B. Normal intima-media thickness

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In patients with long-standing hypertension, there would likely be increased intima-media thickness due to vascular changes. Narrowing of the carotid artery lumen explains the string sign, increased velocity and resultant turbulence. Increased peak systolic velocity (Option A): Seen due to stenosis and narrowing of carotid lumen. String sign (Option C): Thread-like residual lumen in severe (>95%) carotid artery stenosis, seen on

Doppler/angiography. Turbulent blood flow (Option D): Occurs because of irregular lumen narrowing and velocity changes.

References:

Robbins & Cotran's Pathologic Basis of Diseases, 10th Edition, Page 497.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 70-year-old male with a history of hypertension and not on medications has chronic kidney disease . His laboratory tests indicate an estimated glomerular filtration rate of 60 mL/min and elevated protein in his urine. His present blood pressure is 142/90 mmHg. Considering his condition, which of the following antihypertensive medications is most appropriate to initiate? (Q850508)

A. Amlodipine

B. Lisinopril

C. Hydrochlorothiazide

D. Metoprolol

Correct Answer: B. Lisinopril

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In patients with hypertension and chronic kidney disease, ACE inhibitors like Lisinopril and ARBs are preferred first-line agents for hypertension (unless contraindicated). They help control blood pressure and provide renal protection. ACC/AHA Guidelines for Hypertension Management Indications for Use of antihypertensives Secondary prevention of recurrent CVD events in patients with clinical CVD (defined as CHD, CHF, stroke) and BP ≥130/≥80 mmHg Primary prevention in patients with an estimated 10-year ASCVD risk ≥10% and BP ≥130/≥80 mmHg Primary prevention of CVD and low CVD risk in patients with BP ≥140/ ≥90 mmHg Blood Pressure Goal in Treating Hypertension BP target < 130/80 mmHg for adults with confirmed hypertension and known CVD or 10-year ASCVD event risk ≥10% Exceptions to Therapeutic Target of <130/80 mmHg Age >80 years Blood pressure <140/90 mmHg in previously untreated hypertensive patients who experience an ischemic stroke or TIA Acute therapy for most hypertensive urgencies and emergencies Abbreviations: ASCVD - atherosclerotic cardiovascular disease CHD - coronary heart disease CHF - congestive heart failure CVD - cardiovascular disease Amlodipine (Option A): Useful add-on, but does not reduce proteinuria or provide renal protection like ACE inhibitors. Hydrochlorothiazide (Option C): Less effective when eGFR < 30–40 mL/min; also does not reduce proteinuria . Metoprolol (Option D): Beta-blockers are not first-line in CKD unless there is another indication (e.g., CAD, arrhythmia).

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2144.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following is most appropriate step cabout management of poorly controlled asthmatic on daily Formoterol and medium dose inhaled steroids and is still having nocturnal attacks daily? (Q850509)

A. Start Oral corticosteroids

B. Add LAMA

C. Start high dose inhaled corticosteroids

D. Start IV steroids

Correct Answer: B. Add LAMA

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: : The patient has poorly controlled asthma despite medium-dose ICS + LABA, with daily nocturnal symptoms, which classifies as step 4–5 asthma per GINA guidelines. Adding a LAMA (e.g., tiotropium) is the recommended next step before escalating to high-dose ICS or systemic steroids, as it improves lung function and reduces exacerbations. Start oral corticosteroids (Option A): Oral steroids are reserved for acute exacerbations or severe uncontrolled asthma, not as the first escalation step due to systemic side effects. Start high dose inhaled corticosteroids (Option C): High-dose ICS can be considered later if adding LAMA or other controllers fails, because LAMA addition is preferred first to minimize steroid side effects. Start IV steroids (Option D): IV steroids are indicated only in severe acute exacerbations, not for step-up management in stable, poorly controlled asthma.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2137.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 55-year-old male presents with severe headache, nausea, and confusion. His blood pressure is recorded at 190/130 mmHg. Neurological examination reveals

altered mental status, and the patient appears distressed. A fundoscopic exam shows retinal haemorrhages. What is the most appropriate classification of this patient's condition? (Q850510)

A. Hypertensive urgency

B. Hypertensive emergency

C. Malignant hypertension

D. Essential hypertension

Correct Answer: B. Hypertensive emergency

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient exhibits signs of end-organ damage (altered mental status and retinal haemorrhages) classifying his condition as a hypertensive emergency. Condition Features Treatment Approach Hypertensive Urgency (Option A) Systolic BP > 180 mmHg and/or Diastolic BP > 120 mmHg without end-organ damage Reinstitution or increase of oral antihypertensives No hospitalization required Gradual BP reduction over hours/days Hypertensive Emergency The same BP values as urgency but with end-organ damage like Encephalopathy, stroke Retinal haemorrhages Aortic dissection Micronagiopathic hemolytic anemia Target 25% reduction in MAP over next 1-2 hours using IV agents (e.g., Nicardipine, labetalol and sodium nitroprusside) Malignant Hypertension (Option C) Abrupt increase in BP in previously hypertensive or normotensive patients to > 180 /120 mm Hg with papilledema. Renal impairment may coexist Fibrinoid necrosis in wall of blood vessels Intensive management often requires hospitalization and aggressive therapy with Labetaolol or nicardipine

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2148.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 65-year-old man with a history of type 2 diabetes and hypertension presents to his primary care physician for a follow-up appointment. His blood pressure is 160/95 mmHg. The physician wants to start an antihypertensive medication. What is the target blood pressure for this patient? (Q850512)

A. < 140/90 mmHg

B. < 135/85 mmHg

C. < 130/80 mmHg

D. < 150/90 mmHg

Correct Answer: C. < 130/80 mmHg

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: For patients with diabetes, the target blood pressure is set at < 130/80 mmHg. This target is aimed at reducing the risk of complications associated with diabetes, including cardiovascular disease and kidney damage. Condition Target Blood Pressure Recommended Medications General Hypertension < 135-140/85-90 mmHg Initial: Thiazide diuretic, CCB, ACEI, or ARB (non-black) ; Thiazide or CCB (black) Hypertension with Diabetic Nephropathy < 130/80 mmHg ACEI/ARB End-Stage Renal Disease (ESRD) < 130/80 mmHg CCB (e.g., Amlodipine) Alpha blocker like prazosin Chronic Kidney Disease (CKD) Grade I-III < 130/80 mmHg ACEI/ARB + Thiazide + CCB eGFR < 30 ml/min < 130/80 mmHg Metolazone is only thiazide that can be given below eGFR of 30 ml / min

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2145-2147.

↑ *Back to this question in Part A*

@Neet_pg_bot

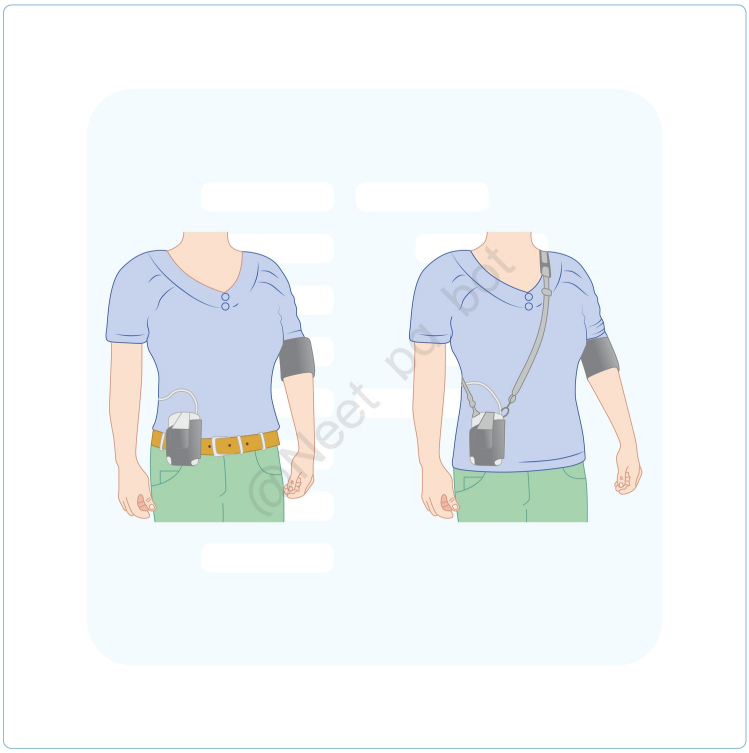
Q10: Which of the following is incorrect regarding the image given? (Q850513)

A. Can help identify the white-coat effect in patients

B. Continuous readings for a full 24-hour period

C. Measures both awake and sleep averages

D. Used to investigate hypertension only

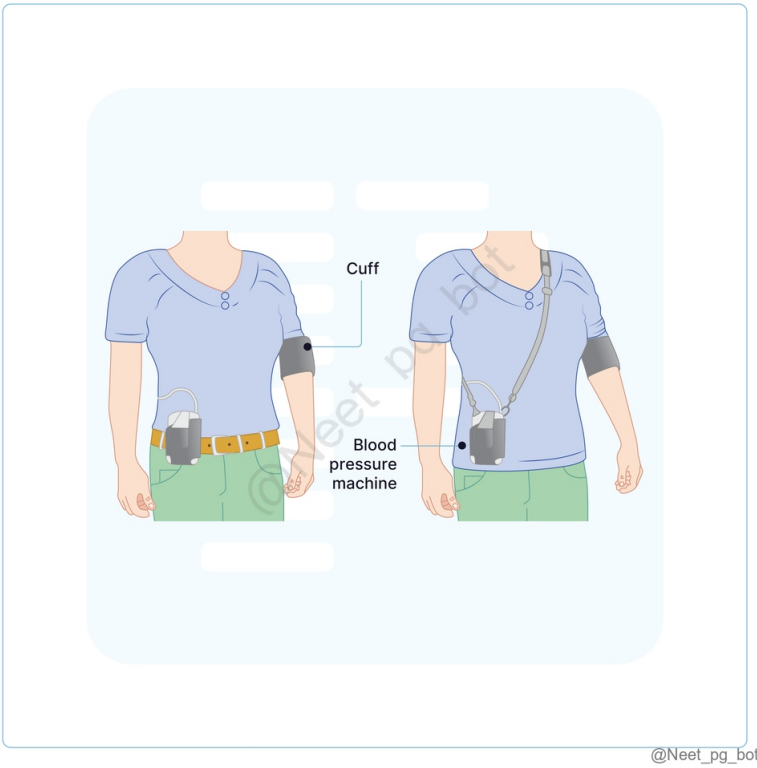


@Neet_pg_bot

Correct Answer: D. Used to investigate hypertension only

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The image depicts Ambulatory BP Monitoring (ABPM). ABPM is used to investigate hypotensive episodes along with hypertension. These hypotensive episodes can occur due to autonomic dysfunction. Parameter Ambulatory BP Monitoring (ABPM) Home Blood Pressure Monitoring (HBPM) Device Type Oscillometric Oscillometric Operation Worn by patient, preprogrammed, fully automatic Self-administered by the patient Monitoring Duration 24 hours (Option B) 7 days (morning and evening) Mean Overall BP Present in report Average of 6 days if > 135/85 mmHg Mean Awake BP Present in report Average of readings during the day Mean Sleep BP Present in the report (Option C ruled out) Not typically calculated Clinical Applications White-coat hypertension (Option A ruled out) Confirm hypertension in children Resistant hypertension Labile hypertension Hypotensive episodes (Option D) Self-monitoring for hypertension management



@Neet_pg_bot

Q1: Which of the following statements is false about first-degree atrioventricular block? (Q850536)

A. Minor Jones criteria in Rheumatic fever

B. Serial prolongation of PR interval

C. Can be physiological

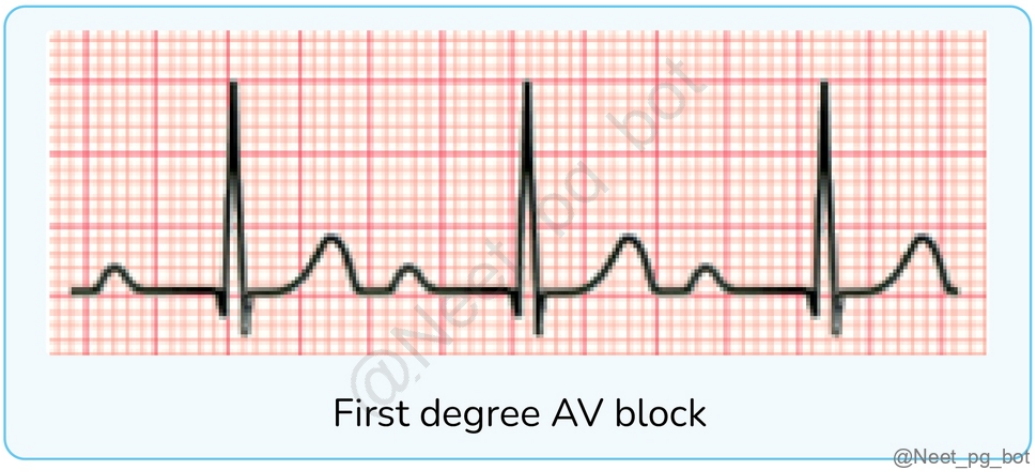
D. Consistent PR interval with no missed beats

Correct Answer: B. Serial prolongation of PR interval

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: n first-degree AV block , the PR interval is prolonged (>200 ms) but remains constant , and every P wave is followed by a QRS complex with no dropped beats. Aschoff nodules can involve the conduction system of the heart leading to PR prolongation and is a minor Jones criteria. It can be physiological due to high vagal tone in athletes.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1925.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 65-year-old man treated with PCI for STEMI develops syncope and is found to have a 2:1 AV block with broad QRS on his ECG. Which of the following is the most likely mechanism behind his AV block, and how would atropine administration affect his condition? (Q850573)

A. The block is most likely in the AV node, and atropine will improve AV conduction.

B. The block is most likely in the His-Purkinje system, and atropine will improve AV conduction.

C. The block is most likely in the AV node, and atropine may increase the degree of AV block.

D. The block is most likely in the His-Purkinje system, and atropine may increase the degree of AV block.

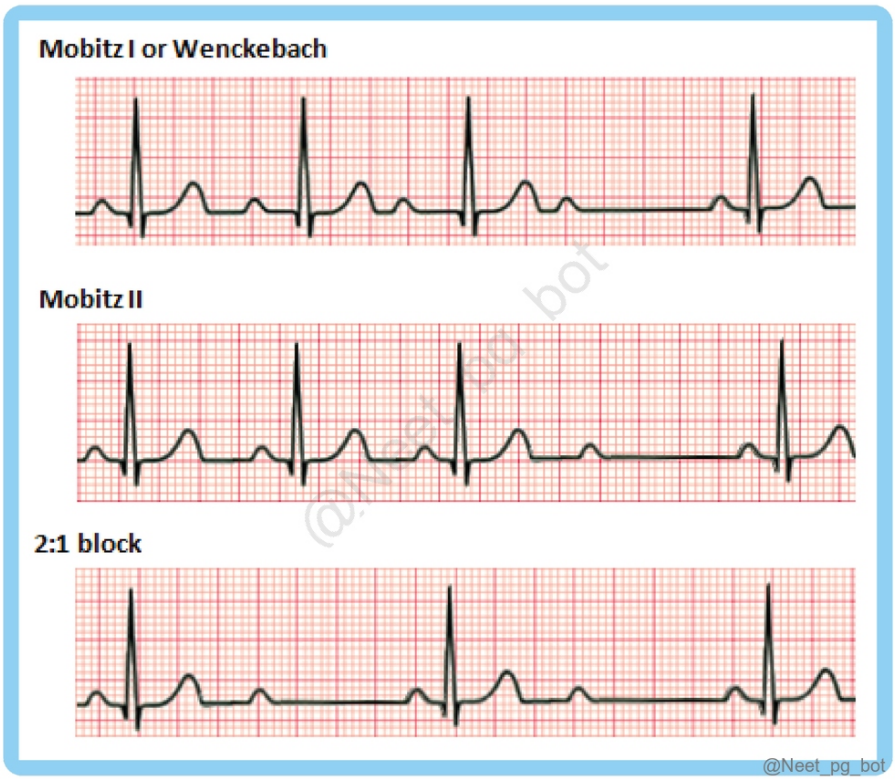
Correct Answer: D. The block is most likely in the His-Purkinje system, and atropine may increase the degree of AV block.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: 2:1 block is the differential diagnosis of Mobitz II and has lesion at the Bundle of his. The widened QRS complex is suggestive of a block in the His-Purkinje system rather than the AV node. Atropine works at AV node by reducing AV block and enhances conduction through the AV node But here the lesion is in His-Purkinje

system, so atropine has no effect or it may increase the block. Atropine will increase sinus firing rate causing increase in AV nodal conduction delay which will add to fixed conduction delay explaining the worsening of this block 2:1 Heart block: It is a condition where there is intermittent failure of conduction between the atrium and ventricle, resulting in every alternate atrial impulse being conducted to the ventricles. This means for every two P waves on an ECG, there is only one QRS complex. {{caption_text}}



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1925.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which among the following are included in the criteria for Metabolic syndrome 1) Waist circumference > 102 cm in men 2) Waist circumference > 88 cm in women 3) HDL > 50 mg/dL in men 4) BP 115/80 mm Hg 5) Fasting plasma glucose > 100 mg/dL 6) LDL > 200 mg/dL (Q850570)

A. 1, 2, 3, 4, 5

B. 1, 4, 5, 6

C. 1, 2, 5

D. 2, 4, 5, 6

Correct Answer: C. 1, 2, 5

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: LDL is not a part of the criteria. HDL > 50 will be protective rather. BP is normal. Only Waist circumference > 102 cms (men) & > 88 cms (women) and Fasting plasma glucose > 100 mg/dL among the given options are part of Metabolic syndrome (Syndrome-X) criteria. Metabolic syndrome/Syndrome-X criteria: 1) Waist circumference > 102 cm in Men > 88 cmin Women 2) HDL levels < 40 mg/dL in Men < 50 mg/dL in Women 3) Triglyceride levels > 150 mg/dL 4) BP (Blood Pressure) > 130/85 mmHg 5) Fasting plasma glucose > 100 mg/dL Extra mile Syndrome-Z: Syndrome-X +Obstructive Sleep Apnoea

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3253.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Drug causing maximum mortality reduction in a patient with HFrEF? (Q850564)

A. Ramipril

B. Carvedilol

C. Spironolactone

D. Canagliflozin

Correct Answer: A. Ramipril

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Ramipril (an ACE inhibitor) provides the greatest mortality reduction in HFrEF . ACE inhibitors are first-line, foundational therapy and have been proven to: Reduce all-cause mortality Reduce HF hospitalization Slow disease progression Improve symptoms Drugs causing mortality reduction in Heart Failure β-blockers (Carvedilol / Metoprolol succinate / Bisoprolol) Aldosterone antagonists (Spironolactone) ACE inhibitors (Ramipril) SGLT2 inhibitors (e.g., Canagliflozin)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1994.

↑ *Back to this question in Part A*

@Neet_pg_bot

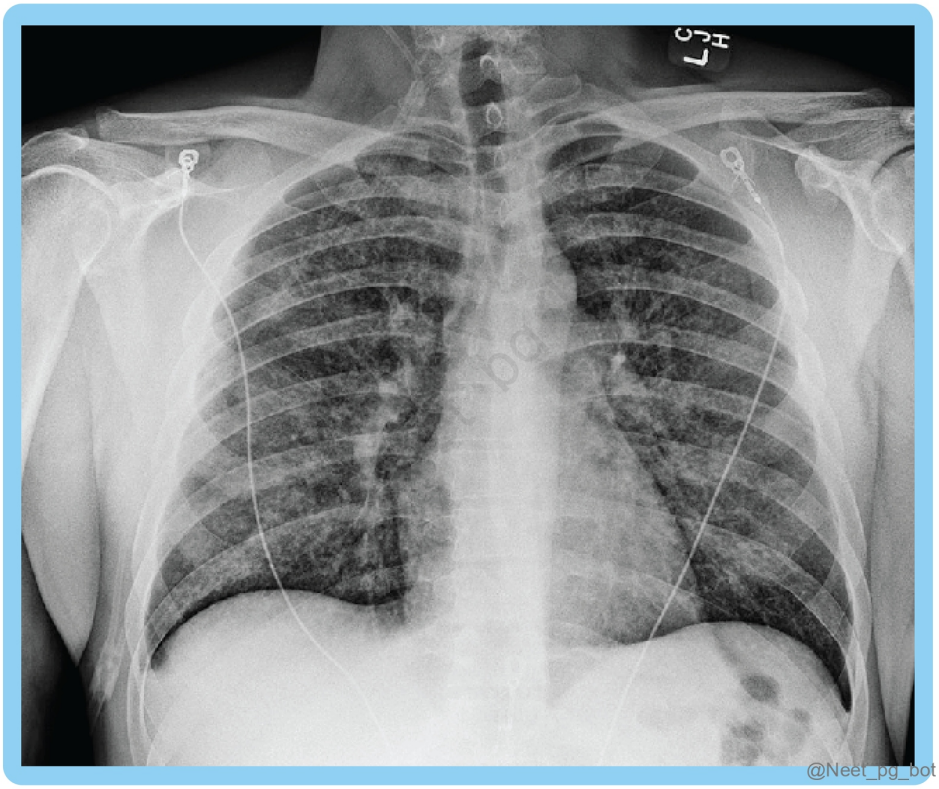
Q5: A patient presents with sudden onset breathlessness. On arrival his vitals were, PR- 130 bpm, BP- 180/110 mmHg and spO 2 - 82% in room air. X-ray done is as shown below.What is the most appropriate next step in managing this patient? (Q850562)

A. Furosemide and Esmolol

B. Furosemide and NTG

C. Furosemide and Diltizaem

D. Furosemide and Digoxin



Correct Answer: B. Furosemide and NTG

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: X-ray shows perihilar infiltrates with increased interstitial markings due to an increase in hydrostatic pressure in vessels. Due to a hypertensive crisis, this patient is developing acute pulmonary edema due to LV failure . Prompt administration of Furosemide will reduce pulmonary edema. NTG is the drug of choice for Hypertensive crisis in LVF as it lowers BP and also reduces pulmonary edema. Beta blockers (Option A) are contraindicated in Acute Heart failure. Negative inotropic effects of diltiazem (Option C) will worsen this patient. Digoxin (Option D) is not used nowadays due to safer alternatives.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1990.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 75-year-old man is a known case of triple vessel disease, presented with fatigue. Echocardiography done showed global reduction in contractility and reduced ejection fraction. What is the most likely electrolyte disturbance seen in this patient? (Q850555)

A. Hyponatremia and Hypokalemia

B. Hypernatremia and Hyperkalemia

C. Hyponatremia and Hyperkalemia

D. Hypernatremia and Hypokalemia

Correct Answer: A. Hyponatremia and Hypokalemia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has developed ischemic cardiomyopathy due to triple vessel disease and going into biventricular heart failure (global hypokinesia on Echocardiography) Due to RAAS activation potassium will be low . Another reason can be the use of diuretics in these patients Due to low BP, increased release of ADH will cause dilutional hyponatremia . Though RAAS is activated , excess of water as compared to sodium will worsen this hyponatremia. CHF has Hypervolemic Hyponatremia.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1984.

↑ *Back to this question in Part A*

@Neet_pg_bot

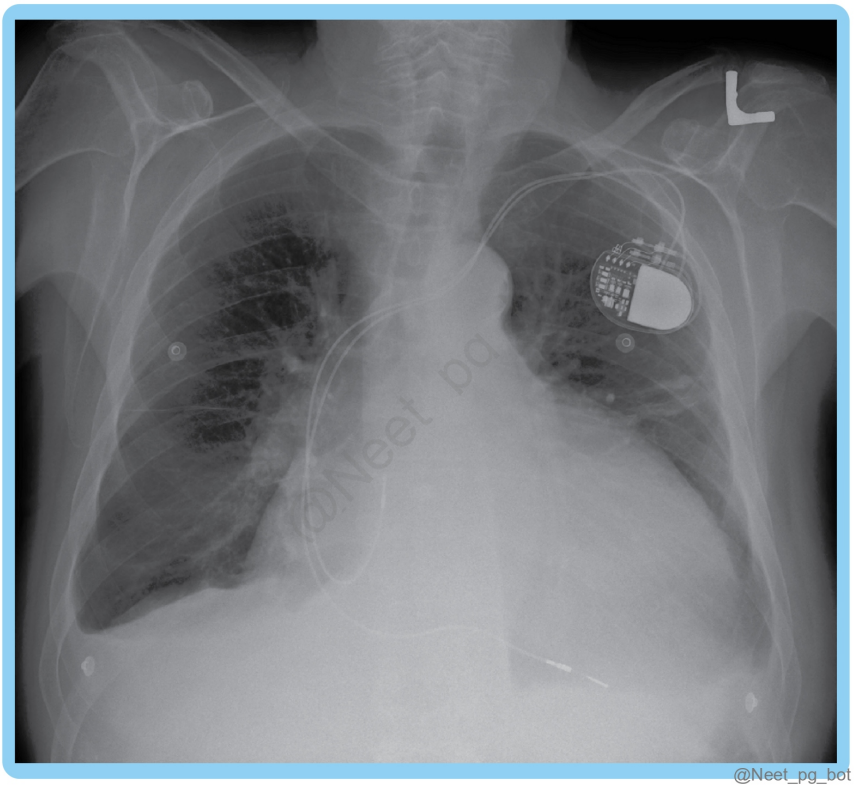
Q7: A 50-year-old male comes with complaints of shortness of breath that worsens upon lying down for the past 1 week. On examination, pulse-130 bpm, BP-150/90 mmHg, neck veins are distended, S3+ on cardiac auscultation. He had developed MI last year and was treated. CXR is shown below. Which among the following is not part of the major Framingham's criteria? (Q850549)

A. Dyspnoea worse upon lying down

B. Neck vein distention

C. HR-130 bpm

D. S3



Correct Answer: C. HR-130 bpm

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Tachycardia can occur in even anxiety or panic attacks and is a minor framingham criteria . S3, Orthopnea and distended neck veins are major diagnostic criteria for heart failure. CXR shows a pacemaker with two leads. The patient could have developed a heart block after his last cardiac event. Framingham diagnostic criteria for Heart Failure: Major criteria Minor criteria Acute pulmonary edema (crepitations/rales) Cardiomegaly

PND/Orthopnoea Elevated JVP, positive abdominojugular reflex S3 gallop rhythm Weight loss of > 4.5 kg in last 5 days Ankle edema (pitting pedal edema) Dyspnoea on exertion Hepatomegaly Nocturnal cough Pleural effusion Tachycardia (HR>120 bpm)

@Neet_pg_bot

Q8: A 68-year-old male is presented with sudden loss of consciousness and collapses. ECG on arrival at ER is shown below and significant perioral pallor was noted while tracing was being done. What is the diagnosis? (Q850544)

A. Third-degree atrioventricular block

B. Mobitz II heart block

C. Mobitz I block

D. First degree heart block

Correct Answer: A. Third-degree atrioventricular block

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The ECG shows complete AV dissociation , where P waves and QRS complexes occur independently at their own intrinsic rates. This results in profound bradycardia , reduced cardiac output, and can cause sudden loss of consciousness and perioral pallor due to poor perfusion. This presentation is classic for Third-degree Atrioventricular Block. Mobitz II Block (Option B): Dropped QRS complexes without PR prolongation, but not complete dissociation . Mobitz I (Wenckebach) (Option C): Progressive PR lengthening with a dropped beat; usually not severe enough to cause collapse. First-degree Block (Option D): Prolonged PR interval only, usually asymptomatic.

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 1925, 1926, 1930.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Identify the type of heart block from the ECG given below. (Q850539)

A. First-degree AV block

B. 2nd degree heart block, intra nodal conduction delay

C. 2nd degree heart block, Infra nodal conduction delay

D. Third-degree atrioventricular block

@Neet_pg_bot

Correct Answer: B. 2nd degree heart block, intra nodal conduction delay

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The ECG shows progressive prolongation of the PR interval until a dropped QRS complex occurs, characteristic of Mobitz Type I second-degree AV block (Wenckebach phenomenon). This reflects an intranodal conduction delay in the AV node. Second-degree heart block Dropped beats occur because some impulses from the atria fail to be transmitted to the ventricles. Types Mobitz Type I (Wenckebach) Mobitz Type II Description Progressive lengthening of PR intervals until a dropped beat occurs. {{caption_text}} PR interval remains constant until a dropped beat occurs {{caption_text}} Clinical Features Often physiological; can occur in young athletes. May not cause symptoms. Caused by His–Purkinje system disease. Higher risk of asystole. Management Typically does not require treatment. Monitor for changes; consider underlying heart disease. May require treatment if symptomatic. Consider temporary pacing. Monitor closely due to the risk of progression.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1925.

↑ *Back to this question in Part A*

@Neet_pg_bot

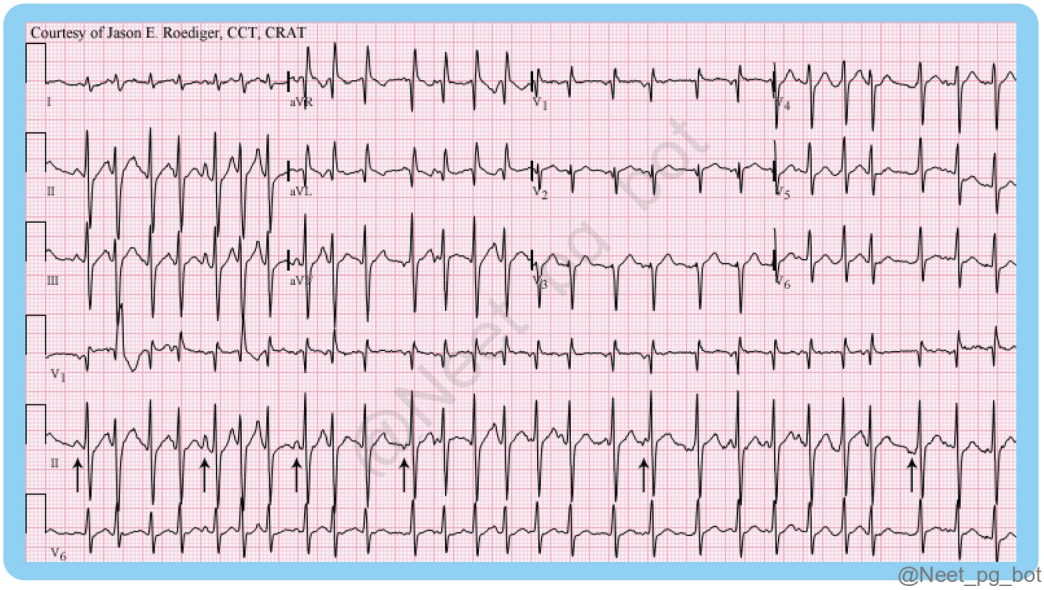
Q10: A 68-year-old smoker presents with breathing trouble and sudden onset palpitations. The ECG is given below and has an irregular rhythm with an average heart rate of 150 beats per minute. What is the most likely diagnosis based on the ECG findings? (Q850516)

A. Atrial Fibrillation

B. Multifocal Atrial Tachycardia

C. Atrial Flutter

D. Sinus Tachycardia

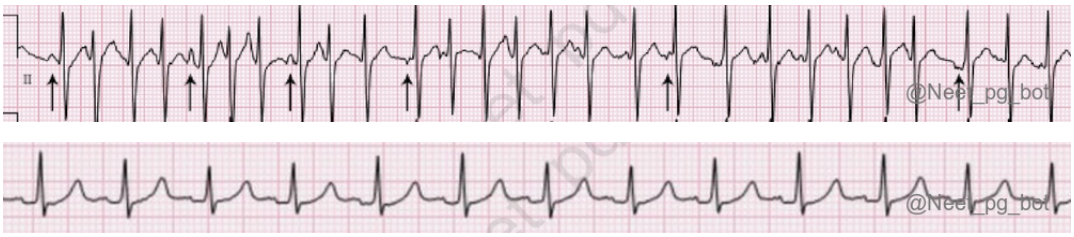


Correct Answer: B. Multifocal Atrial Tachycardia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ECG Shows variable RR interval with P waves that rules out atrial fibrillation. On close observation P waves (vertical arrows) are having variable morphology. The diagnosis is MAT. Smokers develop COPD and resultant hypoxia is the trigger for development of this arrhythmia. Atrial fibrillation (Option A): No distinct P waves; baseline is fibrillatory. Atrial flutter (Option C) has saw-tooth waves. Sinus tachycardia (Option D) has reduced RR interval with T wave and P wave visible independently.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1946.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: Which of the following statements on transvenous pacing is wrong? (Q850532)

A. Central venous access is needed

B. Intracardiac lead placement is done

C. Permanent method of pacing

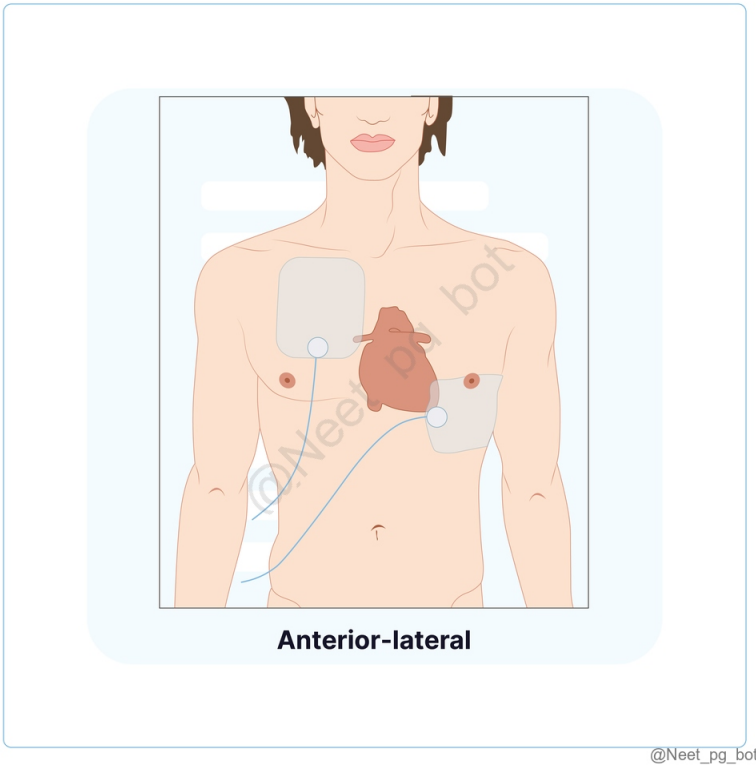
D. Required in inferior wall MI

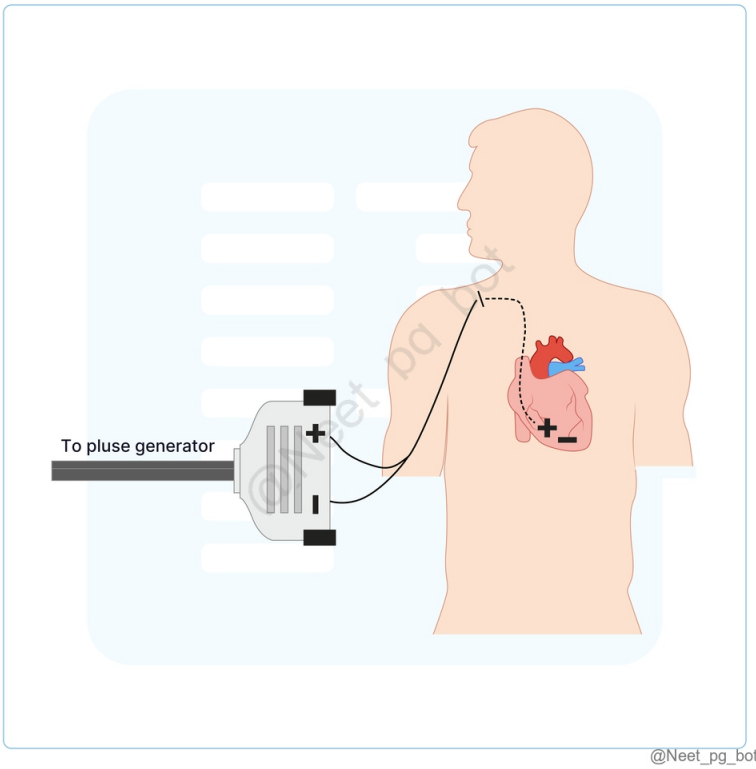
Correct Answer: C. Permanent method of pacing

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Transvenous pacing is a temporary pacing method for symptomatic bradycardia. Inferior wall MI leads to vagus nerve irritation and severe bradycardia that may not respond to atropine. (Option D) Aspect Transcutaneous Pacing Transvenous Pacing Purpose Temporary, fast initiation for symptomatic bradyarrhythmias or cardiac arrest. Longer-term temporary pacing for evaluation of permanent pacemaker need. Initiation Time Fastest method, used in emergencies (e.g., bradycardia, asystole). Requires more time due to the need for central venous access. (Option A) Electrode Placement Anterior pad: cardiac apex or lead V3 position. Posterior pad: inferior to scapula or between scapula and spine. Intracardiac lead placement through a central vein (e.g., femoral, subclavian). (Option B)





@Neet_pg_bot

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1929.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 72-year-old male presents with an inferior wall STEMI. He starts developing altered mental status and heart rate is 38 bpm, blood pressure 80/50 mmHg. Which of the following will be used to manage his bradycadia? (Q850530)

A. IV atropine 1 mg every 3-5 minutes

B. IV atropine 2 mg every 3-5 minutes

C. IV atropine 0.5 mg every 3-5 minutes

D. IV atropine 0.6 mg every 3-5 minutes

Correct Answer: A. IV atropine 1 mg every 3-5 minutes

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Altered mental status implies the patient has hemodynamically unstable bradycardia and the treatment is IV atropine 1 mg every 3-5 minutes. In older guidelines the dose was 0.5 mg for a maximum of 6 doses and now it is 1 mg per dose to maximum of 3 doses. The total maximum dose of 3 mg remains the same.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2124, 2125.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 38-year-old man with a history of fatigue and daily headaches is found to have a blood pressure 150/100 mmHg on multiple occasions. His chest X-ray shows cardiomegaly and echocardiography shows reduced mitral inflow with concentric hypertrophy of heart. Which of the following is correct about this patient? (Q850529)

A. Systolic malfunction of left ventricle

B. Mitral stenosis

C. Diastolic dysfunction of Left ventricle

D. Mitral regurgitation

Correct Answer: C. Diastolic dysfunction of Left ventricle

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The key words in question are reduced mitral inflow and concentric hypertrophy of heart that indicates diastolic malfunction of LV due to hypertension of long standing duration. The increased LV end diastolic pressure explains why mitral inflow is reduced. Mitral stenosis (Option B) is ruled out as it does not have hypertrophy of LV and neither has hypertension. It causes left atria dilation. Mitral regurgitation (Option D) will cause eccentric hypertrophy. Wall thickness Chamber size Causes Concentric hypertrophy increased Normal to reduced Hypertension Eccentric hypertrophy Normal Dilated Mitral regurgitation Aortic regurgitation

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1882, 1978.

↑ *Back to this question in Part A*

@Neet_pg_bot

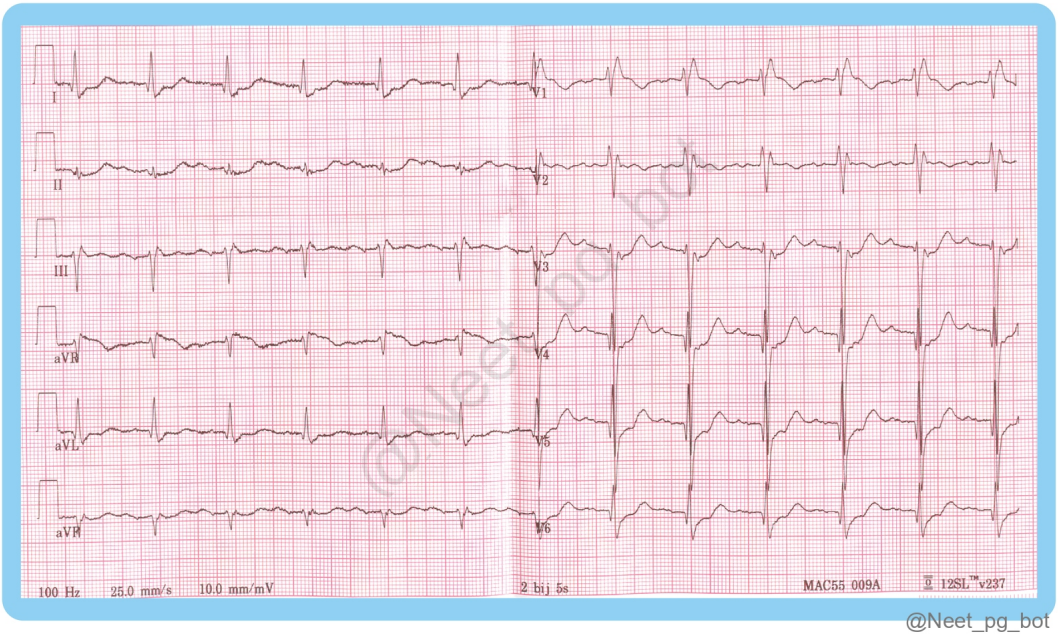
Q14: You are performing an annual medical check up of a 48-year-old man corporate executive. What is the most likely diagnosis based on the ECG findings? {{caption_text}} (Q850526)

A. Brugada Syndrome

B. Ventricular Tachycardia

C. Left Bundle Branch Block (LBBB)

D. Right Bundle Branch Block (RBBB)



@Neet_pg_bot

Correct Answer: D. Right Bundle Branch Block (RBBB)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient is asymptomatic and ECG shows rsR' pattern (rabbit ears) in lead V1, a wide QRS (>120 ms), and a broad S wave in leads I and V6. These are classic features for RBBB. Brugada (Option A) is ruled out as it has Coved or saddle back ST segment elevation. VT (Option B) is ruled as the heart rate is normal. LBBB (Option C) occurs commonly after MI has deep S is lead V1 and notched R showing rabbit ear pattern in V5, V6.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1871, 1872.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 60 year old man presents with central chest pain and breathing difficulty for the last 6 hours. He had tested positive for RT-PCR SARS COV-2 yesterday. Auscultation shows bilateral basal crepitations. ECG shows non-specific ST segment changes. Both NT pro-BNP levels and Troponin I levels are elevated. In cath lab coronary angiography is normal. Diagnosis is? (Q850524)

A. Myocarditis

B. Anterior wall Myocardial infarction

C. Broken heart syndrome

D. Acute pericarditis

Correct Answer: A. Myocarditis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Presence of non specific ST segment changes with elevated NT-ProBNP and troponin I indicates myocardial damage by COVID 19. Myocarditis is causing chest pain and features of pulmonary edema. Anterior wall Myocardial infarction (Option B): Normal coronary angiography that rules out MI. Broken heart syndrome (Option C) requires intense emotional trauma and catecholamine excess. Acute pericarditis (Option D) is ruled out as it has global ST-segment elevation with concavity upwards.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2011, 2012.

↑ *Back to this question in Part A*

@Neet_pg_bot

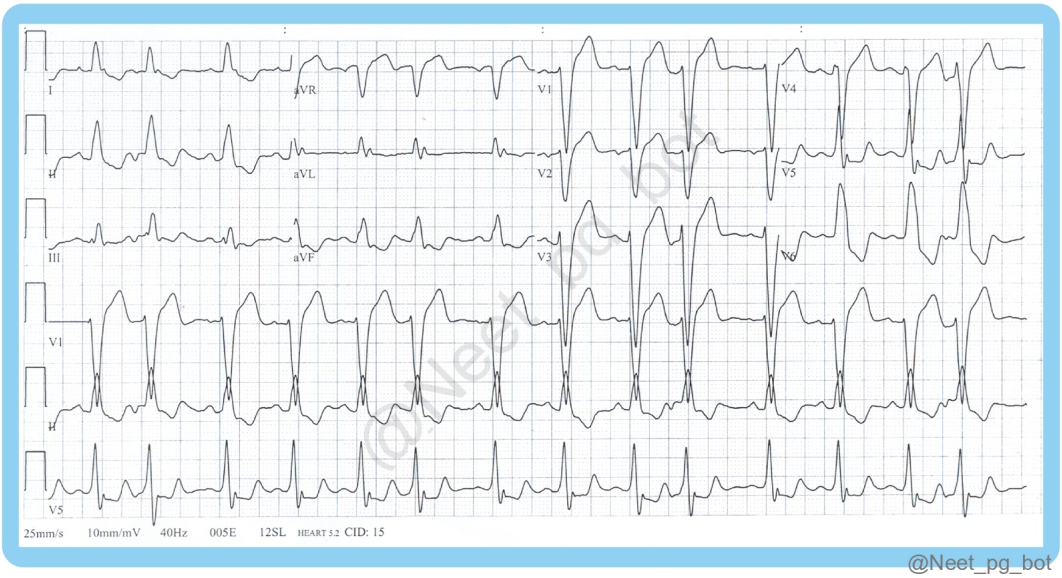
Q16: A 65-year-old diabetic male develops MI and is taken up for thrombolysis in the district hospital. ECG shows which of the following? (Q850523)

A. Ventricular tachycardia

B. Premature Ventricular Contractions (PVCs)

C. Right Bundle Branch Block (RBBB)

D. Left Bundle Branch Block (LBBB)

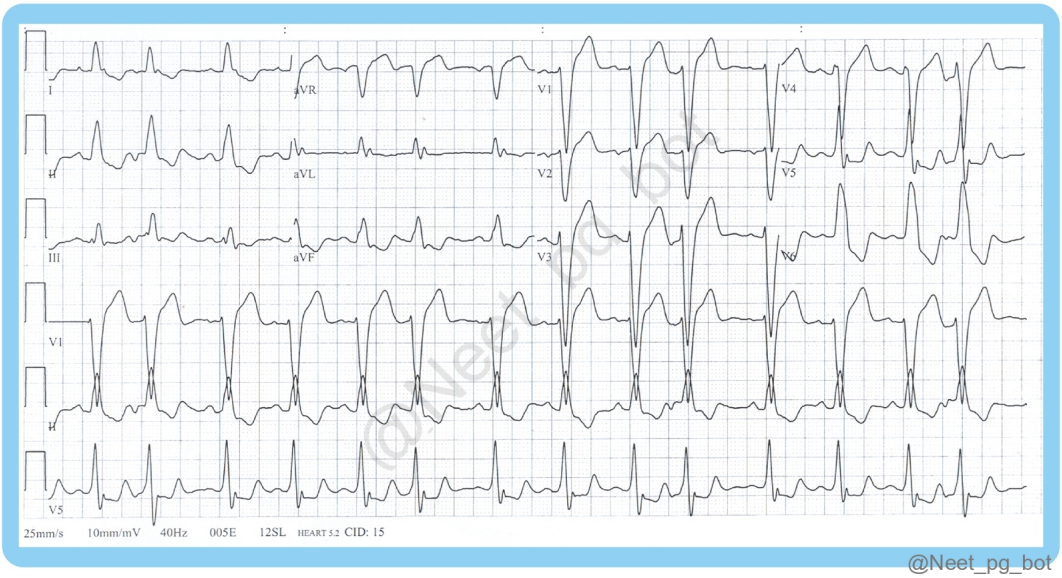


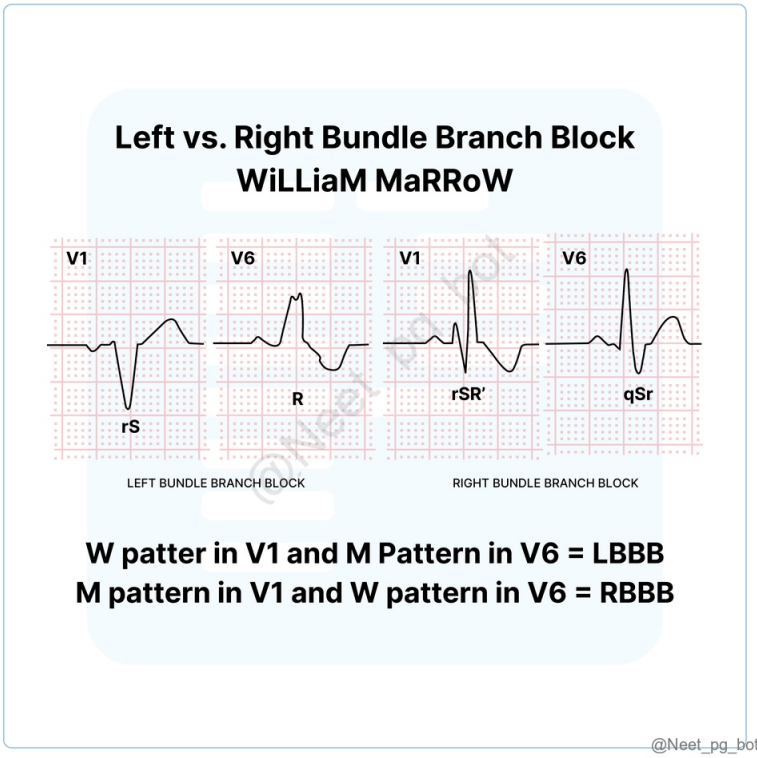
Correct Answer: D. Left Bundle Branch Block (LBBB)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Post MI the patient has developed LBBB . ECG shows a widened QRS complex (>120 ms), a broad and notched R wave in leads I, aVL, V5, and V6 (lateral leads), and a deep S wave in V1 and V2. The lack of Q waves in the lateral leads is also typical. In the context of acute MI, a new-onset LBBB is considered equivalent to STEMI and is an indication for urgent reperfusion (thrombolysis or PCI). This matches the description given: diabetic patient with MI undergoing thrombolysis → ECG showing LBBB. Clinical Significance in Acute MI In the context of an acute myocardial infarction (MI), a newly developed LBBB is a critical finding because: It is often associated with a large MI, as the block is located high up in the conducting system. It can obscure or mimic the typical ST-segment elevation seen in an acute STEMI (ST-Elevation Myocardial Infarction), making diagnosis challenging. When an LBBB is present, the diagnosis of MI is often made using the Sgarbossa criteria or the modified Smith criteria (also known as the modified Sgarbossa criteria). Therefore, an ECG of a patient who develops an LBBB will show the features of LBBB. {{caption_text}} Ventricular tachycardia (Option A): Would show rapid wide-complex tachycardia without organized P waves. Not consistent with the described morphology of lateral R-wave notching. PVCs (Option B): Premature, wide, bizarre QRS complexes occurring early, isolated events, not a sustained pattern across multiple leads. RBBB (Option C): Shows rsR' in V1 ("M-shaped"), and wide S waves in lateral leads, not the broad notched R waves in V5-V6 seen here.





References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1871, 1872.

↑ *Back to this question in Part A*

@Neet_pg_bot

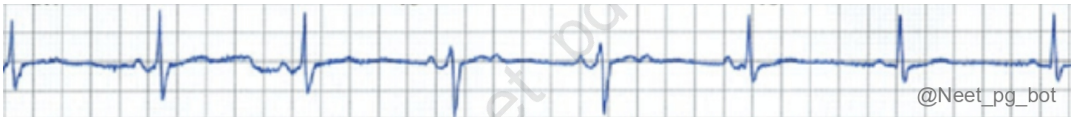
Q17: Calculate the heart rate of the ECG shown below (Q850522)

A. 60 beats per minute

B. 75 beats per minute

C. 100 beats per minute

D. 50 beats per minute

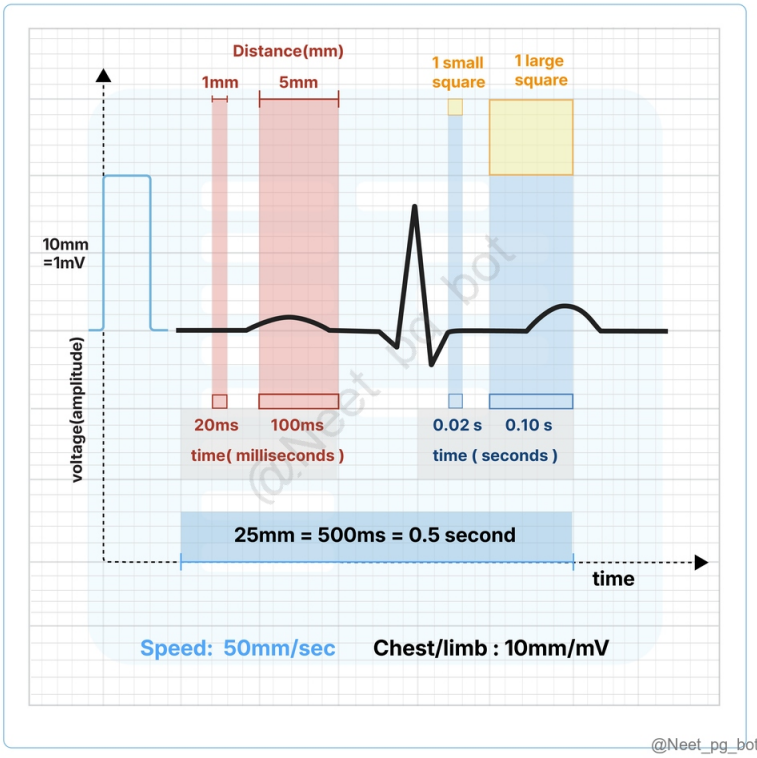


Correct Answer: A. 60 beats per minute

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: There are 5 large boxes separating peaks of R waves. Heart Rate = 300/Number of Large Boxes between R-R interval or 1500/ Number of small boxes between R-R interval Heart rate = 300/5=60 beats per minute



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1868

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 65-year-old smoker with COPD presents to the ER with palpitations and shortness of breath. His ECG shows an irregular rhythm with at least three distinct P-wave morphologies and a heart rate of 120 beats per minute. BP 100/60 mm Hg. Which of the following is the most appropriate management to prevent recurrence of this rythm disorder (Q850520)

A. Electrical cardioversion

B. Intravenous Diltiazem

C. LTOT with LAMA and LABA

D. IV amiodarone

Correct Answer: C. LTOT with LAMA and LABA

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Multifocal atrial tachycardia is often triggered by acute illnesses and hypoxia in patients with COPD. Long term oxygen therapy using oxygen concentrator LAMA and LABA will address hypoxia that is the trigger for development of this dysrhythmia.

Q1: A 25 year old male presents with exertional dyspnea and chest pain while playing table tennis. Echocardiography shows systolic anterior movement of mitral valve with LV free wall thickness of 30 mm. He informs you about the sudden death of his elder brother while dancing at a marriage party. Which of the following is the best intervention for management of this patient? (Q850596)

A. Mitral valvotomy

B. Implantable cardioverter defibrillator

C. Propranolol with Disopyramide

D. Surgical myomectomy

Correct Answer: B. Implantable cardioverter defibrillator

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The diagnosis based on clinical and echo findings is hypertrophic cardiomyopathy. In lieu of significant ventricular hypertrophy of 30 mm thickness and SCD in sibling, implantable cardioverter defibrillator is best intervention in this patient. I mplantable Cardioverter-Defibrillator indications in HCM Unexplained syncope Abnormal blood pressure response during exercise Significant ventricular hypertrophy (>30mm thickness) Family history of SCD Multiple episodes of non-sustained ventricular tachycardia (NSVT)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2008.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 55 year old woman presents with acute chest pain and difficulty breathing after learning of the death of her daughter in an air crash. Her ECG shows ST-segment elevation in lead I, aVL, V2-V4. Cardiac biomarkers are elevated. Bed side echocardiography reveals ballooning of the left ventricular apex. What is the most likely diagnosis? (Q850637)

A. Myocardial Infarction

B. Takotsubo Cardiomyopathy

C. Aortic Dissection

D. Brudaga syndrome

Correct Answer: B. Takotsubo Cardiomyopathy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In the setting of intense emotional trauma causing catecholamine excess and Echo findings of LV apex ballooning , the diagnosis is Takotsubo cardiomyopathy. Myocardial Infarction (Option A) is the first differential diagnosis of this presentation in case the echo findings were not given. Aortic dissection (Option C) will cause unequal BP between both arms and coronary artery dissection. Brugada syndrome (Option D) occurs in young males and causes Sudden nocturnal death.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2019.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 55-year-old patient presents with sharp chest pain, fever, and inspiratory catch on taking deep breath 3 weeks after undergoing coronary artery bypass surgery. Which of the following is the most likely underlying mechanism? (Q850635)

A. Constrictive pericarditis

B. Post cardiac injury syndrome

C. Electro-mechanical dissociation

D. Autoimmune myocarditis

Correct Answer: B. Post cardiac injury syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient’s presentation is consistent with postcardiac injury syndrome, often resulting from an autoimmune response to antigens from the injured myocardium following surgery. The resultant autoimmune pericarditis explains chest pain and pleuritis explains the inspiratory catch in breath. Causes can be Post-MI (Dressler syndrome) Post Surgery (open heart surgery, CABG, Valve replacement) Post trauma (pacemaker lead placement , blunt trauma to chest) Constrictive pericarditis (Option A) has Kussmaul sign, pericardial shock and visible calcification around the heart on CT chest. Electro-mechanical dissociation (Option C) will cause the heart to burst after transmural MI and causes death. Autoimmune myocarditis (Option D) is seen with SLE or vasculitis.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2082.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A post-mortem study reveals deposits between the pericardial layers with a “bread and butter” appearance. Which of the following is most consistent with this form of pericarditis? (Q850633)

A. Hemorrhagic pericarditis

B. Purulent pericarditis

C. Fibrinous pericarditis

D. Caseous pericarditis

Correct Answer: C. Fibrinous pericarditis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The “bread and butter” appearance is characteristic of fibrinous pericarditis, marked by fibrin and leukocytic exudate on the pericardium. {{caption_text}} Bread and butter appearance seen in fibrinous pericarditis Types of Pericarditis Fibrinous pericarditis Often called "bread and butter" pericarditis due to fibrin deposits creating a rough appearance on the pericardium. Caused by conditions like myocardial infarction, infections, trauma, or systemic diseases. Purulent pericarditis (Option C) Caused by bacterial infections, leading to a

pus-filled pericardial sac. Haemorrhagic pericarditis (Option A) Involves blood within the pericardium, often due to trauma, malignancy (lung cancer) or uremia. Caseous pericarditis (Option D) Rare and typically associated with tuberculosis.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2079
https://www.ncbi.nlm.nih.gov/books/NBK538254/

↑ *Back to this question in Part A*

@Neet_pg_bot

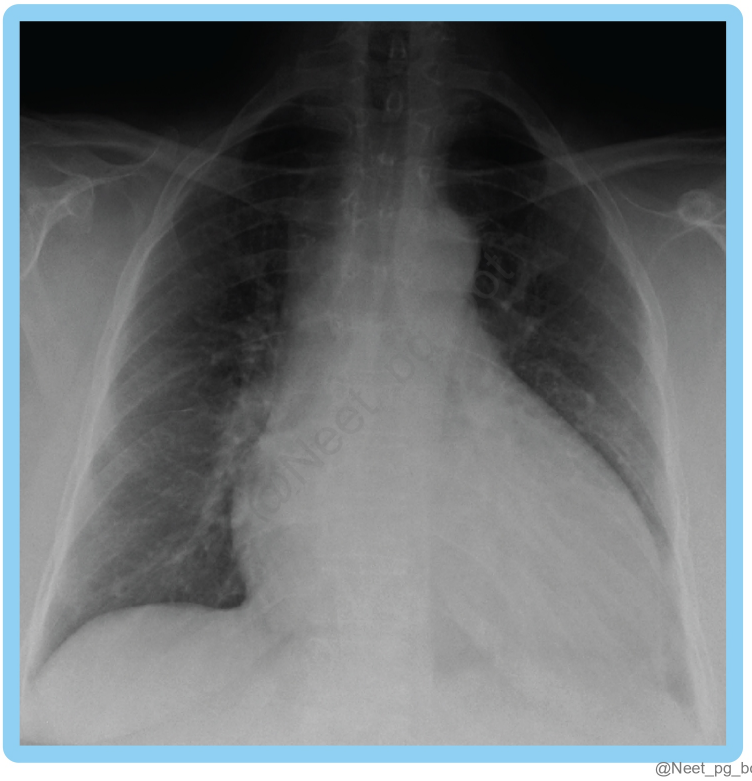
Q5: A 50 year old alcoholic presents with worsening fatigue, shortness of breath, and leg swelling. The Chest X-ray and Cardiac MRI of the patient are given below. Which of the following statements regarding the treatment of her condition is false? (Q850624)

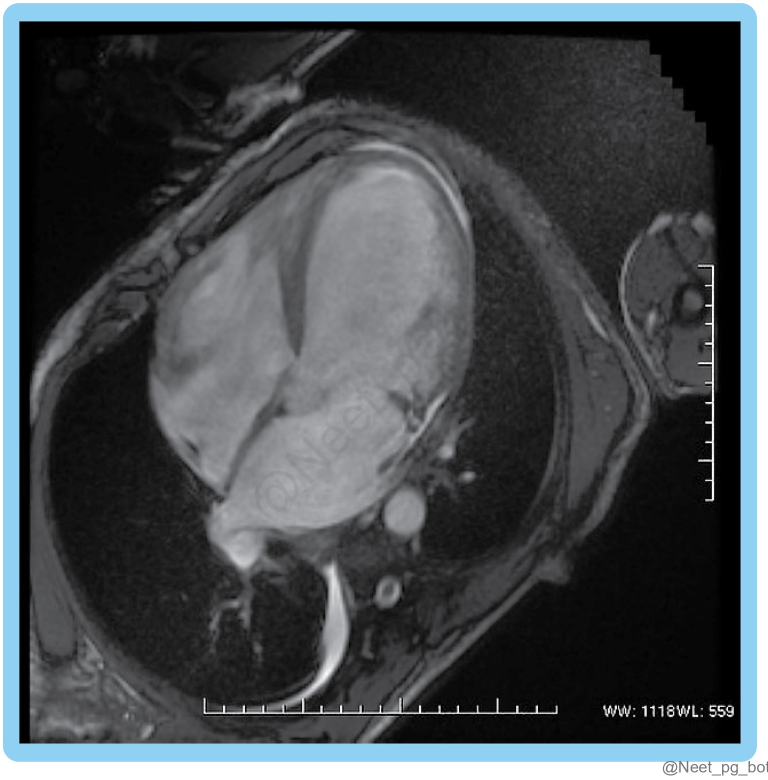
A. Low dose diuretics should be administered to maintain an euvolemic state.

B. ACE inhibitors are recommended for heart failure with reduced ejection fraction.

C. Beta-blockers should not be used in patients with chronic heart failure.

D. Cardiac resynchronization will reduce symptoms





Correct Answer: C. Beta-blockers should not be used in patients with chronic heart failure.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: CXR shows an increased CT ratio. Cardiac MRI shows reduced thickness of all chambers of the heart.. This implies the patient is having alcohol induced dilated cardiomyopathy , causing symptoms of heart failure. Beta blockers reduce mortality in chronic heart failure. Cardiac resynchronisation therapy is done to ensure both ventricles contract simultaneously and helps in reducing symptoms in DCM.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1992.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 50 year old alcoholic presents with shortness of breath and finding shown in the image. Auscultation reveals pan-systolic murmur. Which of the following findings is most consistent with the diagnosis of this patient? (Q850622)

A. Increased dynamic LV outflow tract obstruction

B. Increased Left ventricular diastolic dimension

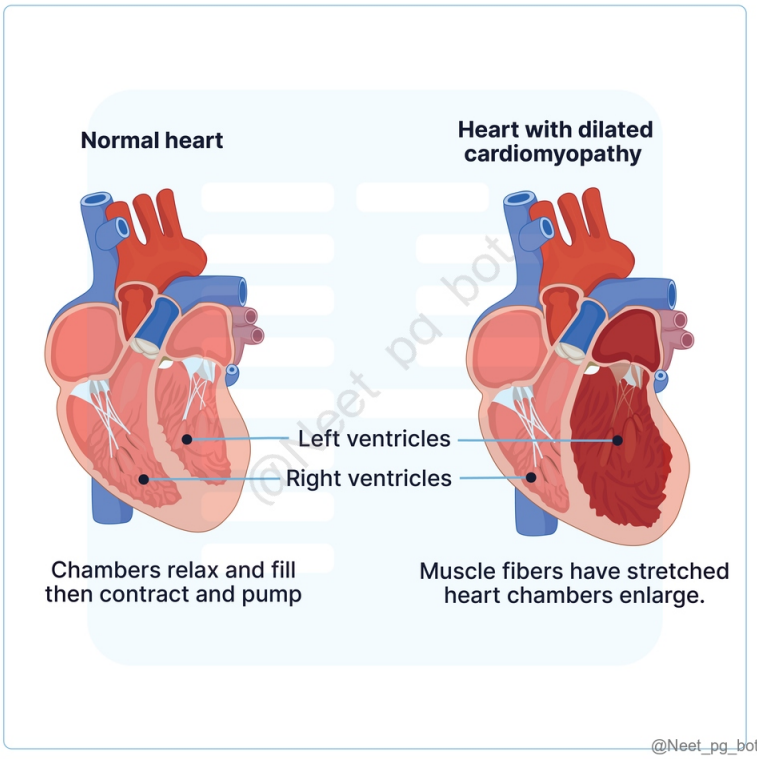
C. Double Apical impulse

D. Point of maximum impulse displaced medially

Correct Answer: B. Increased Left ventricular diastolic dimension

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The patient is having alcohol induced dilated cardiomyopathy. LV malfunction is causing pulmonary edema, and RV malfunction is causing pitting edema shown in the image. DCM will cause displaced hypokinetic apex with dilated, thinned-out cardiac chambers with functional Mitral regurgitation and tricuspid regurgitation, which explains the pansystolic murmur heard in this case. Increased dynamic LV outflow tract obstruction (Option A) and Double Apical impulse (Option C) are seen in HCM. Displacement of the apex beat (Option D) is seen in multiple conditions and hence ruled out.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2015.

Davidson's Principles and Practice of Medicine, 24th Edition, Page 539.

↑ *Back to this question in Part A*

@Neet_pg_bot

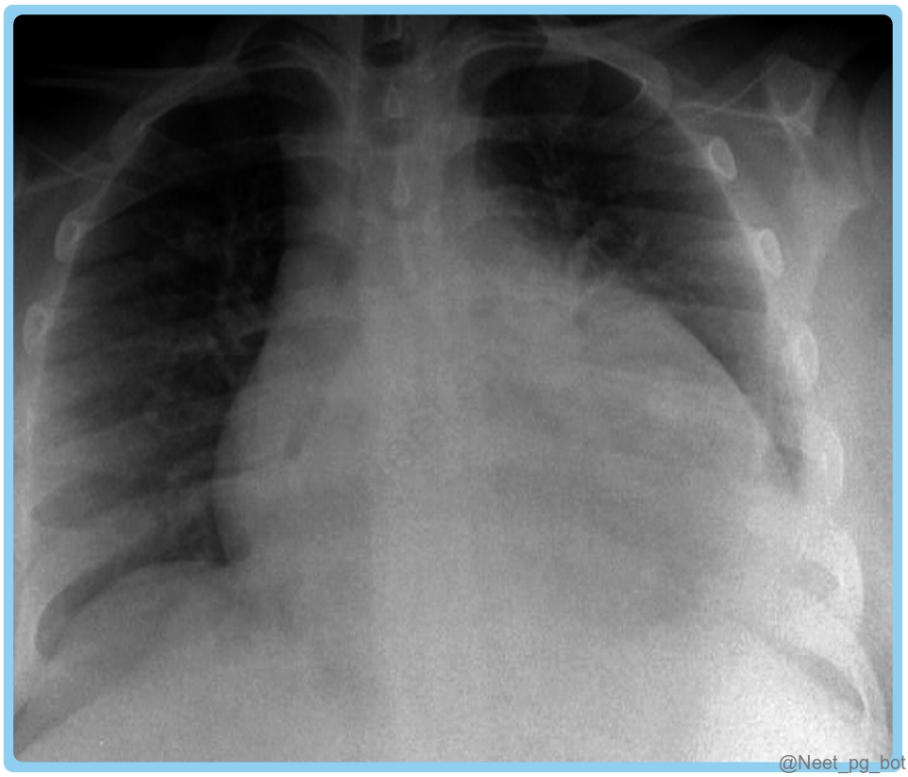
Q7: A 55 year old male presents to the emergency department with fatigue, shortness of breath, and swollen legs. CXR is shown below. Echocardiography shows global hypokinesia with reduced thickness of cardiac chambers. Which of the following is NOT a recognised cause of this patient's diagnosis? (Q850620)

A. Sarcoidosis

B. Chagas disease

C. Scleroderma

D. Heavy metal exposure to lead



Correct Answer: C. Scleroderma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: CXR shows an increased CT ratio. The echo shows global hypokinesia with thinned-out cardiac chambers, indicating dilated cardiomyopathy. Scleroderma causes restrictive cardiomyopathy. Must know causes of Dilated Cardiomyopathy Infective Viral (coxsackievirus, adenovirus, HIV) Parasitic (Chagas' disease, trypanosomiasis, toxoplasmosis) (Option B ruled out) Bacterial (diphtheria) Spirochetal (Lyme disease) Rickettsial (Q fever) Noninfective Granulomatous inflammatory disease Sarcoidosis Giant cell myocarditis Eosinophilic myocarditis Polymyositis, dermatomyositis Collagen vascular disease Toxic Alcohol Catecholamines (amphetamines, cocaine) Chemotherapeutic agents (anthracyclines, trastuzumab) Other therapeutic agents (hydroxychloroquine, chloroquine) Drugs of misuse (emetine, anabolic steroids) Heavy metals (lead, mercury) Metabolic Nutritional deficiencies (thiamine, selenium , carnitine) Endocrinopathy (thyroid disease, pheochromocytoma, diabetes, obesity, hemochromatosis) Dystrophin-related dystrophy (Duchenne's, Becker's) Mitochondrial myopathies (e.g., Kearns-Sayre syndrome)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2016, 2020.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: All of the following are correct about restrictive cardiomyopathy except? (Q850616)

A. Echo shows dilated atria with normal size ventricles and increased LV and RV end diastolic pressures

B. Cardiac MRI shows starry sky appearance due to amyloidosis

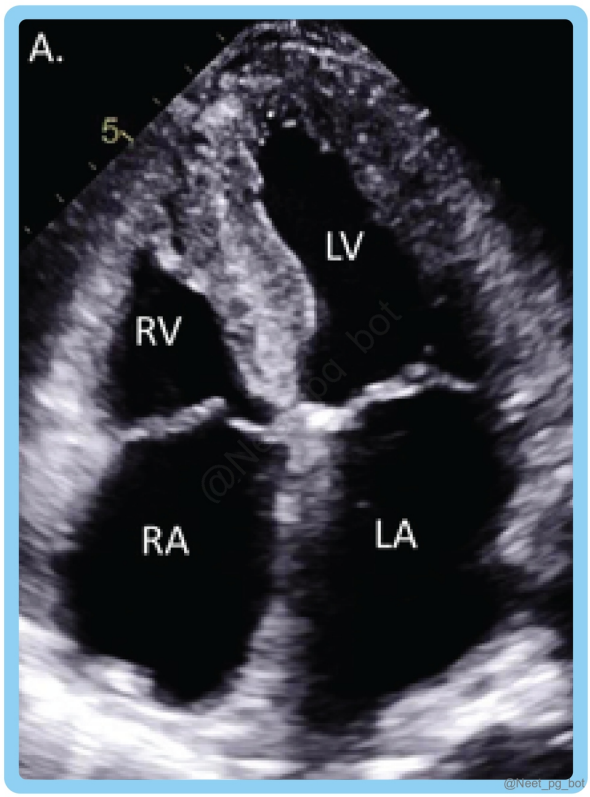
C. Absent y descent and steep x descent

D. Endomyocardial biopsy is the gold standard for diagnosing cardiac amyloidosis.

Correct Answer: C. Absent y descent and steep x descent

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Restrictive cardiomyopathy (RCM): x descent: normal or mildly blunted y descent: prominent (steep) due to rapid early diastolic filling that abruptly stops Cardiac tamponade: x descent: prominent (steep) because atrial relaxation still occurs y descent: blunted or absent because ventricular filling is restricted by pericardial pressure Echocardiography in RCM typically reveals biatrial enlargement , normal or near-normal ventricular dimensions , and elevated diastolic pressures . (Option A) Cardiac MRI shows a starry sky pattern in amyloidosis, which is overall the most common cause of this rarest type of cardiomyopathy. (Option B) The gold standard test to demonstrate fibrosis is endomyocardial biopsy, which is now being replaced by Cardiac MRI since it is non-invasive and has better sensitivity. (Option D) {{caption_text}} Echocardiography showing enlarged atria and speckled appearance of ventricles.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2020, 2081.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 60-year-old male presents with ascites, shortness of breath, and bilateral ankle edema. Kussmaul's sign is noted. An echocardiogram shows normal systolic function but diastolic dysfunction with a speckled pattern in the ventricular wall. The chest X-ray of the patient is given below. Which of the following statements is correct about the diagnosis of this patient? (Q850610)

A. Thinned out, small-size atria

B. Rapid y descent in JVP

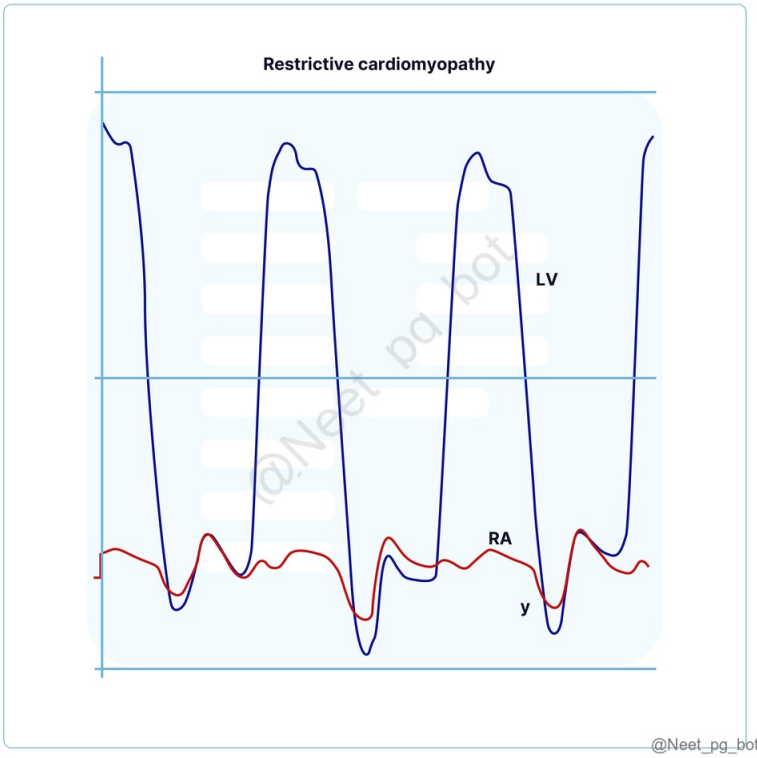
C. Atrial fibrillation is rare in these patients.

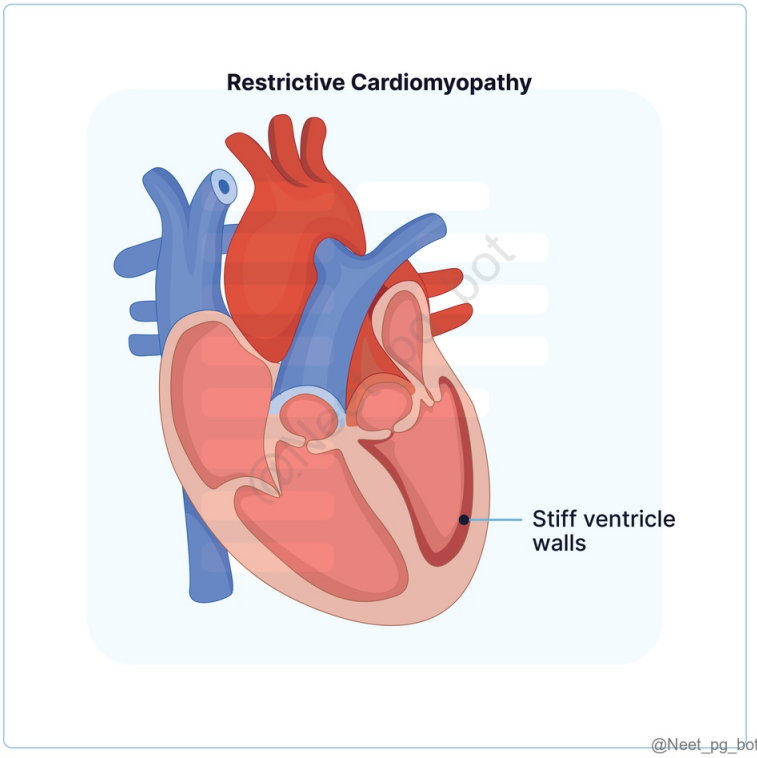
D. Endomyocardial Fibroelastosis is the leading cause

Correct Answer: B. Rapid y descent in JVP

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The echocardiogram showing normal systolic function with evidence of diastolic dysfunction and speckled appearance of ventricles implies RCM. That explains pedal edema and pulmonary edema. Atria are enlarged in RCM (Option A rules out) CXR shows a straight left heart border due to atrial enlargement RCM shows Prominent y descent : Due to elevated atrial pressures, there is rapid early ventricular filling in the diastole, creating a pronounced y descent on atrial pressure curves. RCM shows blunted x descent : Poor atrial relaxation and limited annular descent toward the apex result in a reduced x descent, as the atrium does not effectively empty or relax Atrial fibrillation is very common (Option C ruled out) ; ventricular arrhythmias are rare. Kussmaul's sign is absent in cardiac tamponade and is seen in RCM





References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2020.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 45-year-old man presents with worsening fatigue, shortness of breath, and ankle swelling. His medical history includes joint pain, elevated liver enzymes, hyperpigmentation, and diabetes. He has recently been diagnosed with a metabolic disorder. An echocardiogram reveals elevated filling pressures and bilateral atrial enlargement. Which of the following best explains the underlying pathophysiology of this patient's condition? (Q850607)

A. Increased contractility due to myocardial hypertrophy

B. Impaired diastolic filling due to stiffened ventricular walls

C. Dilated ventricular chambers leading to heart failure

D. Obstruction of blood flow through the left ventricle

Correct Answer: B. Impaired diastolic filling due to stiffened ventricular walls

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The combination of diabetes, liver dysfunction, arthropathy, and hyperpigmentation suggests hemochromatosis , a condition causing iron overload . Excess iron deposition in the myocardium leads to restrictive cardiomyopathy , characterized by stiff, noncompliant ventricles that impair diastolic filling while maintaining normal systolic function. This results in elevated filling pressures, atrial enlargement , and signs of right-sided heart failure . Increased contractility due to myocardial hypertrophy (Option A): Seen in hypertrophic cardiomyopathy , where there is asymmetric septal hypertrophy and dynamic LVOT obstruction — not in restrictive cardiomyopathy. Dilated ventricular chambers leading to heart failure (Option C): Typical of dilated cardiomyopathy , which presents with systolic dysfunction (reduced ejection fraction), not the preserved systolic function of restrictive cardiomyopathy. Obstruction of blood flow through the left ventricle (Option D): Occurs in hypertrophic obstructive cardiomyopathy (HOCM) due to septal hypertrophy and systolic anterior motion of the mitral valve — absent in this case.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2020.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 30-year-old female marathon runner collapses and is found unresponsive during a race. Despite attempts at resuscitation, she is pronounced dead in the ER. Her family reports that she had previously experienced episodes of dizziness and palpitations during training. You re-evaluate her ECG done at time of admission which shows epsilon waves. Which of the following conditions is most likely to contribute to sudden cardiac death in this young athlete? (Q850603)

A. Arrhythmogenic RV dysplasia

B. Commotio cordis

C. HCM

D. Atherosclerotic coronary artery disease

Correct Answer: A. Arrhythmogenic RV dysplasia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The keyword is epsilon wave in ECG that indicates a diagnosis of Arrhythmogenic RV dysplasia (ARVD). These are small positive deflections (notches) found at the end of the QRS complex, typically in the right precordial leads (V1–V3). They represent delayed ventricular activation in the scarred or fatty tissue of the right ventricle. Commotio cordis (Option B): This is a sudden cardiac arrest caused by a blunt, non-penetrating blow to the chest (like a baseball) during a specific phase of the cardiac cycle. It is an impact-related event, not a chronic structural/electrical disease. HCM (Option C): It is a genetic condition characterized by inappropriate thickening (hypertrophy) of the heart muscle, most commonly the interventricular septum. While HCM is the most common cause of sudden cardiac death (SCD) in young athletes, it does not present with epsilon waves. It typically shows LV hypertrophy, deep Q-waves, or T-wave inversions. Atherosclerotic coronary artery disease (Option D): It is the buildup of plaque (cholesterol and calcium) in the arteries that supply blood to the heart muscle, leading to narrowing or blockage. While CAD is the leading cause of exercise-related death in adults over age 35 , it is much rarer in a 30-year-old female athlete without a significant medical history. CAD would present on an ECG as ST-segment changes or T-wave inversions, not epsilon waves.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 1966.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: Which of the following medications is not contraindicated in patients with hypertrophic cardiomyopathy? (Q850601)

A. Amlodipine

B. Verapamil

C. Furosemide

D. Digoxin

Correct Answer: B. Verapamil

■ *Listen to Audio 1*

Explanation: Amlodipine (Option A) reduces afterload , causes vasodilation worsens LVOT obstruction in HCM by: ↓ afterload → ↑ pressure gradient → Reflex ↑ HR → worsens obstruction Furosemide (Option C) reduce preload and reduce inflow to the right ventricle. Less inflow to RV implies less inflow to the left ventricle, which is already small in size in HCM. This causes BP to fall Verapamil does not affect preload. It can be used in patients with hypertrophic cardiomyopathy when beta blockers are contraindicated or not tolerated. It will act on the AV node, reduce heart rate and reduce oxygen consumption of this enlarged heart. Digoxin (Option D) will increase oxygen consumption and worsen pre-existing subendocardial ischemia that is present in these patients.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2007, 2008.

↑ *Back to this question in Part A*

@Neet_pg_bot

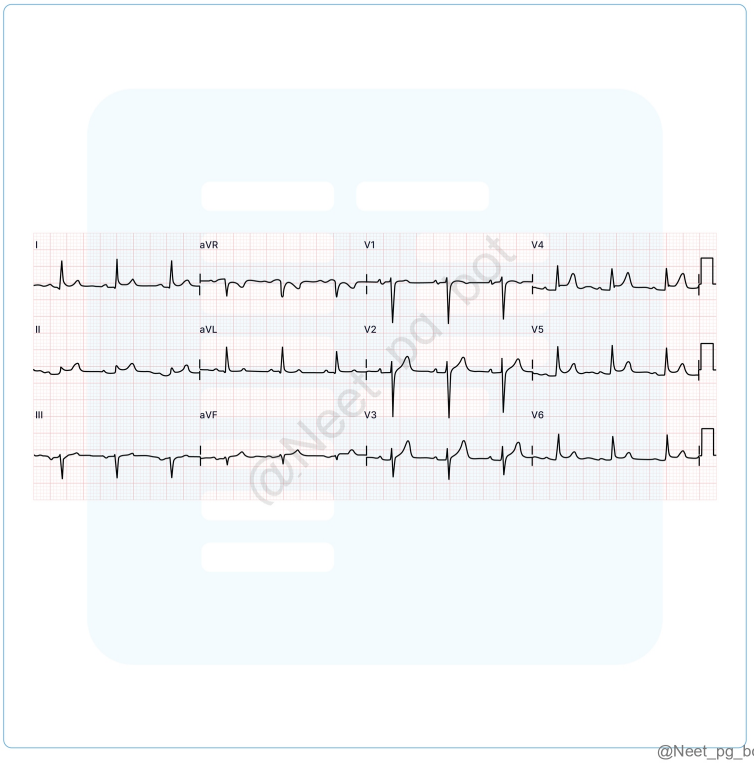
Q13: A 45-year-old male presents with sharp chest pain worsened by lying down and relieved by sitting up. He had a recent viral illness. A friction rub is heard on cardiac auscultation, and the ECG shows the following. What is the most likely diagnosis? (Q850515)

A. Myocardial infarction

B. Pulmonary embolism

C. Acute pericarditis

D. Aortic dissection



Correct Answer: C. Acute pericarditis

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The clinical presentation and ECG findings of diffuse ST-segment elevation with PR-segment depression point to acute pericarditis. Auscultation shows pericardial friction rub, and relief of chest pain on sitting up adds to the ECG diagnosis. Myocardial infarction (Option A): Presents with localized ST elevation confined to leads representing the affected area and reciprocal ST depression in opposite leads. Pain is not positional and typically crushing in nature. Pulmonary embolism (Option B): Typically causes sudden pleuritic chest pain , dyspnea , and tachycardia , with ECG showing S1Q3T3 pattern or sinus tachycardia — not diffuse ST elevation. Aortic dissection (Option D): Causes tearing chest pain radiating to the back , often with unequal pulses or blood pressure between limbs. ECG may be normal or show ischemic changes if coronary involvement occurs, but PR depression and friction rub are absent .

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2079.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 30-year-old male presents with exertional chest pain and occasional fainting spells. His family history includes a relative who experienced sudden cardiac death. An echocardiogram reveals asymmetric septal hypertrophy. Which of the following is not a characteristic investigatory finding in this condition? (Q850592)

A. Brockenbrough-Braunwald-Morrow sign

B. Deep, narrow Q waves in the lateral leads

C. Left ventricle free wall thickness >10 mm

D. Increased precordial voltages

Correct Answer: C. Left ventricle free wall thickness >10 mm

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical scenario suggests hypertrophic obstructive cardiomyopathy (HOCM) due to the athlete's exertional syncope and family history of sudden cardiac death, alongside echocardiographic findings of asymmetric septal hypertrophy, which are characteristic of HOCM. However, left ventricle free wall thickness >10 mm is incorrect as HOCM is characterized by left ventricle thickness >15 mm (typically >30 mm in severe cases) The Brockenbrough–Morrow sign is a paradoxical fall in aortic pulse pressure after a PVC, seen in HOCM, due to worsening dynamic LVOT obstruction. ECG will show increased voltage in precordial leads due to hypertrophy of LV . ECG features of HOCM : Left ventricular hypertrophy (Sokolow-Lyon criteria: S wave depth in V1 + tallest R wave height in V5 or V6 > 35 mm) with increased precordial voltages and non-specific ST segment and T-wave abnormalities (Option D ruled out) Deep, narrow (“dagger-like”) Q waves in lateral (I, aVL, V5-6) +/- inferior (II, III, aVF) leads (Option B ruled out) due to septal hypertrophy. Cardiac catheterization: Brockenbrough–Braunwald–Morrow sign, (Option A ruled out) Trigger: Post-PVC beat. Finding: ↑ LV pressure but ↓ Aortic pulse pressure. Mechanism: Increased contractility worsens outflow obstruction. Constrictive/Restrictive (Square Root Sign) The Dip: Rapid early diastolic filling (sudden pressure drop). The Plateau: Filling hits a "wall" (stiff pericardium/myocardium), causing pressure to flatten abruptly.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2008.

https://pmc.ncbi.nlm.nih.gov/articles/PMC4676455/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 15-year-old male presents to the ED after experiencing syncope while playing basketball. He has a palpable double impulse at the apex, and an ECG shows signs of left ventricular hypertrophy. An echocardiogram reveals asymmetric septal thickening with left ventricular outflow tract obstruction. Which of the following examination findings would not be expected in this patient? (Q850589)

A. Palpable double impulse at the apex

B. Late-peaking ejection systolic murmur best heard at the left sternal border

C. Pulsus bisferiens on peripheral pulse examination

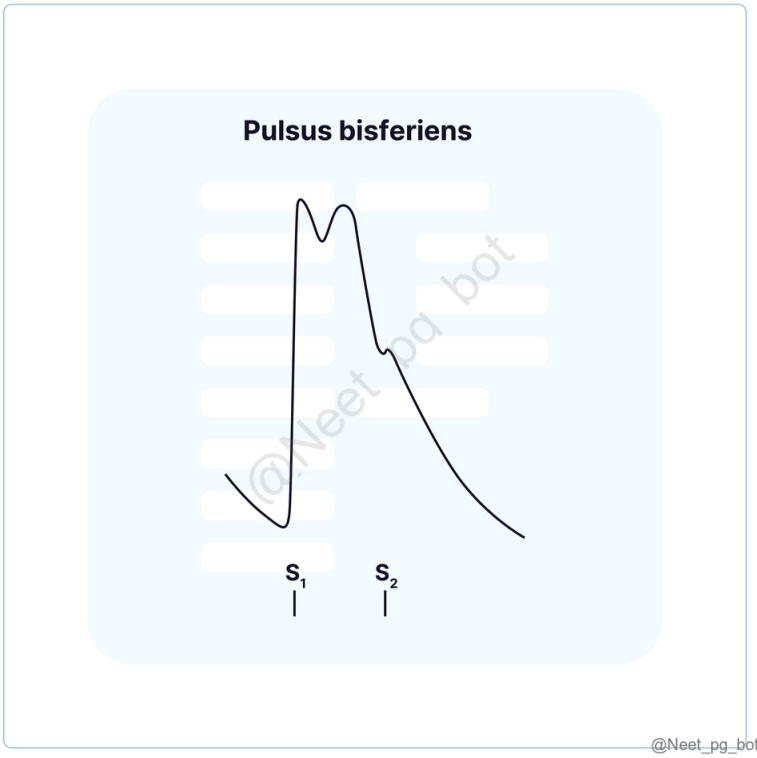
D. Prominent y descent in jugular venous pressure (JVP)

Correct Answer: D. Prominent y descent in jugular venous pressure (JVP)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's symptoms of syncope during exertion, left ventricular hypertrophy, and asymmetric septal thickening with outflow tract obstruction strongly suggest hypertrophic cardiomyopathy (HCM) , specifically hypertrophic obstructive cardiomyopathy (HOCM) . Prominent y descent in jugular venous pressure (JVP) is more typical of constrictive pericarditis rather than HOCM. Palpable double impulse at the apex (Option A): Due to forceful atrial contraction against a stiff hypertrophied ventricle. Late-peaking ejection systolic murmur (Option B): Caused by dynamic LV outflow tract obstruction, best heard at the left sternal border. Pulsus bisferiens (Option C): Bifid pulse due to rapid ejection followed by dynamic obstruction, typical in HOCM.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2006, 2081.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 30-year-old athlete presents with recurrent syncope and exertional chest pain. Exam shows a hyperdynamic apex beat and a mid-systolic murmur at the left lower

sternal border. Echocardiography reveals asymmetric septal hypertrophy and systolic anterior motion of the mitral valve. What is the most likely mechanism of his symptoms? (Q850584)

A. Diastolic heart failure due to a dilated left ventricle

B. Mitral valve prolapse

C. Left ventricular outflow tract obstruction

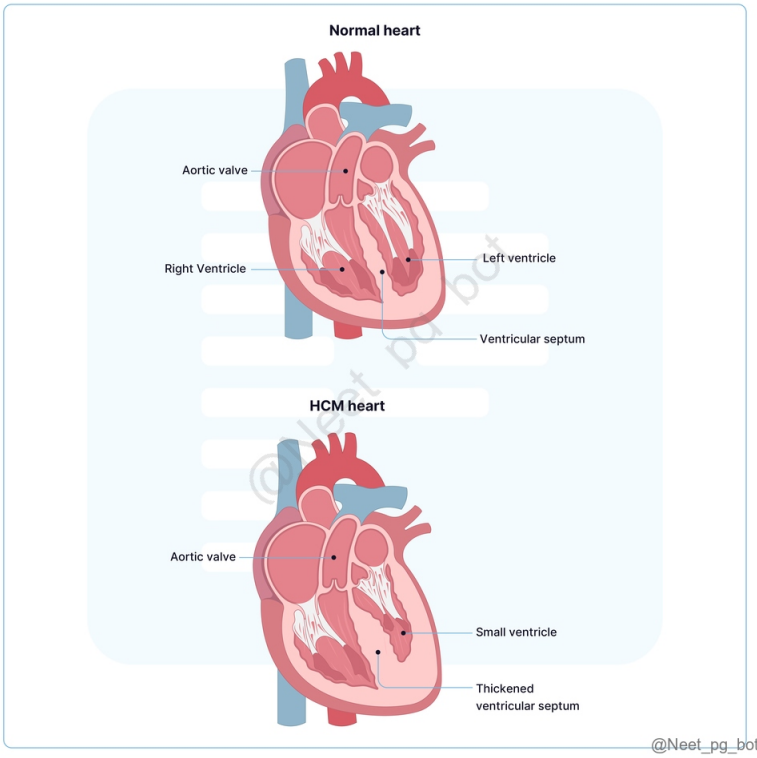
D. Aortic stenosis

Correct Answer: C. Left ventricular outflow tract obstruction

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has hypertrophic obstructive cardiomyopathy (HOCM) . Asymmetric septal hypertrophy and systolic anterior motion (SAM) of the mitral valve create a dynamic obstruction of the left ventricular outflow tract (LVOT) during systole. This obstruction worsens with exercise, standing, or Valsalva , explaining syncope, exertional chest pain, and a murmur that increases in intensity . The hyperdynamic apex beat reflects forceful contraction against the obstructed outflow tract. Coronary artery obstruction (Option A) : Causes ischemic chest pain but does not explain the dynamic murmur or hyperdynamic apex in a young athlete. Aortic stenosis (Option A) : Murmur is mid-systolic at the right 2nd intercostal space radiating to the carotids, not left lower sternal border. Mitral regurgitation(Option D) : Murmur is holosystolic at the apex radiating to the axilla , not mid-systolic at left lower sternal border.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2006.

↑ *Back to this question in Part A*

@Neet_pg_bot

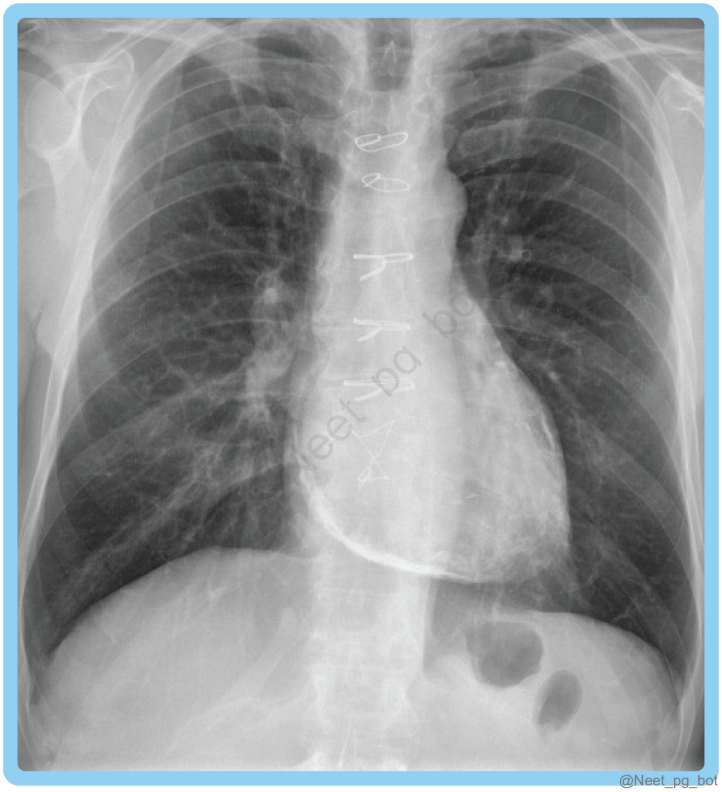
Q17: A 60-year-old male presents with signs of peripheral oedema and ascites. A chest X-ray reveals the following, and echocardiography confirms a thickened pericardium. Which of the following is not correct regarding his likely condition? (Q850580)

A. Diastolic collapse of the ventricles

B. JVP shows a prominent “y” descent

C. Commonly caused by tuberculosis in endemic regions

D. CT scan can assist in visualizing pericardial calcification



Correct Answer: A. Diastolic collapse of the ventricles

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient’s presentation with peripheral oedema, ascites, elevated JVP, pericardial calcification visible on chest X-ray, and a thickened pericardium on echocardiography is suggestive of constrictive pericarditis . This condition is associated with diastolic dysfunction and signs of right-sided heart failure due to a rigid pericardium restricting heart filling. Diastolic collapse of the ventricles is seen in cardiac tamponade and not constrictive pericarditis. JVP shows a prominent “y” descent (Option B): Due to rapid early diastolic filling followed by an abrupt halt. Commonly caused by tuberculosis (Option C): TB is a frequent cause in developing countries. CT scan visualizing pericardial calcification (Option D): Helps confirm diagnosis and assess extent of calcification.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2082.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 45-year-old male presents with fatigue, abdominal swelling, and peripheral oedema. On examination, he has elevated jugular venous pressure, hepatomegaly, and

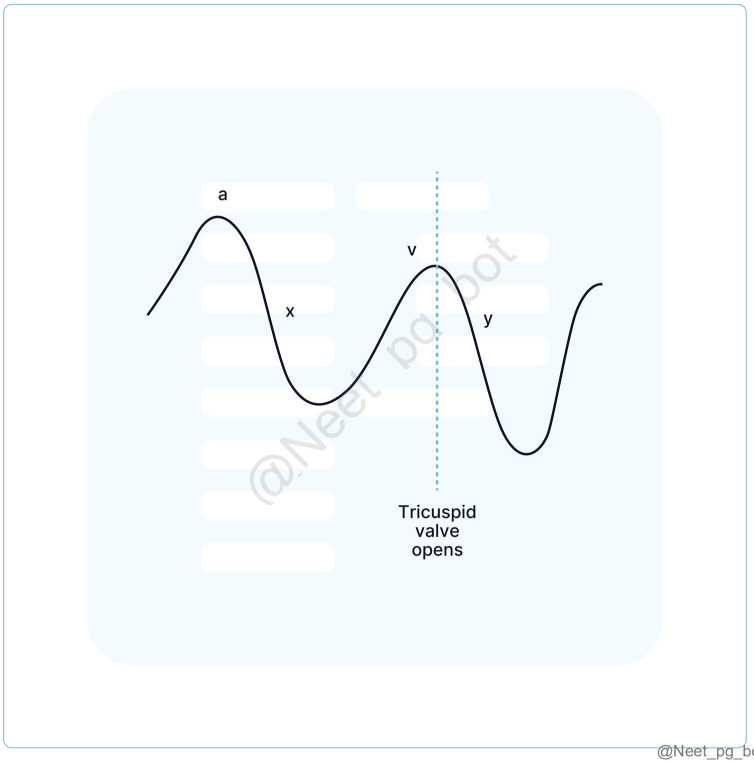
a loud diastolic sound. There is also a rise in JVP during inspiration. Which of the following is the most likely diagnosis? (Q850579)

A. Cardiac Tamponade

B. Constrictive pericarditis

C. Dilated cardiomyopathy

D. Restrictive cardiomyopathy



Correct Answer: B. Constrictive pericarditis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Elevated JVP with a rapid y descent , presence of a pericardial knock , Kussmaul’s sign (rise in JVP during inspiration), hepatomegaly, and peripheral edema are characteristic features of constrictive pericarditis caused by a rigid, fibrotic pericardium restricting diastolic filling. Cardiac tamponade (Option A): Shows absent y descent and pulsus paradoxus , not a pericardial knock. Dilated cardiomyopathy (Option C): Presents with systolic dysfunction and displaced apex beat, without pericardial signs. Restrictive cardiomyopathy (Option D): Mimics constriction but lacks pericardial thickening or knock; myocardial compliance is the issue.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2081.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 25-year-old male is brought to the emergency department after a high-speed car accident. His vitals are heart rate of 120 bpm, blood pressure of 80/50 mmHg, and he is pale with cold, clammy skin. He has a deep laceration on his lower thigh and is actively bleeding. Which of the following is the most appropriate initial management step? (Q850578)

A. Echocardiography guided pericardiocentesis

B. Emergency resuscitative thoracotomy

C. Start intravenous fluid resuscitation

D. Apply a tourniquet to the thigh

Correct Answer: D. Apply a tourniquet to the thigh

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In cases of life-threatening external hemorrhage , such as active arterial bleeding from a limb injury, immediate application of a tourniquet is the first and most critical step — it prevents exsanguination before fluid resuscitation or definitive care. Echocardiography-guided pericardiocentesis (Option A): Indicated for cardiac tamponade , not external limb bleeding. Emergency resuscitative thoracotomy (Option B): Used in penetrating chest trauma with cardiac arrest , not extremity hemorrhage. Start intravenous fluid resuscitation (Option C): Important but secondary to hemorrhage control in active external bleeding.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2293.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A 60 year old woman with stage 4 carcinoma breast presents to the ED with severe shortness of breath. On examination, she is hypotensive with a blood pressure of 80/60 mmHg, has distended neck veins with a jugular venous pressure of 12 cm H2O, and her heart sounds are muffled. An echocardiogram shows the following: What is the most appropriate immediate and definitive treatment for this patient?

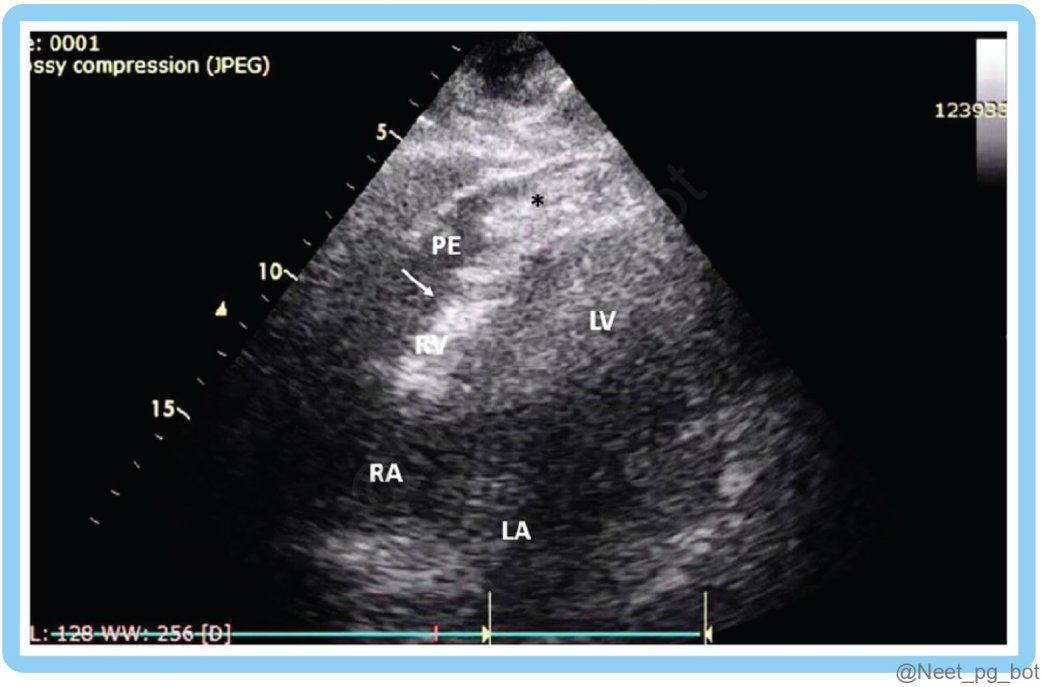
(Q850572)

A. Intravenous saline infusion

B. Pericardiocentesis

C. Diuretics

D. Surgical drainage (pericardiotomy)



Correct Answer: B. Pericardiocentesis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The triad of hypotension, elevated jugular venous pressure, and muffled heart sounds (Beck's triad), along with echocardiographic evidence of right ventricular diastolic collapse, confirms cardiac tamponade . In such cases, immediate pericardiocentesis is both diagnostic and therapeutic—it relieves pericardial pressure, restores ventricular filling, and improves cardiac output. In malignancy-related tamponade, fluid may reaccumulate, and pericardial window or sclerotherapy can be considered later, but the first-line emergency management remains pericardiocentesis . Intravenous saline infusion (Option A): May temporarily improve preload and venous return, but it does not relieve pericardial pressure . It can only serve as a short-term supportive measure before pericardiocentesis. Diuretics (Option C): Reduce venous return and can exacerbate hypotension , worsening cardiac output. Contraindicated in tamponade. Surgical drainage (pericardiotomy) (Option D): Indicated for recurrent or loculated pericardial effusions , but not the immediate emergency treatment in this setting.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2082.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: Which of the following is a classic finding in cardiac tamponade? (Q850571)

A. Pulsus paradoxus

B. S3 heart sound

C. Pulsus alternans

D. High-pitched systolic murmur

Correct Answer: A. Pulsus paradoxus

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Pulsus paradoxus is a hallmark finding in cardiac tamponade, characterized by a significant drop in systolic blood pressure during inspiration (greater than 10 mm Hg). It occurs due to the impaired filling of the heart chambers caused by pericardial fluid compression, limiting cardiac output during inspiration. This phenomenon is commonly observed in cardiac tamponade and serves as a key diagnostic feature in such cases. S3 heart sound (Option B): An S3 heart sound, also known as a ventricular gallop, is typically associated with heart failure or conditions causing rapid filling of the ventricles, such as dilated cardiomyopathy. It is not a classic finding in cardiac tamponade, which is more characterized by restricted ventricular filling and muffled heart sounds rather than additional heart sounds like S3. Pulsus alternans (Option C): Pulsus alternans refers to alternating strong and weak pulse beats, typically seen in left ventricular dysfunction, not cardiac tamponade. High-pitched systolic murmur (Option D): A high-pitched systolic murmur is usually associated with valvular heart diseases, such as aortic stenosis or mitral regurgitation, not cardiac tamponade

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2081.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: A 65-year-old man presents to the emergency department with complaints of shortness of breath, fatigue, and mild chest discomfort. On examination, his blood pressure is low, and his heart sounds are faint on auscultation. The physician orders

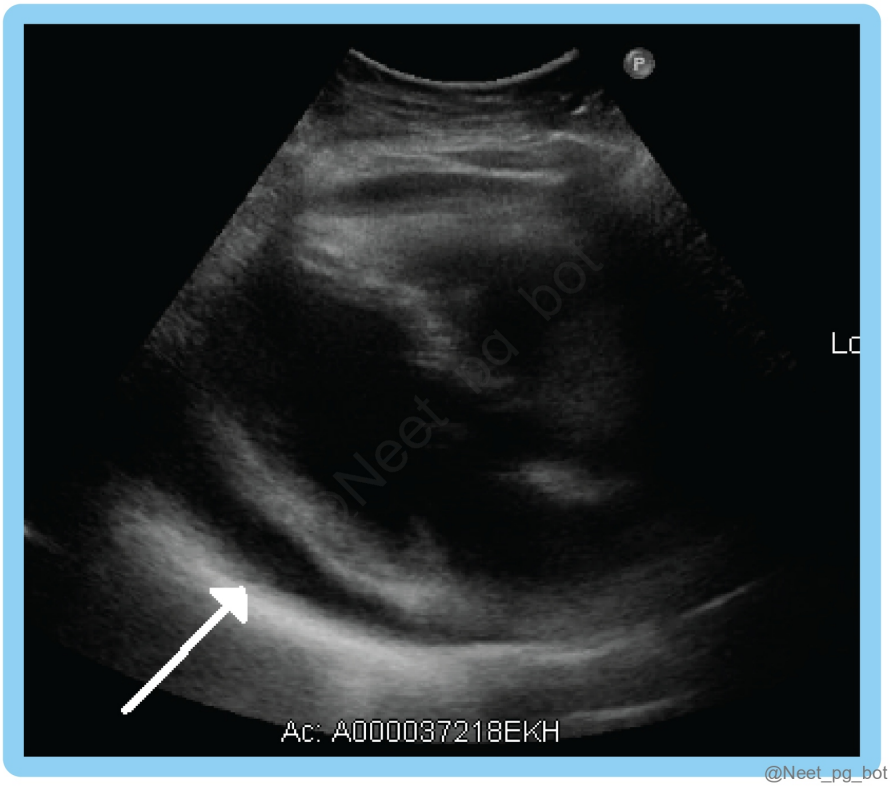
an echocardiogram, which shows the following Based on these findings, which of the following ECG pattern would you most likely expect to see? (Q850557)

A. High-voltage QRS complexes

B. ST-segment elevation in all leads

C. Prolonged PR interval

D. Electrical alternans



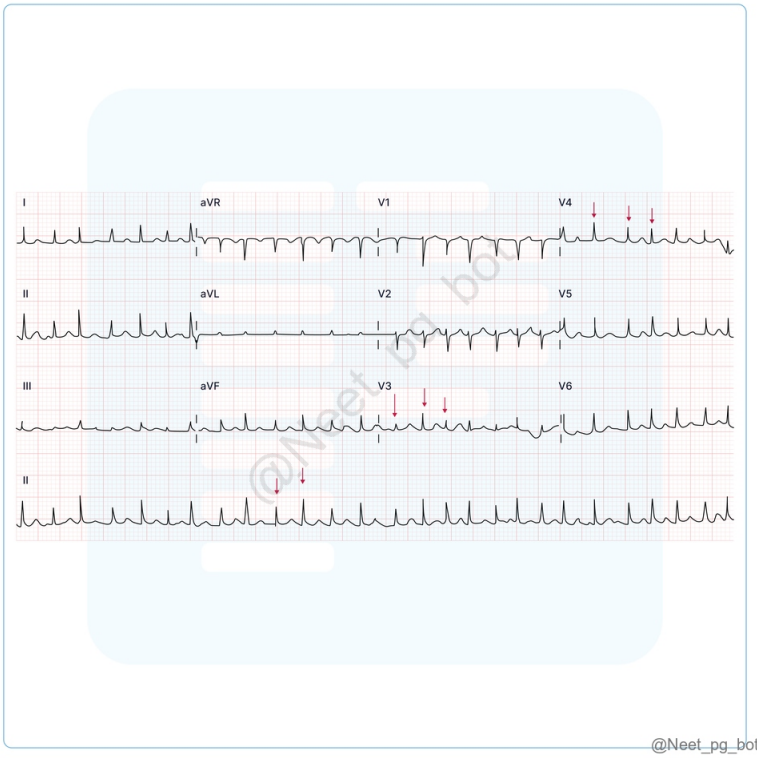
Correct Answer: D. Electrical alternans

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient’s symptoms, vitals and echocardiographic findings which reveal a large fluid collection around the heart , with evidence of impaired filling of the right-sided chambers are suggestive of cardiac tamponade, likely due to a large pericardial effusion. Electrical alternans is a classic ECG finding in pericardial effusion , particularly when it leads to cardiac tamponade. It manifests as beat-to-beat variations in the amplitude of the QRS complexes, reflecting the heart's movement within the fluid-filled pericardial space. This finding is indicative of significant fluid accumulation and increased intrapericardial pressure, which impedes the heart's ability to fill properly during diastole. ECG showing Electrical alternans Red arrows showing variations in the amplitude of QRS complexes High-voltage QRS complexes (Option A): High-voltage QRS complexes suggest an increased electrical activity due to conditions like left ventricular hypertrophy or other myocardial adaptations.

However, in pericardial effusion, there are low-voltage QRS complexes. ST-segment elevation in all leads (Option B): This finding is more characteristic of acute pericarditis, where widespread ST-segment elevations occur due to inflammation of the pericardial sac. In pericardial effusion or tamponade, ST-segment changes are not the defining features. Prolonged PR interval (Option C): A prolonged PR interval typically indicates delayed conduction through the atrioventricular node. Although PR segment depression can occur in acute pericarditis, a prolonged PR interval is not a hallmark of pericardial effusion or tamponade.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2081.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A 60 y/o male with acute pericarditis who has not responded to NSAIDs and colchicine is now experiencing frequent recurrences. He does not tolerate glucocorticoids well. What additional treatment can be considered? (Q850553)

A. Increase the dose of NSAIDs

B. Start azathioprine

C. Begin a higher dose of colchicine

D. Stop all medications and monitor

Correct Answer: B. Start azathioprine

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In cases where NSAIDs, colchicine, and glucocorticoids have failed, immunosuppressive therapy such as azathioprine can be considered. Azathioprine is used for patients with recurrent, refractory pericarditis who have multiple episodes lasting for extended periods. Increase the dose of NSAIDs (Option A): NSAIDs are effective for inflammation control in the short term, but increasing the dosage does not provide additional benefit once recurrences occur. Begin a higher dose of colchicine (Option C): Increasing the dose beyond the recommended levels is not advisable, as colchicine has a narrow therapeutic window . Higher doses increase the risk of gastrointestinal side effects, such as diarrhoea, and can be toxic, especially in patients with liver or kidney problems. Stop all medications and monitor (Option D): Stopping all medications without an alternative treatment plan is not appropriate in recurrent pericarditis cases. It can lead to persistent discomfort and potential complications.

Q1: An alcoholic patient presents with palpitations, dizziness, and syncopal attacks. On examination, irregularly irregular pulse is seen. What will be seen on JVP? (Q866781)

A. Absent a wave

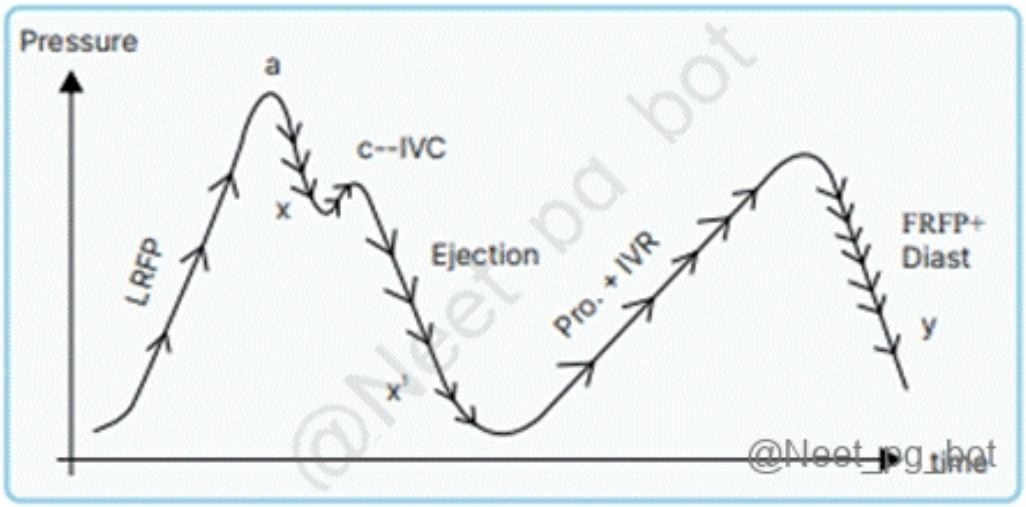
B. Large a wave

C. Canon a wave

D. Steep y descent

Correct Answer: A. Absent a wave

Explanation: The patient’s irregularly irregular pulse suggests atrial fibrillation (AF), which is common in chronic alcoholics (so-called holiday heart syndrome). In AF, the atria do not contract effectively → no coordinated atrial systole → no a wave is produced in the jugular venous pulse (JVP). Therefore, the finding will be absent a wave. Jugular Venous Pulse (JVP) reflects right atrial pressure changes during the cardiac cycle. The a wave corresponds to atrial contraction (just before S1). In AF, there is complete loss of organized atrial contraction → a wave disappears. Chronic alcoholics are prone to AF due to atrial dilation, electrolyte imbalance, and direct myocardial effects. Atrial fibrillation: Feature Details ECG Irregularly irregular RR intervals, absent P waves, fibrillatory baseline Causes Hypertension, valvular heart disease (esp. mitral), alcohol (holiday heart), thyrotoxicosis Complications Stroke, heart failure, tachycardia-induced cardiomyopathy Management Rate control (β-blockers, CCBs), rhythm control (amiodarone, cardioversion), anticoagulation (CHA■DS■-VASc score) JVP Waveform: Positive waves in JVP: a, c and v a wave - Atrium Contraction (Lat Rapid Filling Phase) c wave - Cusp bulging (tricuspid valve cusp bulging towards the atrium) v wave - Venous return Negative waves in JVP: x wave - Atrium relaxation x' wave - Tricuspid valve pulling towards the ventricle y descend - Opening of tricuspid valve JVP finding Cause Absent a wave Atrial fibrillation Large a wave Tricuspid stenosis, pulmonary hypertension Cannon a wave Complete heart block, VT (atria contracting against closed tricuspid valve) Steep y descent Constrictive pericarditis Incorrect Options: Large a wave (Option B) – Seen when the right atrium contracts against high resistance, e.g., tricuspid stenosis or pulmonary hypertension. Canon a wave (Option C) – Occurs when atria contract against a closed tricuspid valve, e.g., complete heart block, VT. Steep y descent (Option D) – Seen in constrictive pericarditis and severe tricuspid regurgitation.



↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 25-year-old female with a previous history of rheumatic fever. Examination shows a loud S1 and mid-diastolic murmur is having which of the following valvular heart disease? (Q866784)

A. TS

B. MR

C. MS

D. AR

Correct Answer: C. MS

Explanation: The patient has a history of rheumatic fever and presents with a loud S1 and mid-diastolic murmur, which are classic findings of mitral stenosis. Rheumatic fever is the most common cause of MS worldwide. Mitral stenosis results from thickening and fusion of the mitral valve leaflets, most often due to rheumatic heart disease. The loud S1 occurs because the stiff valve closes forcefully, and the mid-diastolic murmur is due to turbulent flow across the narrowed mitral orifice during diastole. Other features may include an opening snap and signs of pulmonary congestion. Mitral stenosis: Cause: Rheumatic fever (most common), congenital, calcific degeneration (elderly). Pathophysiology: Narrowed mitral orifice → ↑ left atrial pressure → pulmonary venous hypertension → right heart strain. Clinical features: Dyspnea, orthopnea, hemoptysis, atrial fibrillation. Auscultation: Loud S1, opening snap after S2, low-pitched mid-diastolic murmur at the apex (best heard with the patient in the left lateral position). Complications: Pulmonary hypertension, right heart failure, thromboembolism. Treatment: Medical (diuretics, rate control for AF) or surgical (percutaneous balloon mitral valvotomy, valve replacement). Incorrect Options: Tricuspid Stenosis (TS) (Option A) – Mid-diastolic murmur increases with inspiration; usually occurs with MS but isolated TS is rare. Mitral Regurgitation (MR) (Option B) – Produces a pansystolic murmur at the apex radiating to the axilla, not a mid-diastolic murmur. Aortic Regurgitation (AR) (Option D) – Produces an early diastolic decrescendo murmur at the left sternal border, not associated with loud S1.

@Neet_pg_bot

Q3: A female patient complains of chest pain while waking up in the morning. Pain is more in winter months. Which of the following best describes this patient? (Q866827)

A. Fixed plaque obstruction

B. Ach-induced coronary vasoconstriction

C. Subendocardial ischemia due to increased demand of myocardium

D. Increased sympathomimetic drive in morning hours

Correct Answer: B. Ach-induced coronary vasoconstriction

Explanation: This presentation is classic for Prinzmetal's (variant) angina , which is due to transient vasospasm of coronary arteries often occurring at rest, particularly in the early morning hours and more frequently in cold weather. Acetylcholine and other vasoconstrictors can trigger the spasm. ECG during pain may show transient ST-segment elevation. Incorrect Options: Fixed plaque obstruction (Option A): Seen in stable angina due to atherosclerosis; pain is usually exertional, not at rest. Subendocardial ischemia due to increased demand of myocardium (Option C): Describes the mechanism in stable angina during exercise or stress, not rest-related vasospasm. Increased sympathomimetic drive in morning hours (Option D): Plays a role in acute coronary syndromes but doesn't fully explain the cold-weather, early-morning, rest-related pain due to vasospasm.

Q4: Which type of pulse is based on the Frank-Starling law? (Q865309)

A. Pulsus bisferiens

B. Pulsus paradoxus

C. Pulsus alternans

D. Pulsus parvus

Correct Answer: C. Pulsus alternans

Explanation: Pulsus alternans shows alternating strong and weak pulse beats, often seen in severe left ventricular dysfunction. One proposed mechanism involves the Frank-Starling law , where a weak contraction leads to increased end-diastolic volume, boosting the next beat's strength. This cycle repeats, causing alternating pulse amplitudes. Another theory involves abnormal calcium cycling in cardiac myocytes. The Frank-Starling law of the heart describes the relationship between the volume of blood filling the heart (end-diastolic volume) and the force

of contraction during the next heartbeat (stroke volume) . Mechanism: Preload: Increased venous return leads to increased end-diastolic volume. Myocardial Stretch: Greater end-diastolic volume stretches the myocardial fibers. Force of Contraction: The stretched fibers generate a more forceful contraction due to the optimal overlap of actin and myosin filaments (length-tension relationship). Incorrect Options: Pulsus bisferiens (Option A): Characterised by a double systolic peak; seen in aortic regurgitation or hypertrophic cardiomyopathy—not related to Frank-Starling. Pulsus paradoxus (Option B): An exaggerated decrease in systolic BP during inspiration, typically seen in cardiac tamponade or severe asthma, not explained by Frank-Starling law. Pulsus parvus (Option D): A small, weak pulse seen in aortic stenosis; related to obstruction , not preload or contractility.

@Neet_pg_bot

Q5: Mitral stenosis murmur corresponds to which wave of ECG? (Q865310)

A. QRS complex

B. T wave

C. P wave

D. ST segment

Correct Answer: C. P wave

Explanation: ■The murmur of mitral stenosis is a diastolic rumbling murmur that follows the opening snap of the mitral valve. It is best heard at the apex and is associated with left atrial contraction . The P wave on ECG represents atrial depolarization . Since mitral stenosis involves obstruction to left ventricular filling during atrial contraction , the murmur is timed with and follows the P wave . In severe mitral stenosis, a loud first heart sound and presystolic accentuation of the murmur (due to atrial contraction) are commonly observed, directly relating to the P wave . Mitral stenosis (MS) causes left atrial enlargement , which typically appears on ECG as Broad, bifid P waves , especially in lead II → “P mitrale.” P Wave in ECG: Feature Normal P Wave Right Atrial Enlargement (P Pulmonale) Left Atrial Enlargement (P Mitrale) Cause Normal atrial depolarization Pulmonary disease Congenital heart disease Tricuspid valve disorders Mitral valve disease Left ventricular failure Amplitude < 2.5 mm > 2.5 mm (in leads II, III, aVF, sometimes V1) May be increased but less prominent than in RAA Duration < 0.12 sec (120 ms) Normal (< 0.12 sec) Prolonged > 0.12 sec (broad P wave) Shape Smooth, upright Tall, peaked, narrow Notched/bifid ("M"-shaped) in lead II Lead II Appearance Smooth and positive Tall, peaked P wave Notched/bifid P wave Lead V1 Appearance Biphasic (small negative) Deep P wave Biphasic with prominent, prolonged negative terminal

Goldberger's Clinical Electrocardiography, A Simplified Approach, 9th Edition, Page. 50-53.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 62-year-old male presents with sudden onset of shortness of breath and B/L pedal edema. He is compliant with his antihypertensive medications, and blood pressure is well controlled. ECG reveals an ejection fraction of 60%, concentric left ventricular hypertrophy, left atrial enlargement, and grade 2 diastolic dysfunction. Which of the following is the most appropriate next step to improve his condition? (Q865331)

A. Perform coronary angiography to rule out ischemic cardiomyopathy

B. Initiate loop diuretics and SGLT2 inhibitors for management of HFpEF

C. Start digoxin to enhance myocardial contractility

D. Initiate ivabradine to reduce heart rate and improve diastolic filling

Correct Answer: B. Initiate loop diuretics and SGLT2 inhibitors for management of HFpEF

Explanation: This 62-year-old man presents with sudden shortness of breath and bilateral pedal edema, classic signs of heart failure. His echocardiogram findings show: Ejection fraction (EF) of 60% → Preserved systolic function Concentric left ventricular hypertrophy Left atrial enlargement Grade 2 diastolic dysfunction These findings support a diagnosis of Heart Failure with Preserved Ejection Fraction (HFpEF), which is often related to diastolic dysfunction, especially in older adults with hypertension-induced hypertrophy. Loop diuretics (e.g., furosemide) help relieve volume overload symptoms like dyspnea and edema. SGLT2 inhibitors (e.g., empagliflozin, dapagliflozin) have been shown in recent trials to reduce hospitalization and improve quality of life in HFpEF , regardless of diabetes status . This is the most appropriate and guideline-recommended management . Types of heart failure: HFrEF: Systolic dysfunction, may present acutely. HFpEF: Diastolic dysfunction, usually present as chronic heart failure. Management of CHF: First line drugs used in chronic Heart failure: (mortality-reducing drugs) ARBs/ACE-Inhibitors Beta blockers (2nd gen- cardioselective) SGLT-2 inhibitors (Dapagliflozin, Empagliflozin) Anti-aldosterone (Spironolactone) Acute cases with Pulmonary edema: Oxygen: Secure airway and supplement O2 Loop diuretics: IV Furosemide 20-80 mg , reduces preload and systemic venous congestion IV Morphine: if patient is in severe pain/distress, can cause respiratory depression IV Nitroglycerin infusion: reduce afterload Acute decompensated with cardiogenic shock: (low BP) Vasopressors: Norepinephrine, Dobutamine, Dopamine Inodilators: Milrinone & Amrinone Levosimendan: Ca2+ channel sensitizer Omecamtiv mecarbil: Direct myosin activator Non-pharmacological treatment: Implantable cardioverter defibrillators (ICD) Coronary revascularisation: in Coronary artery disease patients Ventricular assist devices Cardiac transplantation Incorrect Options: Perform coronary angiography to rule out ischemic cardiomyopathy (Option A): Coronary angiography is appropriate if ischemic heart disease is strongly suspected. However, this patient has preserved EF and concentric LVH , which more strongly points toward hypertensive heart disease and HFpEF , not ischemic cardiomyopathy. This is not the most appropriate first step . Start digoxin to enhance myocardial contractility (Option C): Digoxin is not indicated in HFpEF, especially when EF is preserved and there is no indication of systolic dysfunction or atrial fibrillation needing rate control. It is not helpful here. Initiate ivabradine to reduce heart rate and improve diastolic filling (Option D): Ivabradine is indicated in HFrEF with EF ≤35% and sinus rhythm with heart rate ≥70 bpm , despite beta-blockers. It does not have a proven role in HFpEF .

@Neet_pg_bot

Q7: Which of the following is not a symptom of cardiac failure? (Q865338)

A. Right hypochondriac pain

B. Non-pulsatile elevation of JVP

C. Orthopnea

D. Paroxysmal nocturnal dyspnea

Correct Answer: B. Non-pulsatile elevation of JVP

Explanation: Cardiac failure (heart failure) presents with a range of symptoms depending on whether it is right-sided, left-sided, or both. Elevated JVP is a feature of right-sided heart failure , but it is typically pulsatile , reflecting right atrial pressure transmitted through the jugular vein. Non-pulsatile JVP elevation suggests an alternative cause like superior vena cava (SVC) obstruction , not heart failure. Congestive Heart Failure - Clinical Features Cardiac output decreased Stroke volume decreased Heart rate increased Increased sympathetic drive leading to palpitations and diaphoresis Orthopnea Paroxysmal nocturnal dyspnea Clinical Features of Left-Sided vs. Right-Sided Congestive Heart Failure (CHF) Left-Sided Heart Failure Right-Sided Heart Failure Causes : Ischemic heart disease (myocardial infarction). Hypertension Dilated cardiomyopathy. Aortic or mitral valve disease. Causes : Left-sided heart failure (most common cause). Chronic lung diseases (COPD, pulmonary hypertension). Pulmonary embolism. Right ventricular infarction. In left-sided heart failure, the left ventricle cannot effectively pump blood to the body, leading to a backup of blood into the lungs. Clinical features: This primarily results in pulmonary symptoms. Dyspnea Exertional dyspnea). Orthopnea Paroxysmal nocturnal dyspnea Pulmonary Congestion: Crackles (rales) heard on auscultation due to fluid in the alveoli. Cough Wheezing (cardiac asthma). Fatigue and Weakness Decreased Exercise Tolerance Limited physical activity due to breathlessness and fatigue. S3 Gallop Cool Extremities: Reduced cardiac output may cause poor peripheral circulation, leading to cold, pale skin. In right-sided heart failure, the right ventricle fails to pump blood effectively into the pulmonary circulation, leading to systemic venous congestion. It is often secondary to left-sided heart failure or conditions affecting the lungs (cor pulmonale). Clinical Features: Peripheral Edema Jugular Venous Distension (JVD) Hepatomegaly B/L pitting pedal edema Kussmaul sign: JVP elevation on inspiration Ascites Nocturia Weight Gain Anorexia and Nausea Incorrect Options: Right hypochondriac pain (Option A) is a symptom of right-sided heart failure due to liver congestion. Orthopnea (Option C) is a classic symptom of left-sided heart failure, caused by pulmonary congestion when lying flat. Paroxysmal nocturnal dyspnea (PND) (Option D) is a common symptom of left-sided heart failure, due to fluid redistribution at night causing sudden breathlessness.

@Neet_pg_bot

Q8: A 45-year-old male presents to a PHC for a routine check-up. His blood pressure readings on two separate occasions are 148/90 mmHg and 152/96 mmHg. He is asymptomatic and has no known comorbidities. What is the most appropriate next step in management according to current hypertension guidelines? (Q865381)

A. Initiate treatment only if BP exceeds 160/100 mmHg

B. Start Amlodipine 5 mg once daily and advise follow-up in 1 month

C. Refer to a higher center for further evaluation

D. Start the patient on IV anti-hypertensive drugs

Correct Answer: B. Start Amlodipine 5 mg once daily and advise follow-up in 1 month

Explanation: The patient is in Stage 1 Hypertension (140–159/90–99 mmHg) confirmed on two occasions , and since no compelling comorbidities are present, monotherapy with a calcium channel blocker (e.g., Amlodipine) is an appropriate first-line treatment. Follow-up in 1 month is standard to assess BP response and adherence. ACC/AHA Guidelines for Hypertension Management Indications for Use of antihypertensives Secondary prevention of recurrent CVD events in patients with clinical CVD (defined as CHD, CHF, stroke) and BP ≥130/≥80 mmHg Primary prevention in patients with an estimated 10-year ASCVD risk ≥10% and BP ≥130/≥80 mmHg Primary prevention of CVD and low CVD risk in patients with BP ≥140/ ≥90 mmHg Blood Pressure Goal in Treating Hypertension BP target < 130/80 mmHg for adults with confirmed hypertension and known CVD or 10-year ASCVD event risk ≥10% Exceptions to Therapeutic Target of <130/80 mmHg Age >80 years Blood pressure <140/90 mmHg in previously untreated hypertensive patients who experience an ischemic stroke or TIA Acute therapy for most hypertensive urgencies and emergencies Abbreviations: ASCVD - atherosclerotic cardiovascular disease CHD - coronary heart disease CHF - congestive heart failure CVD - cardiovascular disease Patient type First Drug Add a Second Drug If Needed to Achieve the target BP If a Third Drug is Needed to Achieve the target BP Black patients (African ancestry): All ages CCB or thiazide diuretic ARB or ACE inhibitor Combination of CCB + ACE inhibitor or ARB + thiazide diuretic White and other non-black Patients: Younger than 60 years ARB or ACE inhibitor CCB or thiazide diuretic White and other non-black patients: 60 years and older CCB or thiazide diuretic ARB or ACE inhibitor Abbreviations: CCB - Calcium channel blocker ACE - Angiotensin converting enzyme ARB - Angiotensin receptor blocker Hypertension with other associated conditions Initial drug of choice Hypertension and diabetes ARB or ACE inhibitor Hypertension and chronic kidney disease ARB or ACE inhibitor Note: in black patients, good evidence for the renal protective effects of ACE inhibitors Hypertension and clinical coronary artery disease β-Blocker plus ARB or ACE inhibitor Hypertension and stroke history ARB or ACE inhibitor Hypertension and heart failure Regardless of blood pressure, ARB or ACE inhibitor + β-blocker + diuretic + spironolactone. A dihydropyridine CCB can be added if needed for BP control. Pneumonic: ABDS Incorrect Options: Initiate treatment only if BP exceeds 160/100 mmHg (Option A): Older guidelines used this threshold for initiating therapy in asymptomatic patients without comorbidities, but current guidelines recommend starting antihypertensive therapy at ≥140/90 mmHg if confirmed on two separate occasions, even in low-risk individuals. Lifestyle changes + medications are appropriate here. Refer to a higher center for further evaluation (Option C): There is no need for referral at this point. The patient has uncomplicated hypertension and can be managed at the primary health center (PHC) level with basic antihypertensive therapy and lifestyle advice. Start the patient on IV anti-hypertensive drugs (Option D): IV antihypertensives are used for hypertensive emergencies (e.g., BP >180/120 mmHg with end-organ damage). This patient is stable and asymptomatic, with no signs of acute target organ damage — oral therapy is appropriate.

@Neet_pg_bot

Q9: A 30 year old man with 6 month past history of PND and SOB. On examination, JVP is elevated with irregularly irregular pulse and tender hepatomegaly and MDM. past medical history of ARF. Which of the following is not seen in this patient? (Q866488)

A. Presystolic accentuation of mid-diastolic murmur is hallmark feature

B. Patient has increased risk of embolic stroke

C. Absent a wave in JVP

D. Right heart failure

Correct Answer: A. Presystolic accentuation of mid-diastolic murmur is hallmark feature

Explanation: Presystolic accentuation of a mid-diastolic murmur occurs in mitral stenosis with sinus rhythm due to atrial contraction just before systole. This patient has atrial fibrillation (irregularly irregular pulse and absent a wave in JVP), which abolishes the presystolic accentuation because there is no coordinated atrial contraction . Patient has increased risk of embolic stroke (Option B): AF increases the risk of left atrial thrombus and systemic embolism. Absent a wave in JVP (Option C): AF abolishes the a wave due to loss of organized atrial contraction. Right heart failure (Option D): Long-standing MS → pulmonary venous hypertension → pulmonary arterial hypertension → RV hypertrophy/dilatation → systemic venous congestion and signs of right-sided failure (tender hepatomegaly, elevated JVP, peripheral edema).

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A patient presents with palpitations and an irregularly irregular pulse. He presents within 2 hours of symptom onset, and has no history of diabetes or other comorbidities. What is the most appropriate initial management? (Q866489)

A. TEE for starting anticoagulation

B. Cardioversion

C. Control ventricular rate with verapamil

D. Wait and watch

Correct Answer: C. Control ventricular rate with verapamil

Explanation: In symptomatic atrial fibrillation, initial priority is to control the ventricular rate to improve hemodynamics and relieve symptoms Even though AF is of recent onset (<48 hours) and cardioversion could be

considered, rate control is often performed first unless the patient is unstable (hypotension, shock, ongoing ischemia, severe heart failure). Verapamil , a non-dihydropyridine calcium channel blocker, slows AV nodal conduction, reducing ventricular rate and improving cardiac output. Atrial Fibrillation Features Characterized by abnormal automatic firing and multiple re-entry circuits. Atria beat rapidly and ineffectively; ventricles activated irregularly Produces an "irregularly irregular" pulse Palpitations, syncope, and breathlessness can be present Asymptomatic AF: Can present as systemic embolism and stroke ECG Features QRS Complexes: Irregular but normal P Waves: Absent; baseline may show irregular fibrillation waves Ventricular Rate: Fast at onset (120-160 beats/min) Slower in chronic AF due to medication effects and AV nodal fatigue Management Paroxysmal Atrial Fibrillation First-line Therapy: Beta-blockers are effective in patients with CAD, hypertension, and heart failure. Class Ic Drugs: Propafenone or flecainide to prevent episodes (not for patients with CAD or LV dysfunction). Class III Drugs: Amiodarone : Most effective but with significant side effects; used when other treatments fail. Dronedarone : Alternative to amiodarone; contraindicated in heart failure. Rate Control: Digoxin and verapamil for AV node conduction slowing, but not for AF prevention. Catheter Ablation: Considered for patients with drug-resistant AF; prevents AF in ~75% of cases but may have complications. Persistent Atrial Fibrillation Rhythm Control : Cardioversion : Electrical or pharmacological (e.g., intravenous flecainide or amiodarone). Timing: Immediate if AF <48 hours; anticoagulation required if AF ≥48 hours. Prophylactic Amiodarone : To reduce recurrence risk. Rate Control : Medications: Digoxin, β-blockers, or rate-limiting calcium antagonists (verapamil, diltiazem) . Combination Therapy: Digoxin with β-blockers ; avoid combining calcium antagonists with β-blockers. Pace and Ablate: Permanent pacemaker with AV nodal block for symptomatic AF. Thromboprophylaxis Anticoagulation: Required for stroke prevention due to blood stasis in the left atrium. Warfarin : INR target of 2.0–3.0; start 4 weeks prior to cardioversion. DOACs: Rivaroxaban, apixaban, edoxaban, and dabigatran as alternatives to warfarin; no monitoring needed. Risk Assessment: CHA2DS2-VASc Score : For stroke risk; anticoagulate if score ≥2 . HAS-BLED Score: For bleeding risk; monitor patients with score ≥3. Aspirin: Not recommended due to low efficacy in preventing embolic stroke. CHA2DS2-VASc stroke risk scoring system for AF Points Parameters Score C Congestive heart failure 1 H Hypertension history 1 A2 Age (≥75 years) 2 D Diabetes mellitus 1 S2 Previous stroke or transient ischemic attack (TIA) 2 V Vascular disease 1 A Age (65-74 years) 1 Sc Sex category (female) 1 Maximum total score 9 points TEE for starting anticoagulation (Option A): This is indicated if AF duration is >48 hours or unknown, to exclude thrombus before starting anticoagulation. Cardioversion (Option B): Rhythm control is generally attempted after rate control and stabilization, unless there’s severe instability. Wait and watch (Option D): Passive observation is inappropriate in symptomatic AF; early intervention to control rate is required.

@Neet_pg_bot

Q11: A patient presents with frothy sputum, dyspnea, and paroxysmal nocturnal dyspnea (PND) and subsequently dies. Autopsy lung histopathology shows hemosiderin-laden macrophages. Which of the following is least likely to occur in this patient? (Q866493)

A. Volume overload

B. RV failure

C. Pulmonary vein obstruction

D. Protein losing enteropathy

Correct Answer: D. Protein losing enteropathy

Explanation: The clinical features of frothy sputum, dyspnea, and PND , along with hemosiderin-laden macrophages on lung histopathology, are classical for chronic passive pulmonary congestion due to left-sided heart failure . The macrophages (also called “heart failure cells”) contain hemosiderin derived from repeated alveolar hemorrhage secondary to chronically elevated pulmonary venous pressure. Protein-losing enteropathy (PLE) is caused by chronic intestinal lymphatic congestion , most commonly seen in: Constrictive pericarditis Severe chronic right-sided heart failure Intestinal lymphangiectasia PLE is not a direct or typical consequence of isolated left-sided heart failure with pulmonary congestion , and it does not explain the lung pathology described. Therefore, it is the least likely finding in this patient. Volume overload (Option A): Left-sided heart failure leads to reduced cardiac output and activation of the renin–angiotensin–aldosterone system (RAAS) , resulting in sodium and water retention . Hence, volume overload is a common and expected finding. Right ventricular failure (Option B): Chronic elevation of pulmonary venous pressure causes pulmonary arterial hypertension , leading to right ventricular hypertrophy and eventual right ventricular failure (secondary cor pulmonale) . Thus, RV failure can occur as a downstream consequence of chronic left-sided heart failure. Pulmonary venous obstruction (Option C): Although not a mechanical obstruction, elevated left atrial pressure (as seen in LV dysfunction or mitral valve disease) produces a functional pulmonary venous outflow obstruction , resulting in pulmonary congestion and hemosiderin-laden macrophages.

@Neet_pg_bot

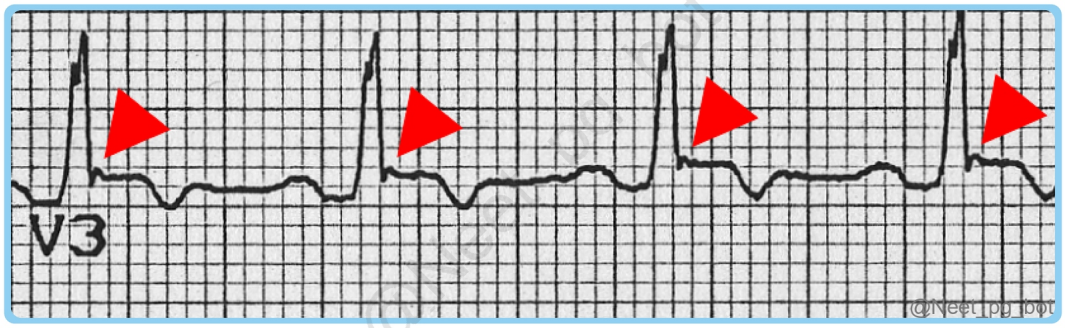
Q12: A female patient comes to the ER with palpitations and syncopal attacks following exercise. She has had similar episodes in the past. An ECG was performed as follows. What is the most probable diagnosis? {{caption_text}} (Q853362)

A. Uhl's disease

B. Arrhythmogenic Right Ventricular Dysplasia

C. Hypertrophic Cardiomyopathy

D. Brugada's syndrome



Correct Answer: B. Arrhythmogenic Right Ventricular Dysplasia

Explanation: The patient's symptoms of palpitations, syncope following exercise, and a suggestive ECG pattern are characteristic of Arrhythmogenic Right Ventricular Dysplasia (ARVD) , a condition that often leads to arrhythmias and sudden cardiac death, particularly in young, athletic individuals. Arrhythmogenic Right Ventricular Dysplasia (ARVD) is an inherited cardiac disorder characterized by the progressive replacement of the right ventricular myocardium with fibrofatty tissue, leading to arrhythmias, particularly ventricular tachycardia and sudden cardiac death. It primarily affects the right ventricle but can involve the left ventricle as well. Etiology Mutations in genes encoding desmosomal proteins (e.g., PKP2, DSP, DSG2, JUP). Clinical Features Palpitations Syncope Exercise-induced arrhythmias Sudden cardiac death, Particularly in young, athletic individuals. Diagnostic Findings Electrocardiogram (ECG): Ventricular arrhythmias, especially ventricular tachycardia. Epsilon waves on ECG (specific to ARVD). Echocardiography: May show right ventricular dilation and dysfunction. Cardiac MRI: Shows fibrofatty infiltration of the right ventricle. Family history: Key in diagnosing genetic basis. Diagnostic Criteria Based on the Task Force Criteria, which include: ECG abnormalities, arrhythmias, imaging findings, and histological evidence. Pathological criteria: Fibrofatty infiltration of the right ventricle. Management Antiarrhythmic drugs Implantable cardioverter-defibrillator (ICD): For preventing sudden cardiac death in high-risk patients. Heart transplantation: In severe cases with progressive heart failure. Uhl's disease (Option A): Also affects the right ventricle but lacks the hallmark epsilon waves and T-wave inversions. Hypertrophic Cardiomyopathy (Option C): More commonly presents with asymmetric septal hypertrophy and deep Q waves, not epsilon waves. Brugada’s Syndrome (Option D): Characterized by ST-segment elevation in V1–V3, not epsilon waves.

Harrison's Principles of Internal Medicine, 21st Edition, Page 1916.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following is associated with a Graham-Steel murmur? (Q852672)

A. Ventricular septal defect (VSD)

B. Hypertrophic obstructive cardiomyopathy (HOCM)

C. Pulmonary regurgitation

D. Aortic regurgitation

Correct Answer: C. Pulmonary regurgitation

Explanation: The Graham-Steel murmur indicates pulmonary regurgitation secondary to pulmonary hypertension. This early diastolic decrescendo murmur is heard best at the left upper sternal border (pulmonic area) and is caused by the backward flow of blood from the pulmonary artery into the right ventricle during diastole. It is specifically associated with pulmonary hypertension, which causes dilation of the pulmonary artery and subsequent incompetence of the pulmonary valve. Cardiac Murmurs and Their Characteristics Common Pathological Murmurs Condition Murmur Characteristics Mitral Stenosis Low-pitched diastolic murmur with an opening snap,

best heard at the apex Aortic Stenosis Crescendo-decrescendo systolic ejection murmur, radiates to carotids, best heard at the right upper sternal border Patent Ductus Arteriosus (PDA) Continuous, machine-like murmur, best heard at the left infraclavicular area Hypertrophic Cardiomyopathy (HOCM) (Option B) Harsh systolic murmur with a crescendo-decrescendo pattern, best heard at the left sternal border, increases with Valsalva maneuver Mitral Regurgitation (MR) Holosystolic murmur, best heard at the apex, radiates to the axilla Aortic Regurgitation (AR) Early diastolic decrescendo murmur, best heard at the left sternal border Ventricular Septal Defect (VSD) (Option A) Harsh holosystolic murmur, best heard at the left lower sternal border (LLSB) Atrial Septal Defect (ASD) Systolic ejection murmur, best heard at the left upper sternal border (LUSB), with fixed, widely split S2 Tricuspid Regurgitation (TR) Holosystolic murmur, best heard at the left lower sternal border, increases with inspiration (Carvallo's sign) Special Murmurs & Their Associations Murmur Cause & Characteristics Graham-Steel Murmur (Pulmonary Regurgitation due to Pulmonary Hypertension) Early diastolic decrescendo murmur, best heard at the left upper sternal border, caused by pulmonary valve incompetence due to pulmonary hypertension Austin Flint Murmur (Severe Aortic Regurgitation) (Option D) Low-pitched, rumbling diastolic murmur, best heard at the apex, due to turbulent flow in the left ventricle compressing the mitral valve Mammary Murmur (Physiologic in Pregnancy) Continuous hissing murmur, heard over the left second and third intercostal spaces, caused by increased blood flow through internal mammary vessels

@Neet_pg_bot

Q14: A 65-year-old male with chronic stable angina presents with worsening chest pain during routine activities. His current medications include aspirin, clopidogrel, metoprolol, and atorvastatin, but his symptoms persist. ECG shows ST-segment depression in V5-V6, and coronary angiography reveals 80% stenosis of the left anterior descending (LAD) artery. What is the most appropriate intervention? (Q852747)

A. Increase the dose of beta-blockers

B. Add Ranolazine

C. Percutaneous coronary intervention (PCI) with drug-eluting stent (DES)

D. Refer for coronary artery bypass grafting (CABG)

Correct Answer: C. Percutaneous coronary intervention (PCI) with drug-eluting stent (DES)

Explanation: The patient has: Significant LAD stenosis (80%) Persistent angina despite optimal medical therapy Evidence of ischemia (ST depression) This fulfills the indication for revascularization . For isolated, proximal LAD stenosis with persistent symptoms, PCI with DES is the preferred intervention because: It relieves symptoms

Improves quality of life DES has a lower restenosis rate than bare-metal stents Increase the dose of beta-blockers (Option A): Already on optimal therapy; dose change won't fix an 80% LAD block. Add Ranolazine (Option B): Add-on drug only; angiography already shows severe LAD stenosis → needs PCI. Refer for coronary artery bypass grafting (CABG) (Option D): Reserved for left main or multivessel disease; this is isolated LAD → PCI preferred.

Harrison's Principles of Internal Medicine, 21st Edition, Pages 2041-2045

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 72 y/o woman presents with severe chest pain and shortness of breath after a stressful argument. She is post-menopausal with no history of heart disease. O/E, she is slightly tachycardic with normal blood pressure. An echocardiogram shows left ventricular ballooning during systole, and cardiac enzymes are minimally elevated. What is the most likely diagnosis? (Q852748)

A. Hypertensive Heart Disease

B. Takotsubo Cardiomyopathy

C. Coronary Artery Disease

D. Pulmonary Embolism

Correct Answer: B. Takotsubo Cardiomyopathy

Explanation: Takotsubo cardiomyopathy, also known as broken heart syndrome, is characterized by transient left ventricular dysfunction often triggered by emotional or physical stress . The patient's recent stressful event, post-menopausal status, ballooning of the left ventricle, and minimal elevation of cardiac enzymes align perfectly with this diagnosis. Takotsubo cardiomyopathy (Gebrochenes-Herz syndrome) About Takotsubo cardiomyopathy, also known as broken-heart syndrome or stress-induced cardiomyopathy, is a non-ischemic condition primarily affecting post-menopausal women. It features temporary left ventricular dysfunction that resembles a heart attack but with minimal cardiac enzyme release and no significant obstructive coronary artery disease. The name "Takotsubo" is derived from Japanese, meaning octopus trap, reflecting the ballooning shape of the left ventricle during contraction. Pathophysiology Catecholamine Hypothesis: Elevated catecholamines (norepinephrine, epinephrine, dopamine) indicate stress-induced sympathetic overdrive, leading to microvascular spasms and myocardial injury. Microvascular Dysfunction: Impaired function is suggested by abnormalities in coronary flow reserve and microvascular resistance. Inflammation: Imaging may show myocardial oedema, necrosis, and fibrosis, with conditions like myocarditis and autoimmune diseases potentially triggering TC. Estrogen Deficiency: Exaggerated vasoconstriction and increased sympathetic activity in post-menopausal women contribute to TC. Clinical features Takotsubo cardiomyopathy often mimics acute coronary syndrome.(MI)

Common Triggers: Emotional Stress: Events like the unexpected death of a loved one, domestic abuse, or financial loss. Physical Stress: Serious medical diagnoses or natural disasters. Symptoms: Chest pain, dyspnea, and syncope. Some patients may have signs of heart failure, such as tachyarrhythmias or bradyarrhythmias. A late-peaking systolic murmur may be present due to LVOTO. About 10% of patients may develop cardiogenic shock. Hypertensive Heart Disease (Option A): Caused by chronic high blood pressure, leading to left ventricular hypertrophy. This patient's history does not indicate long-standing hypertension. Coronary Artery Disease (Option C): Involves plaque buildup in coronary arteries, causing reduced blood flow. The absence of obstructive disease on angiography and minimal enzyme release suggests this is unlikely. Pulmonary Embolism (Option D): Occurs when a blood clot blocks a pulmonary artery, leading to sudden shortness of breath and chest pain. History of long term immobilization/ DVT is present. The patient's findings indicate a cardiac issue, not a pulmonary one.

@Neet_pg_bot

Q16: A 68-year-old man with long-standing hypertension presents to the emergency department with severe chest pain, profuse sweating, and marked tachycardia. He appears acutely ill and hypotensive. His ECG finding is given below. What is the most appropriate immediate management? (Q852749)

A. Amiodarone

B. Radiofrequency catheter ablation

C. Digoxin

D. Synchronized cardioversion

Correct Answer: D. Synchronized cardioversion

Explanation: The patient's clinical presentation with the ECG showing saw-tooth flutter waves indicative of atrial flutter He is hemodynamically unstable which necessitates immediate synchronized cardioversion . Cardioversion restores sinus rhythm rapidly and prevents further hemodynamic collapse Amiodarone (Option A) : Slow-acting antiarrhythmic; not suitable for immediate stabilization in an unstable patient. Radiofrequency catheter ablation (Option B): Definitive long-term treatment for atrial flutter, but not done in emergencies. Digoxin (Option C): Used for rate control in stable patients; acts slowly and cannot stabilize an unstable rhythm

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Page 1899-1902

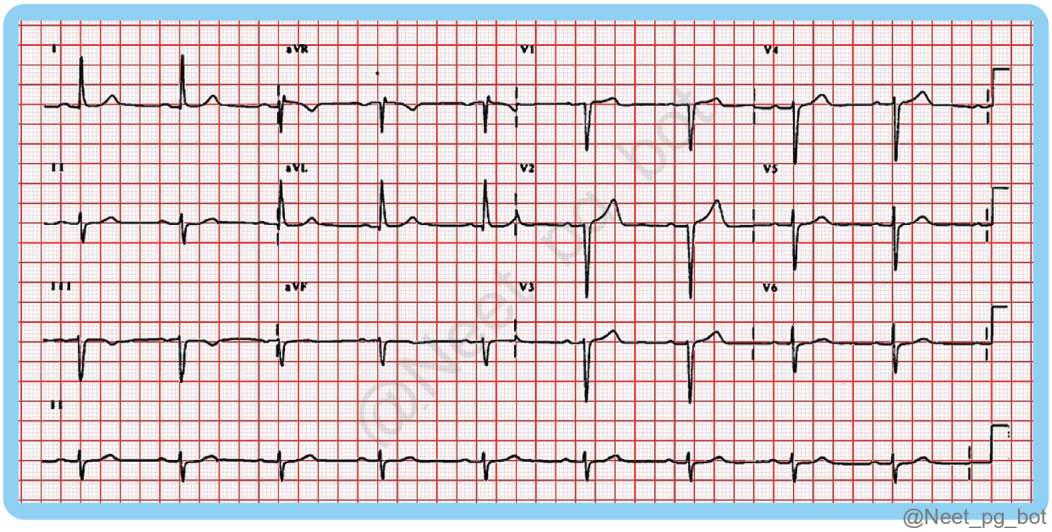
Q17: A 58-year-old woman comes to the clinic for a routine follow-up. She has a history of mild hypertension, which is well-controlled with medication. She reports no symptoms such as palpitations, dizziness, or chest pain. An ECG of the patient is given below. What is the most likely diagnosis based on the ECG findings? {{caption_text}} (Q852750)

A. Second-Degree AV Block

B. First-Degree AV Block

C. Third-Degree AV Block

D. Bundle Branch Block



Correct Answer: B. First-Degree AV Block

Explanation: The ECG shows a prolonged PR interval (>0.20 seconds) but consistently conducts P waves to QRS complexes, indicating first-degree AV block. There are no dropped beats, ruling out higher-degree blocks. Second-Degree AV Block (Option A): This block features progressive lengthening of the PR interval followed by a dropped QRS complex, which is absent in this ECG as there are no dropped beats. Third-Degree AV Block (Option C): Here, there is complete dissociation between P waves and QRS complexes. This is absent in the ECG since P waves are consistently followed by QRS complexes. {{caption_text}} Bundle Branch Block (Option D): This condition shows a wide QRS complex with characteristic morphology. This feature is absent in the ECG, where the QRS complexes are normal in width and shape

@Neet_pg_bot

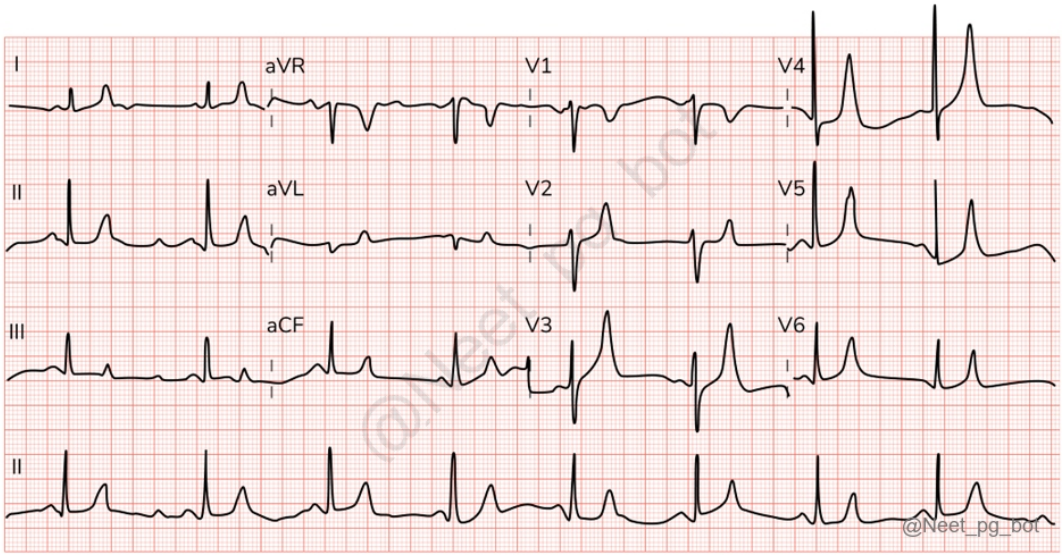
Q18: A patient of CKD has tachycardia. An ECG is taken and shown below. What's the most likely diagnosis? (Q844166)

A. Hyperkalemia

B. Hypokalemia

C. Hypercalcemia

D. Hypocalcemia



Correct Answer: A. Hyperkalemia

Explanation: Correct Option A - Hyperkalemia: C hronic kidney disease (CKD) often leads to electrolyte imbalances due to impaired kidney function. Hyperkalemia is one such common imbalance, which can have significant effects on cardiac function. ECG Findings in Hyperkalemia: Tall, peaked T waves Widened QRS complexes Prolonged PR interval Flattening or absence of P waves Eventually, this can lead to a sine-wave pattern and ventricular fibrillation if untreated. These ECG changes are characteristic of hyperkalemia, particularly in the setting of CKD, where the kidneys are unable to excrete potassium effectively. Incorrect Options: Option B - Hypokalemia: ECG findings typically include U waves, flattened or inverted T waves, and prolonged QT interval. Option C - Hypercalcemia: ECG may show a shortened QT interval. Option D - Hypocalcemia: ECG may show a prolonged QT interval.

@Neet_pg_bot

Q19: A 60-year-old lady presents with SOB and angina pectoris episodes. Work up shows aortic stenosis. Which of the following is the reason behind these chest pain episodes? (Q844172)

A. Increased pressure in aorta

B. Decreased pressure in aorta

C. Increased oxygen consumption in heart

D. Increase in volume overload of heart

Correct Answer: C. Increased oxygen consumption in heart

Explanation: Correct Option C - Increased oxygen consumption in the heart: Aortic Stenosis and Angina: In aortic stenosis, the narrowed aortic valve obstructs blood flow from the left ventricle to the aorta. This obstruction increases the left ventricular pressure as the heart must work harder to overcome the resistance, leading to left ventricular hypertrophy (LVH). The hypertrophied myocardium increases oxygen demand but, due to the narrowed valve, coronary perfusion is compromised, especially during diastole. This imbalance between increased oxygen demand and reduced supply leads to myocardial ischemia and angina. Incorrect Options: Option A - Increased pressure in the aorta: This is not the primary cause of angina. The pressure increases in the left ventricle, not in the aorta. Option B - Decreased pressure in the aorta: While aortic pressure may be lower during ejection, this is not the direct cause of angina. Option D - Increase in volume overload of the heart: Volume overload is more associated with conditions like mitral regurgitation or heart failure, not typically with the chest pain in aortic stenosis.

@Neet_pg_bot

Q20: Patient presents with features of right heart failure and exhibits a rapid Y descent on cardiac examination. What is the most likely diagnosis? (Q844245)

A. Constrictive pericarditis

B. Cardiac tamponade

C. Pulmonary hypertension

D. Right ventricular infarction

Correct Answer: A. Constrictive pericarditis

Explanation: Correct Option A - Constrictive Pericarditis: Constrictive pericarditis is a condition where the pericardium becomes thickened and fibrotic, leading to impaired filling of the heart, particularly the right side. A rapid Y descent on jugular venous pressure (JVP) is a classic finding in constrictive pericarditis, reflecting rapid early diastolic filling of the ventricle due to the rigid pericardium. The patient may present with signs of right heart failure, such as peripheral edema, ascites, and hepatomegaly. Incorrect Options: Option B - Cardiac Tamponade: Cardiac tamponade typically presents with a blunted or absent Y descent on JVP tracing due to the equalization of pressures during diastole, which restricts ventricular filling. The presence of a rapid Y descent makes cardiac tamponade less likely. Option C - Pulmonary Hypertension: Pulmonary hypertension can cause right heart failure, but it is not associated with a rapid Y descent on JVP. The JVP findings in pulmonary hypertension are usually more related to elevated pressure rather than specific waveforms like a rapid Y descent. Option D - Right Ventricular Infarction: Right ventricular infarction can present with signs of right heart failure. However, the JVP typically shows an elevated a-wave or a prominent X descent, not a rapid Y descent.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A pulmonary artery hypertension patient presented with an irregularly irregular pulse with loud P2 on auscultation. Which JVP finding will be seen in this patient? (Q844316)

A. Absent a waves

B. Cannon a waves

C. Rapid x descent

D. Rapid y descent

Correct Answer: A. Absent a waves

Explanation: Correct Option A - Absent a waves: Clinical Context: The patient has pulmonary artery hypertension (PAH) and presents with an irregularly irregular pulse and a loud P2 (second heart sound). The irregularly irregular pulse suggests the presence of atrial fibrillation, which is often associated with PAH due to right atrial enlargement from increased pressure. JVP Findings in Atrial Fibrillation: Absent a Waves: In atrial fibrillation, the irregular and often rapid contractions of the atria lead to ineffective atrial contraction. As a result, the a waves, which represent atrial contractions, are absent in the JVP waveform. This is consistent with the finding in atrial fibrillation where the rhythm is irregular and there is no coordinated atrial contraction. Incorrect Options: Option B - Cannon a Waves: Cannon a waves are seen in conditions where there are atrial contractions against a closed tricuspid valve, as in cases of complete heart block or atrial fibrillation with discordance between atrial and ventricular contractions. However, this finding is not as specific as the absence of a waves in atrial fibrillation. Option C - Rapid x Descent: Rapid x descent is more associated with conditions like constrictive pericarditis rather than atrial fibrillation, which is the primary condition described here. Option D - Rapid y Descent: Rapid y descent is indicative of constrictive pericarditis or other conditions where there is rapid filling of the ventricles. It is not typically associated with atrial fibrillation.

@Neet_pg_bot

Q22: A young athlete underwent testing for a competition and was found to have hypertrophic cardiomyopathy. Which of the following will increase the murmur in this condition? (Q844250)

A. Handgrip

B. Valsalva maneuver

C. Squatting

D. Leaning forward

Correct Answer: B. Valsalva maneuver

Explanation: Correct Option B - Valsalva Maneuver: Hypertrophic cardiomyopathy (HCM) is a condition characterized by the thickening of the heart muscle, particularly the interventricular septum, which can obstruct blood flow out of the left ventricle, leading to a systolic murmur. The murmur associated with HCM is dynamic and can change in intensity with different maneuvers that affect the volume of blood in the left ventricle. The Valsalva maneuver decreases venous return to the heart, leading to reduced left ventricular filling. In HCM, this reduction in ventricular volume increases the obstruction to blood flow, making the murmur louder. This maneuver accentuates the outflow tract obstruction by bringing the hypertrophied septum closer to the anterior mitral valve leaflet. Incorrect Options: Option A - Handgrip: The handgrip maneuver increases systemic vascular resistance, which typically increases murmurs of regurgitant lesions like mitral regurgitation but decreases the murmur in HCM because the increased afterload reduces the degree of outflow tract obstruction. Option C - Squatting: Squatting increases venous return and systemic vascular resistance, leading to increased left ventricular filling and a reduction in the outflow tract obstruction. This typically softens the murmur in HCM. Option D - Leaning Forward: Leaning forward can accentuate murmurs of aortic regurgitation but does not have a significant effect on the murmur of HCM.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: Which of the following drugs will cause Torsades de pointes if given with erythromycin? (Q844254)

A. Astemizole

B. Levofloxacin

C. Amoxicillin

D. Ceftriaxone

Correct Answer: A. Astemizole

Explanation: Correct Option A - Astemizole: Astemizole is an antihistamine that has been associated with QT interval prolongation, a risk factor for Torsades de pointes, a type of life-threatening ventricular tachycardia. Erythromycin, a macrolide antibiotic, is known to inhibit the cytochrome P450 3A4 (CYP3A4) enzyme. Astemizole is metabolized by CYP3A4, and when given together, erythromycin can increase the levels of astemizole, leading to significant QT prolongation and a high risk of Torsades de pointes. Due to this risk, astemizole has been withdrawn from the market in many countries. Incorrect Options Option B - Levofloxacin:

Levofloxacin is a fluoroquinolone antibiotic that can also cause QT interval prolongation. However, when given with erythromycin, the risk of Torsades de pointes is lower compared to astemizole because levofloxacin is not as strongly influenced by CYP3A4 interactions. Option C - Amoxicillin: Amoxicillin is a beta-lactam antibiotic that does not prolong the QT interval and is not associated with Torsades de pointes, either alone or in combination with erythromycin. Option D - Ceftriaxone: Ceftriaxone is a third-generation cephalosporin that also does not prolong the QT interval or interact with erythromycin to increase the risk of Torsades de pointes.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: A patient presents with shortness of breath. Vitals are HR= 120/min, BP= 90/60. Echo shows diastolic collapse of ventricles. CT showed money bag appearance. Which is best for management of this patient? (Q844256)

A. Start diuretic with BP monitoring

B. Intra aortic balloon pump

C. Pericardiocentesis

D. Ventricular assist device

Correct Answer: C. Pericardiocentesis

Explanation: The patient has tachycardia, hypotension, shortness of breath , and imaging consistent with pericardial tamponade : Echo: diastolic collapse of ventricles → hallmark of tamponade CT: “money bag” appearance → large pericardial effusion Pericardial tamponade requires urgent pericardiocentesis to relieve pressure on the heart. Start diuretic with BP monitoring (Option A) Incorrect because diuretics reduce preload and can worsen tamponade by causing cardiovascular collapse. Intra-aortic balloon pump (Option B) Incorrect; used in cardiogenic shock and severe LV failure, not tamponade. Ventricular assist device (Option D) Incorrect; used for advanced heart failure, not acute pericardial tamponade

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: What is the next best step in management of a pulseless patient with the following rhythm? (Q844260)

A. Defibrillate and continue chest compression

B. Defibrillate and check pulse

C. Check pulse and give synchronized DC

D. Give synchronized DC and continue chest compression

Correct Answer: A. Defibrillate and continue chest compression

Explanation: Correct Option A - Defibrillate and continue chest compression: Management of Pulseless Monomorphic Ventricular Tachycardia: Pulseless monomorphic ventricular tachycardia (VT) is a type of ventricular arrhythmia that requires immediate treatment. The absence of a pulse indicates that the patient is in cardiac arrest and effective treatment is critical to restore circulation and potentially save the patient's life. Recommended Steps: Defibrillate: For pulseless VT (or pulseless ventricular fibrillation), immediate defibrillation is indicated. Defibrillation provides an electric shock to the heart to reset the electrical activity and restore a normal rhythm. Continue Chest Compressions: While defibrillation is being administered, chest compressions should continue as they are essential for maintaining blood flow to vital organs until normal rhythm is restored. Incorrect Options: Option B - Defibrillate and check pulse: After defibrillation, checking for a pulse is important, but it should not delay the immediate administration of another shock if the patient remains pulseless. Compressions should continue uninterrupted during this process. Option C - Check pulse and give synchronized DC: Checking for a pulse before defibrillation is inappropriate in the context of pulseless cardiac arrest. Synchronized direct current (DC) cardioversion is used for certain arrhythmias like atrial fibrillation or atrial flutter with a pulse, not for pulseless VT. Option D - Give synchronized DC and continue chest compression: Synchronized DC cardioversion is not the appropriate treatment for pulseless VT. Defibrillation (not synchronized cardioversion) is required in this case.

@Neet_pg_bot

Q26: A patient with a history of hypertension presents with atrial fibrillation, shortness of breath and Bilateral basal crackles on auscultation. Least important in management would be: (Q844277)

A. Start on anticoagulants like warf or Doac

B. Start beta blocker

C. Cardioversion to correct rhythm if hemodynamically remain unstable even after medical management

D. Iv Digoxin to control rate

Correct Answer: B. Start beta blocker

Explanation: Correct Option B - Start beta blocker: Beta blockers are used to control heart rate and manage symptoms related to atrial fibrillation. However, in acute settings with symptoms like shortness of breath and bilateral crackles, especially if heart failure is suspected, other treatments might take precedence. In cases of acute heart failure or unstable hemodynamics, immediate rate control might be achieved using other agents. Incorrect Options: Option A - Start on anticoagulants like warfarin or DOAC: Anticoagulants are crucial in the management of atrial fibrillation to prevent thromboembolic events such as stroke. Given the patient's symptoms and history, anticoagulation should be considered unless contraindicated. Option C - Cardioversion to correct rhythm if hemodynamically unstable even after medical management: If the patient remains hemodynamically unstable despite medical management, cardioversion is necessary to restore normal sinus rhythm and stabilize the patient. This is crucial in managing acute atrial fibrillation. Option D - IV Digoxin to control rate: IV digoxin is used for rapid rate control in atrial fibrillation, especially when accompanied by heart failure. It can be beneficial in acute settings for managing symptoms and controlling the ventricular rate.

@Neet_pg_bot

Q27: The PR interval was measured at 0.21 seconds in a routine ECG of the patient. What is the correct Interpretation? (Q844281)

A. Second degree HB

B. First degree HB

C. Normal rhythm

D. Complete HB

Correct Answer: B. First degree HB

Explanation: Correct Option B - First degree HB: First-degree heart block is defined by a prolonged PR interval greater than 0.20 seconds (200 milliseconds). In this case, a PR interval of 0.21 seconds indicates a prolonged PR interval, which is characteristic of first-degree heart block. Incorrect Options: Option A - Second degree HB: Second-degree heart block (HB) is characterized by intermittent failure of some atrial impulses to be conducted to the ventricles. This is usually identified by a pattern of dropped beats or a varying PR interval. The PR interval in second-degree HB can be normal or prolonged, but it does not specifically represent a fixed interval as seen in first-degree HB. Option C - Normal rhythm: A normal PR interval ranges from 0.12 to 0.20 seconds. A PR interval of 0.21 seconds exceeds this range, indicating that the rhythm is not normal. Option D - Complete HB: Complete heart block (also known as third-degree heart block) is characterized by a complete dissociation between atrial and

ventricular activity, with no correlation between P waves and QRS complexes. The PR interval is not applicable in this context as the atrial impulses do not conduct to the ventricles.

References:

.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q28: A 70 year old male patient presents to the OPD with multiple, recurrent fainting episodes. An ECG was taken and it shows P waves at a rate of 75 bpm and qrs complexes at a rate of 35 bpm. What is the diagnosis? (Q860467)

A. Mobitz type II heart block

B. Stokes adams syndrome

C. First degree heart block

D. Wolf parkinson white syndrome

Correct Answer: B. Stokes adams syndrome

Explanation: The clinical manifestations indicate Stokes Adams syndrome , characterized by complete heart block with recurrent syncope . The ECG findings show P waves at 75 bpm with QRS complexes at 35 bpm , demonstrating AV dissociation typical of complete heart block or IIIrd degree heart block . This indicates a complete interruption of electrical conduction between the atria and ventricles, leading to independent atrial and ventricular rhythms. Third-degree atrioventricular block / Stokes-Adams Syndrome Definition Complete failure of conduction between atria and ventricles, resulting in independent beating (AV dissociation). {{caption_text}} Ventricular Activity Maintained by an escape rhythm from: The AV node or bundle of His (narrow QRS complexes). Distal Purkinje tissues (broad QRS complexes). ECG Findings Prolonged PR interval Broad QRS complex Number of P waves will not be equal to the number of R waves P-R interval (atrial rate) will not match the R-R interval (ventricular rate) Clinical Features Recurrent syncope or 'Stokes–Adams' attacks- sudden loss of consciousness and collapse. Brief anoxic seizure. Pallor and a death-like appearance during the attack; characteristic flush upon recovery. Rapid recovery distinguishes it from epilepsy. Management Depends on clinical circumstances. Transient AV block in acute inferior myocardial infarction- no treatment if the patient remains stable. Symptomatic third-degree AV block- intravenous atropine or intravenous isoprenaline to maintain circulation until temporary pacing is inserted. Permanent pacemaker. Mobitz type II heart block (Option A) presents with intermittent failure of AV conduction with normal PR intervals 200ms. Unlike complete heart block, some P waves still conduct to the ventricles, and the pattern is not consistent with the current ECG findings. First degree heart block (Option C) shows prolonged PR interval >200ms with 1:1 AV conduction. This is typically asymptomatic and would not cause the presenting symptoms of recurrent syncope. Wolf parkinson white syndrome (Option D) presents with a short PR interval <120ms and delta waves. This represents pre-excitation through an accessory pathway and does not cause the AV dissociation seen in this case.

@Neet_pg_bot

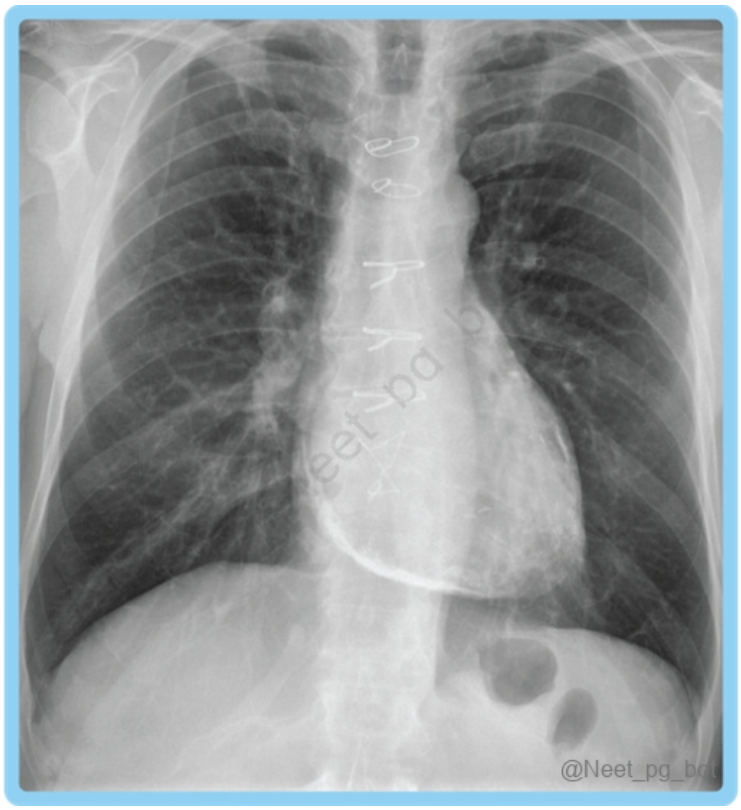
Q29: A 48-year-old man presents with progressive fatigue and breathlessness. On examination, he has distended neck veins, hepatomegaly, ascites, and peripheral edema. Chest X-ray is shown below. Which of the following is the most likely diagnosis? (Q860471)

A. Acute pericarditis

B. Bronchial asthma

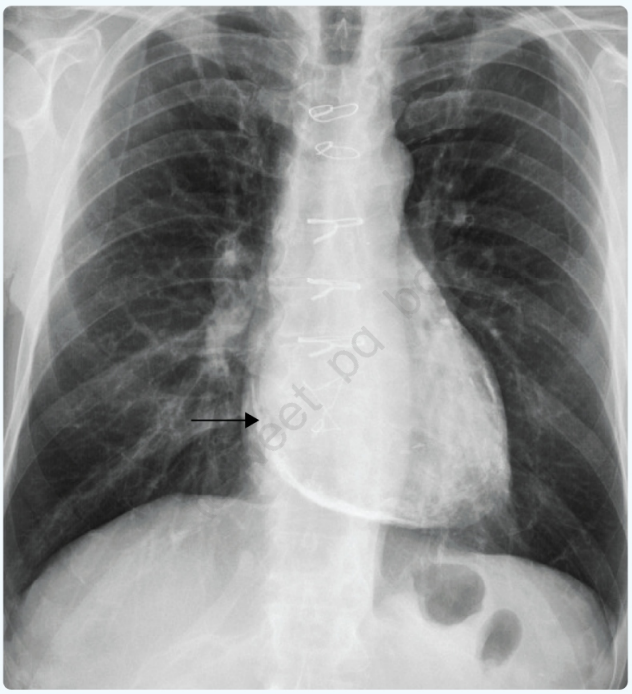
C. Constrictive pericarditis

D. Atrial myxoma



Correct Answer: C. Constrictive pericarditis

Explanation: Constrictive pericarditis is caused by fibrosis and calcification of the pericardium , leading to restricted ventricular filling during diastole . Key Clinical Features: Raised JVP with prominent y descent Systemic venous congestion → hepatomegaly, ascites, pedal edema Pericardial knock (early diastolic sound) Kussmaul's sign (JVP rises on inspiration) Chest X-ray findings: Normal-sized heart Pericardial calcification ("egg-in-cup" appearance) {{caption_text}} Acute pericarditis (Option A) presents with a flask-shaped, enlarged cardiac silhouette while in constrictive pericarditis, the heart is normal sized. Bronchial asthma (Option B) shows pulmonary hyperinflation with bronchial wall thickening. Atrial myxoma (Option D) typically presents with cardiomegaly, left atrial enlargement, and vascular redistribution.



Diffuse pericardial calcification seen along the right lateral and inferior wall of heart

@Neet_pg_bot

Q30: A patient has muffled heart sounds with low blood pressure. What is the correct JVP finding? (Q860477)

A. Steep x descent

B. Absent y descent

C. Steep y descent

D. Blunted x descent

Correct Answer: B. Absent y descent

Explanation: The clinical manifestations such as muffled heart sounds with low blood pressure indicate cardiac tamponade , which is characterized by the accumulation of fluid in the pericardial space, leading to compromised

cardiac filling and subsequent hemodynamic compromise. In cardiac tamponade, the characteristic finding is absent y descent and non-pulsatile elevated JVP due to impaired right ventricular filling during diastole. The condition presents with Beck's triad , which includes muffled heart sounds, hypotension, and elevated JVP. Cardiac Tamponade Definition A condition where the cardiac chambers are compressed by a tense pericardial effusion, limiting cardiac inflow. Fluid accumulation of as little as 200 ml to upwards of 2L may lead to cardiac tamponade development. Clinical Features Beck's triad Jugular Venous Distension : Due to increased central venous pressure. Prominent x descent and an absent y descent. Hypotension : Resulting from impaired cardiac output. Muffled Heart Sounds : Caused by fluid accumulation in the pericardial space, dampening heart sounds. Other features Pulsus Paradoxus : A drop in systolic BP during inspiration, greater than 10 mm Hg. Causes of Pulsus paradoxus: Lung Conditions: Acute asthma, COPD, tension pneumothorax, pleural effusion, pulmonary embolism. Heart Conditions: Cardiac tamponade, constrictive pericarditis. Steep x descent (Option A): Steep x descent is typically seen in constrictive pericarditis. Although prominent x descent is also seen in cardiac tamponade, absent y descent is a more highlighting feature typical of cardiac tamponade. Steep y descent (Option C): Steep y descent is observed in exaggerated tricuspid regurgitation, which allows for rapid right atrial emptying during diastole. Blunted x descent (Option D): Blunted x descent is seen in restrictive cardiomyopathy where there is impaired ventricular relaxation. The clinical presentation of muffled heart sounds and hypotension is more consistent with cardiac tamponade rather than restrictive cardiomyopathy.

@Neet_pg_bot

Q31: A young male patient presents with sudden onset chest pain for one hour with ECG showing STE in lead 2,3 and aVF. Which is the best treatment for this case of inferior wall MI in a multispecialty hospital? (Q860480)

A. Alteplase

B. Streptokinase

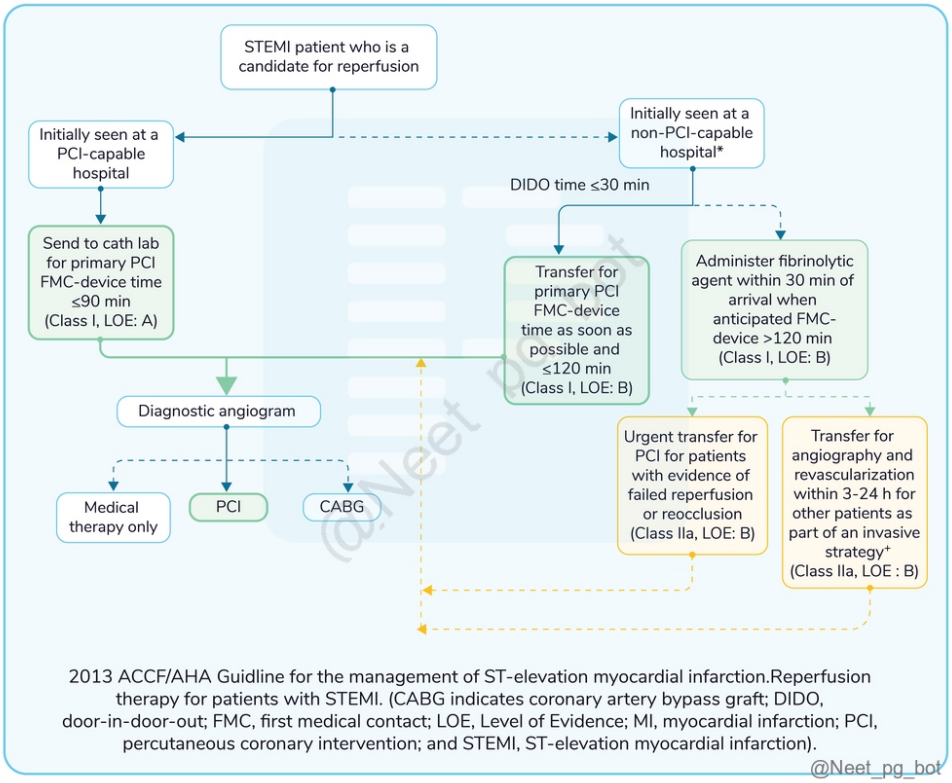
C. Primary angioplasty

D. Dabigatran

Correct Answer: C. Primary angioplasty

Explanation: The clinical manifestations (sudden onset chest pain) with characteristic ECG findings (ST elevation in lead 2,3 and aVF) indicate an acute inferior wall ST-elevation myocardial infarction (STEMI) . Primary angioplasty , also known as Primary Percutaneous Coronary Intervention (PCI) , is the gold standard treatment for STEMI when performed at a capable facility within 120 minutes of first medical contact. Immediate Goals: Control cardiac discomfort. Rapidly identify patients for reperfusion therapy. Proper triage of lower-risk patients. Avoid inappropriate discharge of STEMI patients. Overall Aim: Initiate percutaneous coronary intervention (PCI)

within 120 minutes of first medical contact, including transfer to a PCI-capable facility if necessary. Alteplase (Option A): Alteplase, a tissue plasminogen activator, is only preferred in non-PCI-capable hospitals, where patients are further to be transferred to a PCI capable hospital. In a multispecialty hospital with PCI capabilities, primary angioplasty offers better outcomes with lower bleeding risk. Streptokinase (Option B): Streptokinase is no longer the treatment of choice according to current guidelines due to its risk of anaphylaxis and inferior outcomes compared to primary PCI. Dabigatran (Option D): Dabigatran is an anticoagulant and is not indicated for the treatment of STEMI. While anticoagulation is part of STEMI management, direct oral anticoagulants like dabigatran are not the primary treatment strategy in acute STEMI. PIM050



2013 ACCF/AHA Guidline for the management of ST-elevation myocardial infarction.Reperfusion therapy for patients with STEMI. (CABG indicates coronary artery bypass graft; DIDO, door-in-door-out; FMC, first medical contact; LOE, Level of Evidence; MI, myocardial infarction; PCI, percutaneous coronary intervention; and STEMI, ST-elevation myocardial infarction).

@Neet_pg_bot

Q32: "A 45-year-old female presents to the emergency department with breathlessness. She has a history of a viral infection and chest pain from 7 days ago. A chest X-ray reveals a "water bottle" heart. All of the following statements are true except:" (Q840110)

A. Pulsus paradoxus is observed

B. Loud S1

C. Emergency pericardiocentesis may be required

D. ECG showing RA and RV collapse requires immediate intervention

Correct Answer: B. Loud S1

Explanation: Correct Option B - Loud S1: In the described scenario, viral pericarditis initially occurred, progressing to pericardial effusion and subsequent diastolic collapse of the ventricles, resulting in cardiac tamponade. Due to the presence of fluid surrounding the heart, muffled heart sounds are expected rather than a loud S1. Incorrect Options: Option A - Pulsus paradoxus is observed: Pulsus paradoxus, characterized by a drop in blood pressure of more than 12 mmHg during inspiration, is a feature of cardiac tamponade. Option C - Emergency pericardiocentesis may be required: This statement is true as pericardiocentesis is performed as an emergency measure as there is diastolic collapse of the ventricles. Option D - ECG showing RA and RV collapse requires immediate intervention: This statement is true as there is diastolic collapse of ventricles in cardiac tamponade.

@Neet_pg_bot

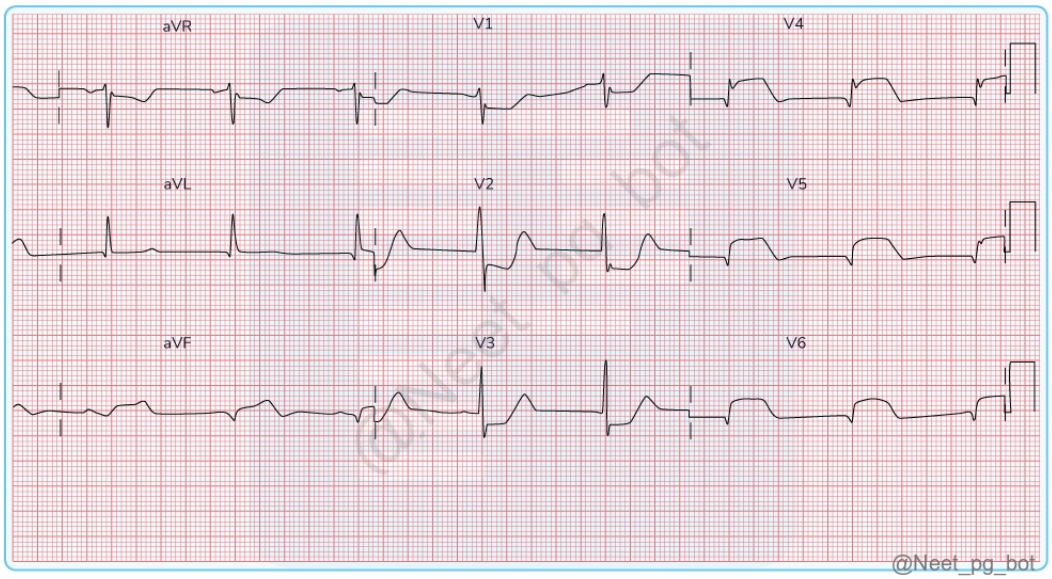
Q33: Which of the following conditions is indicated by the symptoms of chest pain and breathlessness in a 55-year-old male, as revealed by the provided ECG? (Q840116)

A. Unstable angina

B. Non-ST elevation myocardial infarction (NSTEMI)

C. Acute myocarditis

D. Posterior wall myocardial infarction (MI)



Correct Answer: D. Posterior wall myocardial infarction (MI)

Explanation: Correct Option: D) Posterior wall myocardial infarction (MI) ST depression is evident in leads V2, V3, and V4, displaying a predominantly horizontal configuration, with upright T waves. Moreover, the R/S ratio in anterior chest leads is greater than 1. These combined observations suggest the likelihood of a posterior wall myocardial infarction. Options A & B - Unstable angina & NSTEMI: The ECG changes observed in both unstable angina and NSTEMI display similarities and show T wave inversion accompanying ST depression. Option C - Acute myocarditis: There are no pathognomic findings in acute myocarditis as it shows non-specific ST segment changes.

@Neet_pg_bot

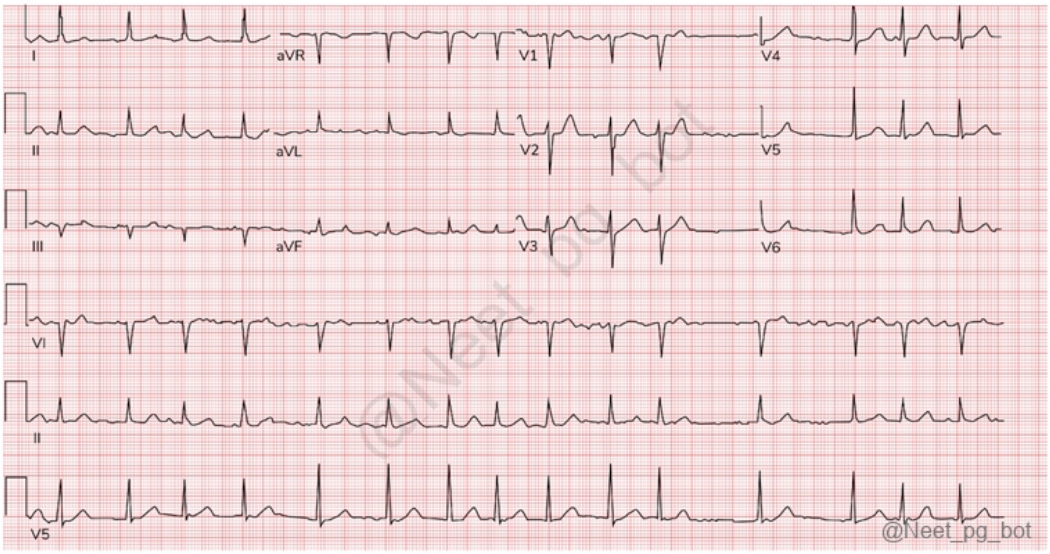
Q34: Which of the following statements is false regarding a 35-year-old male presenting to the emergency department with unconsciousness and the given ECG findings? (Q840119)

A. Atrial fibrillation can occur in structurally normal hearts

B. Direct current cardioversion should always be performed immediately

C. IV digoxin can be used when AF is associated with heart failure

D. Pulse deficit is a useful clinical clue in AF



Correct Answer: B. Direct current cardioversion should always be performed immediately

Explanation: Correct Option: B) Direct current cardioversion should always be performed immediately
Explantion: The ECG shows atrial fibrillation (AF) , characterized by an irregularly irregular rhythm with absent P waves. DC cardioversion is not universally performed in all patients with AF. It is indicated only when AF causes hemodynamic instability (shock, pulmonary edema, severe hypotension). In stable patients, immediate cardioversion is avoided because it can dislodge atrial thrombi and trigger a stroke unless anticoagulation is ensured. Atrial fibrillation can occur in structurally normal hearts (Option A): AF can occur even in a structurally normal heart called "lone AFib," can be triggered by factors like age, genetics, or lifestyle, and can also happen for no obvious reason. While AF often develops in hearts with underlying issues, it is not limited to those with heart disease. IV digoxin can be used when AF is associated with heart failure (Option C): IV digoxin is helpful for rate control , particularly when AF is accompanied by heart failure. Pulse deficit is a useful clinical clue in AF(Option D): Pulse deficit (difference between heart rate and pulse rate) is a classic bedside clue to AF, due to weak ventricular contractions not producing palpable pulses

References:

@Neet_pg_bot

Q35: A 21-year-old man presents with episodes of chest pain. Physical examination reveals a bisferiens pulse and a heaving apex. What is the most likely diagnosis? (Q860218)

A. Dilated Cardiomyopathy (DCM)

B. Hypertrophic Cardiomyopathy (HCM)

C. Mitral Stenosis

D. Aortic Stenosis

Correct Answer: B. Hypertrophic Cardiomyopathy (HCM)

Explanation: The presence of a bisferiens pulse (double-peaked pulse) and a heaving apex are characteristic physical findings of Hypertrophic Cardiomyopathy (HCM) . This condition is characterized by asymmetric hypertrophy of the ventricular septum, which can cause dynamic obstruction of the left ventricular outflow tract. Hypertrophic Cardiomyopathy (HCM) Feature Characteristics Pathophysiology Autosomal dominant genetic disorder Mutations in beta-myosin heavy-chain, troponin, and myosin-binding protein C Inappropriate left ventricular hypertrophy Key Physical Findings Bisferiens (jerky arterial) pulse Heaving apex Mid-systolic murmur Dynamic LVOT obstruction Common Symptoms Angina (chest pain) Dyspnea Syncope MC cause of sudden death Pathological Features Misaligned myocardial fibers Myocardial fibrosis Rigid left ventricle Impaired diastolic filling Examination Findings Clinical Finding Description Palpable Left Ventricular Hypertrophy An enlarged left ventricle can be felt during physical examination, indicating hypertrophy. Double Impulse at the Apex A palpable fourth heart sound suggests forceful atrial contraction against a non-compliant ventricle. Mid-Systolic Murmur at the Base Turbulent blood flow through the obstructed left ventricular outflow tract produces a mid-systolic murmur. Pansystolic Murmur at the Apex Indicates mitral regurgitation caused by abnormal systolic anterior motion of the mitral valve. Jerky Arterial Pulse Characteristic of HOCM, contrasts with the slow-rising pulse seen in aortic stenosis. Pulsus bisferiens A double pulse noticed during systole in the peripheral pulse is called pulsus bisferiens. It is associated with severe aortic disease accompanied by aortic regurgitation and HOCM. Dilated Cardiomyopathy (Option A) is characterized by left ventricular dilation and impaired systolic function. Physical exam findings typically include signs of heart failure, such as elevated jugular venous pressure and displaced apex beat, but bisferiens pulse and heaving apex are not typical features. Mitral Stenosis (Option C) presents with obstruction of blood flow from the left atrium to the left ventricle. Physical exam findings typically include a diastolic murmur best heard at the apex and possible signs of left atrial enlargement, but bisferiens pulse is not a characteristic finding. Aortic Stenosis (Option D) causes obstruction of blood flow from the left ventricle into the aorta. While it can present with chest pain, the classic physical findings include a systolic ejection murmur and a reduced or delayed carotid pulse, not a bisferiens pulse.

@Neet_pg_bot

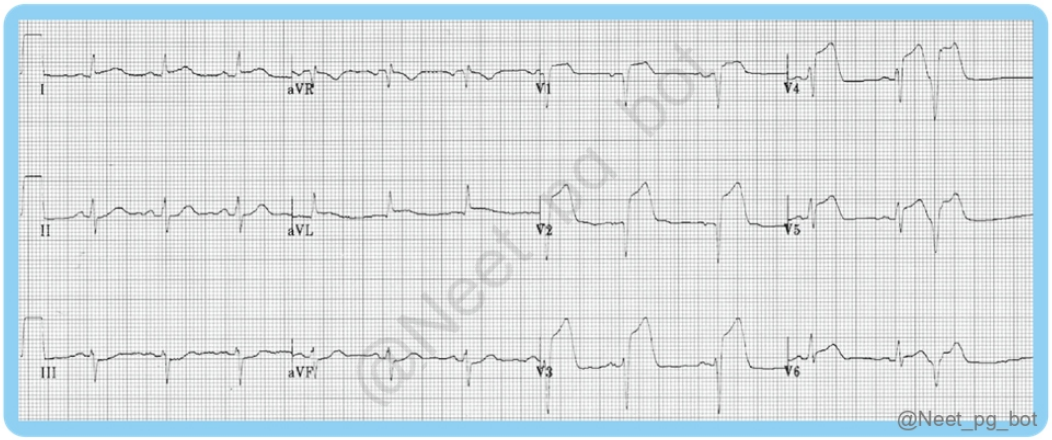
Q36: Based on the given ECG, identify which wall of the myocardium was affected in this patient? (Q860223)

A. Inferior wall

B. Anterior wall

C. Posterior wall

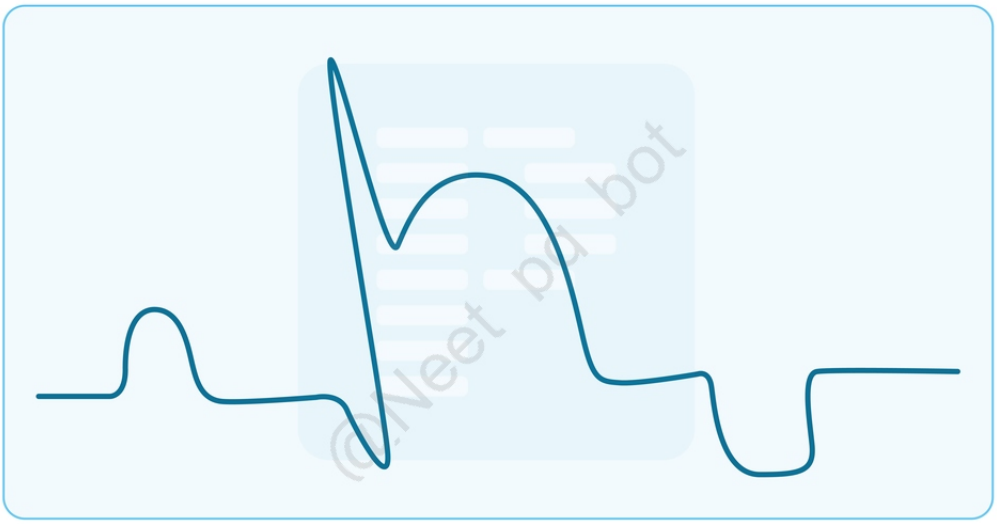
D. Lateral wall



Correct Answer: B. Anterior wall

Explanation: The ECG demonstrates ST elevation in leads V2, V3, and V4 is indicative of an anterior wall myocardial infarction (MI) The ECG shows ST segment elevation with a convex upward shape (Pardee sign) in the precordial leads, which is characteristic of acute anterior wall myocardial infarction supplied by the left anterior descending artery. Infarct Localization based on ECG Infarct Location Affected Coronary Artery Leads Lateral Wall MI (Option D) Left Circumflex Artery (LCx) V5, V6, I, aVL Septal Wall MI Septal Branch of Left Anterior Descending Artery (LAD) V1, V2 Anterior Wall MI (Option A) Left Anterior Descending Artery (LAD) V1-V4, I, aVL Extensive Anterior Wall MI Left Main Coronary Artery (LMCA) V1-V6, I, aVL Posterior Wall MI (Option C) Posterior Descending Artery (PDA) V1-V4 (ST depression), V7, V8, V9 (ST elevation) Inferior Wall MI (Option A) Right Coronary Artery (RCA) Leads II, III, aVF NSTEMI (Anterior Wall) Left Anterior Descending Artery (LAD) Often subtle changes in V1-V4 Inferior wall (Option A) involvement typically shows

ST elevation in leads II, III, and aVF, which is not present in this ECG tracing. The absence of these changes rules out inferior wall MI. Posterior wall (Option C) involvement would show ST depression in leads V1-V4 and ST elevation in leads V7, V8, and V9. This pattern is not seen in the current ECG. Lateral wall (Option D) involvement would show changes in leads V5, V6, I, and aVL. While there may be some changes in these leads, they are not the predominant finding, and the primary area of involvement is clearly anterior.



Pardee Sign- ST segment elevation with a convex upward shape

@Neet_pg_bot

Q37: In which of the following scenarios is Rescue Percutaneous Coronary Intervention (PCI) indicated? (Q860242)

A. Failed thrombolysis

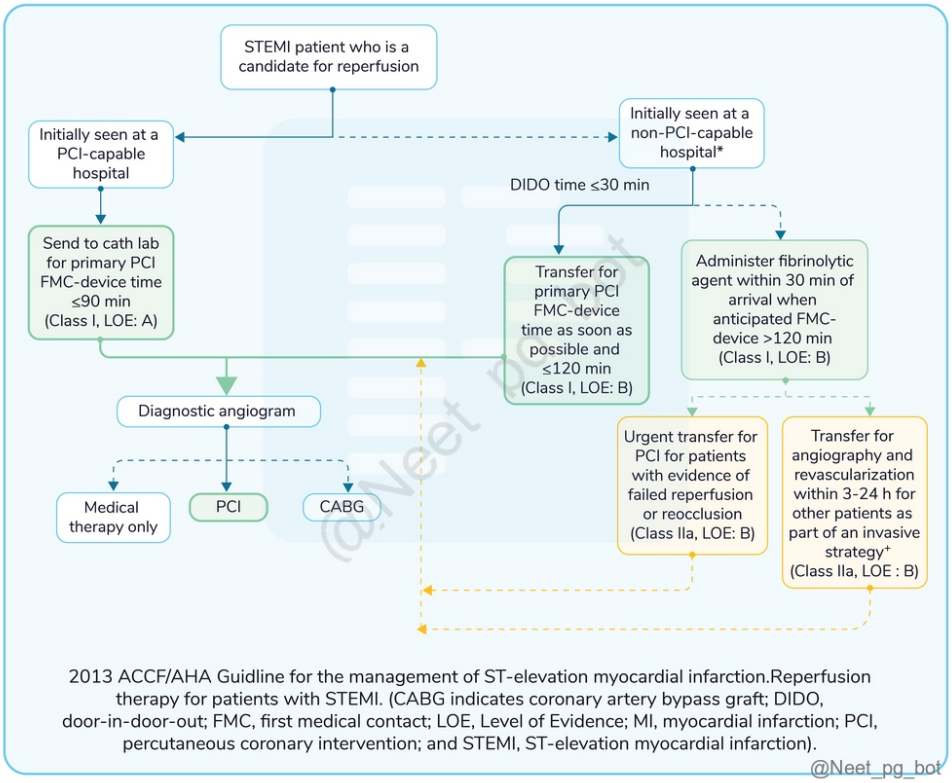
B. Chronic stable angina

C. Prinzmetal's angina

D. NSTEMI

Correct Answer: A. Failed thrombolysis

Explanation: Rescue PCI is specifically indicated when thrombolytic therapy fails to restore coronary blood flow in acute myocardial infarction. This intervention becomes necessary when initial thrombolytic treatment is unsuccessful in dissolving the occluding blood clot, as evidenced by persistent symptoms, ongoing ST-segment elevation, or hemodynamic instability . The procedure serves as a secondary intervention to mechanically reestablish coronary perfusion when pharmacological reperfusion has failed. 2013 ACCF/AHA Guideline for the management of ST-elevation myocardial infarction. Reperfusion therapy for patients with STEMI. (CABG indicates coronary artery bypass graft; DIDO, door-in–door-out; FMC, first medical contact; LOE, Level of Evidence; MI, myocardial infarction; PCI, percutaneous coronary intervention; and STEMI, ST-elevation myocardial infarction) Chronic stable angina (Option B) is characterized by predictable chest pain occurring with exertion or stress. While PCI may be performed for relief in cases where medical management has failed, it is not classified as rescue PCI. The intervention in stable angina is planned and elective rather than emergent. Prinzmetal's angina (Option C) is caused by coronary artery spasm and typically responds to medical management with calcium channel blockers and nitrates. PCI is not usually indicated unless there is a significant fixed obstruction. The primary treatment focuses on managing vasospasm rather than mechanical intervention. NSTEMI (Option D) management follows a different protocol where initial medical therapy is the standard approach, with PCI timing based on risk stratification and response to treatment. While PCI may be indicated in NSTEMI, it is not considered rescue PCI as it is part of the planned treatment strategy rather than a rescue measure after failed therapy.



2013 ACCF/AHA Guidline for the management of ST-elevation myocardial infarction.Reperfusion therapy for patients with STEMI. (CABG indicates coronary artery bypass graft; DIDO, door-in-door-out; FMC, first medical contact; LOE, Level of Evidence; MI, myocardial infarction; PCI, percutaneous coronary intervention; and STEMI, ST-elevation myocardial infarction).

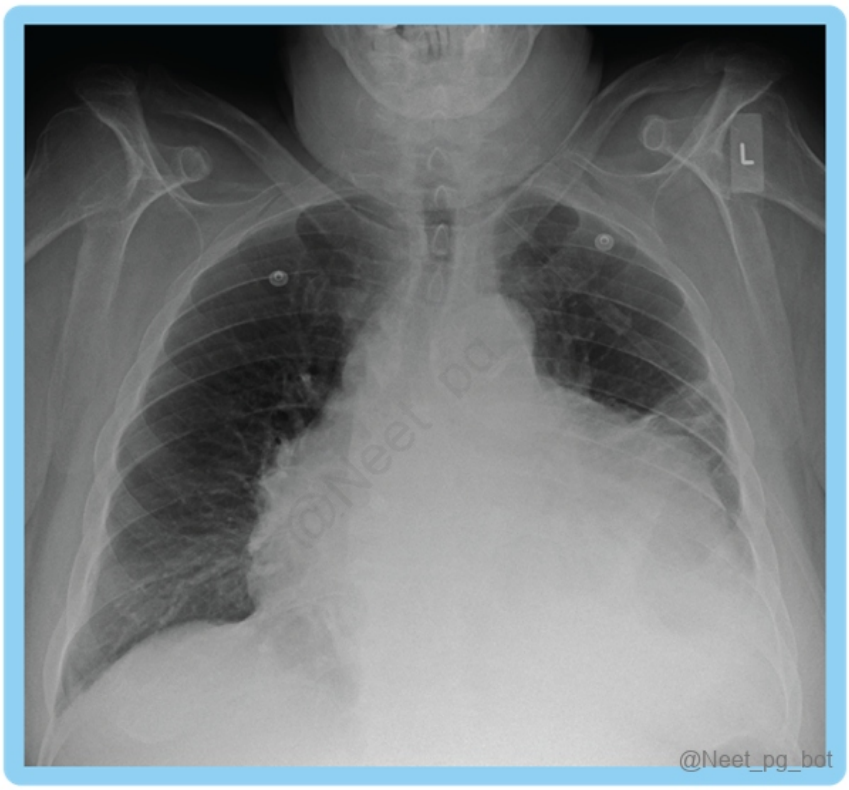
Q38: A 30-year-old man with a past history of tuberculosis now complains of abdominal distension and pedal edema. On examination, his neck veins are prominent. His chest x-ray is given below. Which of the following findings will be seen in this patient? (Q860246)

A. Pulsus bisferiens

B. Kussmaul sign

C. Non pulsatile elevated JVP

D. SBP rises from 80 mmHg to 60 mmHg



Correct Answer: C. Non pulsatile elevated JVP

Explanation: Correct Option C - Non-pulsatile elevated JVP: This patient likely has constrictive pericarditis as a post-tuberculosis complication. Clinical features include ascites, pedal edema, raised non-pulsatile JVP, and prominent neck veins, with pericardial calcification often seen on chest X-ray. The elevated JVP is non-pulsatile due to the rigid pericardium limiting right atrial filling. Incorrect Options: Option A - Pulsus bisferiens: Pulsus bisferiens is seen in hypertrophic obstructive cardiomyopathy or severe aortic regurgitation, not in constrictive

pericarditis Option B - Kussmaul sign: Kussmaul sign (JVP rises on inspiration) may be present in constrictive pericarditis, but it is not universally seen, and the key finding here is non-pulsatile JVP. Option D - SBP rises from 80 mmHg to 60 mmHg: This describes pulsus paradoxus, which is more characteristic of cardiac tamponade, not constrictive pericarditis.

Q39: Which of the following is seen in subclinical acute myocarditis? (Q857252)

A. Palpitations

B. Elevated pro-BNP, Trop T

C. Low LVEF on 2D ECHO

D. Elevated creatinine levels

Correct Answer: B. Elevated pro-BNP, Trop T

Explanation: iomarkers of cardiac injury raised ECG findings suggestive of cardiac injury Abnormal cardiac function on echocardiogram or cardiac MRI Absent Needed Probable acute myocarditis In the clinical context of possible myocardial injury with cardiovascular symptoms and at least one of the following: Biomarkers of cardiac injury raised ECG findings suggestive of cardiac injury Abnormal cardiac function on echocardiogram or cardiac MRI Absent Needed Definite myocarditis Histological or immunohistological evidence of myocarditis Histological or immunohistological evidence of myocarditis Not Needed Options C and D are incorrect as they are not found in subclinical acute myocarditis.

@Neet_pg_bot

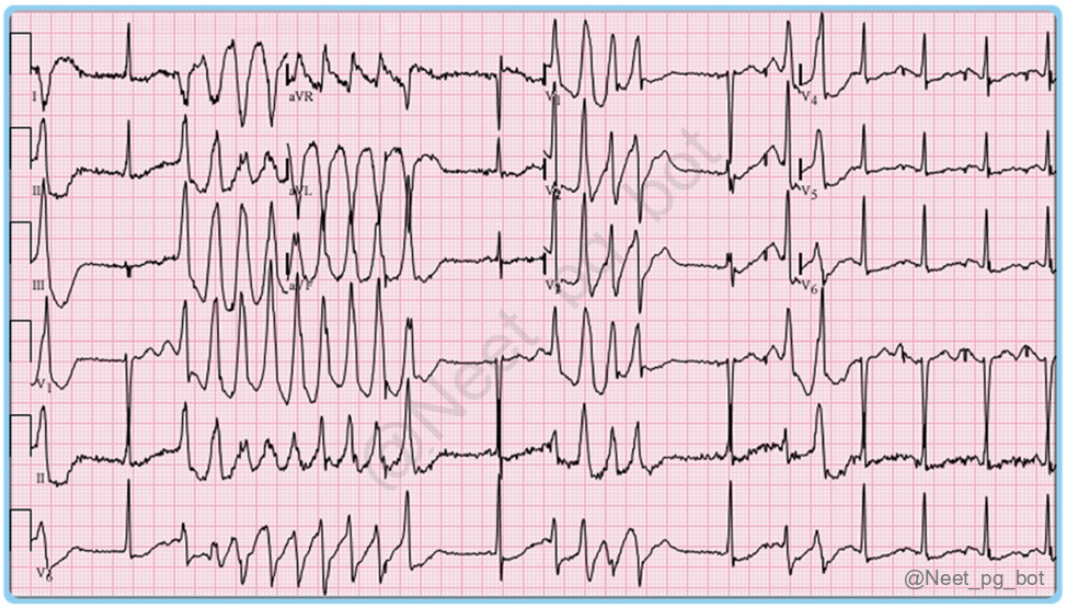
Q41: What does the ECG in the following image depict? (Q857267)

A. Pericarditis

B. Viral myocarditis

C. Torsades de pointes

D. Cardiac tamponade



Correct Answer: C. Torsades de pointes

Explanation: - Torsades de pointes: The polymorphic VT, spindle-shaped pattern, and prolonged QT interval seen in the ECG show the diagnosis of Torsades de Pointes. Torsades de Pointes ECG features : Polymorphic VT : Characterized by variation in QRS direction and amplitude. Spindle-shaped pattern : The QRS complexes form a twisting or spindle-shaped "envelope". {{caption_text}} Prolonged QT interval PVC initiation : Often triggered by a premature ventricular contraction (PVC) on a prolonged T-U wave, creating an "R on T" phenomenon. {{caption_text}} Postectopic pause : A pause following the PVC, further prolonging repolarization. Causes : Mnemonic: "A TIGERS BITE" A - Antiarrhythmics (Class IA and III) T - Tricyclic antidepressants I - Ischemia (myocardial) G - Genetics (congenital long QT syndrome) E - Electrolyte abnormalities (hypokalemia, hypomagnesemia, hypocalcemia) R - Restrictive cardiomyopathy S - Stroke (especially subarachnoid haemorrhage) B - Bradycardia I - Interactions (drug-drug interactions that prolong QT) T - Toxins (organophosphates, arsenic, etc.) E - Endocrine disorders (hypothyroidism, pheochromocytoma) Treatment : Immediate management: Intravenous magnesium sulfate (even if serum magnesium is normal) Discontinue potential QT-prolonging medications Correct electrolyte abnormalities, especially hypokalemia Consider temporary pacing or isoproterenol infusion to increase heart rate and shorten QT interval Acute pericarditis (Option A) shows T-wave inversion following ST-segment elevation in the ECG. Viral myocarditis (Option B) shows prolonged QRS, QT prolongation, diffuse T wave inversion, ventricular arrhythmias, and AV conduction defects in the ECG. Cardiac tamponade (Option D) shows consecutive normally-conducted QRS complexes that alternate in height (electrical alternans) and low QRS voltage with tachycardia in the ECG.

@Neet_pg_bot

Q42: What is the correct order for cardiac auscultation, from superior to inferior? a. Pulmonary b. Tricuspid c. Mitral (Q857280)

A. a > b > c

B. b > a > c

C. c > a > b

D. c > b > a

Correct Answer: A. a > b > c

Explanation: PE to Man) "APE to Man" refers to: Aortic Valve: To listen to the aortic valve closing , place the stethoscope on the right side of the sternum at the 2nd intercostal space . Pulmonary Valve: To listen to the pulmonic valve closing , place the stethoscope on the left side of the sternum at the 2nd intercostal space . Erb's Point (where S2 sound is best heard): Located on the left side at the 3rd intercostal space .

@Neet_pg_bot

Q43: Which of the following jvp findings seen in a patient with muffled heart sounds, hypotension and raised JVP? (Q820395)

A. Absent x descent

B. Absent y descent

C. C waves are enlarged

D. A waves are absent

Correct Answer: B. Absent y descent

Explanation: Correct Option B - Absent y descent: Y descent is the drop in JVP during early diastole when the tricuspid valve opens and blood flows from the right atrium to the right ventricle. In cardiac tamponade, the

elevated pressure in the right atrium due to compression prevents normal descent of the JVP during diastole, leading to an absent y descent. This is the correct finding for the given scenario. Incorrect Options: Option A - Absent x descent: X descent is the drop in JVP during ventricular systole. It's seen in conditions where the right atrium is not excessively obstructed or compressed. In cardiac tamponade, the x descent can actually be exaggerated, not absent. Option C - C waves are enlarged: C waves on the JVP waveform represent the bulging of the tricuspid valve into the right atrium during ventricular contraction. Enlarged C waves are often seen in conditions like tricuspid regurgitation, but they are not specifically associated with the given symptoms of muffled heart sounds, hypotension, and raised JVP. Option D - A waves are absent: A waves correspond to atrial contraction, which occurs just before the tricuspid valve closes. Absent A waves can be seen in conditions like atrial fibrillation or complete heart block, where the atria are not contracting in a coordinated manner. However, absent A waves would not directly explain the combination of symptoms mentioned in the scenario.

@Neet_pg_bot

Q44: Which of the following is correct regarding Wolf Parkinson's white syndrome? (Q820427)

A. Short PJ Interval

B. Broad QRS interval

C. Tall Tented T waves

D. Prolonged PR interval

Correct Answer: B. Broad QRS interval

Explanation: Correct Option B - Broad QRS interval: Wolf-Parkinson-White (WPW) syndrome is a condition in which an abnormal electrical pathway known as an accessory pathway exists between the atria and ventricles of the heart. ECG finding associated with Wolf-Parkinson-White syndrome is a short PR interval and a characteristic broad QRS complex due to the abnormal electrical pathway. The presence of the accessory pathway can lead to a delta wave, which is an initial slurring of the QRS complex, causing it to appear broader than normal. Incorrect Options: Option A - Short PJ Interval: In WPW syndrome, the characteristic finding is a shortened PR interval rather than a short PJ interval. The PR interval represents the time it takes for the electrical signal to travel from the atria to the ventricles. In WPW syndrome, due to the presence of the accessory pathway, the signal bypasses part of the normal conduction system, resulting in a shorter PR interval on an electrocardiogram (ECG). Option C - Tall Tented T Waves: Tall tented T waves are not a typical feature of WPW syndrome. Tall tented T waves are associated with conditions like hyperkalemia (high levels of potassium in the blood) and can be seen in ECGs in those scenarios. Option D - Prolonged PR interval: As mentioned earlier, the PR interval is actually shortened in WPW syndrome due to the accessory pathway bypassing the normal conduction system. A prolonged PR interval

could be indicative of other conditions like first-degree heart block.

@Neet_pg_bot

Q45: The patient presented with pedal oedema, raised JVP till mandible and ascites. What is the most likely diagnosis? (Q820445)

A. Cardiac failure

B. Renal failure

C. Liver failure

D. Brain injury

Correct Answer: A. Cardiac failure

Explanation: Correct Option A - Cardiac failure: The symptoms mentioned - pedal edema, raised jugular venous pressure (JVP) up to the mandible, and ascites - are indicative of congestive heart failure (cardiac failure). Let's go through each option and explain why: Congestive heart failure occurs when the heart's pumping ability is compromised, leading to fluid accumulation in various parts of the body. Pedal edema (swelling in the feet and ankles) occurs due to fluid retention in the lower extremities. Raised JVP is a sign of increased pressure in the veins returning blood to the heart, often observed in heart failure due to the inefficient pumping of blood. Ascites, the accumulation of fluid in the abdominal cavity, can also result from the increased venous pressure caused by heart failure. Incorrect Options: Option B - Renal failure: While renal failure can lead to fluid retention and edema, it typically doesn't cause the specific pattern of JVP elevation and ascites seen in the case. Renal failure might lead to edema and fluid overload, but these symptoms are more directly associated with heart failure in this context. Option C - Liver failure: Liver failure can lead to ascites due to disruptions in fluid balance and decreased production of proteins responsible for maintaining proper fluid distribution. However, the elevated JVP up to the mandible is less likely to be caused by liver failure alone. This sign is more indicative of heart failure. Option D - Brain injury: Brain injury, unless involving specific areas of the brain that control fluid balance, is not a likely cause of the symptoms described. Brain injury might lead to other neurological symptoms, but it wouldn't explain the combination of pedal edema, raised JVP, and ascites.

@Neet_pg_bot

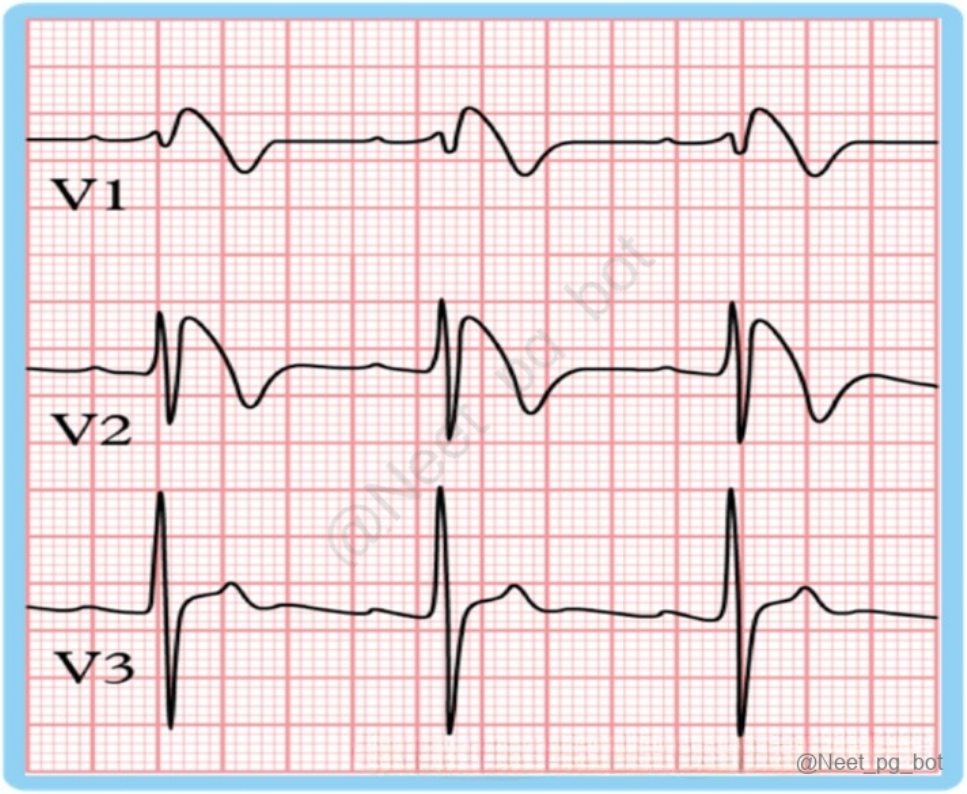
Q47: A 10-year-old boy's father noticed agonal respiration at 5 AM while he was asleep. He was rushed to the ER where an ECG was performed as given. What could be the diagnosis? (Q854656)

A. Early repolarization syndrome

B. Brugada Syndrome

C. Hypertrophic cardiomyopathy

D. Atrial fibrillation



Correct Answer: B. Brugada Syndrome

Explanation: Based on the given scenario and ECG findings (ST elevation in V1-V3), the diagnosis is Brugada Syndrome - a rare, inherited cardiac disorder that predisposes individuals to life-threatening arrhythmias, often occurring during sleep. The presence of agonal respiration at night strongly suggests a ventricular arrhythmia, a hallmark of Brugada Syndrome. Brugada Syndrome About A rare, inherited disease that predisposes patients to potentially fatal cardiac arrhythmias, characterised by right bundle branch block and ST-segment elevations in the right precordial leads (V1-V3) on ECG. Clinical features Symptoms range from asymptomatic to sudden cardiac death, often during sleep. Syncope in 80% of patients with ventricular tachycardia or fibrillation. Other symptoms: Palpitations, dizziness, and fever history may trigger symptoms. ECG findings Type I: Coved ST elevations >2 mm with inverted T wave. Type II: Saddleback-shaped ST elevation >2 mm. Type III: Saddleback-shaped ST elevations <2 mm. Patients with a normal ECG and high-risk factors may need a drug challenge test to reveal ST elevations in leads V1 to V3. {{caption_text}} Drug challenge test Drugs used in the challenge test: Class IA antiarrhythmics (Procainamide, Ajmaline). IC antiarrhythmics (Flecainide, Propafenone). Brugada ECG findings can also emerge from Cocaine use or Tricyclic antidepressant toxicity. Electrolyte abnormalities like Hyperkalemia and Hypercalcemia can reveal ST elevations in the right precordial leads. A normal drug challenge test in pediatric patients may need to be repeated after puberty due to hormonal influences. The "Full Stomach Test" can also help expose ST elevations by increasing vagal tone. Additional diagnostic options include genetic testing for SCN5A mutations and invasive electrophysiology. Treatment Implantable Cardioverter-Defibrillator (ICD) for high-risk patients. Incorrect Options: Early repolarization syndrome (Option A) is a genetic condition presenting with life-threatening arrhythmias and J-point elevation in ECG. This is not the given scenario here. Hypertrophic cardiomyopathy (Option C) is an autosomal dominant cardiac myocyte disease and presents with shortness of breath and chest discomfort. It does not present with agonal respiration at night and is not the given scenario. Atrial fibrillation (Option D) is a type of cardiac arrhythmia that presents with an irregularly irregular rhythm in the ECG. This is not the given ECG picture.

@Neet_pg_bot

Q48: All of the following are the causes of high-output cardiac failure, except? (Q854694)

A. Cor pulmonale

B. Beri Beri

C. Anemia

D. Systemic AV shunt

Correct Answer: A. Cor pulmonale

Explanation: Cor pulmonale is a change in the structure and function of the right ventricle developing as a result of a pulmonary disorder leading to pulmonary hypertension. This is not associated with high-output cardiac failure but with right ventricular hypertrophy. Causes of high-output cardiac failure Category Aetiology Pathophysiology Metabolic Hyperthyroidism Increased thyroid hormone increases contractility, heart rate, and systemic metabolism, causing reduced systemic vascular resistance and eventually cardiomyopathy. Myeloproliferative disorders Increased cellular metabolism and turnover, leading to higher metabolic demand and decreased systemic vascular resistance. Myocardial Sepsis Inflammatory response leads to vasodilation and high cardiac output;

initially hyperdynamic phase with low systemic vascular resistance. Thiamine deficiency (Beriberi) (Option B) Thiamine deficiency causes systemic vasodilation and direct myocardial effects, resulting in high venous return and cardiomyopathy. Chronic lung disease Chronic hypoxia and hypercapnia reduce systemic arterial resistance, causing chronic volume overload and right-sided heart failure. Peripheral vascular Arteriovenous fistulas (AVF) (Option D) Shunt from artery to vein bypasses the arteriolar and capillary bed, increasing venous return to the heart, and requiring increased cardiac output. Liver cirrhosis Impaired clearance of vasoactive substances and bacterial translocation lead to decreased systemic vascular resistance and high-output failure. Obesity Excessive vasodilation due to adipokines and altered myocardial metabolism contribute to high-output cardiac failure. Other Erythroderma Vasoactive changes that may lead to high-output cardiac failure (less defined). Carcinoid syndrome Tumor secretion of vasoactive substances can cause vasodilation and reduced systemic vascular resistance. Mitochondrial disorders Altered cellular metabolism and energy production lead to increased demand and potential high-output failure. Acromegaly Increased growth hormone can lead to increased tissue demand and altered vascular resistance. Paget disease of bone Increased bone turnover leads to AVF formation, contributing to high-output cardiac failure. Conditions Stress, exercise, fever, pregnancy Temporary increases in metabolic demand or vasodilation, though not direct causes of high-output cardiac failure. Anemia (Option C) The attempt to compensate for reduced oxygen delivery by increasing cardiac output leads to high-output cardiac failure later on.

@Neet_pg_bot

Q49: What does the ECG depict in the following image? (Q854707)

A. First-degree heart block

B. Second-degree intra-nodal heart block

C. Complete heart block

D. AV dissociation

Correct Answer: B. Second-degree intra-nodal heart block

Explanation: Given ECG shows progressive lengthening of PR intervals until a dropped beat occurs, which indicates Mobitz type I block, which is a type of second-degree heart block. Second-degree heart block Dropped beats occur because some impulses from the atria fail to be transmitted to the ventricles. Types Mobitz Type I (Wenckebach) Mobitz Type II Description Progressive lengthening of PR intervals until a dropped beat occurs. Cycle repeats itself. {{caption_text}} PR interval remains constant. Some P waves are not conducted. {{caption_text}} Clinical Features Often physiological; can occur in young athletes. May not cause symptoms. Caused by His-Purkinje system disease. Higher risk of asystole. Management Typically does not require treatment. Monitor for changes; consider underlying heart disease. May require treatment if symptomatic. Consider temporary pacing. Monitor closely due to the risk of progression. First-degree heart block (Option A): The PR interval is prolonged but typically not greater than 0.50 seconds, i.e. > 0.20 seconds but < 0.50 seconds. ECG does not show any dropped beat. {{caption_text}} AV dissociation (Option D) is seen in third-degree heart blocks (complete heart block) (Option C) due to complete failure of the conduction between atria and ventricles. {{caption_text}}

@Neet_pg_bot

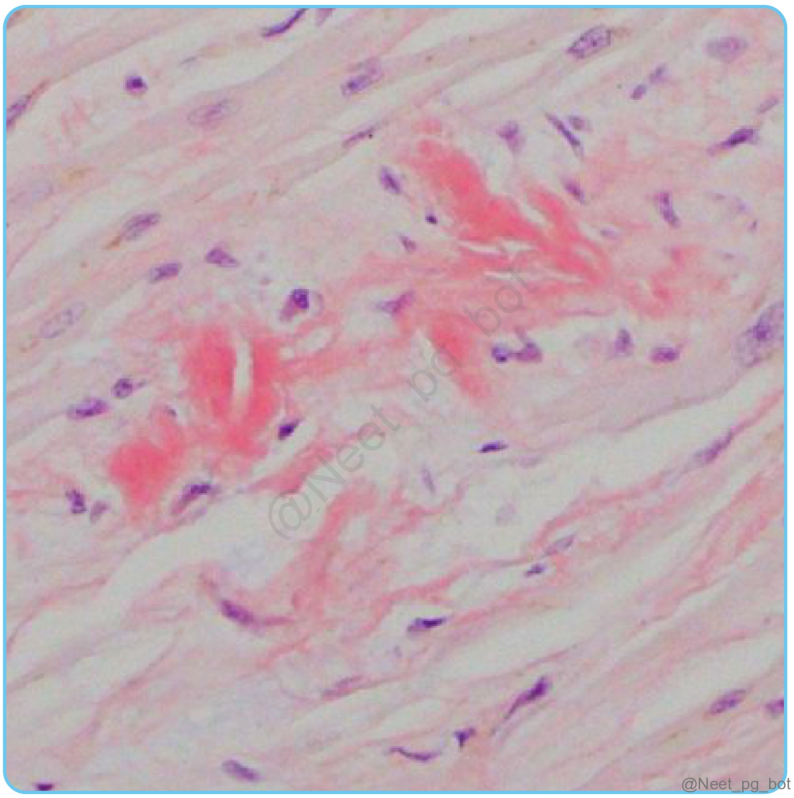
Q50: A 75-year-old woman with Type 2 diabetes mellitus and hypertension, developed features of heart failure and expired. The post-mortem cardiac biopsy slide is given below. What is the likely diagnosis? (Q854713)

A. Dilated Cardiomyopathy

B. Restrictive cardiomyopathy

C. Hypertrophic cardiomyopathy

D. Takotsubo cardiomyopathy



Correct Answer: B. Restrictive cardiomyopathy

Explanation: The image given here is of amyloid deposits (pink hyaline) in the myocardium causing myocardial stiffening and restriction leading to restrictive cardiomyopathy. Restrictive Cardiomyopathy Characterized by abnormal diastolic function, often with mildly reduced contractility and ejection fraction (usually 30–50%). Causes Infiltrative diseases : Amyloidosis (Most common cause) Sarcoidosis Hemochromatosis Fibrotic conditions : Radiation therapy Scleroderma Endomyocardial fibrosis Storage diseases : Glycogen storage diseases (types II, III) Fabry's disease Pathophysiology Abnormal Diastolic Function The primary abnormality in restrictive cardiomyopathy is impaired diastolic filling due to the stiffened ventricular walls. Elevated end-diastolic pressures in both ventricles without significant chamber dilation. Bilateral Atrial Enlargement The non-compliant ventricles lead to increased pressures, resulting in dilation of both atria. Right-Sided Heart Failure The stiff ventricles result in increased filling pressures, particularly affecting the right side, causing peripheral oedema, ascites, and jugular venous distention. Amyloid Infiltration (in amyloidosis) Amyloid fibrils (pink hyaline deposits) accumulate between myocytes, leading to myocardial stiffening and restrictive physiology. {{caption_text}} Cardiac amyloidosis (Congo red stain) Fibrosis In conditions like radiation-induced cardiomyopathy or endomyocardial fibrosis, stiffening of the myocardium occurs due to scarring, further impairing ventricular filling. Dilated cardiomyopathy (Option A) can be due to many causes broadly classified as infective, noninfective, toxic, and metabolic causes. The biopsy shows myocyte shape variation, inflammation, interstitial fibrosis, signs of cardiotoxicity (depending on the cause), etc. This is however not the given scenario. {{caption_text}} Hypertrophic cardiomyopathy (Option C) is a genetic disorder and the histological examination shows enlarged cardiomyocytes with eosinophilic cytoplasm and box-shaped nuclei, normal myocardium in patches, interstitial fibrosis, microvascular ischemia, intercalated discs and desmosomes. {{caption_text}} Takotsubo cardiomyopathy (Option D), or stress cardiomyopathy, is a transient condition characterized by left ventricular apical ballooning often triggered by emotional or physical stress, mimicking acute coronary syndrome without coronary obstruction. The given image does not represent Takotsubo cardiomyopathy.

@Neet_pg_bot

Q51: A 60-year-old diabetic male with central chest pain, shortness of breath and palpitations came to the emergency department. An ECG was taken, which showed NSTEMI. Which of the following is the right treatment? (Q854724)

A. Aspirin + Clopidogrel

B. Aspirin + Statin

C. Aspirin + Clopidogrel + LMWH

D. Aspirin + LMWH

Correct Answer: C. Aspirin + Clopidogrel + LMWH

Explanation: NSTEMI is a form of Non-ST Elevation Acute Coronary Syndrome (NSTE-ACS) caused by partial occlusion of a coronary artery due to a platelet-rich thrombus . Management includes antithrombotic therapy , which consists of: 1. Dual Antiplatelet Therapy (DAPT) Aspirin P2Y12 inhibitor (Clopidogrel / Ticagrelor / Prasugrel) 2. Anticoagulation Low Molecular Weight Heparin (Enoxaparin) or UFH / Fondaparinux ■■■■■■■ Important: Thrombolysis is not indicated in NSTEMI because there is no complete coronary occlusion. ■■■■■■■Aspirin + Clopidogrel (Option A) is incorrect as anticoagulation is also required. Aspirin + Statin (Option B) : Statins are used, but antiplatelet + anticoagulation therapy is essential and prefereed over use of statins. Aspirin + LMWH (Option D) is incorrect as it does not involve a P2Y12 inhibitor (dual antiplatelet therapy required).

@Neet_pg_bot

Q52: Which of the following statements about the culture taken in a suspected case of infective endocarditis is correct? (Q854726)

A. Two samples from peripheral lines 30 minutes apart

B. Three samples from peripheral lines 1 hour apart

C. One sample only from the peripheral line

D. Two peripheral samples, two days apart

Correct Answer: B. Three samples from peripheral lines 1 hour apart

Explanation: The culture taken in a suspected case of infective endocarditis must be by at least 3 blood cultures drawn from separate venipuncture sites over ≥1 hour. Modified Duke’s Criteria - Major criteria Positive blood cultures Identification of a typical organism from two cultures, or persistent positive cultures drawn more than 12 hours apart. At least 3 blood cultures drawn from separate venipuncture sites over ≥1 hour. (Option B) A single positive blood culture for Coxiella burnetii or a phase I IgG antibody titre > 1:800 . Evidence of endocardial involvement Positive echocardiographic findings such as vegetations, abscesses, or new valvular regurgitation. Oscillating intracardiac masses or partial dehiscence of a prosthetic valve. Additional diagnostic tools like FDG-PET/CT or EKG-gated cardiac CT angiograms also meet major criteria for prosthetic valve endocarditis. (Added by the European Society of Cardiology)

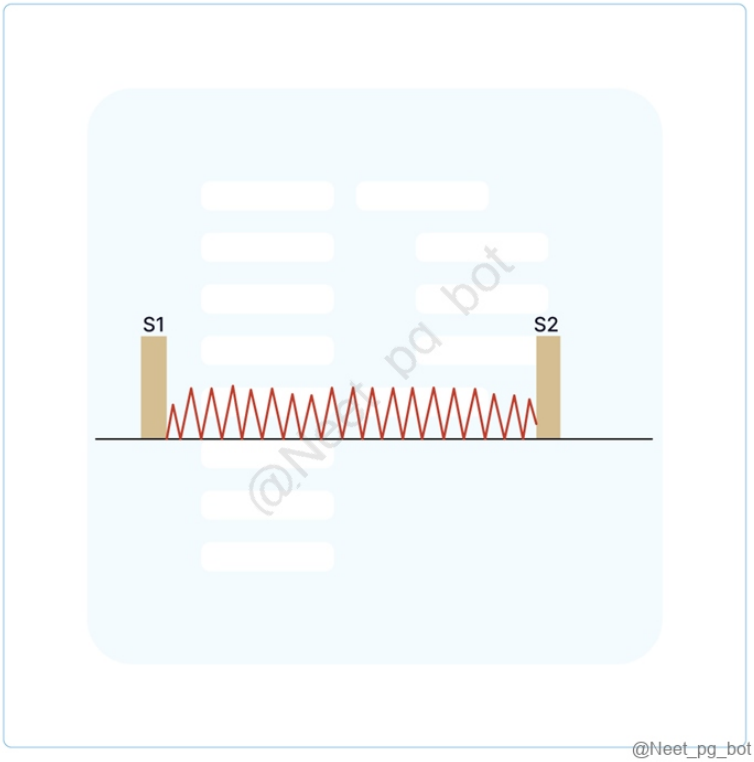
Q53: Identify the condition associated with the murmur depicted in the image below. (Q855412)

A. Mitral Regurgitation

B. Aortic Regurgitation

C. Aortic Stenosis

D. Mitral Stenosis



Correct Answer: A. Mitral Regurgitation

Explanation: Type: Pansystolic murmur. Location: Best heard at the apex, radiates to the axilla. Intensity: Grade II-IV, soft/absent S1 in chronic cases. Dyspnea, fatigue, orthopnea, atrial fibrillation. Aortic Regurgitation (AR) (Option B) Incomplete closure of the aortic valve, causing retrograde flow into LV. Type: Diastolic decrescendo

murmur. Location: Best heard at left sternal border (3rd-4th ICS). Features: High-pitched, decrescendo. Bounding pulses, wide pulse pressure, Water-Hammer pulse, heart failure symptoms. Aortic Stenosis (AS) (Option C) Narrowing of the aortic valve, obstructing LV outflow. Type: Systolic ejection murmur. Location: Best heard at right upper sternal border (2nd ICS), radiates to carotids. Features: Crescendo-decrescendo. Angina, syncope, left ventricular hypertrophy, paradoxical S2 splitting. Mitral Stenosis (MS) (Option D) Narrowing of the mitral valve, obstructing flow from LA to LV. Type: Diastolic rumbling murmur. Location: Best heard at apex in left lateral decubitus position. Features: Low-pitched, with an opening snap after S2. Dyspnea, pulmonary hypertension, right-sided heart failure, atrial fibrillation. Heart Murmurs Definition Abnormal heart sounds caused by turbulent blood flow through valves or cardiac chambers. Classification Systolic Murmurs: Occur between S1 and S2 (e.g., MR, AS). Diastolic Murmurs: Occur between S2 and S1 (e.g., MS, AR). Continuous Murmurs: Occur throughout the cardiac cycle (e.g., PDA). Clinical Assessment Includes murmur timing, intensity, location, radiation, and associated cardiac or systemic features. Grading System (Intensity) Grade I: Barely audible. Grade II: Soft but easily audible. Grade III: Loud without thrill. Grade IV: Loud with a palpable thrill. Grade V: Very loud, audible with edge of stethoscope. Grade VI: Audible without a stethoscope.

@Neet_pg_bot

Q54: A 40-year-old female patient came with complaints of chest pain, palpitation, and shortness of breath. On examination, a mid-diastolic murmur was heard, and a prominent 'a' wave was found on JVP. What is the most likely diagnosis? (Q855479)

A. Mitral stenosis

B. Tricuspid stenosis

C. Mitral regurgitation

D. Tricuspid regurgitation

Correct Answer: B. Tricuspid stenosis

Explanation: The combination of a mid-diastolic murmur and a prominent 'a' wave in the jugular venous pressure (JVP) suggests tricuspid stenosis (TS). The mid-diastolic murmur, which can also occur in mitral stenosis, is best heard along the left sternal border and over the xiphoid process, increasing during inspiration due to enhanced venous return. The prominent 'a' wave in JVP is a result of increased right atrial pressure, which impedes right atrial emptying during diastole, creating a giant 'a' wave. ECG findings typically show right atrial enlargement, with tall, peaked P waves in leads II, III, and aVF. Type Cause Features of Murmur Associated Symptoms JVP Findings Aortic Regurgitation (AR) Incomplete closure of the aortic valve, causing retrograde flow into LV. Type: Diastolic decrescendo murmur. Location: Best heard at left sternal border (3rd-4th ICS). Features: High-pitched,

decrescendo. Bounding pulses Wide pulse pressure Water-Hammer pulse Heart failure symptoms. Normal or minimally elevated JVP unless associated with heart failure. Aortic Stenosis (AS) Narrowing of the aortic valve, obstructing LV outflow. Type: Systolic ejection murmur. Location: Best heard at right upper sternal border (2nd ICS), radiates to carotids. Features: Crescendo-decrescendo. Angina Syncope Left ventricular hypertrophy Paradoxical S2 splitting. Normal JVP unless severe. Mitral Regurgitation (MR) (Option C) Incomplete closure of the mitral valve, causing backflow from LV to LA. Type: Pansystolic murmur. Location: Best heard at the apex, radiates to the axilla. Intensity: Grade II-IV, soft/absent S1 in chronic cases. Dyspnea Fatigue Orthopnea Atrial fibrillation. Elevated JVP, prominent V wave due to regurgitant flow. Mitral Stenosis (MS) (Option A) Narrowing of the mitral valve, obstructing flow from LA to LV. Type: Diastolic rumbling murmur. Location: Best heard at apex in left lateral decubitus position. Features: Low-pitched, with an opening snap after S2. Dyspnea Pulmonary hypertension Right-sided heart failure Atrial fibrillation. Elevated JVP with prominent "a" wave due to increased atrial pressure. Tricuspid Regurgitation (TR) (Option D) Incomplete closure of the tricuspid valve, causing backflow into the right atrium. Type: Pansystolic murmur. Location: Best heard at the lower left sternal border. Features: Holosystolic, blowing murmur. Hepatomegaly Ascites Edema Right-sided heart failure. Elevated JVP with prominent "v" wave due to backflow into the right atrium. Tricuspid Stenosis (TS) Narrowing of the tricuspid valve, obstructing flow from RA to RV. Type: Diastolic murmur. Location: Best heard at the lower left sternal border. Features: Low-pitched rumbling murmur. Fatigue Hepatomegaly Ascites Peripheral edema. Elevated JVP with prominent "a" wave due to increased atrial pressure.

@Neet_pg_bot

Q55: A patient who is a known case of hypertension on multiple antihypertensive medications came to the OPD. His ECG finding is given below. Which of the following drugs is responsible for the ECG finding? (Q855489)

A. Prazosin

B. Metoprolol

C. Hydrochlorothiazide

D. Spironolactone

Correct Answer: D. Spironolactone

Explanation: The ECG finding of tall, peaked T waves suggests hyperkalemia. Among the listed medications, spironolactone is the drug most likely to cause hyperkalemia. Mechanism of Spironolactone: Spironolactone is a potassium-sparing diuretic. It works by blocking the mineralocorticoid receptor in the distal tubule and collecting duct of the kidneys, which inhibits sodium reabsorption and potassium excretion. As a result, it promotes sodium diuresis but retains potassium, potentially leading to hyperkalemia. ECG Changes in Hyperkalemia: Tall, peaked T waves are a classic ECG finding in hyperkalemia. As the potassium level rises, it affects the ST-T segments and can lead to changes in repolarization. Serum Potassium Level (mEq/L) ECG Changes 5.5–6.5 Tall, peaked T waves 6.5–7.5 Loss of P waves 7.0–8.0 Widened QRS complex > 8.0 Sine wave pattern {{caption_text}} Prazosin (Option A): This is an alpha-1 antagonist used in the treatment of hypertension and does not commonly cause hyperkalemia. Metoprolol (Option B): This is a beta-blocker used for hypertension and cardiovascular issues. It does not typically cause hyperkalemia. Hydrochlorothiazide (Option C): This is a thiazide diuretic, which actually promotes potassium loss and would more likely cause hypokalemia rather than hyperkalemia.

@Neet_pg_bot

Q56: A patient presents with dyspnea and distended neck veins that increase on inspiration. There is no murmur. What is the diagnosis? (Q858032)

A. Constrictive pericarditis

B. Aortic regurgitation

C. Tricuspid stenosis

D. Pulmonary arterial hypertension

Correct Answer: A. Constrictive pericarditis

Explanation: onstrictive Pericarditis: Pathophysiology: Progressive thickening, fibrosis, and calcification of the pericardium restrict heart filling. Calcification can extend into the myocardium, impairing myocardial contraction. Restricted ventricular filling leads to elevated atrial pressures, causing: Atrial hypertrophy Atrial dilation Atrial fibrillation (common). Primarily manifests as systemic venous congestion (lung congestion is rare). Examination Findings: Finding Description Elevated JVP with rapid y descent Reflects rapid early diastolic filling of the right ventricle due to pressure gradient. atigue Caused by the heart's inability to meet circulatory demands. Rapid, low-volume pulse Restricted filling limits stroke volume, weakening the pulse. Pericardial knock A loud early S3 from the thickened pericardium during diastolic filling. Kussmaul's sign Paradoxical rise in JVP during inspiration. Hepatomegaly Liver enlargement due to i ncreased venous pressure. Ascites Abdominal fluid accumulation due to systemic venous congestion. Peripheral oedema Swelling in the extremities from fluid retention. Pulsus paradoxus A fall in systolic BP (10mm Hg) during inspiration, potentially impalpable pulse. Atrial fibrillation Common due to atrial hypertrophy and dilation. Aortic regurgitation (Option B) typically presents with a characteristic diastolic murmur, which is absent in this case. Additionally, aortic regurgitation does not cause increased neck vein distention with inspiration. Tricuspid stenosis (Option C) presents with elevated jugular venous pressure, but also includes a diastolic murmur and does not demonstrate Kussmaul's sign. The jugular venous pressure in tricuspid stenosis remains constant or decreases with inspiration. Pulmonary arterial hypertension (Option D) can cause increased jugular venous pressure but does not demonstrate Kussmaul's sign. While it can cause right-sided heart failure symptoms, the characteristic inspiratory increase in neck vein distention is not a typical feature.

@Neet_pg_bot

Q57: Which of the following drugs reduce mortality in a patient with heart failure? (Q858361)

A. Metoprolol

B. Furosemide

C. Prazosin

D. Torsemide

Correct Answer: A. Metoprolol

Explanation: aptopril, Enalapril ARBs: Telmisartan, Olmesartan ARNI: ARB+Neprilysin inhibitor - Valsartan-Sacubitril (most preferred 1st line drug) ADR: Cough, angioedema Beta-blockers Cardioselective (2nd gen): Metoprolol, Bisoprolol 3rd gen: Carvedilol (both α- & β- blocking action) - Best beta blocker for heart failure ADR: Bradycardia, Hypotension SGLT-2 Inhibitors Dapagliflozin, Empagliflozin ADR: UTI, Forunier gangrene, Euglycemic DKA Aldosterone antagonists Spironolactone ADR: Gynaecomastia Furosemide (Option B): While furosemide is commonly used in heart failure for symptom relief and fluid management, it has not been shown to reduce mortality in heart failure patients. It primarily helps manage congestion and improve symptoms but does not affect the underlying disease progression or survival. Prazosin (Option C) : Although prazosin is an alpha-blocker that can reduce afterload, clinical trials have not demonstrated mortality benefit in heart failure patients. In fact, alpha-blockers may increase the risk of heart failure worsening due to their vasodilatory effects and reflex sympathetic activation. Torsemide (Option D) : Similar to furosemide, torsemide is a loop diuretic that helps manage fluid overload and symptoms in heart failure but has not been proven to reduce mortality. While it may have better bioavailability than furosemide, neither medication has shown a survival benefit in clinical trials.

@Neet_pg_bot

Q58: A 65-year-old man with known lung cancer presents with acute shortness of breath and chest discomfort. On examination, percussion over the left infrascapular area is dull, and breath sounds are markedly decreased. He has hypotension, tachycardia, elevated JVP, and muffled heart sounds. What is the most likely diagnosis? (Q793802)

A. Cardiac tamponade

B. Chronic constrictive pericarditis

C. Pulmonary embolism

D. Left-sided pleural effusion

Correct Answer: A. Cardiac tamponade

Explanation: Correct answer : A) Cardiac tamponade Cardiac tamponade occurs when rapid accumulation of pericardial fluid compresses the heart and leads to obstructive shock . Key clinical signs: Beck's triad: Hypotension Elevated JVP (non-pulsatile) Muffled heart sounds Pulsus paradoxus (>10 mmHg fall in SBP during inspiration) Dullness + decreased breath sounds (left infrascapular area): Pericardial effusion from tumor encroachment can cause adjacent lung compression → basal dullness. This combination of respiratory distress + shock + muffled heart sounds strongly suggests tamponade . Chronic constrictive pericarditis (Option B): Chronic, stable condition with Kussmaul's sign, not acute shock. Pulmonary embolism (Option C): Lungs usually clear, percussion normal, and no Beck's triad → not tamponade. Left-sided pleural effusion (Option D): Causes dullness and ↓ breath sounds, but no hypotension, no muffled heart sounds, no JVP rise → not tamponade.

@Neet_pg_bot

Q59: Identify the conduction abnormality from the ECG given below? (Q855705)

A. First degree heart block

B. Ventricular tachycardia

C. Third degree heart block

D. Second degree heart block

Correct Answer: D. Second degree heart block

Explanation: Given ECG shows progressive lengthening of PR intervals until a dropped beat occurs, which indicates Mobitz type I block . It can be further classified into two types: Mobitz Type I (Wenckebach) - is characterized by a progressive prolongation of the PR interval until a beat is dropped Mobitz Type II - involves intermittent blocked beats without progressive PR interval prolongation. First-degree heart block (Option A) is characterized by a prolonged PR interval on the ECG. It indicates a delay in the electrical conduction between the atria and ventricles. Ventricular tachycardia (Option B) is a rapid heart rhythm originating from the ventricles. On the ECG, it appears as a wide QRS complex with a heart rate exceeding 100 beats per minute. Third-degree heart block (complete heart block) (Option C) is a severe conduction abnormality characterised by atrioventricular dissociation.

@Neet_pg_bot

Q60: A 45-year-old patient with suspected mitral stenosis is found to have a soft or absent first heart sound on auscultation. Which of the following conditions is least likely to cause a soft or absent S1? (Q855710)

A. Severe mitral valve calcification

B. Aortic regurgitation

C. First degree heart block

D. Advanced mitral stenosis

Correct Answer: B. Aortic regurgitation

Explanation: : Prolonged PR interval delays ventricular contraction, allowing mitral leaflets to drift partially closed, producing a softer S1. Advanced mitral stenosis (Option D): In severe disease, leaflet stiffness can decrease mobility and soften or abolish S1 ; mild disease usually produces a loud S1.

@Neet_pg_bot

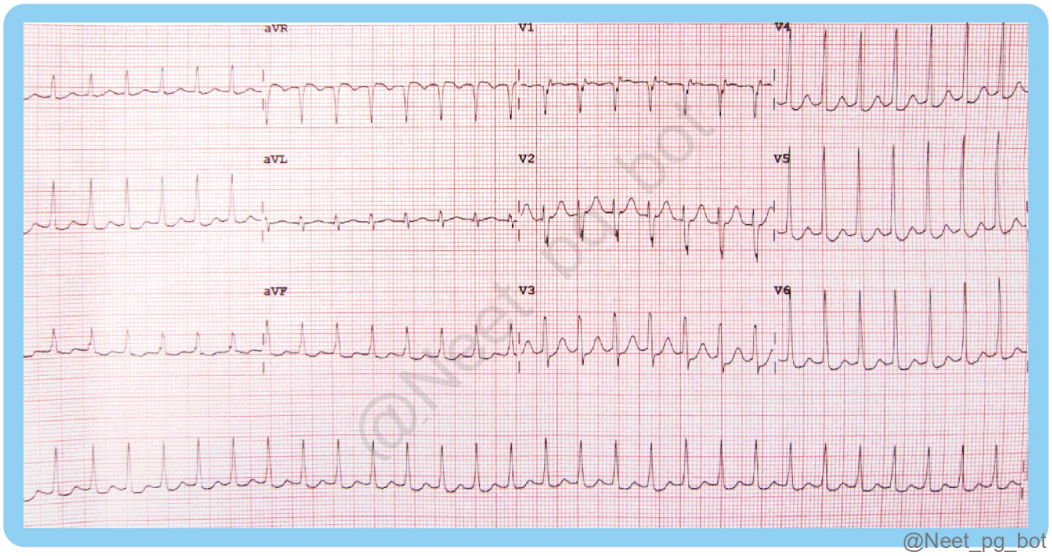
Q61: Which of the following is the initial treatment of choice for managing the condition in a female patient who comes to the hospital with palpitations, having stable vital signs and an ECG showing the following? (Q855330)

A. Amiodarone

B. Adenosine

C. DC cardioversion

D. Primary PCI



Correct Answer: B. Adenosine

Explanation: Adenosine is the first-line management of the presented condition. The ECG pattern shown suggests Paroxysmal SupraVentricular Tachycardia (PSVT) , a common arrhythmia characterized by rapid heart rates originating above the ventricles. Adenosin e is a potent vasodilator and affects the electrical conduction system of the heart. It activates specific receptors in the heart, particularly the adenosine A1 receptors, which help to slow

down the conduction through the AV node. This interruption of the abnormal electrical pathway in SVT can restore normal sinus rhythm. Paroxysmal Supraventricular Tachycardia (PSVT): Signs and Symptoms: Sudden onset of rapid, regular palpitations Dizziness or lightheadedness Shortness of breath Chest discomfort or pressure Anxiety Fatigue In severe cases: syncope, hypotension, or heart failure symptoms ECG Findings: Regular, narrow-complex tachycardia (QRS duration <120 ms) Reduced R-R interval Heart rate between 150-250 bpm P waves often not visible or buried in T waves {{caption_text}} Common types include: a) AV Nodal Reentrant Tachycardia (AVNRT): Retrograde P waves may appear as pseudo R' in V1 or pseudo S in inferior leads b) AV Reentrant Tachycardia (AVRT): Retrograde P waves may be visible after the QRS complex Management: Acute termination: Vagal maneuvers (e.g., Valsalva, carotid sinus massage) If vagal maneuvers fail, IV adenosine is the first-line pharmacological treatment: 6 mg - 12mg fast iv push. Alternative drugs: verapamil, diltiazem, or beta-blockers Synchronized cardioversion for hemodynamically unstable patients Long-term management: Catheter ablation: Often curative, especially for AVNRT and AVRT Pharmacological therapy: Beta-blockers or calcium channel blockers for prevention Class IC or III antiarrhythmic drugs in selected cases Patient education on performing vagal maneuvers Lifestyle modifications Avoid triggers (e.g., caffeine, alcohol, stress) Regular exercise Adequate sleep Amiodarone (Option A) is used to treat Stable Monomorphic Ventricular tachycardia. DC Cardioversion (Option C) is used to treat Atrial flutter, Atrial fibrillatio.n Primary PCI (Option D) is used to treat acute myocardial infarctio.n

@Neet_pg_bot

Q62: A patient with heart disease has breathlessness when going to the bathroom. What grade does he belong to? (Q855360)

A. NYHA 3

B. NYHA 4

C. mMRC 4

D. mMRC 5

Correct Answer: A. NYHA 3

Explanation: NYHA 3 indicates moderate symptoms. Patients classified as NYHA 3 experience symptoms such as marked limitation of physical activity, becoming symptomatic with less than ordinary activity (such as going to the bathroom) and having no symptoms at rest. NYHA functional classification assesses the impact of heart disease on a patient's daily activities. NYHA 4 (Option B) indicates severe symptoms. Patients classified as NYHA 4 experience symptoms even at rest and are unable to carry out any physical activity without discomfort. The mMRC (Option C) dyspnea scale is used to assess dyspnea (shortness of breath) in patients with respiratory conditions. mMRC 4 indicates severe dyspnea, where patients become too breathless to leave the house or experience significant discomfort even while at rest. mMRC 5 (Option D) is not a standard category in the MMRC dyspnea scale. The scale typically ranges from 0 to 4, with 0 indicating no dyspnea and 4 indicating the most severe dyspnea.

↑ *Back to this question in Part A*

@Neet_pg_bot

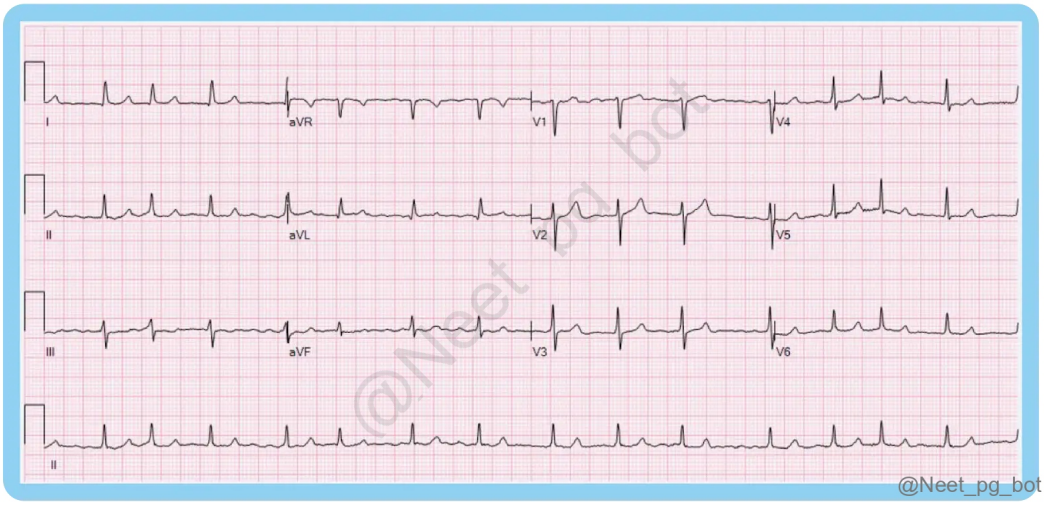
Q63: Based on the ECG given below, which of the following is not used in the management of the condition? (Q855364)

A. Verapamil

B. Metoprolol

C. Amiodarone

D. Non-synchronised DC shock



Correct Answer: D. Non-synchronised DC shock

Explanation: ECG is suggestive of atrial fibrillation a s there is an irregularly irregular rhythm and absent P waves with narrow QRS complexes are present. In atrial fibrillation, synchronised DC shock/cardioversion can be used. Nonsynchronised DC shock (Defibrillation) is not used in the management of these patients. Verapamil (Option A) can be used in the management of patients with atrial fibrillation. Metoprolol (Option B) can be used in the management of patients with atrial fibrillation. Amiodarone (Option C) can be used in the management of patients with atrial fibrillation.

@Neet_pg_bot

Q64: Which of the following foods is not included in the DASH diet? (Q857042)

A. Rich in potassium

B. Rich in calcium

C. Rich in sodium

D. Rich in magnesium

Correct Answer: C. Rich in sodium

Explanation: The DASH diet (Dietary Approaches to Stop Hypertension) recommends limiting the intake of sodium, as high sodium consumption is associated with increased blood pressure. The DASH diet suggests reducing the use of table salt and avoiding processed foods that are typically high in sodium, such as fast food, canned soups, and salty snacks. DASH-type dietary plan: A diet rich in fruits, vegetables, and low-fat dairy products with reduced saturated and total fat content. Diet is also rich in potassium (Option A), calcium (Option B), and magnesium (Option D) . DASH Diet Originated in the 1990s through NIH-funded research, found to lower systolic BP by 6-11 mm Hg. It promotes fruits, vegetables, lean meats, and low sodium (~1500 mg/day) and encourages fresh, minimally processed food. Key Nutrients in DASH diet: Carbohydrates: Whole grains, legumes, leafy greens. Fats: Healthy fats (olive oil, nuts, omega-3 fish), avoid trans fats. Proteins: Plant-based proteins preferred, lean meats, low-fat dairy. Electrolytes: Potassium: Helps lower BP, prevents muscle cramps, and supports heart function. Sources: bananas, oranges, spinach, beans. Sodium: DASH limits sodium to ~1500 mg/day to reduce hypertension risk. Calcium: Essential for bone health and muscle function. Sources: dairy, leafy greens. Magnesium: Aids blood vessel relaxation and BP control. Sources: whole grains, nuts, seeds. Clinical Significance of DASH diet: Lowers BP, blood glucose, LDL, triglycerides, and insulin resistance. Helps with metabolic syndrome, diabetes, and heart failure. Linked to reduced risk of colorectal cancer, liver disease, and celiac disease. Reduces hospitalization and mortality in heart failure patients. Meets ADA recommendations for diabetes management.

@Neet_pg_bot

Q65: A patient has presented with features of cardiac tamponade. Which of the following is correct regarding this condition? (Q857043)

A. Pulsus Paradoxus is always present

B. Kussmaul sign is always present

C. Tall A wave is present

D. Jugular veins column is visibly distended without pulsations

Correct Answer: D. Jugular veins column is visibly distended without pulsations

Explanation: Cardiac tamponade refers to the accumulation of fluid in the pericardial sac, which puts pressure on the heart and impairs its ability to pump effectively. Jugular veins column distending without pulsations is a characteristic finding in cardiac tamponade. Due to the increased pressure in the pericardial sac, the jugular veins become visibly distended, but the normal pulsations with each heartbeat are diminished or absent. Cardiac Tamponade Definition A condition where the cardiac chambers are compressed by a tense pericardial effusion, limiting cardiac inflow. Fluid accumulation of as little as 200 ml to upwards of 2L may lead to cardiac tamponade development. Beck's triad Jugular Venous Distension: Due to increased central venous pressure. Prominent x descent and an absent y descent. Hypotension : Resulting from impaired cardiac output. Muffled Heart Sounds : Caused by fluid accumulation in the pericardial space, dampening heart sounds. Other Clinical features Pulsus Paradoxus : A drop in systolic BP during inspiration, greater than 10 mm Hg. It is present in most of the conditions but not always (Option A) and can vary depending on the severity of tamponade and other factors. Causes of Pulsus paradoxus: Lung Conditions: Acute asthma, COPD, tension pneumothorax, pleural effusion, pulmonary embolism. Heart Conditions: Cardiac tamponade, constrictive pericarditis. Kussmaul sign refers to an abnormal rise in jugular venous pressure during inspiration. It is not specific to cardiac tamponade (Option B) and can be seen in various cardiac and respiratory conditions. It is not always present in cardiac tamponade. The A wave represents atrial contraction on the jugular venous pulse waveform. In cardiac tamponade, the elevated pressure in the pericardial sac can impair atrial filling, leading to a reduced or absent A wave rather than a tall A wave (Option C).

@Neet_pg_bot

Q66: What is the clinical diagnosis for a young male who has no symptoms but is found to have a wide fixed split S2 during auscultation? (Q857046)

A. ASD

B. VSD

C. TOF

D. BAV

Correct Answer: A. ASD

Explanation: A wide fixed split S2 on auscultation is a characteristic finding in atrial septal defects (ASD), where there is abnormal communication between the atria. It allows increased blood flow from the left atrium to the right atrium, causing a delay in the closure of the pulmonic valve, resulting in a wide fixed split S2. Types of S2 split Conditions causing split Narrow split S2 Mild Left Ventricular Failure Early Aortic Stenosis wide split fixed S2 Atrial Septal Defect (ASD) Wide split variable S2 Ventricular Septal Defect (VSD) Right Bundle Branch Block (RBBB) Paradoxical split S2 Left Bundle Branch Block Severe Aortic Stenosis Atrial Septal Defect: Congenital, low-pressure, left to right shunt. The right ventricle will have volume overloading. Types of ASD: Ostium Secundum (most common), Ostium Primum, Sinus Venosus On auscultation: Wide fixed split S2 sound Chest x-ray: May show enlarged right atrial and right ventricular enlargement and increased pulmonary markings Transthoracic echocardiogram: Gold standard imaging modality, helps to detect size and assess the direction of blood flow. A ventricular septal defect (Option A) is another type of congenital heart defect where there is an abnormal opening in the septum between the two ventricles. It typically produces a harsh holosystolic murmur, rather than a wide fixed split S2 heard on auscultation. Tetralogy of Fallot (Option C) is a congenital heart condition characterized by a combination of four heart defects: ventricular septal defect, pulmonary stenosis, right ventricular hypertrophy, and overriding aorta. The characteristic murmur in TOF is a systolic ejection murmur and not specifically associated with a wide fixed split S2. Bicuspid Aortic Valve (Option D) can be associated with aortic stenosis or regurgitation, it is not specifically associated with a wide fixed split S2.

@Neet_pg_bot

Q67: Which of the following is contraindicated in a patient with Wolff–Parkinson–White (WPW) syndrome presenting with atrial fibrillation? (Q857052)

A. Treadmill test

B. Electrophysiological studies

C. Oral beta blocker

D. Procainamide

Correct Answer: A. Treadmill test

Explanation: Wolff–Parkinson–White (WPW) syndrome is a ventricular pre-excitation syndrome caused by an accessory pathway (Bundle of Kent) that bypasses the AV node, allowing rapid conduction from atria to ventricles. In WPW with atrial fibrillation , impulses can be conducted rapidly to the ventricles through the accessory pathway, predisposing to ventricular fibrillation and sudden cardiac death . Beta blockers are AV nodal–blocking agents . In WPW with atrial fibrillation, AV nodal blockade: Slows AV node conduction Favors rapid conduction via the accessory pathway Increases the risk of ventricular fibrillation Hence, beta blockers are contraindicated in this setting. Option-wise

@Neet_pg_bot

Q68: Which of the following is not correct about Defibrillation? (Q857055)

A. Only be used by a trained person

B. Decrease in success rate with delay in initiation

C. Improve prognosis

D. 1 minute gap between 2 shocks

Correct Answer: D. 1 minute gap between 2 shocks

Explanation: A 1-minute gap between 2 shocks is incorrect, as defibrillation should be delivered without delay to maximize the chances of successful resuscitation. Defibrillation: Indications: Ventricular fibrillation (VF) Pulseless ventricular tachycardia (VT) Personnel Involved: Defibrillation is typically performed by medical personnel trained in Advanced Cardiac Life Support (ACLS) or Pediatric Advanced Life Support (PALS). (Option A) Preparation: Resuscitation (CPR) continues while preparing the defibrillator. Once available, the defibrillator should be used immediately , taking precedence over other measures. Defibrillation Technique: Manual defibrillator paddles or hands-free defibrillator pads are placed on the chest (right sternal border and cardiac apex, or in anteroposterior configuration). The defibrillator is charged and set to the manufacturer's recommended initial energy level (120-200 joules for biphasic defibrillators, 360 joules for monophasic). A shock is delivered after confirming no one is in contact with the patient. Post-Defibrillation: CPR is resumed immediately for 2 minutes after the shock. The pulse and rhythm are checked to assess if VF or pulseless VT has been terminated. If VF or VT persists, defibrillation is repeated, with increasing energy as per guidelines. Medications During Resuscitation: Epinephrine (1 mg IV every 3-5 minutes) should be given after the first unsuccessful shock. Amiodarone (300 mg IV bolus) may be administered if VT or VF persists, with additional doses (150 mg) as needed. Lidocaine can be used in place of amiodarone in some cases, but epinephrine and amiodarone are preferred. Clinical Significance: Early defibrillation increases the chances of survival in VF . After 10 minutes of VF, the chances of successful resuscitation decrease significantly. (Option B & C) Contraindications: There are no contraindications for defibrillation in the presence of VF or pulseless VT.

@Neet_pg_bot

Q69: Modified duke criteria are used for diagnosis of? (Q857066)

A. Infective endarteritis

B. Infectious mononucleosis

C. Inflammatory myopathy

D. Infective endocarditis

Correct Answer: D. Infective endocarditis

Explanation: Modified duke criteria are used for diagnosis of infective endocarditis. Modified Duke Criteria (2023 update): I. Definite Endocarditis: A. Pathologic Criteria 1. Microorganisms identified in the context of clinical signs of active endocarditis in a vegetation from cardiac tissue; from explanted prosthetic valve or sewing ring; from ascending aortic graft (with concomitant evidence of valve involvement); from an endovascular intra cardiac implantable electronic device (CIED) or from an arterial embolus OR 2. Active endocarditis in the same above mentioned locations. Microorganisms identified in appropriate sample by PCR, amplicon or metagenomic sequencing, or in situ hybridization B. Clinical Criteria (mentioned below) 1. 2 Major Criteria OR 2. 1 Major and 3

Minor Criteria OR 3. 5 Minor Criteria II. Possible Endocarditis: A. 1 Major Criterion and 1 Minor Criterion OR B. 3 Minor Criteria III. Rejected Endocarditis: A. Firm alternate diagnosis explaining signs/symptoms OR B. Lack of recurrence despite antibiotic therapy for only < 4 days OR C. No pathologic/macroscopic evidence of IE at surgery or autopsy with antibiotic therapy for less than 4 days OR D. Does not meet criteria of possible IE Clinical Criteria I. Major Criteria A. Microbiologic Major Criteria (i) Positive blood cultures Microorganisms that commonly cause IE isolated from 2 or more separate blood culture sets OR Microorganisms that occasionally or rarely cause IE isolated from 3 or more separate blood culture sets (ii) Positive laboratory tests Positive polymerase chain reaction (PCR) or other nucleic acid-based technique for Coxiella burnetii , Bartonella species, or Tropheryma whipplei from blood OR Coxiella burnetii antiphase I immunoglobulin G (IgG) antibody titer > 1:800 or isolated from a single blood culture OR Indirect immunofluorescence assays (IFA) for IgM and IgG antibodies to Bartonella henselae or Bartonella quintana with IgG titer ≥ 1:800 B. Imaging Major Criteria (i) Echocardiography and cardiac computed tomography (CT) imaging Echocardiography and cardiac CT showing vegetation, valve/leaflet perforation, valve/leaflet aneurysm, abscess, pseudoaneurysm, or intracardiac fistula OR Significant new valvular regurgitation on echocardiography as compared with previous imaging. Worsening or changing of preexisting regurgitation is not sufficient OR New partial dehiscence of prosthetic valve as compared with previous imaging. (ii) 18F-FDG PET/CT imaging Abnormal metabolic activity involving a native or prosthetic valve, ascending aortic graft (with concomitant evidence of valve involvement), intracardiac device leads, or other prosthetic material C. Surgical Major Criteria Evidence of IE documented by direct inspection during heart surgery neither Major Imaging Criteria nor subsequent histologic or microbiologic confirmation II. MINOR CRITERIA A. Predisposition Previous history of IE Prosthetic valve Previous valve repair Congenital heart disease More than mild regurgitation or stenosis of any etiology Endovascular intracardiac implantable electronic device (CIED) Hypertrophic obstructive cardiomyopathy Intravenous drug use B. Fever Temperature greater than 38.0°C C. Vascular Phenomena Clinical or radiological evidence of arterial emboli, septic pulmonary infarcts, cerebral or splenic abscess, mycotic aneurysm, intracranial hemorrhage, conjunctival hemorrhages, Janeway lesions, purulent pericardium D. Immunologic Phenomena Positive rheumatoid factor, Osler nodes, Roth spots, or immune complex-mediated glomerulonephritis E. Microbiologic Evidence (Falling Short of Major Criterion) Positive blood cultures for a microorganism consistent with IE but not meeting the requirements for Major Criterion OR Positive culture, PCR, or other nucleic acid-based test (amplicon or shotgun sequencing, in situ hybridization) for organisms consistent with IE from a sterile body site other than cardiac tissue, cardiac prosthesis, or arterial embolus F. Imaging Criteria Abnormal 18F-FDG PET/CT within 3 months of implantation of prosthetic valve G. Physical Examination Criteria New valvular regurgitation identified on auscultation if echocardiography is not available.

@Neet_pg_bot

Q70: Which of the following indicators shall be seen with use of a small-sized BP cuff? (Q857069)

A. False elevation of BP

B. Falsely low value of BP

C. Cancels the effects of calcified arteries

D. Increases trans arm impedance

Correct Answer: A. False elevation of BP

Explanation: False elevation of BP is observed when using a small-sized blood pressure cuff. Errors in Blood Pressure Measurement Due to Improper Cuff Size: Cuff Too Narrow: Overestimates blood pressure. Applies excessive pressure to a smaller area, leading to falsely high readings. Cuff Too Wide: Underestimates blood pressure. (Option B) Distributes pressure over a larger area, resulting in falsely low readings. Importance of Proper Cuff Size: Ensures accurate blood pressure measurement. Avoids misdiagnosis of hypertension or hypotension. Cancels the effects of calcified arteries (Option C): A small-sized BP cuff does not negate the effects of calcified arteries. While arterial calcification can lead to inaccurate BP measurements, using the correct cuff size is essential for obtaining accurate readings. Increases trans-arm impedance (Option C): A small-sized BP cuff does not directly increase trans-arm impedance. Trans-arm impedance refers to resistance encountered in certain BP measurement techniques, but it is not specifically affected by cuff size.

@Neet_pg_bot

Q71: Elderly male patient has presented with recurrent falls. Which of the following medicines is responsible? (Q857070)

A. Prazocin

B. Metformin

C. Acarbose

D. Thiazide

Correct Answer: A. Prazocin

Explanation: Prazosin is an alpha-1 adrenergic antagonist that can cause orthostatic hypotension and syncope, leading to an increased risk of falls, particularly in elderly patients. Prazosin: Quinazoline derivative that acts as competitive alpha-1 adrenergic receptor antagonist Mechanism of Action: Alpha-1 adrenergic receptor antagonist

Smooth muscle relaxation → ↓ systemic vascular resistance → ↓ blood pressure Affects various tissues (blood vessels, prostate, urethra, iris dilator muscle, brain) Crosses the blood-brain barrier → contributes to cognitive effects (basis for PTSD use) Metabolism: Hepatic (via CYP450 enzymes) Half-life: ~2.5 hours (prolonged in chronic renal failure and congestive heart failure) Uses: FDA-approved Indication: Hypertension (alone or in combination with other antihypertensives) but not a first-line agent. Non-FDA-approved Indication: Benign prostatic hyperplasia (BPH) Post-traumatic stress disorder (PTSD)-associated nightmares Raynaud phenomenon Pheochromocytoma Scorpion envenomation Adverse Effects: Serious Adverse Effects: First-dose hypotension (recommend initial dose at bedtime) Orthostatic hypotension Syncope Intraoperative Floppy Iris Syndrome (IFIS) Priapism Common Adverse Effects: Dizziness Headache Drowsiness Lack of energy Weakness Palpitations Nausea Metformin (Option B) is used for managing type 2 diabetes. While it may cause gastrointestinal side effects like nausea and diarrhea, it does not directly contribute to falls. Acarbose (Option C) is an alpha-glucosidase inhibitor used to manage diabetes by delaying carbohydrate absorption. It can cause gastrointestinal issues but does not lead to falls. Thiazide (Option D) diuretics can sometimes cause orthostatic hypotension, especially in elderly patients, but this side effect is less common and less pronounced compared to prazosin, which is more strongly associated with orthostatic hypotension and falls.

@Neet_pg_bot

Q72: What is the waist to hip ratio that is associated with an increased risk of heart disease? (Q857072)

A. > 0.80 in males

B. > 0.80 in females

C. > 0.85 in males

D. > 0.85 in females

Correct Answer: D. > 0.85 in females

Explanation: The waist to hip ratio that is associated with an increased risk of heart disease is > 0.85 in females. Waist-to-Hip Ratio: Waist-to-hip ratio is a more accurate measure of obesity-related cardiovascular risk than BMI, with specific cut-offs of 0.83 for women and 0.9 for men significantly increasing the risk for myocardial infarction. Physicians should prioritize measuring waist-to-hip ratio, along with waist circumference, to assess cardiovascular risk, particularly in specific ethnic groups. Reducing abdominal obesity and increasing hip circumference, potentially through muscle mass development, may reduce cardiovascular risk.

@Neet_pg_bot

Q73: Best management of a hemodynamically stable patient with ECG showing Broad QRS complex with antidromic tachycardia is? (Q857074)

A. Oral verapamil

B. Oral Beta-blocker

C. Cardioversion

D. Intravenous Procainamide

Correct Answer: D. Intravenous Procainamide

Explanation: Intravenous procainamide is the best management for a hemodynamically stable patient with broad QRS complex antidromic tachycardia, as it terminates the arrhythmia by slowing conduction through the accessory pathway. Atrioventricular Reentrant Tachycardia (AVRT): AVRT is a type of supraventricular tachycardia that occurs in patients with an accessory pathway, such as in Wolff-Parkinson-White (WPW) syndrome. Pathology: AVRT involves a reentrant circuit that includes the normal AV conduction system and the accessory pathway. Two types exist: Orthodromic AVRT (more common): Conduction travels down the AV node and up the accessory pathway. Antidromic AVRT (less common): Conduction travels down the accessory pathway and up the AV node. ECG Features: Orthodromic AVRT: Narrow QRS complex tachycardia (QRS < 120 ms) Regular rhythm with heart rates typically 150-250 bpm Retrograde P waves often visible in the ST segment or early T wave Antidromic AVRT: Wide QRS complex tachycardia (QRS > 120 ms) Regular rhythm with heart rates typically 170-240 bpm Retrograde P waves may be obscured by the wide QRS AVRT can be initiated by premature atrial or ventricular complexes that block one pathway and conduct through the other, setting up the reentrant circuit. Management: Acute Termination of Orthodromic AVRT: Stable patients: Start with vagal maneuvers (Valsalva or carotid sinus massage). If unsuccessful: IV adenosine (first-line pharmacologic treatment), IV verapamil, IV procainamide or IV beta-blockers. Acute Termination of Antidromic AVRT: If confirmed, avoid AV nodal blockers (adenosine, beta-blockers , verapamil , digoxin). (Option A & B) IV procainamide is the preferred treatment. Cardioversion (Option D): Reserved for hemodynamically unstable patients; unnecessary in a stable patient where pharmacologic management with IV procainamide is effective.

Q74: What is the diagnosis for a 23-year-old female who has been experiencing fever for the past week and displays the following rhythm on the monitor? {{caption_text}} (Q857095)

A. Atrial fibrillation

B. Atrial flutter

C. Supra ventricular tachyarrhythmia

D. Ventricular tachyarrhythmia

Correct Answer: A. Atrial fibrillation

Explanation: The given image shows Atrial fibrillation Atrial fibrillation is a cardiac rhythm disorder characterized by rapid, irregular electrical impulses in the atria. This results in a rapid and irregular ventricular response, leading to an irregular heart rate on the monitor. {{caption_text}} Atrial flutter (Option B): typically appears as a regular, sawtooth pattern on the monitor, rather than the irregular pattern seen in this case. {{caption_text}} Supraventricular tachyarrhythmia (Option C): is a broad term that encompasses various rapid heart rhythms originating from above the ventricles. It includes conditions like atrial fibrillation, atrial flutter, and other supraventricular tachycardias. While atrial fibrillation is a type of supraventricular tachyarrhythmia, it is more specific than the general term used in this option. {{caption_text}} Ventricular tachyarrhythmia (Option D): refers to abnormal rapid rhythms that originate in the ventricles. This rhythm disorder is characterized by a wide QRS complex on the monitor, unlike the narrow QRS complex typically seen in atrial fibrillation.

@Neet_pg_bot

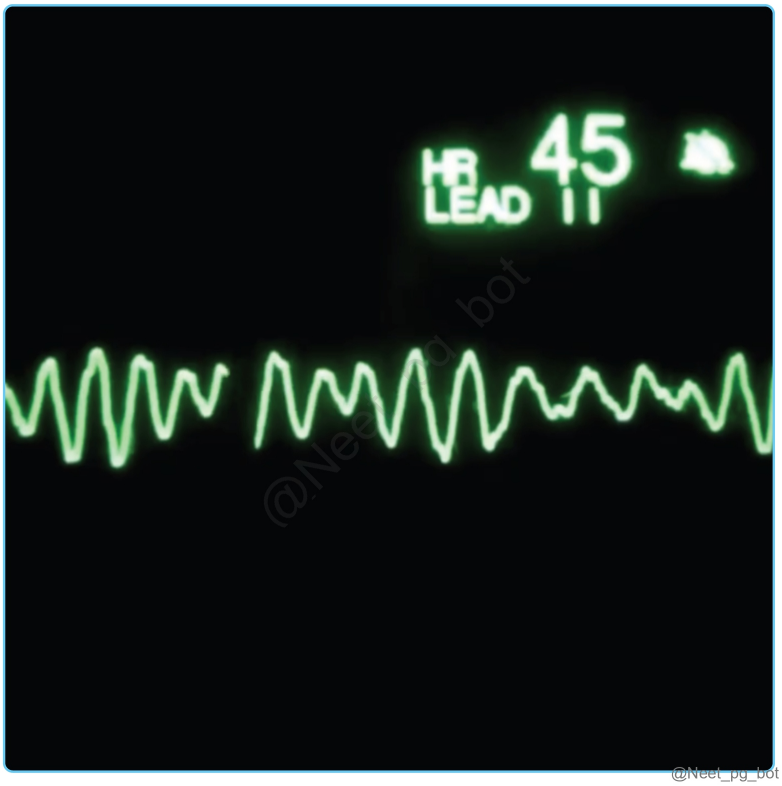
Q75: An intern observed that a patient in the ward was unresponsive, and an ECG which was performed urgently showed a rhythm as depicted below. DC shock was delivered but the arrhythmia persisted and the patient is still unresponsive. What is the next best step in the management of this patient? (Q857615)

A. Synchronized cardioversion

B. Start CPR

C. Deliver another DC shock

D. 1 mg epinephrine



Correct Answer: B. Start CPR

Explanation: The ECG shows ventricular fibrillation (VF) —a shockable cardiac arrest rhythm. The patient is unresponsive and persistent VF continues even after a defibrillation attempt. According to ACLS guidelines , after a shock: Immediate next step is to start CPR for 2 minutes. Defibrillation must always be followed by CPR , because coronary and cerebral perfusion must be restored while the myocardium recovers. Synchronized cardioversion (Option A): Not used for VF. Cardioversion requires an organized QRS, which VF does not have. Deliver another DC shock (Option C): Shocks must be alternated with 2-minute CPR cycles, not delivered back-to-back. 1 mg epinephrine (Option D): Epinephrine is given after 2 minutes of CPR following the second shock , not immediately after the first shock. ■■■■■■■Management of Shockable (VT/ V Fib) Conditions: Immediate Recognition Identify Shockable Rhythm: Recognize VF or pulseless VT. Activate Emergency Response: Call for advanced life support. ↓ Initiate CPR Start High-Quality CPR: Perform chest compressions at a rate of 100-120/min, with a depth of 5-6 cm. Continue CPR for 2 minutes. ↓ Defibrillation After 2 minutes of CPR, deliver a Non-Synchronized DC Shock to restore normal rhythm. If no change, administer a second shock immediately. ↓ Continue CPR Resume CPR for 2 Minutes Place an intravenous or intraosseous line for drug administration. ↓ Administer Epinephrine Epinephrine 1 mg (1:10,000): Given IV/IO after 2 minutes of CPR to enhance coronary perfusion pressure. ↓ Advanced Airway Management Secure Airway: Perform endotracheal intubation if necessary. Capnography: Monitor end-tidal CO2 levels. Ventilation: Provide 1 breath every 6 seconds post-intubation. ↓ Further Defibrillation Third Shock: If VF or pulseless VT persists, deliver a third non-synchronized shock. Continue CPR for 2 More Minutes: Follow with additional CPR. ↓ Administer Antiarrhythmic Medication Amiodarone 300 mg IV: Administer for shock-refractory VT to stabilize heart rhythm. ↓ Identify and Treat Reversible Causes

@Neet_pg_bot

Q76: Pulsus paradoxus is seen in: (Q857626)

A. Coronary artery disease

B. Severe Asthma or Chronic Obstructive Pulmonary Disease

C. Atrial Fibrillation

D. Right ventricular myocardial infarction

Correct Answer: B. Severe Asthma or Chronic Obstructive Pulmonary Disease

Explanation: Pulsus paradoxus is an ominous sign in a patient with obstructive lung disease, as it is associated with significant negative intrathoracic (pleural) pressures, affecting venous return to the heart and causing a drop in systolic blood pressure during inspiration. During severe asthma attacks or exacerbations of COPD, airway resistance increases significantly during inspiration and significant rise in negative intrathoracic pressure. Pulsus Paradoxus Definition: A fall in systolic blood pressure >10 mmHg during inspiration. Pathophysiology: Exaggerated interventricular dependence → Increased right ventricular filling during inspiration shifts the septum leftward, reducing left ventricular output and causing a more pronounced drop in systolic pressure. Associated Conditions: Pericardial tamponade (classic association) External pressure on the heart limits filling Inspiration compresses the RV, preventing normal inspiratory RV filling Interventricular septum shifts left, restricting LV filling and output → Marked fall in BP Massive pulmonary embolism Hemorrhagic shock Severe obstructive lung disease (e.g., asthma, COPD) Tension pneumothorax Effusive Constrictive Pericarditis Restrictive Cardiomyopathy Measurement: Auscultatory method: Identify the systolic pressure during expiration and independent of respiration. The difference between these two is the pulsus paradoxus . If the difference exceeds 15 mmHg, pulsus paradoxus may be palpable at the brachial or femoral artery. Tachycardia, atrial fibrillation, tachypnea will make it difficult to measure. Respiratory Changes in Cardiac Output, Blood Pressure, and Pulse Rate: Physiological Changes with Respiration: Inspiration: ↓ Intrathoracic pressure → ↑ Venous return to the right heart ↑ Right ventricular (RV) output ↑ Pulmonary vascular capacitance → Blood is sequestered in the lungs, reducing flow to the left heart ↓ Left ventricular (LV) output → ↓ Blood pressure (BP) Expiration: ↓ Venous return to the right heart → ↓ RV output ↑ Venous return to the left heart → ↑ LV output → ↑ BP

@Neet_pg_bot

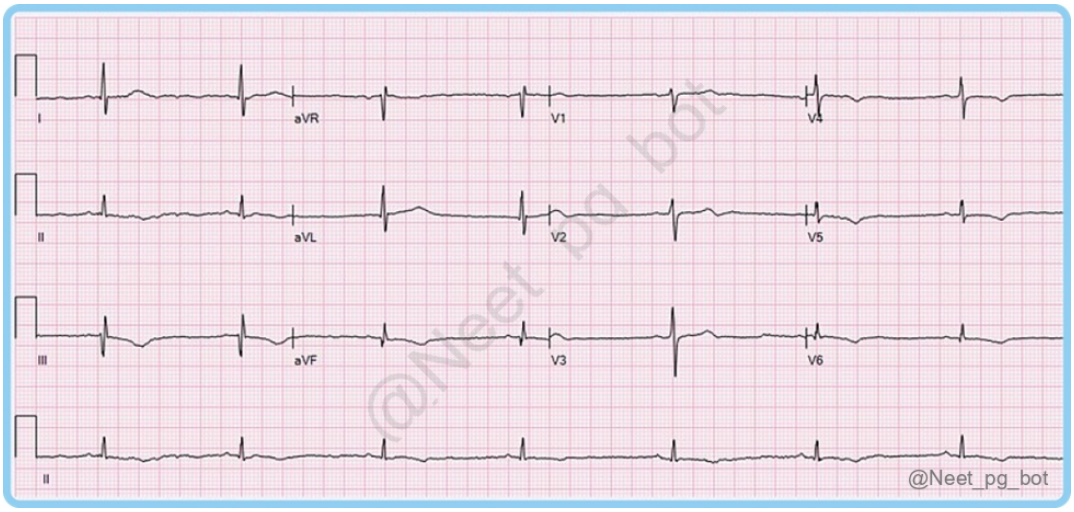
Q77: A 64-year-old man presents with complaints of palpitations and syncope. He has a history of inferior-wall myocardial infarction a year ago. Holter study was done and his 24 hour ECG strip obtained is given below. What is the long-term treatment for this condition? (Q857641)

A. Amiodarone

B. Atropine only

C. Permanent pacemaker

D. Atropine and isoproterenol



Correct Answer: C. Permanent pacemaker

Explanation: The 24-hour ECG strip suggests the presence of sinus node dysfunction (sick sinus syndrome) characterized by bradycardia (slow heart rate), pauses, and sinus arrests. This condition is commonly seen in individuals who have had a previous myocardial infarction. Long-term treatment for this would be a "Permanent pacemaker." Sinus bradycardia Definition Sinus bradycardia is a cardiac rhythm with normal sinus node depolarization but a rate < 60 bpm. Diagnostic Criteria ECG showing sinus rhythm at a rate lower than 60 bpm. Common Etiologies Normal in athletes Medications (beta-blockers, calcium channel blockers, digoxin) Hypothyroidism, hypothermia Sick sinus syndrome, myocardial infarction Vagal stimulation (e.g., vasovagal syncope) Clinical Features Asymptomatic (in many patients) Fatigue Dizziness or lightheadedness Exercise intolerance Syncope or presyncope Cognitive slowing Worsening angina or heart failure symptoms Evaluation Assess hemodynamic stability ECG to confirm sinus rhythm Review medication list for bradycardic agents Evaluate for comorbidities (e.g., hypothyroidism, myocardial infarction) Management If Hemodynamically Unstable: IV atropine 0.5 mg every 3-5 minutes (max 3 mg) If there is no improvement, consider a temporary pacemaker If Stable, for long term mamagement: Treat underlying causes Withdraw bradycardia-inducing medications Permanent pacemaker Amiodarone (Option A) is an antiarrhythmic medication used to treat various

cardiac arrhythmias. However, it is not the primary treatment for sinus node dysfunction. Atropine only (Option B) is a medication used for acute management of symptomatic bradycardia. It is used only in emergency situations or as a temporary measure before definitive treatment such as a pacemake r is implemented. Isoproterenol is a medication that acts as a cardiac stimulant and can increase heart rate. While it may be used in certain acute situations , it is not an appropriate long-term treatment for sinus node dysfunction. Additionally, combining atropine and isoproterenol (Option D) is not a typical approach for managing this condition.

@Neet_pg_bot

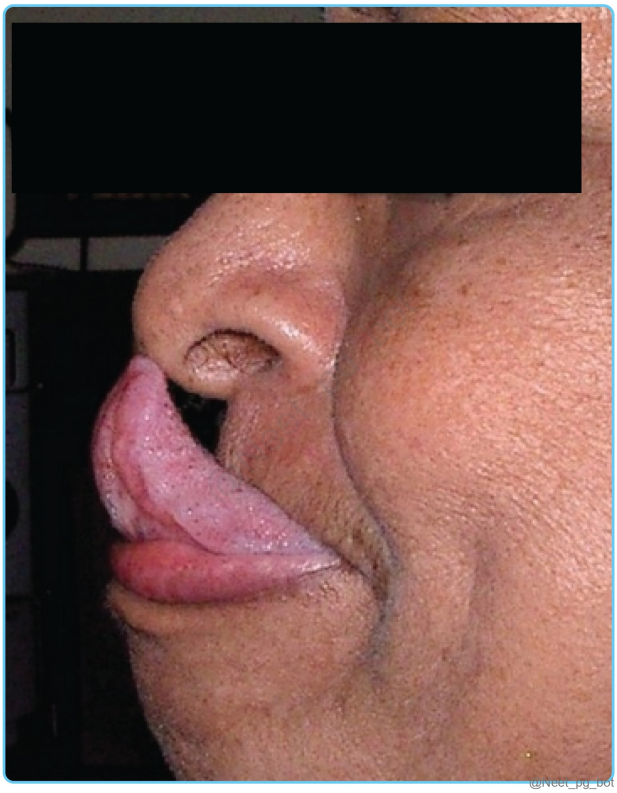
Q78: A 5 year old child has flexible fingers and can even touch the back of his hand with his wrist extended. The child also demonstrates the sign shown in the image below. On auscultation, a click is heard after S1, followed by a late systolic murmur. What is the probable diagnosis? (Q857653)

A. Ehlers-Danlos syndrome

B. Marfan’s syndrome

C. Loeys-Dietz syndrome

D. Osteogenesis imperfecta



Correct Answer: A. Ehlers-Danlos syndrome

Explanation: Hypermobility of joint, the ability to touch the back of the hand with the wrist extended, tongue to nose sign (Gorlin's sign) and auscultatory findings of mitral valve prolapse suggests that this could be Ehlers-Danlos syndrome (EDS) which is a genetic disorders that affects the connective tissues and shows various systemic manifestations, primarily involving the skin, joints, and blood vessels. Ehlers-Danlos Syndrome (EDS): Genetically heterogeneous connective tissue disorders Common features: Skin: Soft, hyperextensible , fragile, slow healing, atrophic scars Joints: Hypermobility, subluxations, chronic pain Vascular fragility: Risk of arterial & organ rupture in some types Gorlin's sign is seen Classification: 13 clinical types (linked to 20 genes) Common mutations: COL1A1, COL1A2, COL3A1, COL5A1, COL5A2 Major EDS Types & Features: Type Gene Key Features Classical (cEDS) COL5A1, COL5A2 Hyperextensible skin, atrophic scars, joint hypermobility Vascular (vEDS) COL3A1 Thin skin, visible veins, arterial/organ rupture, Hypermobile (hEDS) Unknown Joint hypermobility , chronic pain, POTS, mitral valve prolapse Kyphoscoliotic PLOD1, FKBP14 Severe scoliosis, hypotonia, vascular rupture Arthrochalasia COL1A1, COL1A2 Congenital hip dislocation, severe joint hypermobility Dermatosparaxis ADAMTS2 Severe skin fragility, sagging skin, large hernias Periodontal C1R, C1S Severe gum disease, tooth loss, vascular fragility Diagnosis: Clinical criteria + genetic testing (except hEDS) hEDS diagnosed using: Modified Beighton Score ≥4 Arthralgia in ≥4 joints Differential diagnoses: Marfan syndrome Osteogenesis Imperfecta Loeys-Dietz syndrome Management: EDS is a diverse group of connective tissue disorders with no cure, requiring symptom-based management and specialized care. Multidisciplinary care Musculoskeletal: Physiotherapy, braces, joint protection Vascular monitoring (for vEDS) Low-impact exercise (swimming, walking) Avoid high-impact sports (gymnastics, weightlifting) Emergency preparedness (MedicAlert, ER protocol for vEDS) Psychological support for chronic pain & genetic diagnosis

@Neet_pg_bot

Q79: Which of the following is the most appropriate position for placement of single lead pacemaker ? (Q857654)

A. Right ventricle

B. Left atrium

C. Left ventricle

D. Superior vena cava

Correct Answer: A. Right ventricle

Explanation: The pacemaker lead is typically placed in the right ventricle for most pacemaker implantations. This positioning allows the electrical impulses generated by the pacemaker to be delivered to the right ventricle, which then stimulates the heart muscle to contract and maintain an appropriate heart rhythm. Pacemakers of the Heart: Natural Pacemaker sites and their depolarization rates: Sinoatrial node: 60 to 100 beats per minute Atria: less than 60 beats per minute Atrioventricular node: 40 to 60 beats per minute Ventricles: 20 to 40 beats per minute Artificial Pacemaker: An artificial pacemaker is a small battery-operated device that helps regulate the heart's rhythm by producing electrical impulses. It typically consists of three parts: a generator, leads (wires), and sensors (electrodes). Traditional pacemakers are implanted under the skin, usually on the chest just below the collarbone or in the stomach area, and they connect to the heart through tiny wires. There are several types of traditional pacemakers: Single-lead pacemakers: One lead is placed in the right ventricle. Dual-lead pacemakers: One lead is placed in the right atrium and one in the right ventricle. Biventricular pacemakers (CRT): Three leads are used, placed in the right atrium, right ventricle, and left ventricle. Wireless pacemakers are smaller and consist of a pulse generator and electrodes in one device. They are implanted inside the heart through a catheter inserted via internal jugular or femoral or subclavian vein, sending impulses to the right ventricle without the need for traditional surgery. {{caption_text}}

@Neet_pg_bot

Q80: What is the most probable diagnosis for a female patient, aged 65, who visits the outpatient department with symptoms of breathlessness and fatigue? During examination, the patient's neck veins were engorged, and her jugular venous pulse displayed a swift X and Y descent. (Q857667)

A. Constrictive pericarditis

B. Cardiac tamponade

C. Dilated cardiomyopathy

D. Restricted cardiomyopathy

Correct Answer: A. Constrictive pericarditis

Explanation: The most likely diagnosis is constrictive pericarditis. Constrictive pericarditis is a condition characterized by inflammation and fibrosis of the pericardium, the sac-like structure surrounding the heart. It leads to the stiffening of the pericardium, impairing the normal filling and functioning of the heart. Constrictive Pericarditis: Progressive inflammation, thickening, fibrosis, and calcification of the pericardium restrict heart filling. Calcification can extend into the myocardium, impairing myocardial contraction. Restricted ventricular filling leads to elevated atrial pressures, causing: Atrial hypertrophy Atrial dilation Atrial fibrillation (common). Primarily manifests as systemic venous congestion (lung congestion is rare). Examination Findings: Finding Description Elevated JVP with rapid y descent Reflects rapid early diastolic filling of the right ventricle due to pressure gradient. Fatigue Caused by the heart's inability to meet circulatory demands. Rapid, low-volume pulse Restricted filling limits stroke volume, weakening the pulse. Pericardial knock A loud early S3 from the thickened pericardium during diastolic filling. Kussmaul's sign Paradoxical rise in JVP during inspiration. Hepatomegaly Liver enlargement due to i ncreased venous pressure. Ascites Abdominal fluid accumulation due to systemic venous congestion. Peripheral oedema Swelling in the extremities from fluid retention. Pulsus paradoxus A fall in systolic BP (10mm Hg) during inspiration, potentially impalpable pulse. Atrial fibrillation Common due to atrial hypertrophy and dilation. Cardiac tamponade (Option B): Typically presents with elevated JVP, but it shows a prominent X descent and an absent Y descent (due to impaired filling), not rapid X and Y descents. Dilated cardiomyopathy (Option C): This condition generally presents with signs of heart failure and an elevated JVP, but the JVP waveform does not typically show rapid X and Y descents. Restrictive cardiomyopathy (Option D): This condition can present with symptoms similar to constrictive pericarditis, but it usually has a slow Y descent in the JVP rather than a rapid one.

@Neet_pg_bot

Q81: A 35 year old female patient with fever and malar rashes was found to have vegetations on either side of the heart valves. What can be the diagnosis of the patient? (Q857674)

A. Infective endocarditis

B. Libman sacks endocarditis

C. Rheumatic Heart Disease

D. None of the above

Correct Answer: B. Libman sacks endocarditis

Explanation: A 35 year old female presents with fever and malar rashes suggests that this could be systemic lupus erythematosus (SLE) and the cardiac involvement of SLE shows Libman-Sacks endocarditis (LSE) . Libman-Sacks endocarditis is a form of nonbacterial endocarditis (also known as nonbacterial thrombotic endocarditis) that is commonly associated with systemic lupus erythematosus (SLE). It is characterized by the presence of small, sterile vegetations on both sides of the heart valves, particularly the mitral and aortic valves. Systemic Involvement in SLE System Manifestations Pulmonary system Pleuritis (most common): Prevalence (30 - 50%) Pneumonitis Atelectasis Reduced lung volume and Pulmonary ■brosis Shrinking lung syndrome, (< 5%) Intra-alveolar hemorrhage Pulmonary HTN (< 5 %) (Option C) Acute Respiratory Distress Syndrome (ARDS) (< 5%) Musculoskeletal system It is the most commonly involved system Polyarthritis (symmetrical) Polyarthralgia Rheumatoid arthritis Myositis Jaccoud arthropathy is a reversible deformity caused by ligament laxity, capsule fibrosis, and muscular imbalance. Axial skeletal involvement is uncommon. {{caption_text}} Renal system Lupus nephritis (most common) Proteinuria Nephrotic syndrome Rarely End-stage Renal Disease (ESRD) Nervous system Headache, Seizures, Stroke, Polyneuropathy, TIA, Acute confusional state, Movement disorder, Aseptic meningitis, Myelopathy, Psychosis and Mood disorders. Cardiovascular system Coronary artery disease - common cause of death Pericarditis Coronary vasculitis Myocarditis Libman sacks endocarditis Accelerated atherosclerosis Hematological manifestations Anemia of chronic disease Leucopenia Lymphopenia Thrombocytopenia Autoimmune Hemolytic anemia-MCC of anemia in SLE Splenomegaly GI involvement Abdominal pain Nausea, diarrhoea Abnormal liver enzymes Ocular manifestation Sicca syndrome: Dry eyes (keratoconjunctivitis sicca) and dry mouth (xerostomia). Conjunctivitis Episcleritis Vasculitis While infective endocarditis (Option A) can also cause vegetations on the heart valves, the presence of malar rashes suggests an autoimmune condition like SLE rather than an infectious etiology.

@Neet_pg_bot

Q82: PR segment in ECG indicates: (Q857686)

A. Atrial depolarization

B. Atrioventricular nodal conduction

C. Ventricular depolarization

D. Ventricular repolarization

Correct Answer: B. Atrioventricular nodal conduction

Explanation: The PR segment represents the period of atrioventricular nodal conduction in the cardiac cycle. Component Cause Normal Duration and Size P wave Atrial depolarization is initiated by the SA node. (Option A Ruled Out) 0.08–0.11 seconds 2–2.75 small boxes <2.5 mm (0.25 mV) in amplitude/ height <0.12 sec (120 msec or 3 small boxes) in width PR interval Time from onset of atrial depolarization (P wave) to onset of ventricular depolarization (electrical impulse passing through AV node) (Option B) 0.12–0.20 seconds 3–5 small boxes Q wave Initial depolarization of the interventricular septum, directed from left to right. <0.04 seconds <1 small box Depth: <1/4 of R wave or ~1–2 mm (<0.5 small boxes) QRS complex Ventricular depolarization - the time taken for the electrical impulse to spread through the ventricles. (Option C Ruled Out) <0.10 seconds <2.5 small boxes in width Height: 5–30 mm (1–6 big boxes) QT interval Time from the start of ventricular depolarization to the end of ventricular repolarization. Duration depends on HR. HR inversely proportional QT length. Rate-corrected (QTc) 330–350 msec ~11 small boxes ST segment Represents the early part of ventricular repolarization. It is isoelectric (flat). (Option D Ruled Out) 0.08–0.12 seconds 2–3 small boxes Normally isoelectric (flat), deviations >1 small box indicate pathology T wave Represents the later stage of ventricular repolarization. <0.04 seconds 2.5–6.25 small boxes Height: Varies. Normally <5 mm (1 big box) in limb leads, <10 mm (2 big boxes) in precordial leads U wave Unknown origin; possibly related to repolarization of Purkinje fibers or ventricular walls. Not always measurable {{caption_text}}

@Neet_pg_bot

Q83: Most sensitive and specific marker for MI is? (Q857691)

A. Troponin

B. Cytokeratin

C. Myoglobin

D. CPK-MM

Correct Answer: A. Troponin

Explanation: Troponin as the most sensitive and specific biomarker for myocardial infarction (MI). Troponin is a regulatory protein complex found specifically in cardiac muscle tissue. It begins to rise within 3-6 hours of injury, peaks at 24-48 hours, and can remain elevated for 7-10 days, providing a wide diagnostic window. Cardiac troponins (cTnI and cTnT) have nearly absolute myocardial tissue specificity and high clinical sensitivity. Cardiac Biomarkers for Acute Myocardial Infarction (AMI): {{caption_text}} 1. Cardiac Troponin: Preferred biochemical markers due to their sensitivity and specificity. Criteria for ACS: Requires rise and/or fall in biomarker values, with at least one value above the 99th percentile upper reference limit. Troponin T (cTnT) and Troponin I (cTnI)

increase significantly after STEMI. Can detect concentrations <1 ng/L in non-ischemic conditions. Troponin levels: Increase within 3-6 hours. Peak at around 36 hours. Remains elevated for 7-10 days after STEMI. Troponin should be measured at presentation and repeated at 1-3 hours (high-sensitivity assays) or 3-6 hours (conventional assays). Further troponin tests are advised beyond 3-6 hours if AMI remains a possibility or there is diagnostic uncertainty. Causes of elevated Serum Troponin other than MI Cardiorespiratory Causes Non-Cardiorespiratory Causes Pulmonary embolism Aortic dissection Acute pulmonary edema Tachyarrhythmias Myocarditis/Myopericarditis Cardiac trauma Cardiac surgery/ablation Prolonged hypotension Severe sepsis Severe burns Stroke Subarachnoid hemorrhage End-stage renal failure Cardiac troponin levels remain elevated for several days after an acute myocardial infarction (AMI), making them unreliable for detecting reinfarction. 2. Creatine Phosphokinase (CK) and CK-MB: CK rises within 4-8 hours. Peaks by 24 hours. Returns to normal within 48-72 hours. CK lacks specificity for STEMI since it can be elevated in skeletal muscle disease, trauma, or injections. CK-MB isoenzyme is more specific for the heart CK-MB elevated: Cardiac surgery Myocarditis Electrical cardioversion CK-MB/CK ratio >2.5 suggests a myocardial source, though it's not diagnostic. CK-MB levels normalize within 48 to 72 hours , so a subsequent rise can confirm reinfarction. 3. Lactate Dehydrogenase (LDH): Increase in the blood 6 to 12 hours after ACS. Peak within 24 to 72 hours. Normalize within 8 to 14 days. LDH is no longer used to diagnose myocardial infarction because it is not specific to cardiac myocytes. 4. Heart-type Fatty Acid-Binding Protein (H-FABP): Sensitivity of H-FABP in detecting AMI within 4 hours of symptom onset was 60%, significantly higher than troponin (18.8%) and CK-MB (12.5%). But the specificity of H-FABP in detecting AMI was less than that of troponin and CK-MB. Cytokeratin (Option B): Cytokeratin is a protein found in epithelial cells and has no role in cardiac injury detection. It is primarily used as a tumor marker for certain types of cancers and has no relevance in diagnosing myocardial infarction. Myoglobin (Option C): While myoglobin is released during muscle injury and rises earlier than troponin (2-3 hours after injury), it lacks cardiac specificity as it is found in both cardiac and skeletal muscle. CPK-MM (Option D): Creatine Phosphokinase-MM is the skeletal muscle isoform of CPK. It is predominantly found in skeletal muscle. Its elevation can occur in condition causing skeletal muscle damage, making it a poor choice for specific MI diagnosis.

@Neet_pg_bot

Q84: Which of the following is given lifelong for patient receiving prosthetic mitral valve replacement? (Q857693)

A. Aspirin

B. Clopidogrel

C. Atorvastatin

D. Warfarin

Correct Answer: D. Warfarin

Explanation: Warfarin is given as the lifelong medication for patients with prosthetic mitral valve replacement . All mechanical valves require long-term anticoagulation because they can cause systemic thromboembolism or may develop valve thrombosis or obstruction . Warfarin, a v itamin K antagonist , works by inhibiting the clotting proteins in the blood, providing necessary anticoagulation to prevent thromboembolic complications in patients with mechanical heart valves. For patients with mechanical heart valve replacements, warfarin therapy requires a higher target INR range of 3.0 to 3.5 . This higher intensity of anticoagulation is necessary to prevent thromboembolic complications associated with mechanical valves. Warfarin Use Target INR Range Atrial Fibrillation 2.0 - 2.5 Venous Thromboembolism (VTE) Prophylaxis Bioprosthetic Heart Valves (first 3 months) Post-Myocardial Infarction Treatment of DCT, PE, TIA 2.5 - 3.0 Mechanical Prosthetic Heart Valves 3.0 - 3.5 Recurrent Thromboembolism Aspirin (Option A): While aspirin is an antiplatelet agent that acts on blood platelets, it alone is insufficient for mechanical valve anticoagulation. Unlike warfarin, which inhibits the circulating blood clotting proteins, aspirin's antiplatelet action is not potent enough to prevent valve thrombosis in mechanical valves. Clopidogrel (Option B): Clopidogrel, like aspirin, has anti-platelet action and is not adequate for mechanical valve anticoagulation. Both these drugs act on platelets and not on clotting proteins, making them insufficient for preventing mechanical valve thrombosis. Atorvastatin (Option C): Atorvastatin is an anti-dyslipidemic drug that has no anticoagulant properties. While patients with prosthetic valves may require statins for other cardiovascular indications, the primary requirement is anticoagulation, not lipid management.

@Neet_pg_bot

Q85: A 68-year-old male presents with palpitations and shortness of breath. His medical history includes hypertension, diabetes, and coronary artery disease. On examination, irregularly irregular heartbeats are noted. An electrocardiogram (ECG) reveals irregularly irregular rhythm , no P waves, and absence of an isoelectric baseline. His blood pressure is 132/84 mmHg, heart rate 130 bpm, and oxygen saturation 94% on room air. Given the patient's clinical presentation and history, which of the following treatment options should be considered as a first-line approach for managing this case? (Q855706)

A. Amiodarone

B. Metoprolol

C. Electrical cardioversion

D. Direct oral anticoagulant (DOAC) therapy

Correct Answer: B. Metoprolol

Explanation: The clinical scenario of a patient with a history of hypertension, diabetes, and coronary artery disease, irregularly irregular heartbeats on examination, along with an ECG showing irregularly irregular rhythm, no P waves, and absence of an isoelectric baseline, points towards a diagnosis of atrial fibrillation. The first-line approach for managing this case is beta blockers , such as metoprolol , to achieve rate control. Atrial Fibrillation Features Characterized by abnormal automatic firing and multiple re-entry circuits. Atria beat rapidly and ineffectively; ventricles activated irregularly Produces an "irregularly irregular" pulse Palpitations, syncope, and breathlessness can be present Asymptomatic AF: Can present as systemic embolism and stroke ECG Features QRS Complexes: Irregular but normal P Waves: Absent; baseline may show irregular fibrillation waves Ventricular Rate: Fast at onset (120-160 beats/min) Slower in chronic AF due to medication effects and AV nodal fatigue {{caption_text}} Management Paroxysmal Atrial Fibrillation First-line Therapy: Beta-blockers are effective in patients with CAD, hypertension, and heart failure. Class Ic Drugs: Propafenone or flecainide to prevent episodes (not for patients with CAD or LV dysfunction). Class III Drugs: Amiodarone : Most effective but with significant side effects; used when other treatments fail. (Option A) Dronedarone : Alternative to amiodarone; contraindicated in heart failure. Rate Control: Digoxin and verapamil for AV node conduction slowing, but not for AF prevention. Catheter Ablation: Considered for patients with drug-resistant AF; prevents AF in ~75% of cases but may have complications. Persistent Atrial Fibrillation Rhythm Control : Cardioversion : Electrical or pharmacological (e.g., intravenous flecainide or amiodarone). Timing: Immediate if AF <48 hours in unstable patients. (Option C) Anticoagulation is required if AF ≥48 hours to prevent thromboembolic events. (Option D) Prophylactic Amiodarone : To reduce recurrence risk. Rate Control : Medications: Digoxin, β-blockers, or rate-limiting calcium antagonists (verapamil, diltiazem) . Combination Therapy: Digoxin with β-blockers ; avoid combining calcium antagonists with β-blockers. Pace and Ablate: Permanent pacemaker with AV nodal block for symptomatic AF.

@Neet_pg_bot

Q86: All are true regarding heart failure except: (Q855713)

A. Regardless of ejection fraction and the type of heart failure, the 5-year mortality rate is around 50%

B. Non-cardiovascular death is more in HFrEF-30-40% as compared to HFpEF-15%

C. Angiotensin converting enzyme (ACE) inhibitors cause cough in 15% and angioedema in 1%

D. Atrial fibrillation is common in elderly and is the cause of stroke in quarter of the stroke cases

Correct Answer: B. Non-cardiovascular death is more in HFrEF-30-40% as compared to HFpEF-15%

Explanation: Noncardiac causes account for a significant proportion of deaths, with 62% in HFpEF , 54% in HFmrEF, and 35% in HFrEF. Classification of Heart Failure by Left Ventricular Ejection Fraction: Type of Heart Failure Definition Heart failure with reduced ejection fraction (HFrEF) LVEF ≤40% Heart failure with improved ejection fraction (HFimpEF) Previous LVEF ≤40% and a follow-up LVEF >40% Heart failure with mildly reduced ejection fraction (HFmrEF) LVEF 41%–49% Heart failure with preserved ejection fraction (HFpEF) LVEF ≥50% Regardless of ejection fraction and the type of heart failure, the 5-year mortality rate is around 50% (Option A) : The 5-year mortality rate for heart failure patients, regardless of ejection fraction, is approximately 50%. The development of symptomatic heart failure carries a poor prognosis, with around 30-40% of patients dying within 1 year of diagnosis, and 60-70% dying within 5 years, which is correct. Angiotensin converting enzyme (ACE) inhibitors cause cough in 15% and angioedema in 1% (Option C) : ACE inhibitors are known to cause a cough in 15% of patients and rarely cause rashes or angioedema in 1% due to the accumulation of bradykinin and substance P, which is true. Atrial fibrillation is common in elderly and is the cause of stroke in quarter of the stroke cases (Option D) : Atrial fibrillation is common in elderly patients, with more than 95% of patients being over 60 years old. It increases the risk of stroke by five-fold and is responsible for around 25% of strokes, which is accurate.

@Neet_pg_bot

Q87: In atrial fibrillation, choose the correct statements: Novel oral anticoagulants (NOACs) used in the treatment of moderate to severe MS Anticoagulants should be given in patients with ischemic stroke due to atrial fibrillation NOACs are contraindicated in prosthetic valves All patients with atrial fibrillation who are not candidates for cardiac surgery can be started on beta-blockers (Q855730)

A. 1,2,3 and 4 correct

B. 1,2 and 3 correct

C. 2 and 3 correct

D. 1 and 4 correct

Correct Answer: C. 2 and 3 correct

Explanation: The correct statements are 2 and 3. Atrial Fibrillation Features Characterized by abnormal automatic firing and multiple re-entry circuits. Atria beat rapidly and ineffectively; ventricles activated irregularly Produces an "irregularly irregular" pulse Palpitations, syncope, and breathlessness can be present Asymptomatic AF: Can present as systemic embolism and stroke ECG Features QRS Complexes: Irregular but normal P Waves: Absent; baseline may show irregular fibrillation waves Ventricular Rate: Fast at onset (120-160 beats/min) Slower in chronic AF due to medication effects and AV nodal fatigue {{caption_text}} Management Paroxysmal Atrial Fibrillation: First-line Therapy: Beta-blockers are effective in patients with CAD, hypertension, and heart failure. (4) Class Ic Drugs: Propafenone or flecainide to prevent episodes (not for patients with CAD or LV dysfunction). Class III Drugs: Amiodarone : Most effective but with significant side effects; used when other treatments fail. Dronedarone : Alternative to amiodarone; contraindicated in heart failure. Rate Control: Digoxin and verapamil for AV node conduction slowing, but not for AF prevention. Catheter Ablation: Considered for patients with drug-resistant AF; prevents AF in ~75% of cases but may have complications. Persistent Atrial Fibrillation: Rhythm Control : Cardioversion : Electrical or pharmacological (e.g., intravenous flecainide or amiodarone). Timing: Immediate if AF <48 hours in unstable patients. Anticoagulation is required if AF ≥48 hours to prevent thromboembolic events. Prophylactic Amiodarone : To reduce recurrence risk. Rate Control : Medications: Digoxin, β-blockers, or rate-limiting calcium antagonists (verapamil, diltiazem) . Combination Therapy: Digoxin with β-blockers ; avoid combining calcium antagonists with β-blockers. Pace and Ablate: Permanent pacemaker with AV nodal block for symptomatic AF. Thromboprophylaxis: Anticoagulation: Required for ischemic stroke prevention due to blood stasis in the left atrium. (2) Warfarin : INR target of 2.0–3.0; start 4 weeks prior to cardioversion. DOACs/NOACs: Rivaroxaban, apixaban, edoxaban, and dabigatran as alternatives to warfarin; no monitoring needed; contraindicated in atrial fibrillation with rheumatic mitral stenosis (1) or mechanical heart valves due to insufficient evidence supporting their safety and efficacy in these conditions. (3) Risk Assessment: CHA2DS2-VASc Score : For stroke risk; anticoagulate if score ≥2 . HAS-BLED Score: For bleeding risk; monitor patients with score ≥3. Aspirin: Not recommended due to low efficacy in preventing embolic stroke.

@Neet_pg_bot

Q88: A 60 year old male patient with critical mitral stenosis presented with atrial fibrillation. He has a history of multiple episodes of transient ischemic attacks. Which of the following are true regarding the prevention of stroke in this patient? Only aspirin is given Warfarin is given Direct oral anticoagulants are not indicated Mitral valvotomy should be recommended (Q855731)

A. 1 only

B. 2 and 3

C. 2,3 and 4

D. 1,2,3 and 4

Correct Answer: B. 2 and 3

Explanation: The true statements regarding the prevention of stroke in this patient are 2 and 3. Atrial Fibrillation Features Characterized by abnormal automatic firing and multiple re-entry circuits. Atria beat rapidly and ineffectively; ventricles activated irregularly Produces an "irregularly irregular" pulse Palpitations, syncope, and breathlessness can be present Asymptomatic AF: Can present as systemic embolism and stroke ECG Features QRS Complexes: Irregular but normal P Waves: Absent; baseline may show irregular fibrillation waves Ventricular Rate: Fast at onset (120-160 beats/min) Slower in chronic AF due to medication effects and AV nodal fatigue {{caption_text}} Management Paroxysmal Atrial Fibrillation: First-line Therapy: Beta-blockers are effective in patients with CAD, hypertension, and heart failure. Class Ic Drugs: Propafenone or flecainide to prevent episodes (not for patients with CAD or LV dysfunction). Class III Drugs: Amiodarone : Most effective but with significant side effects; used when other treatments fail. Dronedarone : Alternative to amiodarone; contraindicated in heart failure. Rate Control: Digoxin and verapamil for AV node conduction slowing, but not for AF prevention. Catheter Ablation: Considered for patients with drug-resistant AF; prevents AF in ~75% of cases but may have complications. Persistent Atrial Fibrillation: Rhythm Control : Cardioversion : Electrical or pharmacological (e.g., intravenous flecainide or amiodarone). Timing: Immediate if AF <48 hours in unstable patients. Anticoagulation is required if AF ≥48 hours to prevent thromboembolic events. Prophylactic Amiodarone : To reduce recurrence risk. Rate Control : Medications: Digoxin, β-blockers, or rate-limiting calcium antagonists (verapamil, diltiazem) . Combination Therapy: Digoxin with β-blockers ; avoid combining calcium antagonists with β-blockers. Pace and Ablate: Permanent pacemaker with AV nodal block for symptomatic AF. Thromboprophylaxis: Anticoagulation: Required for ischemic stroke prevention due to blood stasis in the left atrium. Warfarin : INR target of 2.0–3.0; start 4 weeks prior to cardioversion; recommended in patients with moderate to severe mitral stenosis or mechanical valves. (2) DOACs/NOACs : Rivaroxaban, apixaban, edoxaban, and dabigatran as alternatives to warfarin; no monitoring needed; contraindicated in atrial fibrillation with rheumatic mitral stenosis or mechanical heart valves due to insufficient evidence supporting their safety and efficacy in these conditions. (3) Risk Assessment: CHA2DS2-VASc Score : For stroke risk; anticoagulate if score ≥2 . HAS-BLED Score: For bleeding risk; monitor patients with score ≥3. Aspirin: Not recommended due to low efficacy in preventing embolic stroke. (1) Mitral valvotomy should be recommended (Option 1) : Mitral valvotomy is not recommended for stroke prevention in this patient as it is indicated for symptomatic patients with isolated severe mitral stenosis and a valve area < 1.5 cm^2. It is contraindicated in the presence of left atrial thrombus, which is a common concern in atrial fibrillation.

@Neet_pg_bot

Q89: For the diagnosis of resistant hypertension, the patient should have uncontrolled hypertension despite taking three antihypertensive drugs. This should include at least one: (Q856598)

A. Calcium channel blocker

B. Beta blocker

C. Alpha blocker

D. Diuretic

Correct Answer: D. Diuretic

Explanation: iuretic For the diagnosis of resistant hypertension, the patient must have uncontrolled hypertension despite taking three antihypertensive drugs, including at least one diuretic. While calcium channel blockers , beta blockers , or alpha blockers can be part of the treatment regimen, the inclusion of a diuretic is essential to confirm the diagnosis of resistant hypertension. Resistant Hypertension: Refers to blood pressure persistently greater than 140/90 mmHg despite using three or more antihypertensive agents, including a diuretic. Population at Risk: It is more common in individuals over 60 years old and those at higher cardiovascular risk. Causes: Nonadherence to therapy. Secondary causes such as obesity, primary aldosteronism, and excessive alcohol intake. Use of certain nonprescription or prescription drugs. Evaluation: Home blood pressure monitoring can help determine if office readings are accurate. Secondary hypertension evaluation is recommended if no apparent cause of resistance is found. Management: Mineralocorticoid receptor antagonists, particularly spironolactone , are effective as add-on therapies.

@Neet_pg_bot

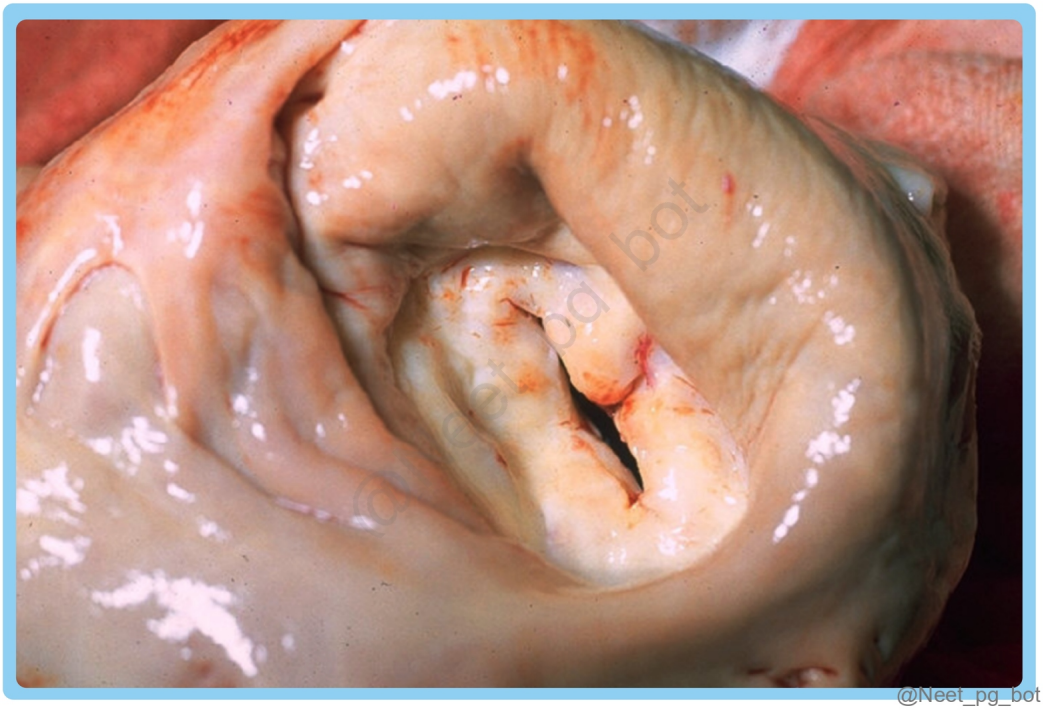
Q90: Identify the disease? (Q856617)

A. Tricuspid stenosis

B. Mitral stenosis

C. Dilated cardiomyopathy

D. Hypertrophic obstructive cardiomyopathy



Correct Answer: B. Mitral stenosis

Explanation: - Mitral stenosis: The reduced area of the mitral valve with a "fish mouth" appearance is a hallmark feature of mitral stenosis. Mitral Stenosis (MS): Aetiology: Primary Cause : Rheumatic fever is the leading cause of mitral stenosis, accounting for about 40% of cases in patients with a history of rheumatic heart disease. Congenital abnormalities (e.g., parachute valve, cor triatriatum) Mitral annular calcification with involvement of leaflets Autoimmune diseases (e.g., systemic lupus erythematosus, rheumatoid arthritis) Left atrial myxoma Infective endocarditis with large vegetation Pathology : Chronic inflammation leads to thickening of the valve leaflets, fibrous tissue formation, calcific deposits, and fusion of the mitral commissures and chordae tendinae. This process results in a narrowed, funnel-shaped valve. (Fish-mouth Appearance) Normal mitral valve area : 4-6 cm^2; significant obstruction of <2 cm^2. Hemodynamics : In severe MS (<1.5 cm^2), a left atrial (LA) pressure of ~25 mmHg is needed to maintain normal cardiac output (CO). Effects of Heart Rate : Increased heart rate diminishes diastolic filling time, raising the LA pressure and transvalvular gradient Symptoms : Exertional dyspnea, cough, and progressive limitation of daily activities. Orthopnea and paroxysmal nocturnal dyspnea can develop as MS worsens. Atrial fibrillation (AF) often accelerates symptom progression. Complications: Pulmonary Hypertension (Leading to RVH & RHF) Atrial Fibrillation (Due to Left atrial enlargement) Thrombus Formation: Stasis of blood in the enlarged left atrium, increases the risk of thrombus formation, especially in patients with atrial fibrillation. Hemoptysis (Elevated pulmonary venous pressure - rupture of small veins) Infective Endocarditis Pulmonary Infections Findings: Inspection : Malar flush, jugular venous distension, and right ventricular (RV) enlargement. Auscultation : A loud S1, an opening snap (OS) after S2, and a low-pitched, rumbling mid-diastolic murmur with presystolic accentuation- heard best at the apex. Characteristics of a murmur in severe MS: Decreased interval between A2 & OS. Wide splitting of S2. Palpable systolic thrill. The duration of the murmur increases. Investigations: ECG : Often shows LA enlargement, right axis deviation, and RV hypertrophy. Echocardiogram : Measures mitral inflow velocity and transvalvular gradients and evaluates for associated mitral regurgitation (MR) or other valvular lesions. Chest X-ray : Shows LA enlargement, pulmonary vein dilation, and Kerley B lines indicating pulmonary congestion.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q91: A patient who is a known case of atherosclerosis underwent a circumflex artery bypass. The stent is now placed successfully. He's already taking lisinopril, verapamil, and metoprolol. Which drug should be added? (Q856117)

A. PDE 3 inhibitor

B. Direct oral anticoagulant

C. P2Y12 receptor blocker

D. PDE 5 inhibitor

Correct Answer: C. P2Y12 receptor blocker

Explanation: P2Y12 receptor blockers , such as clopidogrel, ticagrelor, and prasugrel, are antiplatelet medications commonly used in patients undergoing percutaneous coronary intervention (PCI), including the placement of stents. Percutaneous Coronary Intervention (PCI) PCI involves balloon dilatation and stenting for symptomatic IHD with suitable stenoses in epicardial coronary arteries. Indications : Symptom-limiting angina despite optimal medical therapy. Evidence of ischemia during stress tests. Post-PCI Management : Aspirin is administered indefinitely, and P2Y12 antagonists for 1-3 months. P2Y12 receptor antagonists are used with aspirin for up to 12 months. Clopidogrel (300mg, followed by 75 mg daily) with aspirin reduces death, reinfarction, and stroke risks in STEMI patients. Newer drugs like ticagrelor (180 mg, followed by 90 mg twice daily) and prasugrel (60 mg, followed by 10 mg daily) are more effective than clopidogrel for ischemic complication prevention in STEMI patients undergoing PCI but have a higher bleeding risk. Current-generation drug-eluting stents reduce restenosis but require prolonged dual antiplatelet therapy (DAPT). Incorrect Options: Phosphodiesterase-3 (PDE 3) inhibitors (Option A) are commonly used in the treatment of heart failure and peripheral vascular disease. Direct oral anticoagulants (DOACs) (Option B) may be considered in some patients with certain indications, such as atrial fibrillation or mechanical heart valves. The routine use of DOACs may not be necessary in all patients who undergo a circumflex artery bypass for atherosclerosis. Phosphodiesterase-5 (PDE 5) inhibitors (Option D) , such as sildenafil, tadalafil, and vardenafil, are primarily used for the treatment of erectile dysfunction and pulmonary arterial hypertension.

@Neet_pg_bot

Q92: A male patient had feeble femoral pulses with an upper-limb blood pressure of 186/90 mmHg. Chest x-ray showed enlarged intercostal arteries. What is the likely diagnosis? (Q856118)

A. Coarctation of aorta

B. Atrial septal defect

C. Bicuspid aortic valve

D. Patent ductus arteriosus

Correct Answer: A. Coarctation of aorta

Explanation: The feeble femoral pulses and raised upper limb blood pressure indicate the diagnosis of coarctation of the aorta. The enlarged intercostal vessels indicate collaterals. Coarctation of the Aorta: It is a congenital condition leading to the narrowing of the aortic arch. This narrowing causes a shelf-like obstruction in the descending aorta, typically near the junction of the main and left pulmonary arteries. Less commonly affects the transverse aortic arch. Physical Examination Findings: Characteristic features: Elevated blood pressure in the upper limbs. Brachiofemoral delay: Diminished or delayed femoral pulses compared to brachial or radial pulses. Lower extremity blood pressure and pulses are lower and delayed than upper extremities (systolic pressure gradient > 20 mmHg between upper & lower extremities) unless significant aortic collaterals have developed. A continuous murmur may be heard over the scapula due to collateral blood flow. Hemodynamic Effects: Increased afterload on structures receiving oxygenated blood, including the left ventricle, coronary arteries, ascending/transverse aorta, cerebral and arm vessels, and proximal descending aorta. Associations: A bicuspid aortic valve (typically with right-left commissural fusion) is commonly seen. Turner syndrome should be considered, especially in women with short stature, webbed neck, lymphedema, and primary amenorrhea. Turner syndrome often indicates a more severe condition with increased risks. Prognosis and Risks Post-Surgical Repair: Generally good prognosis after surgical repair. However, patients remain at risk for: Systemic hypertension Premature atherosclerosis Left ventricular failure Aortic aneurysm, dissection, and recurrent coarctation. Incorrect Options: Atrial septal defect (Option B) typically causes right heart volume overload, with a fixed split S2 and a systolic ejection murmur at the pulmonary area, reflecting increased pulmonary flow. It does not produce a blood pressure difference between the upper and lower limbs or weak femoral pulses. The bicuspid aortic valve (Option C) has a varied presentation and has findings of low-pitched systolic ejection murmur and ejection click. Patent ductus arteriosus (Option D) is a congenital anomaly of the heart where the ductus arteriosus fails to completely close and leads to a continuous machinery murmur below the clavicle, prominent precordial impulse, tachycardia, and bounding peripheral pulses.

@Neet_pg_bot

Q93: A 45-year-old woman with a history of hypertension presented to the emergency room with loss of consciousness, chest pain, and diaphoresis. On examination, she was grossly unstable, and the bilateral pulses were unequal. ECG showed nonspecific ST-T changes. What is the next best investigation? (Q856130)

A. MRI

B. Transoesophageal echocardiography

C. Cardiac enzymes

D. X-ray

Correct Answer: B. Transoesophageal echocardiography

Explanation: The clinical features here point to the diagnosis of aortic dissection, and the most sensitive and specific investigation for this is transesophageal endoscopy. Transesophageal Echocardiography (TEE) TEE uses a transducer at the tip of an endoscope inserted into the oesophagus for clearer views of the heart. Provides better image quality and spatial resolution, especially for posterior structures. Preferred for assessing small cardiac lesions like valvular vegetations, intracardiac thrombi, and congenital abnormalities. Requires topical and systemic anaesthesia, usually conscious sedation. Risks include oesophagal damage, perforation, aspiration, and anaesthesia complications. Used in intubated patients and for intraoperative monitoring during cardiac surgeries. Clinical Features of Aortic Dissection: Pain: Sudden onset, severe, tearing chest pain , often associated with diaphoresis . Pain location: Can be anterior or posterior chest, commonly in the interscapular region, and may migrate as the dissection progresses. Associated Symptoms: Syncope , dyspnea, and weakness. Neurological symptoms (e.g., hemiplegia, hemianesthesia due to carotid artery obstruction, paraplegia due to spinal cord ischemia). Bowel ischemia, hematuria, and myocardial ischemia. Physical Findings: Hypertension or hypotension, loss of pulses, aortic regurgitation, pulmonary oedema. Horner's syndrome, superior vena cava syndrome, hoarseness, dysphagia, and airway compromise (from adjacent structure compression). Complications: Acute aortic regurgitation (in >50% of proximal dissections), often causing bounding pulses, wide pulse pressure, and diastolic murmur. Hemopericardium and cardiac tamponade, especially in type A lesions with retrograde dissection. Investigations/Diagnosis of Aortic Dissection: Chest X-ray: (Option D) Widened superior mediastinum, left-sided pleural effusion in ascending aorta dissection. Widened mediastinum and potentially wider descending aorta in descending aorta dissection. Not highly specific, especially in cases suspecting cardiovascular events. Electrocardiogram (ECG): No myocardial ischemia on ECG helps differentiate aortic dissection from myocardial infarction. Transthoracic Echocardiography: Simple and rapid, with a sensitivity of 60-85% for aortic dissection. Most effective for proximal ascending aorta dissections. Transesophageal Echocardiography: Highly sensitive (98%) and specific (~90%) for detecting dissections of the ascending and descending aorta. Less effective for diagnosing arch dissections. CT and MRI : (Option A) Highly accurate (>90% sensitivity and specificity) for identifying intimal flaps, dissection extent, and involvement of major arteries. Useful for detecting intramural haemorrhage and penetrating ulcers. Selection between CT, MRI, and echocardiography depends on institutional resources and patient hemodynamic stability. Cardiac enzymes (Option C) , such as troponin and creatine kinase-MB elevation, indicate injury or infarction of the heart muscle, which can occur in conditions like a heart attack. While cardiac enzymes are essential in the evaluation of chest pain and suspected myocardial injury, they do not provide immediate information about the current hemodynamic instability and the cause of the patient's

symptoms.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q94: A 50-year-old man presents with a history of recurrent retrosternal chest pain, with each episode lasting for 3-5 min and subsiding with sublingual nitrate. ECG shows left ventricular hypertrophy and flat T-wave. He has a known case of hypertension, diabetes mellitus, and hypercholesterolemia and is currently on aspirin, atenolol, metformin, and lovastatin. What is the next best step in management? (Q856171)

A. IV glyceryl trinitrate infusion

B. Injection enoxaparin

C. Add clopidogrel

D. Increase the dose of beta blocker

Correct Answer: B. Injection enoxaparin

Explanation: The patient's clinical presentation, history of recurrent chest pain, and ECG findings of left ventricular hypertrophy and flat T-waves raise concerns for NSTEMI-acute coronary syndrome. Injection enoxaparin , a low molecular weight heparin, is often used as an initial treatment to prevent clot formation and progression of coronary artery disease. Management of NSTEMI-ACS Management of NSTEMI involves evaluating patients with a low likelihood of ischemia in emergency settings, continuous ECG monitoring, stress testing, and serum troponin assessments, while those who meet criteria for NSTE-ACS are admitted for further monitoring and medical treatment aimed at stabilizing their condition and preventing future events. Medical management Anti-ischemic therapy: Sublingual glyceryl trinitrate/nitroglycerin: DOC for unstable angina For ischemic discomfort IV beta-blockers (Atenolol, Metoprolol): They reduce the oxygen demand of the myocardium They relieve pain, reduce arrhythmias, and reduce short-term mortality Verapamil and diltiazem: Given if symptoms are not relieved by full dose beta blockers and nitrates They decrease the heart rate IV morphine sulfate or diamorphine: For analgesia Antiemetics like metoclopramide (For symptomatic relief) Nifedipine or amlodipine (If chest discomfort persists) Atorvastatin and other HMG-CoA reductase inhibitors: Reduces occurrence of MI and recurrences of acute coronary syndrome Ezetimibe or alirocumab, evolocumab: Given if unresponsive to full dose statins They reduce LDL cholesterol and prevent further cardiovascular events Antithrombotic therapy: Antiplatelet drugs: Cyclooxygenase inhibitor: aspirin Platelet P2Y12 receptor inhibitor: clopidogrel Anticoagulants: Unfractionated heparin. Low molecular heparin: Enoxaparin. Direct thrombin inhibitor: bivalirudin. Synthetic factor Xa inhibitor: fondaparinux. Invasive management Done if the medical management

fails and symptoms do not improve. Coronary arteriography must be done within 48 hours of presentation. Coronary revascularisation includes PCI (percutaneous coronary intervention) or coronary artery bypass grafting (CABG) . IV glyceryl trinitrate infusion (Option A) is given in case of patients presenting with ongoing chest pain. The given scenario here gives a history of recurrent chest pains but does not specify that the patient suffers from it at presentation. Hence, it is not the best step for management. Add clopidogrel (Option C): Clopidogrel is an antiplatelet drug that has antithrombotic action, however, enoxaparin is a better agent than clopidogrel and hence not preferred. Increase the dose of beta-blocker (Option D) : This step is not preferred over anticoagulation therapy using enoxparin.

@Neet_pg_bot

Q95: Evaluation of a patient revealed the presence of a mid-diastolic murmur. JVP showed prominent a-waves. What is the likely diagnosis? (Q856199)

A. Mitral stenosis

B. Tricuspid stenosis

C. Mitral regurgitation

D. Tricuspid regurgitation

Correct Answer: B. Tricuspid stenosis

Explanation: The mid-diastolic murmur and the prominent a-waves on the JVP suggest the narrowing of the tricuspid valve, called tricuspid stenosis . Tricuspid Stenosis Aetiology Congenital Rheumatic origin (often coexists with mitral stenosis) Pathophysiology RA pressure ↑ , due to the diastolic pressure gradient between RA and RV, results in systemic venous congestion. Restricted forward flow of blood leads to ↓ cardiac output. Clinical features Fatigue Mild dyspnea Venous congestion (right-side heart failure): Hepatomegaly, ascites, oedema and may lead to cardiac cirrhosis. Physical examination: Jugular venous distension with prominent ‘a’ waves Auscultation: Mid-diastolic murmur at left lower sternal border Murmur increases with inspiration (Carvallo's sign). If mitral stenosis coexist Pulmonary artery hypertension Orthopnea due to pulmonary oedema Investigations Chest X-ray and ECG show features of RA enlargement Echocardiogram: Thickened tricuspid valve with diastolic

doming and increased pressure gradient between RV and RA. Management Medical management: To reduce systemic venous congestion symptoms Dietary salt restriction Loop diuretics Surgical intervention: Valvular repair or Prosthetic valve replacement. Incorrect Options: Mitral stenosis (MS) (Option A) causes left atrial pressure overload, leading to pulmonary congestion and dyspnea, often with orthopnea and paroxysmal nocturnal dyspnea. It is associated with a low-pitched rumbling mid-diastolic murmur with an opening snap but no prominent a-waves in JVP unless it is a severe case. Mitral regurgitation (Option C) presents with a holosystolic murmur radiating to the axilla, which is not the given scenario. The JVP changes are seen only in severe cases. Tricuspid regurgitation (Option D) is associated with a 'C-v' wave and steep 'y' descent in the JVP and has a blowing holosystolic murmur.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q96: A 20-year-old woman presents with breathlessness and chest pain. She is a known case of mitral stenosis. Her pulse is irregularly irregular. No thrombus is seen on echocardiography. What is the best agent to prevent future thrombotic events? (Q856202)

A. Dabigatran

B. Aspirin 150mg

C. Oral warfarin

D. Aspirin + Clopidogrel

Correct Answer: C. Oral warfarin

Explanation: Oral warfarin is the best agent to prevent thrombotic events in case of mitral stenosis. Mitral Stenosis (MS): Aetiology: Primary Cause : Rheumatic fever is the leading cause of mitral stenosis, accounting for about 40% of cases in patients with a history of rheumatic heart disease. Congenital abnormalities (e.g., parachute valve, cor triatriatum) Mitral annular calcification with involvement of leaflets Autoimmune diseases (e.g., systemic lupus erythematosus, rheumatoid arthritis) Left atrial myxoma Infective endocarditis with large vegetation Symptoms : Exertional dyspnea, cough, and progressive limitation of daily activities. Orthopnea and paroxysmal nocturnal dyspnea can develop as MS worsens. Atrial fibrillation (AF) often accelerates symptom progression. Complications: Pulmonary Hypertension (Leading to RVH & RHF) Atrial Fibrillation (Due to Left atrial enlargement) Thrombus Formation: Stasis of blood in the enlarged left atrium, increases the risk of thrombus formation, especially in patients with atrial fibrillation. Hemoptysis (Elevated pulmonary venous pressure - rupture of small veins) Infective Endocarditis Pulmonary Infections Management of Mitral Stenosis: Medical Management: Patients with mild symptoms may be managed medically. Penicillin Prophylaxis : Essential for preventing rheumatic fever in risk patients. Symptomatic Relief : Sodium restriction, diuretics, beta-blockers, and Calcium channel blockers help manage symptoms and control heart rate in atrial fibrillation (AF). Anticoagulation : Warfarin is for patients with AF, a history of thromboembolism , or left atrial thrombus; INR target 2–3. Cardioversion : For recent-onset AF, ensure anticoagulation for at least three weeks. Infective Endocarditis Prophylaxis : Routine antibiotic prophylaxis is no longer recommended. Interventional: Considered if patients remain symptomatic despite medical management or if pulmonary hypertension develops/Severe MS (<1.5 cm^2) Balloon valvuloplasty Mitral valvotomy/Mitral valve replacement Incorrect Options: Dabigatran (Option A) is an alternative anticoagulant but is not preferred as the first-line treatment as it has an increased risk of causing thromboembolic events. Aspirin + Clopidogrel (Option B & D) is not approved for use in mitral stenosis to prevent thrombotic events.

@Neet_pg_bot

Q97: Resistant hypertension is defined as? (Q856945)

A. BP >160/90 mmHg with one antihypertensive

B. BP >140/90 mmHg with one antihypertensive

C. BP >160/90 mmHg with three or more antihypertensive

D. BP >140/90 mmHg with three or more antihypertensive

Correct Answer: D. BP >140/90 mmHg with three or more antihypertensive

Explanation: Resistant hypertension is defined as persistently elevated blood pressure (BP) that remains >140/90 mmHg despite the use of three or more antihypertensive medications, being one of them is diuretic, and at optimal doses. Hypertension Diagnosis Based on ABPM (ambulatory blood pressure monitoring) 24-h Average ≥130/80 mm Hg Awake (daytime) average ≥135/85 mm Hg Asleep (night-time) average ≥120/70 mm Hg Hypertension category based on the American College of Cardiology (ACC) Blood pressure category Systolic (mm Hg) Diastolic (mm Hg) Normal < 120 < 80 Elevated 120-129 <80 Stage 1 hypertension 130 – 139 80 – 89 Stage 2 hypertension ≥140 ≥90 Hypertensive crisis >180 >120 Measurement of automated office Blood Pressure (AoBP) : 3 readings to be taken Discard 1st reading The next 2 readings need to be averaged HTN if BP> 135/85 mmHg

@Neet_pg_bot

Q98: Which among the following investigations is the most suitable for diagnosing myocardial infarction (MI) within a timeframe of 2-4 hours of onset of chest pain? (Q856953)

A. LDH

B. CKMB

C. Troponin-T

D. BNP

Correct Answer: C. Troponin-T

Explanation: Troponin-T is a cardiac biomarker that is highly specific to cardiac muscle injury. It typically starts to rise within 3-4 hours after the onset of myocardial injury and remains elevated for several days. Therefore, it is considered the best investigation for diagnosing MI within 2-4 hours of symptom onset. Cardiac Biomarkers for

Acute Myocardial Infarction (AMI): 1. Cardiac Troponin Preferred biochemical markers due to their sensitivity and specificity. Criteria for ACS: Requires rise and/or fall in biomarker values, with at least one value above the 99th percentile upper reference limit. Troponin T (cTnT) and Troponin I (cTnI) increase significantly after STEMI. Can detect concentrations <1 ng/L in non-ischemic conditions. Troponin levels: Increase within 3-6 hours Peak at around 36 hours Remains elevated for 7-10 days after STEMI. Troponin should be measured at presentation and repeated at 1-3 hours (high-sensitivity assays) or 3-6 hours (conventional assays). Further troponin tests are advised beyond 3-6 hours if AMI remains a possibility or there is diagnostic uncertainty. Causes of elevated Serum Troponin other AMI Cardiorespiratory Causes Non-Cardiorespiratory Causes Pulmonary embolism Aortic dissection Acute pulmonary edema Tachyarrhythmias Myocarditis/Myopericarditis Cardiac trauma Cardiac surgery/ablation Prolonged hypotension Severe sepsis Severe burns Stroke Subarachnoid hemorrhage End-stage renal failure Cardiac troponin levels remain elevated for several days after an acute myocardial infarction (AMI), making them unreliable for detecting reinfarction. 2. Creatine Phosphokinase (CK) and CK-MB (Option B): CK rises within 4-8 hours. Peaks by 24 hours. Returns to normal within 48-72 hours. CK lacks specificity for STEMI since it can be elevated in skeletal muscle disease, trauma, or injections. CK-MB isoenzyme is more specific for the heart CK-MB elevated: Cardiac surgery Myocarditis Electrical cardioversion CK-MB/CK ratio >2.5 suggests a myocardial source, though it's not diagnostic. CK-MB levels normalize within 48 to 72 hours , so a subsequent rise can confirm reinfarction. 3. Lactate Dehydrogenase (LDH) (Option A): Increase in the blood 6 to 12 hours after ACS. Peak within 24 to 72 hours. Normalize within 8 to 14 days. LDH is no longer used to diagnose myocardial infarction because it is not specific to cardiac myocytes. 4. Heart-type Fatty Acid-Binding Protein (H-FABP): Sensitivity of H-FABP in detecting AMI within 4 hours of symptom onset was 60%, significantly higher than troponin (18.8%) and CK-MB (12.5%). But the specificity of H-FABP in detecting AMI was less than that of troponin and CK-MB. 5. BNP (B-type natriuretic peptide) (Option D): BNP is a hormone released by the ventricles of the heart in response to increased stretching of cardiac muscle cells. It is primarily used for diagnosing and assessing the severity of heart failure. BNP levels are not specific to myocardial infarction and do not provide timely diagnosis within 2-4 hours

@Neet_pg_bot

Q99: Which of the following treatment options is not suitable for managing a patient with non-ST-elevation myocardial infarction (NSTEMI)? (Q856335)

A. Aspirin

B. Clopidogrel

C. Streptokinase

D. Prasugrel

Correct Answer: C. Streptokinase

Explanation: In a patient with Non-ST-elevation myocardial infarction (NSTEMI) , streptokinase is not typically used for treatment. Streptokinase belongs to the class of fibrinolytic agents and is commonly used for the management of ST-elevation myocardial infarction (STEMI) to dissolve blood clots causing the blockage in the coronary arteries. However, in NSTEMI, the underlying mechanism is often different, and the management approach focuses on antiplatelet therapy and anticoagulation rather than fibrinolysis. Management of NSTEMI-ACS: Management of NSTEMI involves evaluating patients with a low likelihood of ischemia in emergency settings, continuous ECG monitoring, stress testing, and serum troponin assessments, while those who meet criteria for NSTE-ACS are admitted for further monitoring and medical treatment aimed at stabilizing their condition and preventing future events. Medical management Anti-ischemic therapy: Sublingual glyceryl trinitrate/nitroglycerin: DOC for unstable angina For ischemic discomfort IV beta-blockers (Atenolol, Metoprolol): They reduce the oxygen demand of the myocardium They relieve pain, reduce arrhythmias, and reduce short-term mortality Verapamil and diltiazem: Given if symptoms are not relieved by full dose beta blockers and nitrates They decrease the heart rate IV morphine sulfate or diamorphine: For analgesia Antiemetics like metoclopramide (For symptomatic relief) Nifedipine or amlodipine (If chest discomfort persists) Atorvastatin and other HMG-CoA reductase inhibitors: Reduces occurrence of MI and recurrences of acute coronary syndrome Ezetimibe or alirocumab, evolocumab: Given if unresponsive to full dose statins They reduce LDL cholesterol and prevent further cardiovascular events Antithrombotic therapy: Antiplatelet drugs: Cyclooxygenase inhibitor: aspirin (Option A) Platelet P2Y12 receptor inhibitor: clopidogrel, Prasugrel (Option B, D) Anticoagulants: Unfractionated heparin. Low molecular heparin: enoxaparin. Direct thrombin inhibitor: bivalirudin. Synthetic

factor Xa inhibitor: fondaparinux. Invasive management Done if the medical management fails and symptoms do not improve. Coronary arteriography must be done within 48 hours of presentation. Coronary revascularization includes PCI (percutaneous coronary intervention) or coronary artery bypass grafting (CABG) .

@Neet_pg_bot

Q100: A 65 year old male patient presented to the emergency room with symptoms of palpitation, dizziness. On examination pulse is 180 beats per minute and his blood pressure is 70 mmHg systolic. The electrocardiogram (ECG) reveals a narrow QRS complex tachycardia with a regular heart rate. What should be the next course of action in managing this patient? (Q856342)

A. DC cardioversion

B. Adenosine

C. Valsalva Maneuver

D. Verapamil

Correct Answer: A. DC cardioversion

Explanation: In this patient, immediate cardioversion is the most appropriate next step in the management. DC cardioversion Electrical cardioversion (DC cardioversion) is used to terminate organized arrhythmias such as atrial fibrillation (AF) or ventricular tachycardia (VT). It is the treatment of choice for unstable tachyarrhythmias . The electric current interrupts the arrhythmia, causing a brief asystole , usually followed by the return of sinus rhythm . It is usually performed as an elective procedure under general anesthesia . The shock is delivered immediately after the R wave to avoid triggering ventricular fibrillation (VF) , which may occur if applied during ventricular repolarization (T wave) . High-energy shocks may cause chest wall pain post-procedure . If there is no urgency , it is best to start with a lower-energy shock (around 50 joules) and increase if necessary. Adenosine (Option B) is commonly used for the acute termination of supraventricular tachycardia (SVT) episodes. However, it is not the preferred initial treatment for a patient with signs of hemodynamic instability and low blood pressure. Adenosine can cause a transient period of asystole when administered, which can further compromise the patient's blood pressure. Valsalva Maneuver (Option C) involves straining against a closed glottis, can be attempted as a non-invasive method to terminate certain types of supraventricular tachycardias. Verapamil (Option D) is a calcium channel blocker that can be effective in terminating certain types of supraventricular tachycardias, such as atrioventricular nodal reentrant tachycardia.

@Neet_pg_bot

Q101: What would be the most appropriate approach for a patient experiencing chest pain for the past 3 hours, where an ECG shows ST depression in anterior chest leads and T wave inversion? (Q856351)

A. Intra aortic balloon pump(IABP)

B. Thrombolysis with alteplase

C. Prophylaxis for arrhythmia

D. Aspirin with heparin

Correct Answer: D. Aspirin with heparin

Explanation: As the patient presented within 3 hours of the onset of chest pain, which suggests an acute coronary syndrome (ACS) and the ECG findings of ST depression in anterior chest leads and T wave inversion are consistent with myocardial ischemia.. Aspirin is an antiplatelet agent that inhibits platelet aggregation and Heparin is an anticoagulant that prevents the formation and propagation of blood clots. It is administered promptly to patients suspected of having ACS to minimize ongoing thrombosis. Management of NSTEMI-ACS: Management

of NSTEMI involves evaluating patients with a low likelihood of ischemia in emergency settings, continuous ECG monitoring, stress testing, and serum troponin assessments, while those who meet criteria for NSTE-ACS are admitted for further monitoring and medical treatment aimed at stabilizing their condition and preventing future events. Medical management Anti-ischemic therapy: Sublingual glyceryl trinitrate/nitroglycerin: DOC for unstable angina For ischemic discomfort IV beta-blockers (Atenolol, Metoprolol): They reduce the oxygen demand of the myocardium They relieve pain, reduce arrhythmias, and reduce short-term mortality Verapamil and diltiazem: Given if symptoms are not relieved by full dose beta blockers and nitrates They decrease the heart rate IV morphine sulfate or diamorphine: For analgesia Antiemetics like metoclopramide (For symptomatic relief) Nifedipine or amlodipine (If chest discomfort persists) Atorvastatin and other HMG-CoA reductase inhibitors: Reduces occurrence of MI and recurrences of acute coronary syndrome Ezetimibe or alirocumab, evolocumab: Given if unresponsive to full dose statins They reduce LDL cholesterol and prevent further cardiovascular events Antithrombotic therapy: Antiplatelet drugs: Cyclooxygenase inhibitor: aspirin Platelet P2Y12 receptor inhibitor: clopidogrel Anticoagulants: Unfractionated heparin. Low molecular heparin: enoxaparin. Direct thrombin inhibitor: bivalirudin. Synthetic factor Xa inhibitor: fondaparinux. Invasive management Done if the medical management fails and symptoms do not improve. Coronary arteriography must be done within 48 hours of presentation. Coronary revascularization includes PCI (percutaneous coronary intervention) or coronary artery bypass grafting (CABG) . PCI (percutaneous coronary intervention) (Option A) is a preferred treatment option for patients with ST-segment elevation myocardial infarction (STEMI). Thrombolysis with alteplase (Option B) is primarily indicated for patients with STEMI who present within a specific time window and are not candidates for primary PCI. While arrhythmias can be a complication of ACS, prophylactic treatment for arrhythmias (Option C) is not the primary management strategy in the acute phase. The focus initially is on addressing the underlying ischemia and preventing further thrombosis through antiplatelet and anticoagulant therapy.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q102: A 45-year-old female patient presents to the clinic with complaints of increasing fatigue and shortness of breath. Upon auscultation, the physician detects a pan systolic murmur that is best heard at the right side of the heart. The murmur radiates to the axilla and is louder during inspiration. The patient denies any history of fever, chest pain, or recent infections. What is the most probable diagnosis for this patient's condition based on the described findings? (Q856358)

A. Aortic stenosis

B. Mitral valve prolapse

C. Ventricular septal defect

D. Tricuspid regurgitation

Correct Answer: D. Tricuspid regurgitation

Explanation: Tricuspid regurgitation is characterized by a pan systolic murmur heard best along the right side of the heart and it radiates to the right of the sternum. Additionally, tricuspid regurgitation is often secondary to other conditions affecting the right side of the heart, such as pulmonary hypertension or right heart failure. The characteristics of a pan systolic murmur heard at the right side of the heart and radiating to the axilla, along with the absence of signs of aortic stenosis, mitral valve prolapse, and ventricular septal defect, point toward tricuspid regurgitation as the most likely diagnosis in this case. It's important to consider the entire clinical picture and potentially perform further tests (e.g., echocardiography) to confirm the diagnosis and assess the severity of the condition. Aortic Stenosis (Option A) Systolic ejection murmur, crescendo-decrescendo pattern, radiating to carotids, best heard at the right upper sternal border Mitral Valve Prolapse (Option B) Late systolic murmur is best heard at the apex, not a pan systolic murmur. Typically preceded by a non-ejection click, and intensity and duration increases with maneuvers that decrease ventricular volume. Ventricular Septal Defect (Option C) Harsh, holosystolic murmur heard, best at the left lower sternal border , as blood flows from the higher-pressure left ventricle to the lower-pressure right ventricle.

@Neet_pg_bot

Q103: Correct sequence after p wave: A - ‘a’ wave B - 1 st heart sound C - Rapid filling of ventricles D - ‘t’ wave (Q856377)

A. ABCD

B. ABDC

C. CABD

D. ACBD

Correct Answer: B. ABDC

Explanation: ABDC The correct sequence after the P wave is as follows: A. The 'a' wave represents atrial contraction. It occurs during atrial systole when the atria contract to push blood into the ventricles. B. The 1st heart sound, also known as S1, is the closure of the atrioventricular (AV) valves (mitral and tricuspid valves) at the beginning of ventricular systole. It marks the onset of ventricular contraction. D. The 't' wave is a repolarization phase of the ventricles. It represents the relaxation and resetting of the ventricles after contraction. C. After the 't' wave, the ventricles enter the diastole phase, during which they passively fill with blood from the atria. This is known as rapid ventricular filling. Jugular Venous Pressure (JVP) Waveform a wave Caused by atrial systole.

Atrial contraction results in a temporary halt in venous inflow. Some blood flows back into the veins, causing a rise in venous pressure. c wave Arises from the increase in atrial pressure during isovolumetric ventricular contraction. Pressure is transmitted through the closed and bulging tricuspid valve. x descent Ventricular systole pulls the tricuspid valve down v wave Corresponds to the rise in atrial pressure as blood fills the atria. Occurs during diastole while the tricuspid valve is still closed. y descent Opening of tricuspid valve causing emptying of right atrium into ventricle Respiration Influence : Venous pressure decreases during inspiration due to negative intrathoracic pressure, and rises during expiration.

@Neet_pg_bot

Q104: Water hammer pulse is seen in which of the following conditions? (Q855002)

A. Aortic stenosis

B. Aortic regurgitation

C. Aortic stenosis and aortic regurgitation

D. Mitral regurgitation

Correct Answer: B. Aortic regurgitation

Explanation: Water hammer pulse is seen in Aortic regurgitation. Signs of Aortic Regurgitation Muller Sign It is a visible systolic pulsation of the uvula Rosenbach sign Systolic pulsations of the Liver Gerhardt's sign Systolic pulsations of the Spleen Quincke's sign Repeatedly alternating blushing and blanching of capillaries in the nail folds upon palpation (Capillary Pulsations) Landolphi sign Alternating systolic constriction and diastolic dilatation of pupils Traube Sign It is pistol shot sounds that are heard while auscultating over the femoral artery. Water-Hammer pulse/ Corrigan's pulse Strong pulse that rises quickly and then drops off suddenly. Duroziez Sign It is a to-and-fro murmur heard while auscultating the femoral artery. De-Musset sign The jarring motion of the head with each heartbeat Aortic stenosis (Option A): Severe aortic stenosis is associated with pulsus parvus et tardus, characterized by a carotid pulse that rises slowly and peaks late due to restricted blood flow through the narrowed valve, which is distinct from the bounding water hammer pulse seen in aortic regurgitation. Aortic stenosis and aortic regurgitation (Option C): In cases where aortic stenosis and aortic regurgitation coexist, the stenosis reduces the stroke volume ejected into the aorta, limiting the high-amplitude and rapid upstroke typical of a water hammer pulse seen in isolated aortic regurgitation. Mitral regurgitation (Option D): Chronic mitral regurgitation shows a sharp, low-volume pulse due to reduced forward cardiac output, while acute mitral regurgitation may present with a narrow pulse pressure. Neither scenario produces the rapid upstroke and collapse characteristic of a water hammer pulse.

@Neet_pg_bot

Q105: A 70-year-old man with a known history of DM and HTN on regular medications presents with a history of progressively worsening dyspnoea on exertion. On examination, there’s elevated JVP, positive hepatojugular reflux, crackles at the

lung bases, hepatomegaly, ascites and pedal oedema. What is your provisional diagnosis? (Q855008)

A. Heart failure

B. Hypertrophic cardiomyopathy

C. Mitral regurgitation

D. Portal hypertension

Correct Answer: A. Heart failure

Explanation: The patient’s symptoms, including progressively worsening dyspnea on exertion, elevated jugular venous pressure (JVP), positive hepatojugular reflux, crackles at the lung bases, hepatomegaly, ascites, and pedal edema, are indicative of heart failure. Clinical features of Congestive Heart Failure: Cardiac output decreased Stroke volume decreased Heart rate increased Increased sympathetic drive leading to palpitations and diaphoresis Orthopnea Paroxysmal nocturnal dyspnea Clinical Features of Left-Sided vs. Right-Sided Congestive Heart Failure (CHF) Left-Sided Heart Failure Right-Sided Heart Failure Causes : Ischemic heart disease (myocardial infarction). Hypertension Dilated cardiomyopathy. Aortic or mitral valve disease. Causes : Left-sided heart failure (most common cause). Chronic lung diseases (COPD, pulmonary hypertension). Pulmonary embolism. Right ventricular infarction. In left-sided heart failure, the left ventricle cannot effectively pump blood to the body, leading to a backup of blood into the lungs. Clinical features: This primarily results in pulmonary symptoms. Exertional dyspnea Orthopnea Paroxysmal nocturnal dyspnea Pulmonary Congestion: Crackles (rales) heard on auscultation due to fluid in the alveoli. Cough Wheezing (cardiac asthma). Fatigue and Weakness Decreased Exercise Tolerance Limited physical activity due to breathlessness and fatigue. S3 Gallop Cool Extremities: Reduced cardiac output may cause poor peripheral circulation, leading to cold, pale skin. In right-sided heart failure, the right ventricle fails to pump blood effectively into the pulmonary circulation, leading to systemic venous congestion. It is often secondary to left-sided heart failure or conditions affecting the lungs (cor pulmonale). Clinical Features: Peripheral Edema Jugular Venous Distension (JVD) Hepatomegaly B/L pitting pedal edema Kussmaul sign: JVP elevation on inspiration Ascites Nocturia Weight Gain Anorexia and Nausea Hypertrophic cardiomyopathy (Option B): While hypertrophic cardiomyopathy can cause dyspnea, the patient’s clinical signs of elevated JVP, hepatojugular reflux, crackles, hepatomegaly, ascites, and pedal edema are more indicative of heart failure due to volume overload, which is not a characteristic feature of hypertrophic cardiomyopathy. Mitral regurgitation (Option C) : Although mitral regurgitation can lead to heart failure, the signs observed here (e.g., ascites, pedal edema, crackles) indicate a more generalized failure of the heart to pump blood effectively, which is more consistent with heart failure (particularly congestive heart failure) rather than isolated mitral regurgitation. Portal hypertension (Option D) can occur secondary to right heart failure, but the progressive dyspnea, along with the extensive signs of systemic congestion (e.g., elevated JVP, ascites, hepatojugular reflux), points toward a primary cardiac condition like heart failure.

@Neet_pg_bot

Q106: Which of the following is not a radiological finding in a patient with left heart failure? (Q855046)

A. Kerley B lines

B. Focal oligemia

C. Increased venous blood in lung

D. Change in upper lobe circulation

Correct Answer: B. Focal oligemia

Explanation: hanges in Left Heart Failure: Pulmonary venous dilation and congestion (Option C) Cephalization of pulmonary veins: Upper lobe vessels become more prominent due to redistribution of blood flow (Option D) Kerley B (septal) lines: Horizontal lines caused by interstitial edema (Option A) Thickened interlobar fissures Pulmonary interstitial edema: Blurring of vascular margins and peribronchial cuffing Pulmonary alveolar edema: Bat-wing or butterfly pattern of opacities Pleural effusion Cardiomegaly (increased cardiothoracic ratio) {{caption_text}}

@Neet_pg_bot

Q107: A 60-year-old man presented with an episode of acute onset dizziness and loss of consciousness, which lasted for a few seconds, followed by a regain of full consciousness. There were no similar episodes in the past. Which of the following is a true statement regarding this scenario? (Q855052)

A. ECG to rule out atrial fibrillation

B. If ECG is normal, CT scan should be done

C. Tilt-table testing

D. Vestibular neuritis is a possible condition that can cause these symptoms

Correct Answer: A. ECG to rule out atrial fibrillation

Explanation: The patient’s presentation of acute onset dizziness and loss of consciousness, which lasted only a few seconds and was followed by full recovery, suggests a transient loss of consciousness episode, likely syncope . This could be due to arrhythmias (atrial fibrillation , sinus node dysfunction, atrioventricular block, ventricular tachyarrhythmia) or structural cardiac abnormalities, making an ECG crucial in this case to rule out cardiac causes. Syncope: Transient, self-limited loss of consciousness due to acute global impairment of cerebral blood flow. Rapid onset, brief duration, and spontaneous, complete recovery. Categories of Syncope Causes: Neurally mediated syncope (reflex or vasovagal syncope) Orthostatic hypotension Cardiac syncope Initial Evaluation of Syncope: Detailed history and thorough questioning of eyewitnesses. Complete physical and neurologic examination. Measure blood pressure and heart rate in the supine position and after 3 minutes of standing to assess for orthostatic hypotension. ECG Indications: If there is suspicion of syncope due to arrhythmia or underlying cardiac disease. Relevant electrocardiographic abnormalities include bradyarrhythmias, tachyarrhythmias, AV block, acute myocardial ischemia, old myocardial infarction, long QT, and bundle branch block. If ECG is normal, CT scan should be done (Option B): A CT scan would only be required if a seizure or transient ischemic attack (TIA) is suspected. Given that the episode lasted only a few seconds, the patient has no history of similar events, and there are no lasting neurological deficits, a CT scan is not typically needed at this point. Tilt-table testing (Option C) is generally reserved for patients with recurrent or unexplained syncope. It is not typically used for a single isolated episode of syncope, especially in the absence of a history of similar events. Vestibular neuritis (Option D) typically causes dizziness and a sense of spinning (vertigo), but it does not generally lead to loss of consciousness. Since the patient’s primary symptom is syncope (brief loss of consciousness), vestibular neuritis is not the most likely diagnosis in this case.

@Neet_pg_bot

Q108: A 58-year-old male patient has been diagnosed with hypertension. On examination, there is no existing cardiovascular disease, no hypertension-mediated organ damage (HMOD), and renal function is normal. He should be immediately started on pharmacological management if his blood pressure is more than (Q855064)

A. >130/80 mmHg

B. >160/100 mmHg

C. >150/100 mmHg

D. >140/90 mmHg

Correct Answer: D. >140/90 mmHg

Explanation: guidelines for hypertension management: Indications for Immediate Pharmacological Treatment: Adults aged 18-79 years with: Systolic Blood Pressure (SBP): ≥140 mmHg Diastolic Blood Pressure (DBP): ≥90 mmHg In patients with no cardiovascular disease, no hypertension-mediated organ damage (HMOD), and normal renal function, immediate pharmacological therapy is initiated if the BP is ≥140/90 mmHg. AHA Hypertension Grading Category Systolic BP (mmHg) Diastolic BP (mmHg) Normal <120 <80 Elevated 120–129 <80 Hypertension Stage 1 130–139 80–89 Hypertension Stage 2 ≥140 ≥90 Hypertensive Crisis >180 >120 ACC/AHA Guidelines for Hypertension Management Indications for Use of antihypertensives Secondary prevention of recurrent CVD events in patients with clinical CVD (defined as CHD, CHF, stroke) and BP ≥130/≥80 mmHg Primary prevention in patients with an estimated 10-year ASCVD risk ≥10% and BP ≥130/≥80 mmHg Primary prevention of CVD and low CVD risk in patients with BP ≥140/ ≥90 mmHg Blood Pressure Goal in Treating Hypertension BP target < 130/80 mmHg for adults with confirmed hypertension and known CVD or 10-year ASCVD event risk ≥10% Exceptions to Therapeutic Target of <130/80 mmHg Age >80 years Blood pressure <140/90 mmHg in previously untreated hypertensive patients who experience an ischemic stroke or TIA Acute therapy for most hypertensive urgencies and emergencies Abbreviations : ASCVD - atherosclerotic cardiovascular disease CHD - coronary heart disease CHF - congestive heart failure CVD - cardiovascular disease Patient type First Drug Add a Second Drug If Needed to Achieve the target BP If a Third Drug is Needed to Achieve the target BP Black patients (African ancestry): All ages CCB or thiazide diuretic ARB or ACE inhibitor Combination of CCB + ACE inhibitor or ARB + thiazide diuretic White and other non-black Patients: Younger than 60 years ARB or ACE inhibitor CCB or thiazide diuretic White and other non-black patients: 60 years and older CCB or thiazide diuretic ARB or ACE inhibitor Abbreviations : CCB - Calcium channel blocker ACE - Angiotensin converting enzyme ARB - Angiotensin receptor blocker Hypertension with other associated conditions Initial drug of choice Hypertension and diabetes ARB or ACE inhibitor Hypertension and chronic kidney disease ARB or ACE inhibitor Note: in black patients, good evidence for the renal protective effects of ACE inhibitors Hypertension and clinical coronary artery disease β-Blocker plus ARB or ACE inhibitor Hypertension and stroke history ARB or ACE inhibitor Hypertension and heart failure Regardless of blood pressure, ARB or ACE inhibitor + β-blocker + diuretic + spironolactone. A dihydropyridine CCB can be added if needed for BP control. Pneumonic: ABDS

@Neet_pg_bot

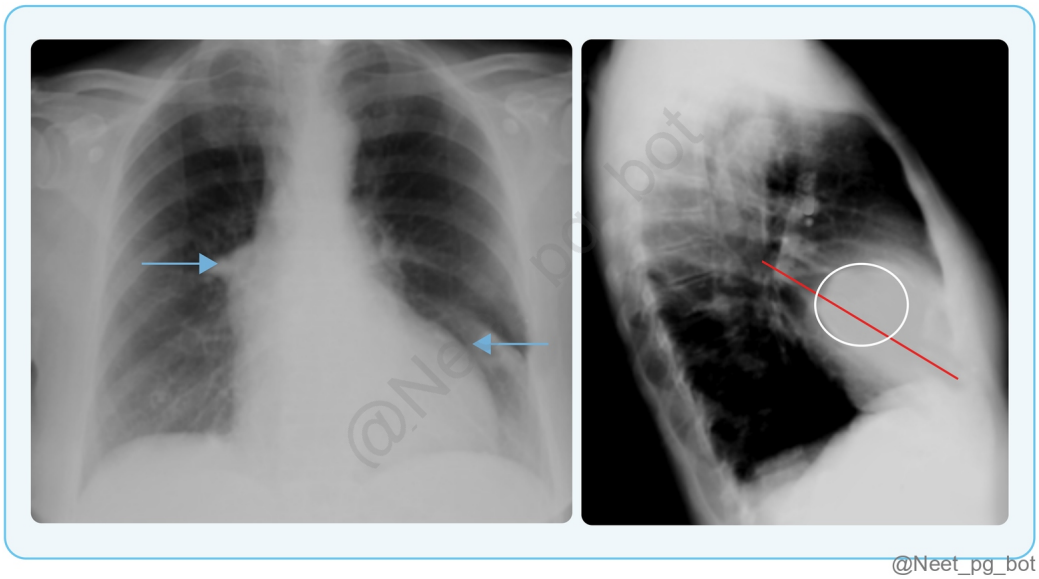
Q109: A 65-year-old male patient presented with chest pain, exertional dyspnea and syncope. He was diagnosed with a case of aortic stenosis and his chest x-ray was taken which is shown below. What is the most likely diagnosis? (Q859523)

A. Dilated aortic root

B. Widening of aortic knob

C. Widening of the vascular pedicle

D. Post stenotic dilatation of aorta



Correct Answer: D. Post stenotic dilatation of aorta

Explanation: Based on the given clinical presentation of chest pain, exertional dyspnea, and syncope, along with the diagnosis of aortic stenosis and chest x-ray findings, the most likely diagnosis in this case is post-stenotic dilatation of the aorta . Aortic Stenosis Symptom onset: AS is clinically significant when the aortic valve orifice narrows to ~1 cm^2. Severe AS can remain asymptomatic for years due to LV compensation. Symptom progression: Often develops in the sixth to eighth decades; patients with bicuspid aortic valves may experience symptoms 10-20 years earlier. Clinical Manifestations of Aortic Stenosis: Triad: Exertional dyspnea, Angina pectoris, Syncope on exertion Early symptoms : Fatigue and reduced exercise tolerance. Advanced stages: Orthopnea Paroxysmal nocturnal dyspnea Pulmonary edema. Late Findings: RV failure Systemic venous hypertension Hepatomegaly Atrial fibrillation Tricuspid regurgitation Post-Stenotic Aortic Dilatation (PSAD) Definition : Post-stenotic aortic dilatation refers to the enlargement of the aortic vessel wall distal to a stenotic or malformed aortic valve. It typically involves the ascending aorta, with a diameter greater than 4.0 cm, and is characterized by a progressive increase in size of more than 0.3 cm per year. Risk : It is considered a precursor to serious conditions like aortic dissection and rupture, which can be fatal. Aetiology : PSAD can occur in patients with aortic stenosis (AS) or aortic regurgitation (AR), and even in those with a normal aortic valve (e.g., in the case of a bicuspid aortic valve, BAV), or after aortic valve replacement (AVR). PSAD is not solely related to the severity of AS but may have a genetic basis, alongside mechanical stresses placed on the aortic wall. The bicuspid aortic valve is an independent risk factor for both AS and progressive aortic dilatation. Imaging findings: Dilatation of the aorta immediately distal to the stenosis. Normal or narrowed aortic segment proximal to stenosis. Additional findings depend on aetiology. Incorrect Options: Aortic root dilatation (Option A) is typically asymptomatic and discovered incidentally, but in rare cases, it can lead to severe complications like aortic dissection, rupture, or congestive heart failure due to aortic insufficiency. This is not the given scenario. Widening of the aortic knob (Option B) is seen in congenital heart diseases, aortic dissection, systemic hypertension, post-stenotic dilatation, etc. However, the location of the given lesion is not of the aortic knob. Widening of the vascular pedicle (Option C) : The vascular pedicle is measured between parallel lines drawn from the point at which the superior vena cava intersects the right main bronchus and a line drawn at the takeoff of the left subclavian artery from the aorta. This is not the given

radiograph.

@Neet_pg_bot

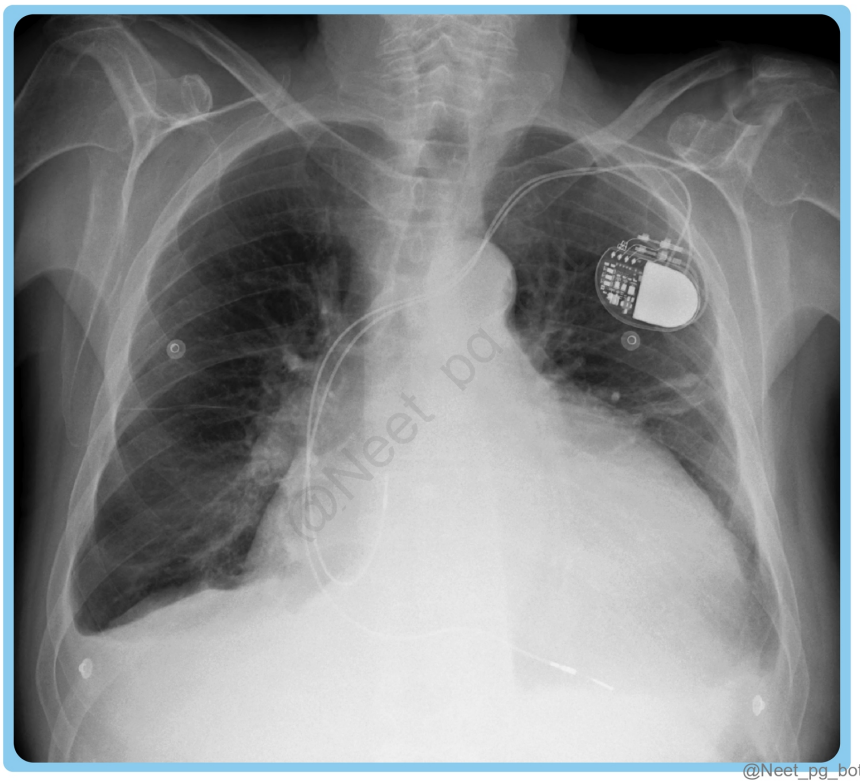
Q110: The device seen in the following image is? (Q859525)

A. Cardiac pacemaker

B. Chemo port device

C. Travel tract for accessory

D. Chest X-ray artefact



Correct Answer: A. Cardiac pacemaker

Explanation: The device shown in the x-ray is a cardiac pacemaker . Cardiac Conduction Devices (CCDs) Implantable Cardioverter Defibrillators (ICD): Function: Delivers electrical shocks to treat dysrhythmias and restore normal sinus rhythm. Types: Transvenous ICDs (T-ICD): Leads placed at the junction of the brachiocephalic vein/superior vena cava and right ventricle (RV). Can be combined with biventricular pacemakers for Cardiac Resynchronization Therapy (CRT). Subcutaneous ICDs (S-ICD): No transvenous lead insertion. The pulse generator is placed subcutaneously, and the shock is delivered via a left parasternal subcutaneous lead. Components of CCDs: Pulse Generator: Provides the electrical signals. Electrode: Sends electrical impulses to the heart. Lead Wires: Connect the electrode to the pulse generator, with different tips for attachment to the heart. Active Fixation: Leads with helical tips screw into the myocardium. Passive Fixation: Leads anchor onto heart trabeculae through fibrosis. Chest Radiography for CCD Evaluation: Preferred imaging modality for assessing CCD location, lead integrity, and complications. Two Views Required: Posterior-Anterior (PA) View : Provides a 2D view for lead integrity. Lateral (LAT) View: Essential for evaluating lead tip location and distinguishing between leads in the right or left ventricle. {{caption_text}} Purpose of Imaging: To ensure correct positioning of leads, diagnose complications, and confirm device functionality for maximal therapeutic benefit. Chemoport device (Option B) Implantable ports, commonly referred to as chemoports, totally implantable central venous access ports, or Port-A-Caths, are a type of central venous catheter designed for patients needing extended venous access. These devices provide a long-term solution for central venous access, offering a distinct advantage over peripherally inserted central catheters (PICC). {{caption_text}} Options C and D are incorrect .

@Neet_pg_bot

Q111: A 55-year-old male patient came to the hospital complaining of palpitations. During the examination, a diastolic murmur is detected in the left third intercostal space, along with the presence of a pistol shot sound over the femoral arteries. What is the diagnosis here? (Q859528)

A. Aortic regurgitation

B. Aortic stenosis

C. Tricuspid regurgitation

D. Mitral regurgitation

Correct Answer: A. Aortic regurgitation

Explanation: The diastolic murmur and the pistol shot sound over the femoral artery along with palpitations signify the diagnosis of aortic regurgitation . Signs of Aortic Regurgitation Muller Sign It is a visible systolic pulsation of the uvula Rosenbach sign Systolic pulsations of the Liver Gerhardt's sign Systolic pulsations of the Spleen Quincke's sign Repeatedly alternating blushing and blanching of capillaries in the nail folds upon palpation (Capillary Pulsations) Landolphi sign Alternating systolic constriction and diastolic dilatation of pupils Traube Sign It is pistol shot sounds that are heard while auscultating over the femoral artery. Water-Hammer pulse Strong pulse that rises quickly and then drops off suddenly. Duroziez Sign It is a to-and-fro murmur heard while auscultating the femoral artery. De-Musset sign The jarring motion of the head with each heartbeat Blood Pressure Elevated systolic pressure and decreased diastolic pressure result in increased arterial pulse pressure . Atrio-ventricular malformation and Atrio-ventricular ■stula also show low diastolic BP due to continuous Korotko■ sounds. Positive Hill’s sign is an abnormal difference in BP in the upper limb and lower limb. On Palpation Heaving LV impulse is noted, which is displaced laterally and inferiorly Diastolic and Systolic Thrills were noticed at the left lower sternal border and suprasternal notch, respectively. On Auscultation Heart Sounds A2 is absent In the Bicuspid aortic valve, systolic ejection sound is present Sometimes, A4 is also heard Murmurs A decrescendo diastolic murmur , best heard when sitting up and leaning forward, is an early diastolic murmur that becomes holo-diastolic as the condition progresses to a severe stage. Musical diastolic murmur is aortic cusp fluttering in the regurgitant flow. Mid-diastolic murmur Austin Flint murmur is a soft, low-pitched, mid- to end-diastolic murmur caused by mitral valve displacement due to AR. Ejection systolic murmur is commonly heard in AR along with AS . Incorrect Options: Aortic stenosis (Option B) presents with a midsystolic ejection murmur at the upper sternal border. Tricuspid regurgitation (Option C) presents with a holosystolic murmur at the lower left sternal border. Mitral regurgitation (Option D) presents with a systolic murmur at the apex of the heart with radiation to the left axilla.

@Neet_pg_bot

Q112: A person with dyspnea has a slight limitation in physical activity and doing ordinary activity causes symptoms but he is asymptomatic at rest. To which class does he belong, based on the New York Heart Association functional classification? (Q859529)

A. Class I

B. Class II

C. Class III

D. Class IV

Correct Answer: B. Class II

Explanation: The given scenario belongs to Class II in the New York Heart Association classification for heart failure. New York Heart Association (NYHA) Classification Class Symptoms I (Option A) No limitation of physical activity. No symptoms with ordinary exertion (e.g. shortness of breath when walking, climbing stairs etc). II Slight limitation of physical activity. Ordinary activity causes symptoms. III (Option C) Marked limitation of physical activity. Less than ordinary activity causes symptoms. Asymptomatic at rest. IV (Option D) Inability to carry out any physical activity without discomfort. Symptoms at rest.

Harrison's Principles of Internal Medicine, 21st Edition, Page: 1798.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q113: A 56-year-old woman who had a heart attack 2 years ago is currently experiencing a cough and difficulty breathing while walking short distances. Physical examination revealed dullness upon percussion and reduced breath sounds on the right side. A chest x-ray indicated the presence of moderate pleural effusion. Thoracocentesis, guided by ultrasound, was performed and the laboratory results are provided below. Pleural fluid findings: Appearance: turbid pH: 7.1 Protein: 3.2 g/dL Lactate dehydrogenase: 80 U/L (normal serum LDH- 50-150 U/L) Pleural fluid protein/serum protein ratio: 0.34 Pleural fluid LDH /serum LDH: 0.3 Glucose: 54 mg/dL WBC count: 4000 cells/µL with >50% lymphocytes Adenosine deaminase: 30 U/L AFB smear microscopy: Negative Gram staining and microscopy: No organisms, no pus cells (Q859532)

A. Parapneumonic pleural effusion

B. Malignant pleural effusion

C. Congestive heart failure

D. Tubercular pleural effusion

Correct Answer: C. Congestive heart failure

Explanation: The above case with the given clinical findings is suggestive of the diagnosis of congestive heart failure . The effusion is transudative in nature here according to Light’s criteria. Congestive Heart Failure: Clinical features Cardiac output decreased Stroke volume decreased Heart rate increased Increased sympathetic drive leading to palpitations and diaphoresis Orthopnea Paroxysmal nocturnal dyspnea Clinical Features of Left-Sided vs. Right-Sided Congestive Heart Failure (CHF) Left-Sided Heart Failure Right-Sided Heart Failure Causes : Ischemic heart disease (myocardial infarction). Hypertension Dilated cardiomyopathy. Aortic or mitral valve disease. Causes : Left-sided heart failure (most common cause). Chronic lung diseases (COPD, pulmonary hypertension). Pulmonary embolism. Right ventricular infarction. In left-sided heart failure, the left ventricle cannot effectively pump blood to the body, leading to a backup of blood into the lungs. Clinical features: This primarily results in pulmonary symptoms. Dyspnea Exertional dyspnea). Orthopnea Paroxysmal nocturnal dyspnea Pulmonary Congestion: Crackles (rales) heard on auscultation due to fluid in the alveoli. Cough Wheezing (cardiac asthma). Fatigue and Weakness Decreased Exercise Tolerance Limited physical activity due to breathlessness and fatigue. S3 Gallop Cool Extremities: Reduced cardiac output may cause poor peripheral circulation, leading to cold, pale skin. In right-sided heart failure, the right ventricle fails to pump blood effectively into the pulmonary circulation, leading to systemic venous congestion. It is often secondary to left-sided heart failure or conditions affecting the lungs (cor pulmonale). Clinical Features: Peripheral Edema Jugular Venous Distension (JVD) Hepatomegaly B/L pitting pedal oedema Kussmaul sign: JVP elevation on inspiration Ascites Nocturia Weight Gain Anorexia and Nausea Pleural fluid Analysis Light's Criteria Differentiates transudative from exudative pleural effusions based on LDH and protein levels in pleural fluid. An exudative pleural effusion meets at least one of the following: Pleural fluid protein/serum protein > 0.5 Pleural fluid LDH/serum LDH > 0.6 Pleural fluid LDH exceeds two-thirds of the normal upper limit for serum. ~25% of transudates may be misidentified as exudates. If exudative criteria are met but a transudative condition is suspected, measure protein difference; if >31 g/L (3.1 g/dL), likely transudative. Parapneumonic pleural effusion (Option A) has increased in WBCs, especially neutrophils and the appearance is cloudy. Malignant pleural effusion (Option B) and tubercular pleural effusion (Option D) are exudative in nature

@Neet_pg_bot

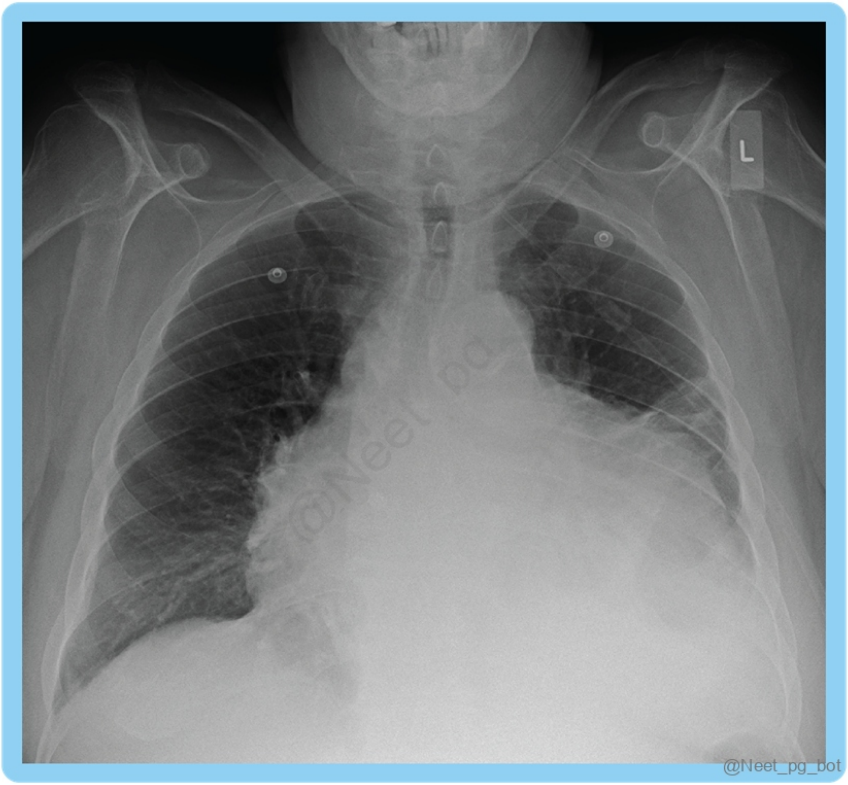
Q114: What is the most likely diagnosis for a 45-year-old man who experiences chest pain and difficulty breathing that worsens when lying down but improves when sitting upright, and has muffled heart sounds during examination? (Q859534)

A. Pericardial effusion

B. Tetralogy of Fallot

C. Transposition of great arteries

D. Pulmonary hypertension



Correct Answer: A. Pericardial effusion

Explanation: The above presentation of breathlessness on lying down and it being relieved on sitting, and the X-ray given which shows an enlarged cardiac silhouette is suggestive of a probable diagnosis of pericardial effusion. Pericardial effusion: Pericardial effusion can lead to cardiac tamponade if rapid. Faint heart sounds and a large cardiac silhouette on X-ray. Chest X-ray showing waterbottle configuration in Pericardial effusion {{caption_text}} Electrical alternans is a classic ECG finding in pericardial effusion, particularly when it leads to cardiac tamponade. It manifests as beat-to-beat variations in the amplitude of the QRS complexes, reflecting the heart's movement within the fluid-filled pericardial space. This finding is indicative of significant fluid accumulation and increased intrapericardial pressure, which impedes the heart's ability to fill properly during diastole. {{caption_text}} ECG showing Electrical alternans White arrows showing variations in the amplitude of QRS complexes Incorrect Options: Tetralogy of Fallot (Option B) shows a boot-shaped heart on an x-ray. Transposition of great arteries (Option C) shows an egg-on-string appearance on x-ray. Pulmonary hypertension (Option D) shows a pruned tree appearance of the pulmonary vasculature.

Harrison’s Principles of Internal Medicine, 21st Edition, Page: 1830, 1853, 2020, 2028.

↑ *Back to this question in Part A*

@Neet_pg_bot

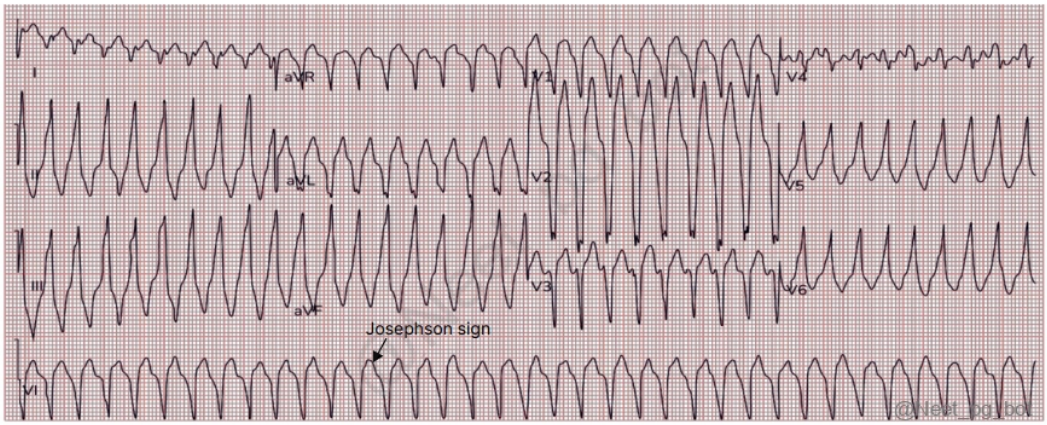
Q115: A 62-year-old man with a history of coronary artery disease presents with sudden onset palpitations, dizziness, and mild chest discomfort. His blood pressure is 90/60 mmHg and ECG is given below. What is the most likely diagnosis? (Q859535)

A. Atrial fibrillation

B. Atrial flutter

C. Ventricular tachycardia

D. Ventricular fibrillation



Correct Answer: C. Ventricular tachycardia

Explanation: ECG shows broad QRS tachycardia (>100/min) with classic VT features such as wide complexes , extreme axis deviation , and possible capture/fusion beats , strongly suggesting ventricular tachycardia Key Features of Ventricular Tachycardia Tachycardia: HR > 100/min (short R-R interval) Broad QRS complexes due to slower myocyte-to-myocyte conduction Josephson sign: Notch on the downslope of the S-wave Capture beats: Normal QRS amidst VT Fusion beats: Mixed SVT + VT impulse → intermediate QRS Extreme axis deviation Treatment of VT Pulseless VT: Defibrillation (unsynchronized shock) Stable VT: IV Amiodarone Post-MI VT (DOC): Amiodarone If BP unrecordable: Defibrillation Cardioversion: Synchronized DC shock Defibrillation: Unsynchronized DC shock Atrial fibrillation (Option A): Irregularly irregular rhythm, no P waves, variable R-R, usually narrow QRS. Not compatible with a regular wide-complex tachycardia. Atrial flutter (Option B): Saw-tooth waves, atrial rate ~300/min, usually narrow QRS. Ventricular fibrillation (Option D): Completely chaotic rhythm, no QRS, no pulse. Patient would be pulseless, unlike in this case.

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Page: 1899-1902.

Davidson’s Principles and Practice of Medicine, 24th Edition, Page: 470.

Atrial Flutter - StatPearls - NCBI Bookshelf

↑ *Back to this question in Part A*

@Neet_pg_bot

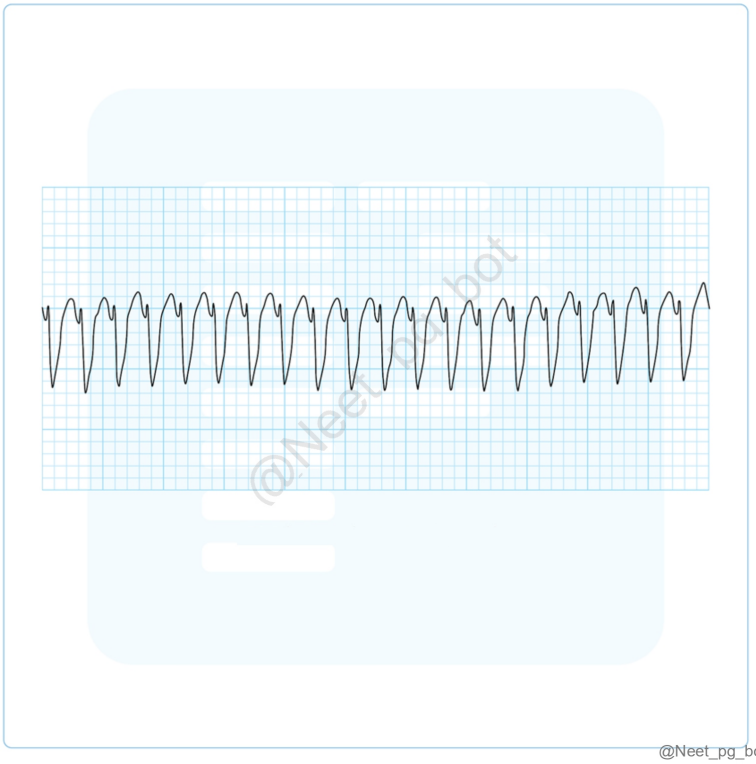
Q116: Based on the ECG given below, what is the most likely diagnosis? (Q859537)

A. Normal ECG

B. Ventricular fibrillation

C. Ventricular tachycardia

D. Misplaced leads



Correct Answer: C. Ventricular tachycardia

Explanation: The given ECG shows ventricular tachycardia with wide, regular QRS complexes and a rate typically over 100 bpm. Ventricular tachycardia Pathology: VT is defined as three or more consecutive premature ventricular contractions (PVCs) with a heart rate of over 100 bpm. It can be either monomorphic (all QRS complexes appear similar) or polymorphic (QRS complexes vary in shape). Monomorphic VT is often related to a

reentry circuit around a myocardial scar, typically after myocardial infarction, while polymorphic VT, especially Torsades de Pointes, is related to prolonged QT intervals, ischemia, or electrolyte imbalances. ECG Findings: Monomorphic VT : Wide QRS complexes (>120 ms), regular rhythm, and consistent morphology across leads. The QRS axis may vary depending on the site of origin (e.g., LBBB or RBBB-like morphology). {{caption_text}} Polymorphic VT : Continuously changing QRS morphology, often associated with prolonged QT intervals (in Torsades de Pointes). {{caption_text}} Treatment: Stable Monomorphic VT : Intravenous procainamide or amiodarone can be used. Unstable Monomorphic VT : Immediate synchronized cardioversion is required. Polymorphic VT (Torsades de Pointes) : IV magnesium sulfate and correction of underlying electrolyte abnormalities (e.g., hypokalemia) are crucial, along with discontinuation of QT-prolonging drugs. Incorrect Options: The above is not a normal ECG (Option A) as it has tachycardia, absent P wave, and vast QRS complexes. Ventricular fibrillation (Option B) usually has no identifiable QRS complex hence the given ECG does not show ventricular fibrillation. Misplaced leads (Option D) do not produce the given ECG.

Goldberger’s Clinical Electrocardiography, A Simplified Approach, 9th Edition, Page: 167.

↑ *Back to this question in Part A*

@Neet_pg_bot

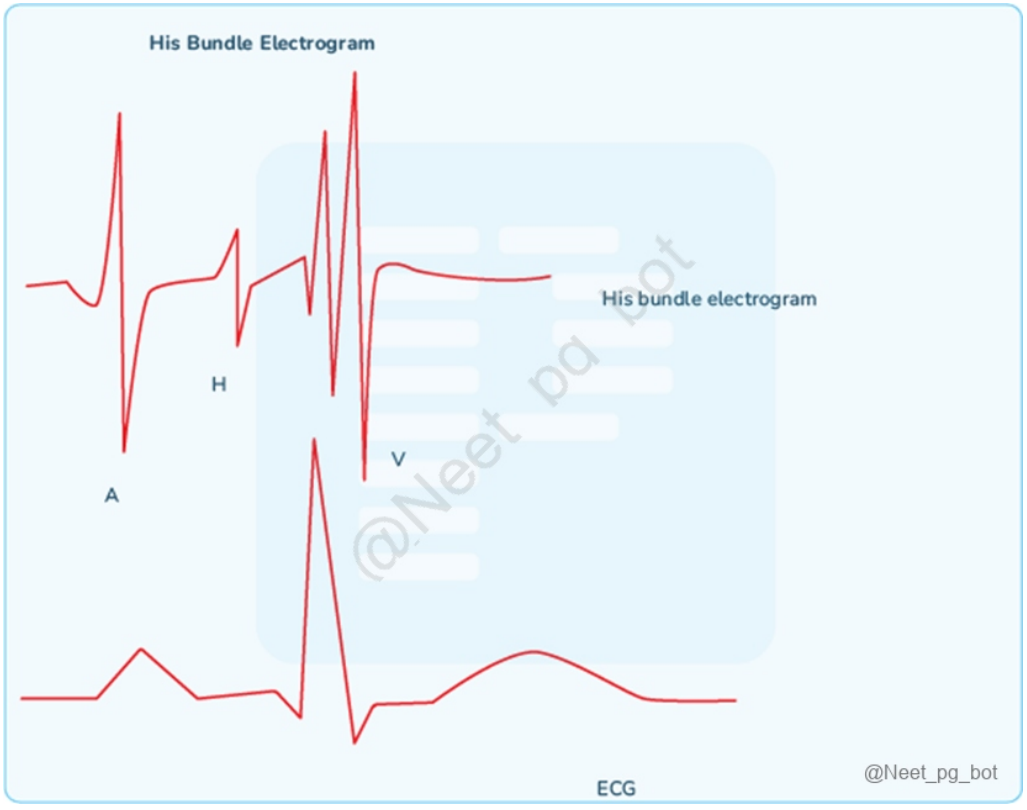
Q117: HV interval in the below given His bundle electrogram is for conduction: (Q859559)

A. Through the His-Purkinje system

B. From AV node to bundle of His

C. Purkinje to ventricular fibres

D. From a bundle of His and bundle branches to ventricles



Correct Answer: D. From a bundle of His and bundle branches to ventricles

Explanation: The HV interval represents the time it takes for electrical conduction to occur from the His bundle and bundle branches to the ventricles of the heart. A typical His bundle electrogram includes the following components: A: Atrial deflection H: His deflection QRS: Ventricular depolarization The intervals measured are as follows: P-H: The interval from the start of the P wave (either from a standard lead ECG or high atrial lead) to the initial rapid deflection of the His bundle spike . (Option B) A-H: The interval from the onset of the atrial deflection on the His bundle electrogram (low RA) to the His bundle deflection . (Option A) H-V : The interval from the first

rapid deflection of the His bundle to the onset of ventricular depolarization, measured either from the His bundle electrogram or standard leads. Option C is incorrect.

https://www.ahajournals.org/doi/pdf/10.1161/01.cir.47.4.897

↑ *Back to this question in Part A*

@Neet_pg_bot

Q118: A 50-year-old man presents with recurrent episodes of chest pain which is seen only on exertion or exercise and lasts 2-5 minutes. He was assessed and was diagnosed with a case of stable angina however his BP was consistently elevated. What is the most appropriate antihypertensive for this patient (Q859560)

A. Atenolol

B. Thiazides

C. Enalapril

D. Amlodipine

Correct Answer: D. Amlodipine

Explanation: The most appropriate antihypertensive for a patient with stable angina and consistently elevated blood pressure would be Amlodipine . It is particularly beneficial in patients with stable angina, as it can improve coronary blood flow by reducing vasospasm and decreasing myocardial oxygen demand. Additionally, amlodipine has a favourable effect on blood pressure control, which makes it suitable for patients with both stable angina and hypertension. Medical management of stable angina Medication Class Function/Mechanism Indications Nitrates Sublingual nitroglycerin (0.4 or 0.6 mg) Long-acting forms (oral, transdermal) Systemic venodilation Reduces LV end-diastolic volume and pressure Releases nitric oxide (NO) to relax vascular smooth muscle Angina relief Preemptive use before activities Improves exercise tolerance Beta-Blocker (Option A) Reduces heart rate, arterial pressure, and myocardial contractility Improves survival post-MI Angina relief Reduces mortality and reinfarction rates Calcium Channel Blockers Coronary vasodilators Reduces myocardial oxygen demand and arterial pressure Dihydropyridines (e.g., amlodipine) and non-dihydropyridines (e.g., verapamil) Angina treatment when beta-blockers are ineffective Variant angina Antiplatelet Drugs Aspirin : inhibits platelet activation Clopidogrel 75mg : blocks platelet aggregation Reduces coronary events in high-risk populations Stent placement Thiazide (Option B) diuretics are a class of medications used to treat hypertension. They help reduce blood pressure by promoting diuresis and decreasing fluid volume. However, they may not be the most appropriate choice in this case since the patient already has stable angina, and thiazides are not specifically indicated for the treatment of angina. Enalapril (Option C) is an angiotensin-converting enzyme (ACE) inhibitor that is commonly used in the management of hypertension and are effective antihypertensive agent, they may not be the initial choice in this case, considering the patient's primary symptom of stable angina

@Neet_pg_bot

Q119: A postoperative cardiac surgery patient developed sudden hypotension, raised central venous pressure, and pulsus paradoxus at the 4 th postoperative hour. The most probable diagnosis is. (Q859565)

A. Ventricular dysfunction

B. Cardiac tamponade

C. CHF

D. Excessive mediastinal effusion

Correct Answer: B. Cardiac tamponade

Explanation: Based on the symptoms described in the postoperative cardiac surgical patient, the most probable diagnosis is cardiac tamponade which is a medical emergency characterized by the accumulation of fluid or blood in the pericardial sac, which leads to compression of the heart and impaired cardiac function. Cardiac Tamponade Definition A condition where the cardiac chambers are compressed by a tense pericardial effusion, limiting cardiac inflow. Fluid accumulation of as little as 200 ml to upwards of 2 L may lead to cardiac tamponade development. Clinical Features Beck's triad Jugular Venous Distension : Due to increased central venous pressure. Prominent x descent and an absent y descent. Hypotension : Resulting from impaired cardiac output. Muffled Heart Sounds : Caused by fluid accumulation in the pericardial space, dampening heart sounds. Other features Pulsus paradoxus : A drop in systolic BP during inspiration, greater than 10 mm Hg. Causes of Pulsus paradoxus: Lung Conditions: Acute asthma, COPD, tension pneumothorax, pleural effusion, pulmonary embolism. Heart Conditions: Cardiac tamponade, constrictive pericarditis. Low-Pressure Cardiac Tamponade Definition This occurs when lower pericardial pressure leads to tamponade, often in cases of intravascular fluid depletion (e.g., hypovolemia). Features Jugular Venous Distension: Often absent Pulsus Paradoxus: Rare Requires a high degree of suspicion due to the absence of typical signs like jugular venous distension and pulsus paradoxus. Incorrect Options: While ventricular dysfunction (Option A) can cause hypotension and cardiac symptoms, it does not typically present with raised central venous pressure or pulsus paradoxus. Additionally, the sudden onset of symptoms in this case suggests a more acute problem like cardiac tamponade rather than chronic ventricular dysfunction. CHF (Option C) can cause fluid retention, leading to increased venous pressure and symptoms such as dyspnea and oedema. However, it does not typically present with sudden hypotension, raised central venous pressure, or pulsus paradoxus. Excessive mediastinal effusion (Option D) can potentially cause compression of the heart and lead to symptoms similar to cardiac tamponade. However, the specific mention of raised central venous pressure and pulsus paradoxus points more towards cardiac tamponade as the likely diagnosis.

@Neet_pg_bot

Q120: A male patient in his youth comes to the clinic complaining of a persistent high fever over the past 5 days. During the examination of his hands, painless lesions are observed, and a new regurgitant murmur is detected. The echocardiogram reveals the existence of a mass on the mitral valve. Based on these findings, which of the following abdominal findings would be expected in this case? (Q859791)

A. Ascites

B. Splenomegaly

C. Hepatomegaly

D. Portal hypertension

Correct Answer: B. Splenomegaly

Explanation: The presence of high-grade fever, painless lesions on the hands (Janeway lesions), and a new regurgitant murmur suggests the possibility of infective endocarditis. The most likely abdomen finding in this case would be splenomegaly . Acute Bacterial Endocarditis Aggressive course compared to subacute endocarditis. Causative organisms : S. aureus (Most common cause) (including MRSA), S. pneumoniae, L. monocytogenes, Haemophilus species, streptococci (groups A, B, G). Risk factors : Comorbid conditions like malignancy, diabetes mellitus, IV drug use, or alcoholism. Presentation : Fever, fatigue, and malaise within <2 weeks of infection. Changing heart murmur, potential congestive heart failure. Possible signs: Janeway lesions (hemorrhagic macules on palms/soles), petechiae Roth's spots Splinter haemorrhages Splenomegaly (rare). (Option B) Peripheral manifestations : Janeway lesions: Painless, erythematous macules on palms and soles. Related to septic microembolization, {{caption_text}} Osler's nodes: Small painful pea-shaped nodules located at the tips of fingers and toes (Immune complex-mediated). {{caption_text}} Subungual haemorrhages/Splinter haemorrhages; More common in acute S. aureus IE. Haemorrhages below nails- multiple linear lesions, initially red then turning brown or black. {{caption_text}} Roth spots: Pale-centred retinal haemorrhages that are seen in the fundus examination {{caption_text}} Arterial emboli : Occur in up to 50% of patients, often preceding IE diagnosis, causing organ dysfunction (e.g., stroke, kidney, spleen , or limb ischemia). Neurologic complications : Strokes complicate 15-35% of cases; also include encephalopathy, seizures, meningitis, intracranial haemorrhage, mycotic aneurysms, and brain abscesses. Renal complications : Hypocomplementemic glomerulonephritis due to immune complex deposition, often improving with antimicrobial therapy; renal infarcts may cause flank pain and hematuria. Ascites (Option A) occurs due to portal hypertension, chronic liver disease, nephrotic syndrome, or severe right-sided heart failure , and it is not a typical abdominal manifestation of infective endocarditis. Hepatomegaly (Option C) is usually seen in congestive hepatopathy due to right-sided heart failure, viral hepatitis, or infiltrative liver diseases , whereas infective endocarditis primarily produces splenic enlargement rather than liver enlargement . Portal hypertension (Option D) results from increased resistance to portal blood

flow , most commonly due to cirrhosis or portal vein obstruction , and is not associated with infective endocarditis
.

Q121: Which of the following leads to a continuous murmur? (Q859800)

A. Peripheral Pulmonic stenosis

B. Severe Pulmonary artery hypertension

C. Type A aortic dissection

D. Rupture of cardiac chamber

Correct Answer: A. Peripheral Pulmonic stenosis

Explanation: Peripheral Pulmonic stenosis produces a characteristic continuous murmur due to persistent turbulent blood flow through narrowed pulmonary artery branches. This congenital condition creates turbulence in blood flow that begins in systole, peaks near the second heart sound, and continues through diastole. The continuous nature of the murmur occurs because the pressure gradient between the pulmonary artery and its branches remains throughout the cardiac cycle, maintaining constant turbulent flow. Continuous murmur Definition Murmur that persists across systole and diastole Begins in at S1, continues through second heart sound (S2) and tapers at next S1 Causes Patent Ductus Arteriosus (PDA) Peripheral Pulmonic stenosis Valsalva aneurysm Aortopulmonary window Great vessel arteriovenous fistula Coronary to pulmonic fistula Severe Pulmonary artery hypertension (Option B) typically causes leakage of blood into the RV during the diastole due to the high pressure in the pulmonary arteries, characteristically producing a diastolic murmur. Type A aortic dissection (Option C) is a medical emergency and the presentation mainly accompanies classical signs like blood pressure discrepancies between the upper extremities, pulse deficits & hypotension. Murmur is rarely seen and if seen its mostly diastolic murmur. Rupture of cardiac chamber (Option D) is a medical emergency. The hemodynamic compromise would be severe and acute, leading to cardiogenic shock and unrecordable BP. No murmur will be heard.

@Neet_pg_bot

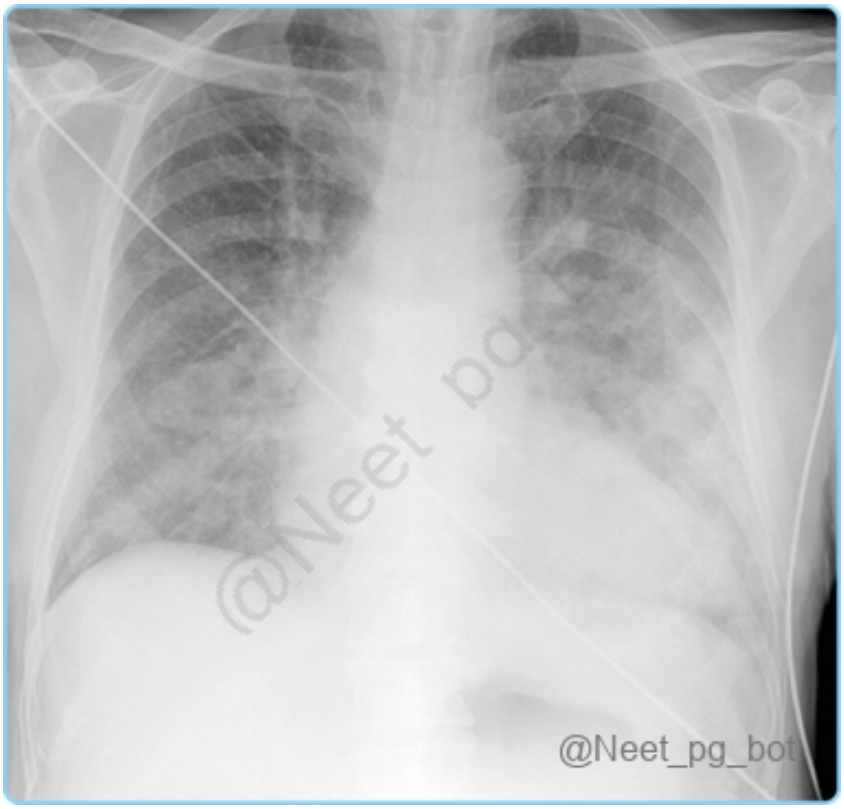
Q122: A hypertensive patient who is non-compliant with medication presents with sudden-onset breathlessness. A chest X-ray reveals findings consistent with pulmonary edema. How will you manage this patient? (Q855894)

A. Intravenous salbutamol

B. Intravenous nitroglycerin

C. Nebulization with salbutamol

D. Oxygen and antibiotics



Correct Answer: B. Intravenous nitroglycerin

Explanation: The clinical scenario suggests acute cardiogenic pulmonary edema (ACPE). Precipitating factors: Severe hypertension Acute myocardial infarction Chronic heart failure exacerbation Medication non-compliance Excessive salt intake Symptoms: Sudden severe dyspnea Pink frothy sputum Cyanosis Rales and rhonchi heard on auscultation Chest X-ray findings: Interstitial edema Alveolar edema in a butterfly pattern Possible cardiomegaly Management of Cardiogenic Pulmonary Edema: IV Nitroglycerin Mechanism: Reduces preload and afterload by causing venodilation, lowering pulmonary venous pressure. Indication: Rapid relief of pulmonary edema symptoms without causing hypotension. Administration: Start with sublingual nitroglycerin; escalate to intravenous if symptoms persist. Oxygen Therapy: Maintain oxygen saturation >92%. Use non-invasive positive pressure ventilation (NIPPV) or intubation if oxygenation fails. Diuretics (e.g., Furosemide): Used to remove excess fluid but only after stabilizing the patient's hemodynamics. Morphine: Provides venodilation and reduces anxiety, but use is controversial due to the risk of respiratory depression. Positioning: Sitting upright with legs dependent to reduce venous return in patients without hypotension. Intravenous salbutamol (Option A): Salbutamol is a β2-agonist used for acute severe asthma or hyperkalemia, not pulmonary edema. Nebulization with salbutamol (Option C): Similar to Option A, it is used in asthma management, not for ACPE. Oxygen and antibiotics (Option D): Oxygen therapy is indicated, but antibiotics are not used in cardiogenic pulmonary edema unless there is an underlying infection like pneumonia.

@Neet_pg_bot

Q123: A patient on antidepressants presents with hypotension. An ECG reveals wide QRS complexes and right axis deviation. How will you manage this patient? (Q855897)

A. Antiarrhythmics

B. Intravenous sodium bicarbonate

C. Propranolol

D. Phenytoin

Correct Answer: B. Intravenous sodium bicarbonate

Explanation: The clinical scenario indicates tricyclic antidepressant (TCA) toxicity, characterized by: Hypotension Wide QRS complexes Right axis deviation QT prolongation on ECG TCAs block sodium channels in the myocardium, leading to arrhythmias and conduction delays. Side effects of Tricyclic antidepressants: Mechanism of side effect Side effect H1 receptor blockade Sedation, weight gain Anticholinergic action on muscarinic receptors Hyperthermia Dry eyes/mouth Mydriasis (C/I in glaucoma) Urinary retention Constipation Tachycardia Increase in serotonin in the brain Seizure threshold reduction Alpha 1 adrenergic receptor antagonism Postural hypotension Sodium channel block Arrhythmia/ QT prolongation Bradycardia in heart block due to overdose Management of TCA Toxicity: Intravenous Sodium Bicarbonate Mechanism: Reverses the sodium channel blockade by alkalinizing the serum, stabilizing myocardial membranes. Indication: For QRS widening (>100 ms), hypotension, or arrhythmias due to TCA toxicity. Dose: Bolus of 50–100 mEq; repeat as necessary until QRS duration normalizes. Activated Charcoal: If ingestion is recent (within 2 hours), it helps reduce absorption of the drug. Other Measures for Complications: Seizures: Benzodiazepines are preferred. Polymorphic ventricular tachycardia (Torsades de Pointes): Use intravenous magnesium sulfate. Antiarrhythmics (Option A): Class IA, IC, and III antiarrhythmics (e.g., quinidine, flecainide, amiodarone) are contraindicated as they exacerbate sodium channel blockade. Propranolol (Option C): A beta-blocker, it is not effective in treating TCA-induced arrhythmias or QRS widening. It can worsen hypotension and bradycardia caused by TCA toxicity. Phenytoin (Option D): An antiepileptic drug, it has no role in TCA toxicity. It can displace TCAs from protein-binding sites, worsening toxicity symptoms.

@Neet_pg_bot

Q124: A 25-year-old patient is undergoing tooth extraction for dental caries. Which of the following does not require prophylaxis against infective endocarditis? (Q855912)

A. Prior history of endocarditis

B. Atrial septal defect

C. Unrepaired cyanotic heart disease

D. Prosthetic heart valves

Correct Answer: B. Atrial septal defect

Explanation: Atrial septal defect (ASD) is a congenital heart defect; however, it is generally not considered a high-risk condition for infective endocarditis unless there are other complicating factors, such as a significant shunt or right-sided heart failure. Infective Endocarditis (IE) Infective endocarditis (IE) is a bacterial or fungal infection of the endocardial surface of the heart, typically affecting the heart valves. Prophylaxis against infective endocarditis is recommended before certain invasive procedures (like dental extractions) for patients at high risk of developing this condition. Indications for Prophylaxis in Infective Endocarditis: High-Risk Patients: Prosthetic heart valves (mechanical/bioprosthetic) (Option D) History of infective endocarditis (Option A) Congenital heart disease (CHD): Unrepaired cyanotic CHD (Option C) Repaired CHD with prosthetic material (first 6 months) Repaired CHD with residual defects Cardiac transplantation recipients with valvulopathy Procedures Requiring Prophylaxis: Dental: Extractions, periodontal surgery, root canal, dental implants Respiratory: Tonsillectomy, adenoidectomy, bronchoscopy with biopsy GI/GU: Endoscopy with biopsy, colonoscopy, cystoscopy (high-risk patients) Prophylaxis Regimen: Amoxicillin: 2 grams orally, 30–60 minutes before Alternative (Penicillin allergic): Clindamycin: 600 mg orally Azithromycin: 500 mg orally Causes of Infective endocarditis Condition Most Common Organism Community-acquired native valve endocarditis Staphylococcus aureus Healthcare-associated native valve endocarditis Streptococci Endocarditis in injection drug users (Right side) Staphylococcus aureus Endocarditis in injection drug users (Left side) Staphylococcus aureus Most common organism causing prosthetic valve endocarditis Enterococci and Staphylococcus aureus Most common group of

organisms causing early prosthetic valve endocarditis (<12 months after surgery) Coagulase-negative staphylococci (CoNS) Late prosthetic valve endocarditis (>12 months after surgery) Streptococci Acute infective endocarditis Staphylococcus aureus Subacute infective endocarditis Streptococcus viridans Cardiovascular implantable electronic device (CIED)-associated endocarditis Enterococci and Coagulase-negative Staphylococci (CoNS) Culture-negative endocarditis HACEK organisms Coxiella burnetii Bartonella

@Neet_pg_bot

Q125: A patient presents to you with an irregularly irregular pulse of 120/minute and a pulse deficit of 20. Which of the following would be the jugular venous pressure (JVP) finding? (Q855932)

A. Absent p wave

B. Absent a wave

C. Cannon a wave

D. Raised JVP with normal waveform

Correct Answer: B. Absent a wave

Explanation: The clinical scenario suggests atrial fibrillation (AF), a common arrhythmia with an irregularly irregular heartbeat, often accompanied by a fast heart rate (e.g., 120 beats/min). The pulse deficit of 20 indicates that not every atrial contraction is passed to the ventricles due to irregular conduction through the atrioventricular (AV) node, meaning some atrial beats are not followed by ventricular contractions. Atrial Fibrillation Features Characterized by abnormal automatic firing and multiple re-entry circuits. Atria beat rapidly and ineffectively; ventricles activated irregularly Produces an "irregularly irregular" pulse Palpitations, syncope, and breathlessness can be present Asymptomatic AF: Can present as systemic embolism and stroke ECG Features QRS Complexes: Irregular but normal P Waves: Absent; baseline may show irregular fibrillation waves Ventricular Rate: Fast at onset (120-160 beats/min) Slower in chronic AF due to medication effects and AV nodal fatigue {{caption_text}} JVP Absent a wave Management Paroxysmal Atrial Fibrillation First-line Therapy: Beta-blockers are effective in patients with CAD, hypertension, and heart failure. Class Ic Drugs: Propafenone or flecainide to prevent episodes (not for patients with CAD or LV dysfunction). Class III Drugs: Amiodarone : Most effective but with significant side effects; used when other treatments fail. Dronedarone : Alternative to amiodarone; contraindicated in heart failure. Rate Control: Digoxin and verapamil for AV node conduction slowing, but not for AF prevention. Catheter Ablation: Considered for patients with drug-resistant AF; prevents AF in ~75% of cases but may have complications. Persistent Atrial Fibrillation Rhythm Control : Cardioversion : Electrical or pharmacological (e.g.,

intravenous flecainide or amiodarone). Timing: Immediate if AF <48 hours; anticoagulation required if AF ≥48 hours. Prophylactic Amiodarone : To reduce recurrence risk. Rate Control : Medications: Digoxin, β-blockers, or rate-limiting calcium antagonists (verapamil, diltiazem) . Combination Therapy: Digoxin with β-blockers ; avoid combining calcium antagonists with β-blockers. Pace and Ablate: Permanent pacemaker with AV nodal block for symptomatic AF. Thromboprophylaxis Anticoagulation: Required for stroke prevention due to blood stasis in the left atrium. Warfarin : INR target of 2.0–3.0; start 4 weeks prior to cardioversion. DOACs: Rivaroxaban, apixaban, edoxaban, and dabigatran as alternatives to warfarin; no monitoring needed. Risk Assessment: CHA2DS2-VASc Score : For stroke risk; anticoagulate if score ≥2 . HAS-BLED Score: For bleeding risk; monitor patients with score ≥3. Aspirin: Not recommended due to low efficacy in preventing embolic stroke. CHA2DS2-VASc stroke risk scoring system for AF Points Parameters Score C Congestive heart failure 1 H Hypertension history 1 A2 Age (≥75 years) 2 D Diabetes mellitus 1 S2 Previous stroke or transient ischemic attack (TIA) 2 V Vascular disease 1 A Age (65-74 years) 1 Sc Sex category (female) 1 Maximum total score 9 points Management option for AF as per CHA2DS2-VASc score 0: need not anticoagulate 1: Give aspirin >=2: Warfarin/Dabigatran/Rivaroxaban Absent p wave (Option A): This is a characteristic ECG finding in atrial fibrillation. The absence of the P wave on ECG signifies that there is no organized atrial contraction, which leads to the irregularly irregular ventricular rhythm. Cannon a wave (Option C): Cannon a waves occur in atrioventricular (AV) dissociation, where the atria contract against a closed tricuspid valve, leading to a large, prominent a wave. Raised JVP with normal waveform (Option D): A raised JVP with a normal waveform is typically seen in conditions like congestive heart failure, right ventricular infarction, or superior vena cava obstruction. In atrial fibrillation, the JVP may be raised, but the waveform will not be normal.

@Neet_pg_bot

Q126: An 11-year-old child with a history of streptococcal pharyngitis presents with fever and arthralgia. There is no past history of rheumatic heart disease or carditis. How often is 600,000 IU of benzathine penicillin recommended for prophylaxis of rheumatic heart disease? (Q856007)

A. Immediately

B. Thrice weekly lifelong

C. Once in three weeks for 5 years or till the age of 18, whichever is longer

D. Once in three weeks for 10 years or till the age of 25, whichever is longer

Correct Answer: C. Once in three weeks for 5 years or till the age of 18, whichever is longer

Explanation: The clinical scenario describes acute rheumatic fever (ARF) in a child, which follows a group A streptococcal (GAS) pharyngitis infection. Secondary prophylaxis is essential to prevent recurrent episodes of ARF, which increases the risk of developing rheumatic heart disease (RHD). Secondary prophylaxis for Rheumatic Fever: Dose and Frequency: Patients weighing <27 kg: 600,000 IU benzathine penicillin every 3 weeks. Patients ≥27 kg: 1.2 million IU benzathine penicillin every 3 weeks. Condition Recommended Duration Without Carditis 5 years after the last attack or until 18 years of age, whichever is longer With Carditis but No Residual Valvular Disease 10 years or until 21–25 years of age, whichever is longer With Persistent Valvular Disease At least 10 years or until 40 years of age; lifelong prophylaxis may be required Revised Jones Criteria for the diagnosis of Acute Rheumatic Fever (ARF) Criteria Low-risk Populations Moderate- and High-risk Populations Major Criteria Carditis Clinical or subclinical Clinical or subclinical Arthritis Polyarthritis only Polyarthritis, polyarthralgia, or monoarthritis Chorea Yes Yes Erythema Marginatum Yes Yes Subcutaneous Nodules Yes Yes Minor Criteria Carditis Clinical or subclinical Clinical or subclinical Arthritis Polyarthritis only Polyarthritis, polyarthralgia, or monoarthritis Polyarthralgia Not applicable Yes Fever ≥38.5°C ≥38.0°C ESR ≥60 mm in the first hour ≥30 mm/hr and/or CRP ≥3.0 mg/dL Prolonged PR Interval Yes, after age variability Yes, after age variability Monoarthralgia Not applicable Yes For All Patient Populations Evidence of Preceding Group A Streptococcal Infection Increased ASLO/anti-DNAse B titer or positive throat culture or positive rapid strep test Diagnosis of Initial ARF 2 Major criteria or 1 Major + 2 Minor criteria Diagnosis of Recurrent ARF 2 Major criteria or 1 Major + 2 Minor or 3 Minor criteria

@Neet_pg_bot

Q127: A man on diuretics presents with weakness. An ECG shows flat T waves and prominent U waves. What is the most likely diagnosis? (Q856009)

A. Hypocalcemia

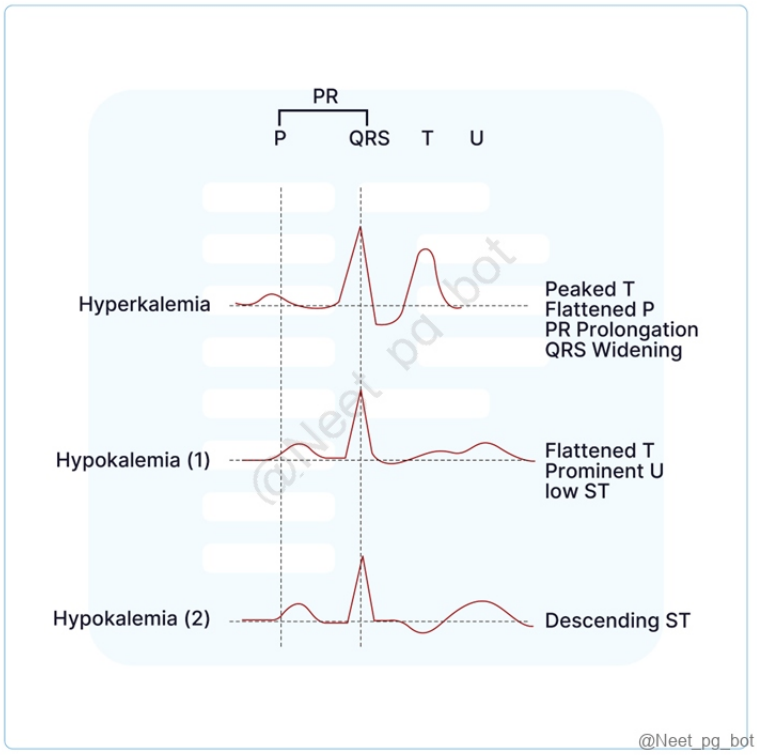
B. Hypomagnesemia

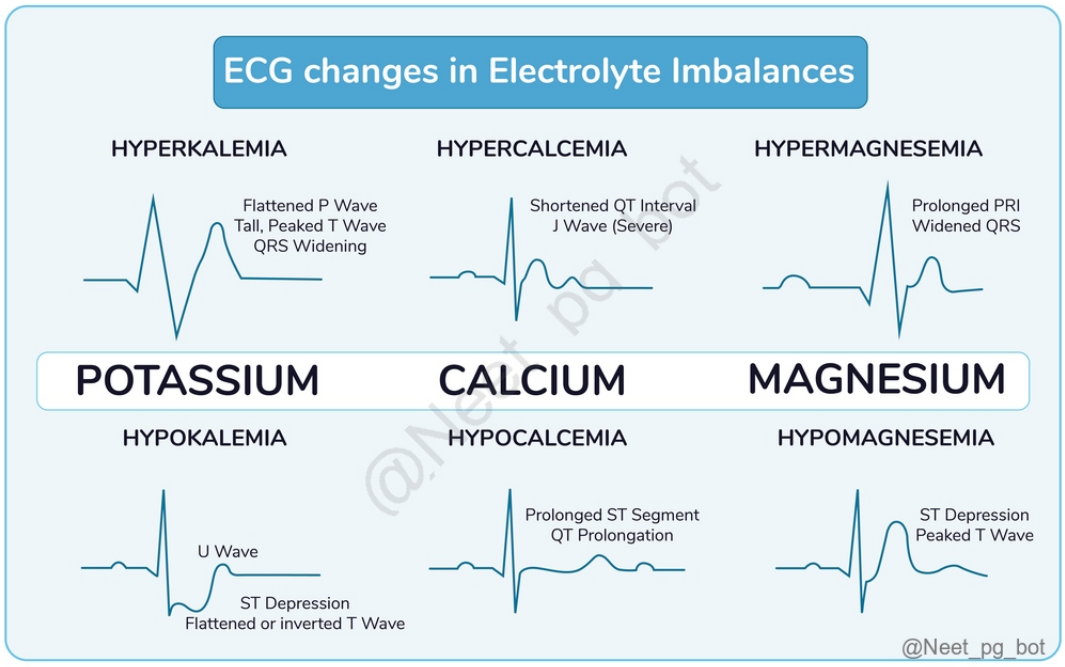
C. Hyperkalemia

D. Hypokalemia

Correct Answer: D. Hypokalemia

Explanation: The clinical presentation and ECG findings strongly suggest hypokalemia, a condition defined as a serum potassium level <3.5 mEq/L. Symptoms: Muscle weakness, cramps, or paralysis. Fatigue and lethargy. Constipation or ileus (due to smooth muscle dysfunction). Severe cases may lead to cardiac arrhythmias. Causes of Hypokalemia: Diuretic Use (Loop and Thiazide Diuretics): Increased renal excretion of potassium. Metabolic Alkalosis: Intracellular shift of potassium due to increased extracellular pH. Excessive β-agonist Activity: Intracellular potassium shift (e.g., in asthma treatment with salbutamol). Gastrointestinal Losses: Vomiting or diarrhea leading to potassium depletion. Other Causes: Insulin administration (drives potassium into cells). Magnesium deficiency (worsens renal potassium loss). Hyperaldosteronism (increased potassium excretion). ECG Changes in Hypokalemia: Flattened T waves. Prominent U waves. ST depression. Prolonged QT interval. Severe cases: Risk of ventricular tachycardia or fibrillation. Management: Potassium Replacement: Oral potassium chloride for mild cases. Intravenous potassium for severe or symptomatic cases (administer cautiously to avoid hyperkalemia). Correct Underlying Cause Hypocalcemia (Option A): Presents with muscle cramps, tetany, or paresthesias. ECG: Prolonged QT interval but no prominent U waves. Hypomagnesemia (Option B): Causes muscle weakness and arrhythmias. ECG: Torsades de Pointes (polymorphic ventricular tachycardia). Hyperkalemia (Option C): Presents with muscle weakness or paralysis. ECG: Tall, peaked T waves, shortened QT interval, and widened QRS complex.





References:

Harrison's Principles of Internal Medicine, 21st Edition, Page: 168, 181, 296, 346, 348, 350, 351, 352, 358

↑ *Back to this question in Part A*

@Neet_pg_bot

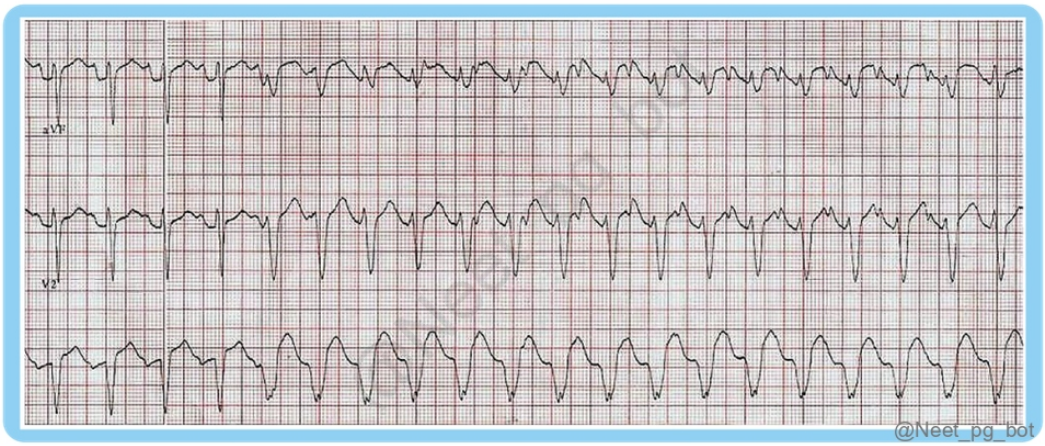
Q128: A patient with coronary artery disease presents to you with chest pain and palpitations. The ECG is shown below. Which of the following can be used in the management? (Q856017)

A. Oral metoprolol

B. Oral amiodarone

C. Intravenous amiodarone

D. Intravenous metoprolol



Correct Answer: C. Intravenous amiodarone

Explanation: The clinical scenario and ECG findings suggest ventricular tachycardia (VT) in a patient with coronary artery disease. ECG Findings: Wide QRS complexes (>120 ms). Absence of P waves or atrioventricular dissociation. Ventricular rate >100 bpm. Symptoms: Palpitations, chest pain, syncope, and dyspnea. Management Hemodynamically Stable VT: Drug of Choice: Intravenous amiodarone. Mechanism: Class III antiarrhythmic, prolongs action potential duration and refractory period. Hemodynamically Unstable VT: Immediate Electrical Cardioversion. Torsades de Pointes (Polymorphic VT): Treat with intravenous magnesium sulfate. Resuscitation Steps for Shockable & Non-Shockable Conditions Shockable Conditions Non-Shockable Conditions Ventricular Fibrillation Asystole Ventricular Tachycardia Pulseless Electrical Activity Shockable Conditions Non-Shockable Conditions Immediate Recognition Identify Shockable Rhythm: Recognize VF or pulseless VT. Activate Emergency Response: Call for advanced life support. ↓ Initiate CPR Start High-Quality CPR: Perform chest compressions at a rate of 100-120/min, with a depth of 5-6 cm. Continue CPR for 2 minutes. ↓ Defibrillation After 2 minutes of CPR, deliver a Non-Synchronized DC Shock to restore normal rhythm. If no change, administer a second shock immediately. ↓ Continue CPR Resume CPR for 2 Minutes Place an intravenous or intraosseous line for drug administration. ↓ Administer Epinephrine Epinephrine 1 mg (1:10,000): Given IV/IO after 2 minutes of CPR to enhance coronary perfusion pressure. ↓ Advanced Airway Management Secure Airway: Perform endotracheal intubation if necessary. Capnography: Monitor end-tidal CO2 levels. Ventilation: Provide 1 breath every 6 seconds post-intubation. ↓ Further Defibrillation Third Shock: If VF or pulseless VT persists, deliver a

third non-synchronized shock. Continue CPR for 2 More Minutes: Follow with additional CPR. ↓ Administer Antiarrhythmic Medication Amiodarone 300 mg IV: Administer for shock-refractory VT to stabilize heart rhythm. ↓ Identify and Treat Reversible Causes Immediate Recognition Identify Non-Shockable Rhythm: Recognize asystole or pulseless electrical activity (PEA). Activate Emergency Response: Call for advanced life support. ↓ Initiate CPR Start High-Quality CPR: Perform chest compressions at a rate of 100-120/min, with a depth of 5-6 cm. Continue CPR for 2 minutes. ↓ Establish intravenous or intraosseous line for medication administration. ↓ Administer Epinephrine Epinephrine 1 mg (1:10,000): Administer IV/IO after the first 2 minutes of CPR. ↓ Identify Rhythm Non-Shockable Rhythm: Continue CPR and administer epinephrine every 3-5 minutes. Goal: To increase the likelihood of developing a shockable rhythm, such as ventricular fibrillation (VF), which is necessary for effective defibrillation. Shockable Rhythm: Administer a Non-Synchronized DC Shock to restore normal rhythm. ↓ Advanced Airway Management Airway: Secure the airway with endotracheal intubation if necessary. Capnography: Monitor end-tidal CO2 levels. Ventilation: Provide 1 breath every 6 seconds post-intubation for adequate oxygenation. ↓ Continue CPR Resume chest compressions for 2 minutes. ↓ Identify and Treat Reversible Causes Primary Focus: Address reversible causes, especially hypothermia. ↓ Repeat CPR and Epinephrine Cycle: Continue repeating CPR and epinephrine administration every 3-5 minutes. Oral Metoprolol (Option A): Selective β1-antagonist used in angina, hypertension, and chronic heart failure; not indicated for acute ventricular tachycardia management, especially when rapid control is needed. Oral Amiodarone (Option B): Used for chronic treatment of VT, atrial fibrillation, and ventricular fibrillation; delayed onset makes it unsuitable for acute management. Intravenous Metoprolol (Option D): Used in acute myocardial infarction to reduce heart rate and myocardial oxygen demand; not a first-line treatment for ventricular tachycardia.

@Neet_pg_bot

Q129: A 20-year-old female presents with septic shock, blood pressure 58/30 mmHg, and MAP 58 mmHg. She has received 30 mL/kg of crystalloid fluid, but her MAP remains <65 mmHg. What is the next best step in management? (Q865315)

A. Start dopamine

B. Start noradrenaline

C. Repeat crystalloid fluid

D. Start vasopressin

Correct Answer: B. Start noradrenaline

Explanation: Noradrenaline (norepinephrine) is the vasopressor of choice in septic shock due to its potent alpha-1 effects (vasoconstriction) and minimal beta effects, improving MAP without excessive tachycardia. Septic Shock Management: 1. Source Control Start broad-spectrum antibiotics within 1 hour. Remove infected/ necrotic tissue or devices if they are the source. 2. Shock Management (within 6 hours) Fluids: Crystalloids (NS/albumin) up to 80 mL/kg. Target: CVP 8–12 mmHg, MAP ≥65 mmHg, ScvO■ ≥70%. Use norepinephrine (warm shock) or epinephrine (cold shock) as first-line vasopressors if fluid therapy fails. Dopamine is no longer preferred due to adverse hormonal effects. 3. Enhancing Host Response Steroids if shock is vasopressor-refractory or cortisol is low. Vasopressin can be added in refractory shock. Start dopamine (Option A) Less preferred due to higher risk of arrhythmias and worse outcomes compared to noradrenaline. Repeat crystalloid fluid (Option C) Already received appropriate volume; additional fluid may cause fluid overload without improving perfusion. Start vasopressin (Option D) Vasopressin is used as an adjunct to noradrenaline in refractory cases, not as initial therapy.

@Neet_pg_bot

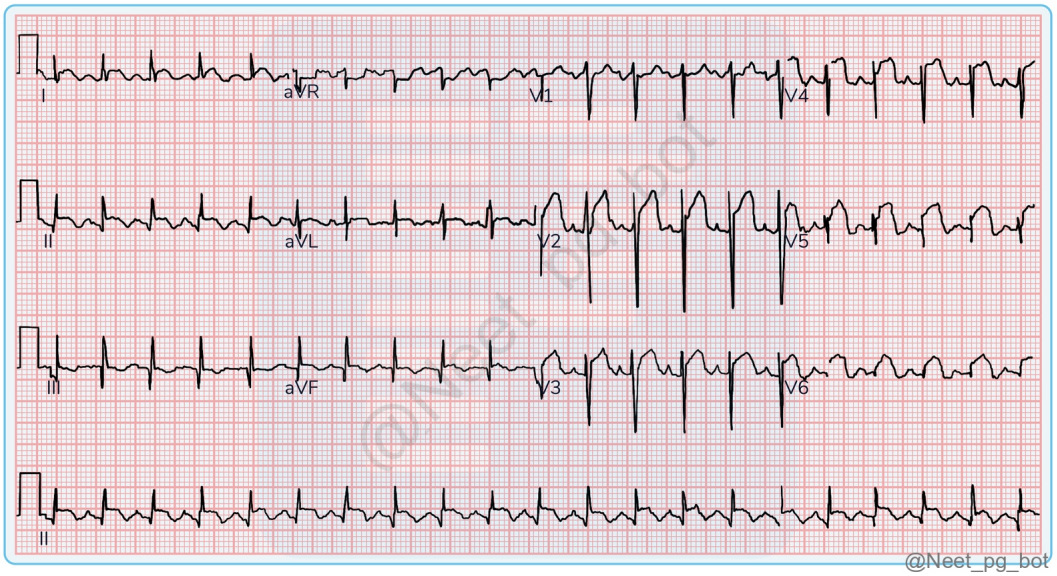
Q130: A patient presents to the ER with central chest pain. He has a past medical history of heart disease. ECG is shown below. What is the diagnosis? (Q866785)

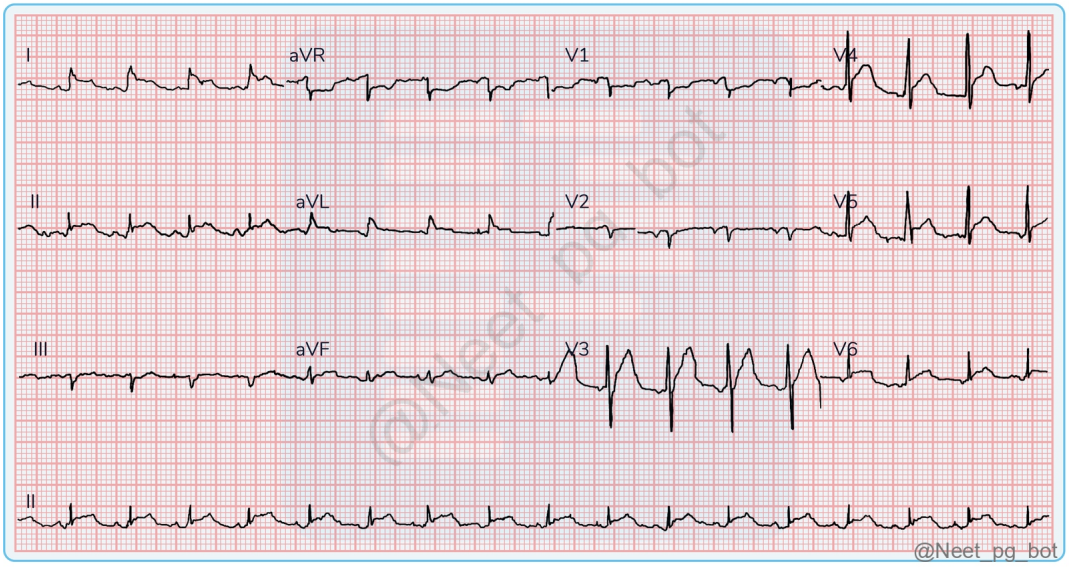
A. Anterolateral MI

B. Inferolateral MI

C. Acute pericarditis

D. Constrictive pericarditis





Correct Answer: A. Anterolateral MI

Explanation: ECG Findings: ST-segment elevation: Anterior leads: V2–V4 Lateral leads: I, aVL, V5, V6 Reciprocal ST-segment depression: leads III and aVF (inferior leads) Interpretation: This combination indicates acute injury involving both the anterior wall (supplied by the LAD) and the lateral wall (supplied by the LCX or diagonal branches of LAD) — hence, anterolateral MI. Reciprocal changes (ST depression in inferior leads) strengthen the diagnosis of acute MI and help differentiate from pericarditis. MI location vs. ECG leads MI Location Leads with ST Elevation Likely Artery Anterior V1–V4 LAD Lateral I, aVL, V5, V6 LCX or diagonal branch Anterolateral V2–V6, I, aVL LAD + LCX/diagonal branch Inferior II, III, aVF RCA or LCX Inferolateral II, III, aVF, I, aVL, V5, V6 RCA + LCX Posterior V7–V9 (or tall R in V1–V2) RCA or LCX Incorrect Options: Inferolateral MI (Option B): Inferolateral MI would have ST elevation in inferior leads (II, III, aVF) plus lateral leads (I, aVL, V5, V6). Here, inferior leads show ST depression, not elevation → rules out this option. Acute pericarditis (Option C): Pericarditis usually has diffuse ST elevation across almost all leads without reciprocal ST depression (except in aVR/V1) and PR segment depression. This ECG shows localized ST elevation with clear

reciprocal changes — typical of MI, not pericarditis. Constrictive pericarditis (Option D): Constrictive pericarditis is a chronic condition; ECG may show low voltage QRS or nonspecific changes, not acute ST elevation patterns. It presents with signs like Kussmaul's sign, pericardial knock, and right heart failure — not acute chest pain + STEMI pattern.

@Neet_pg_bot

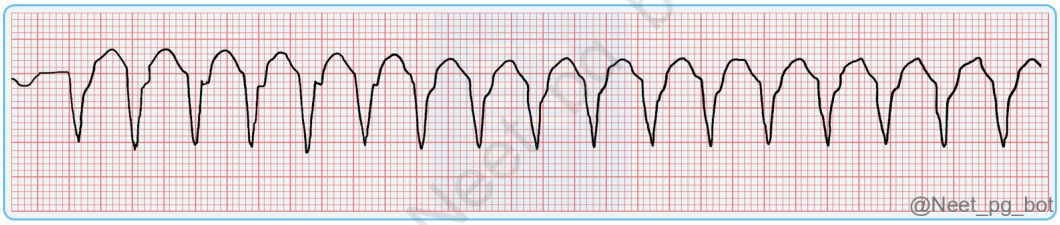
Q131: A patient after MI develops a broad QRS complex tachycardia. His BP is 120/85 mm Hg. ECG is given below. Best management? (Q866787)

A. Amiodarone iv

B. Labetalol iv

C. Metoprolol iv

D. Nitroglycerin iv



Correct Answer: A. Amiodarone iv

Explanation: Step 1: Recognising the rhythm Broad QRS (>120 ms) Regular tachycardia Monomorphic appearance Post-MI patient → high risk of ventricular tachycardia (VT) Diagnosis: Sustained monomorphic VT Step 2: Assessing stability BP = 120/85 mm Hg → patient is hemodynamically stable (no shock, syncope, severe hypotension, or heart failure). In stable VT, first-line pharmacologic management = IV amiodarone (or procainamide in some guidelines). Class III antiarrhythmic that prolongs repolarisation and suppresses ventricular ectopy. Preferred in structural heart disease post-MI because other agents (like some beta-blockers) may worsen VT in the acute setting. Stable vs. unstable broad complex tachycardia (VT) Status First-line management Stable VT IV amiodarone (or procainamide) Unstable VT Immediate synchronized DC cardioversion Pulseless VT / VF Immediate defibrillation + CPR Incorrect Options: Labetalol IV (Option B): Labetalol is an alpha- and beta-blocker used for hypertension, not for acute VT management. Giving it here will not terminate VT and can worsen instability. Metoprolol IV (Option C): While beta-blockers are used post-MI for arrhythmia prevention, they are not the first choice for terminating sustained VT in the acute phase. Risk of worsening hypotension or bradyarrhythmia once VT resolves. Nitroglycerin IV (Option D) Used for angina or heart failure due to ischemia.

Has no role in terminating VT. May cause hypotension in this context.

@Neet_pg_bot

Q132: A man presents to the emergency department unconscious and hypotensive. His ECG reveals narrow complex tachycardia. What is the next best step in management? (Q840106)

A. Synchronized DC cardioversion

B. Carotid massage

C. IV adenosine 6 mg

D. IV amiodarone

Correct Answer: A. Synchronized DC cardioversion

Explanation: Correct Option A - Synchronized DC cardioversion: The patient is unconscious and hypotensive , indicating hemodynamic instability . His ECG shows a narrow-complex tachycardia , most consistent with paroxysmal supraventricular tachycardia (PSVT) . In any patient with tachyarrhythmia + hemodynamic instability , the immediate management is synchronized DC cardioversion (except for AF) , regardless of the specific narrow-complex rhythm (except polymorphic VT where unsynchronized shock is used). Incorrect Options: Options B, C & D: They are usually administered in a hemodynamically stable patient. Additionally, amiodarone is given to patients with broad QRS complex tachycardia.

@Neet_pg_bot

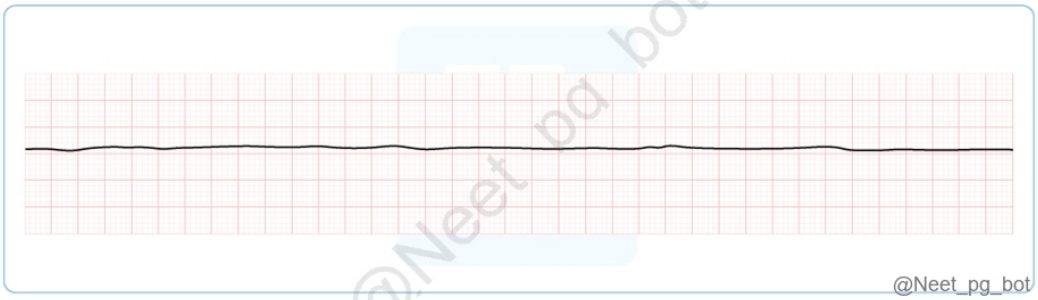
Q133: A 70-year-old man collapsed in his house and was rushed to the hospital. On arrival, his ECG tracing was as shown below. Which of the following is the best intervention for this patient? (Q859568)

A. Use of automated external defibrillator

B. Injection of vasopressin 40 IU

C. Injection of Adrenaline 1mg IV

D. Injection of Atropine 0.5mg IV



Correct Answer: C. Injection of Adrenaline 1mg IV

Explanation: The ECG here is starting to show asystole and the best treatment modality is CPR and injection of Adrenaline 1mg IV. Resuscitation Steps for Asystole {{caption_text}} Options A, B, and D are incorrect.

@Neet_pg_bot

Q134: Which of these conditions will cause a large ‘P’ wave in ECG? (Q879158)

A. Mitral stenosis

B. Aortic stenosi

C. Aortic regurgitation

D. Tricuspid stenosis

Correct Answer: D. Tricuspid stenosis

Explanation: The P wave represents atrial depolarisation, and the size of the wave reflects atrial muscle mass. The initial part of the P wave is due to depolarisation of the right atrium (RA) and the terminal part is due to left atrial (LA) depolarisation. Right atrial enlargement → tall, peaked P wave Left atrial enlargement → broad, notched P wave Tricuspid stenosis obstructs the flow from RA to RV, which results in: Increased RA pressure Chronic RA volume overload Right atrial enlargement (hypertrophy and dilation) More muscle to depolarise, resulting in a larger P wave amplitude. On ECG, right atrial enlargement produces P pulmonale (height >2.5 mm in lead II, peaked P waves in III, aVF and prominent first part of P wave in V1). This pattern is characteristic of right-sided pathology such as COPD, pulmonary hypertension, tricuspid stenosis and regurgitation. Mitral stenosis (Option A): It obstructs LA to LV, causing left atrial enlargement, resulting in P mitrale (broad, notched P wave) on ECG. Aortic stenosis (Option B): It causes LV pressure overload, leading to concentric LV hypertrophy, seen as tall R waves in V5-V6, deep S waves in V1-V3, increased Sokolow–Lyon index (S in V1 + R in V5 or V6 > 35 mm) on ECG. In later stages, LV diastolic dysfunction can lead to increased LA pressure, causing left atrial enlargement (P mitrale). Aortic regurgitation (Option C): It causes LV volume overload, leading to left ventricular dilatation and later LA enlargement.

@Neet_pg_bot

Q135: Which of the following conditions does NOT share the same initial mechanism leading to heart failure as the others? (Q879211)

A. High salt intake

B. Anemia

C. Fever

D. Thyrotoxicosis

Correct Answer: A. High salt intake

Explanation: Anemia, fever, and thyrotoxicosis all cause high-output heart failure, where the primary mechanism is an increase in cardiac output due to elevated metabolic demand or decreased systemic vascular resistance. In contrast, high salt intake leads to volume overload, causing low-output (congestive) heart failure through increased preload rather than increased metabolic demand.

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Pages 1651-1653.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q136: A 20-year-old athlete died during a practice session, and the attending doctor declared him dead on arrival and sent for an autopsy. The gross specimen of his heart is shown below. What is the plausible cause and advice to the family? (Q879215)

A. Cardiac arrest, check cholesterol in family members

B. Cardiac arrest due to hypertrophic cardiomyopathy, screen family members

C. Sudden cardiac death due to valvular pathology caused by rheumatic etiology

D. Cardiac arrest due to arrhythmias and heart blockwith no significant lesion on cardiac autopsy

Correct Answer: B. Cardiac arrest due to hypertrophic cardiomyopathy, screen family members

Explanation: In a young athlete who dies suddenly during exertion, the most likely cause is hypertrophic cardiomyopathy (HCM), typically showing asymmetric septal hypertrophy and a banana-shaped left ventricular cavity on gross pathology. HCM is a genetic (autosomal dominant) disorder involving mutations in sarcomeric proteins, predisposing to ventricular arrhythmias and sudden cardiac death. Hence, first-degree relatives should be screened by echocardiography and genetic testing.

Harrison's Principles of Internal Medicine, 21st Edition, Pages 1600-1603.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q137: A patient presents with exertional dyspnea and pedal oedema. His echocardiogram shows a dilated left ventricle with reduced systolic function. Which of the following statements regarding this condition is false? (Q879444)

A. Pulmonary hypertension may develop in this patient

B. Ejection fraction will be reduced in this condition

C. Long-term anticoagulation is not needed for this patient

D. Beta blockers are indicated in chronic management

Correct Answer: C. Long-term anticoagulation is not needed for this patient

Explanation: The patient is a classic case of Heart Failure with Reduced Ejection Fraction (HFrEF). Option C is false because patients with HFrEF (NYHA II-III) have a significant risk of LV thrombus and embolic events due to low-flow dilated ventricles. Hence, anticoagulation is recommended in such patients. Incorrect Options: Pulmonary hypertension may develop in this patient (Option A): This is true because patients with left ventricular heart failure have a risk of developing right heart failure, which in turn is associated with pulmonary hypertension. Moreover, class II Pulmonary hypertension occurs due to an ↑ in LAP, which in turn is due to an ↑ in LVDEP. Ejection fraction will be reduced in this condition (Option B): By definition of HFrEF, EF < 40% , so this is true. Beta blockers are indicated in chronic management (Option D): Evidence-based beta blockers (carvedilol, metoprolol succinate, bisoprolol) improve survival in chronic HFrEF.

@Neet_pg_bot

Q138: Which of the following conditions is characterized by the absence of P waves? (Q793825)

A. Ventricular tachycardia

B. Focal atrial tachycardia

C. Ventricular fibrillation

D. Atrial fibrillation

Correct Answer: D. Atrial fibrillation

Explanation: Correct Option D - Atrial Fibrillation: The P wave on an electrocardiogram (ECG) represents the depolarization of the atria. Atrial fibrillation (AF) is a common cardiac arrhythmia characterized by a fast and irregular heartbeat originating from multiple areas in the atria. Absent P waves are a feature of AF because the atria are not depolarizing in a coordinated fashion. Instead of a regular P wave preceding each QRS complex, there are rapid, irregular fibrillatory waves with no discernible P waves. Incorrect Options: Options A, B and C are incorrect.

References:

Harrison's Principles of Internal Medicine, 21e

↑ *Back to this question in Part A*

@Neet_pg_bot

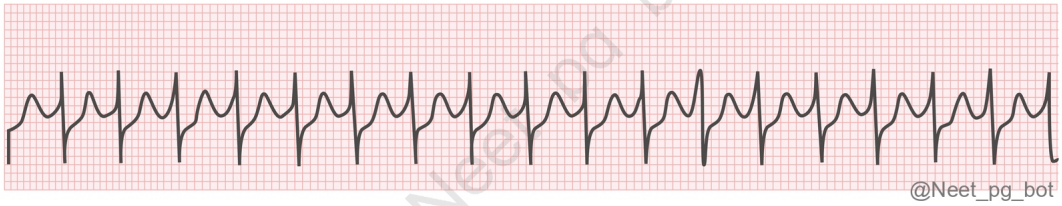
Q139: Interpret the ECG given below. (Q793832)

A. Ventricular fibrillation

B. Atrial fibrillation

C. Supra ventricular tachycardia

D. Ventricular tachycardia



Correct Answer: C. Supra ventricular tachycardia

Explanation: Correct Option C - Supra ventricular tachycardia: The ECG in the question shows a narrow QRS complex with an increased heart rate. Supraventricular tachycardia (SVT) is a type of arrhythmia that originates above the ventricles and can cause a rapid heartbeat. The ECG tracing for SVT shows a regular rhythm with a narrow QRS complex, often with a sudden onset and termination. Thus, the above ECG indicates supraventricular tachycardia. Incorrect Options: Option A - Ventricular fibrillation: Ventricular fibrillation is a life-threatening arrhythmia that occurs when the ventricles (lower chambers) of the heart quiver instead of contracting properly, leading to a lack of blood flow to the body's vital organs. The ECG tracing for ventricular fibrillation shows a rapid and chaotic pattern with no identifiable P, QRS, or T waves. Option B - Atrial fibrillation: Atrial fibrillation is a common arrhythmia that occurs when the atria (upper chambers) of the heartbeat irregularly and often rapidly, leading to inefficient blood flow to the ventricles. The ECG tracing for atrial fibrillation shows an irregular rhythm with no discernible P waves and an irregularly spaced QRS complex Option D - Ventricular tachycardia: Ventricular tachycardia is a type of arrhythmia that originates in the ventricles and can lead to a fast and potentially life-threatening heart rate. The ECG tracing for ventricular tachycardia shows a regular or irregular rhythm with a wide QRS complex, often with a repeating pattern.

@Neet_pg_bot

Q140: J-wave is seen in? (Q793859)

A. Hypothermia

B. Heat stroke

C. High-altitude pulmonary edema

D. Drowning

Correct Answer: A. Hypothermia

Explanation: Correct Option A - Hypothermia: J wave, also known as an Osborn wave, is a small hump or notch that appears on the QRS complex of an electrocardiogram (ECG) in certain conditions. It is most commonly associated with hypothermia, a condition in which the body temperature drops below normal. The exact mechanism by which J waves develop in hypothermia is not fully understood, but it is believed to be related to changes in the electrical properties of the heart caused by cold temperatures. Specifically, hypothermia can cause a decrease in the speed of electrical conduction in the heart, which can lead to the development of the J wave. Incorrect Options: Options B, C, and D are not associated with J waves.

@Neet_pg_bot

Q141: A 26-year-old male patient, an accident victim started developing difficulty in breathing . On examination, his BP as 80/40 mmHg and pulses were feeble, JVP was found to be elevated with an absent Y descent, and heart sounds were muffled . What is the most likely diagnosis? (Q793863)

A. Constrictive pericarditis

B. Cardiac tamponade

C. Acute pericarditis

D. Cardiac failure

Correct Answer: B. Cardiac tamponade

Explanation: Correct Option B - Cardiac tamponade: The given scenario describes a young male patient who has developed difficulty in breathing and has signs of hemodynamic compromise, including hypotension and weak pulses, elevated jugular venous pressure with absent Y descent, and muffled heart sounds. Based on these findings, the most likely diagnosis is cardiac tamponade. Cardiac tamponade is a medical emergency that occurs when there is an accumulation of fluid in the pericardial sac surrounding the heart, leading to compression of the cardiac chambers and impaired filling during diastole. This can result in decreased cardiac output and hemodynamic compromise, which may manifest as hypotension, tachycardia, elevated jugular venous pressure, and muffled heart sounds. Cardiac tamponade can be caused by a variety of conditions, including trauma, infection, malignancy, and autoimmune disorders. Incorrect Options: Option A - Constrictive pericarditis: Constrictive pericarditis is a chronic condition that results from the thickening and fibrosis of the pericardial sac, leading to impaired diastolic filling of the heart chambers. This can result in similar symptoms to those seen in cardiac tamponade, including elevated jugular venous pressure and muffled heart sounds, but the onset is typically more gradual, and the symptoms are not as severe. Constrictive pericarditis is also associated with other signs, such as Kussmaul's sign and pericardial knock. Option C - Acute pericarditis: Acute pericarditis is an inflammatory condition of the pericardial sac, which can lead to chest pain, fever, and pericardial friction rub on auscultation. However, the signs and symptoms are not typically as severe as those seen in cardiac tamponade, and there is no significant hemodynamic compromise. Option D - Cardiac failure: Cardiac failure is incorrect because while cardiac tamponade can lead to heart failure, it is not the primary diagnosis in this case. Furthermore, cardiac failure typically presents with different symptoms such as shortness of breath, fatigue, and fluid accumulation in the legs.

@Neet_pg_bot

Q142: A known hypertensive patient is brought to the ER with palpitations and breathlessness. On examination, his BP was 220/140 with signs of encephalopathy. All of the following can be used to treat this condition except? (Q793876)

A. IV Nicardipine

B. IV Mannitol

C. IV Esmolol

D. IV Sodium Nitroprusside

Correct Answer: B. IV Mannitol

Explanation: IV Mannitol does not play a role in the management of patients with hypertensive encephalopathy. caution must be exercised to avoid precipitous drops in blood pressure, which can exacerbate cerebral ischemia. V Mannitol is not typically used to lower blood pressure in hypertensive emergencies. Instead, it is used to reduce intracranial pressure in conditions such as cerebral edema or increased intracranial pressure due to trauma, tumors, or cerebral hemorrhage. It can indirectly lower blood pressure by reducing intracranial pressure and improving cerebral perfusion, it is not a primary agent for managing hypertensive emergencies. IV Nicardipine (Option A): A first-line IV antihypertensive for hypertensive emergency; safely reduces BP. IV Esmolol (Option C): Short-acting β-blocker used in hypertensive emergencies, especially with tachycardia. IV Sodium Nitroprusside (Option D): Potent arterial + venous vasodilator; rapidly reduces BP in severe hypertensive encephalopathy.

@Neet_pg_bot

Q143: A patient with chronic stable angina is having signs of heart failure. The use of which of the following drugs can decrease mortality? (Q793889)

A. Nifedipine

B. Digoxin

C. Lisinopril

D. Torsemide

Correct Answer: C. Lisinopril

Explanation: Correct Option C - Lisinopril: The patient has chronic stable angina + signs of heart failure , which indicates left ventricular dysfunction . ACE inhibitors (like Lisinopril) are proven to reduce mortality in: Heart failure with reduced ejection fraction (HFrEF) Post-myocardial infarction patients Patients with LV dysfunction, even if asymptomatic They prevent remodeling, reduce afterload, improve symptoms, and significantly improve survival . Digoxin improves symptoms but does NOT reduce mortality. Incorrect Options: Options A, B and D are incorrect.

@Neet_pg_bot

Q144: A person collapses following a road traffic accident, and you begin performing CPR. The rescue team arrives with an automated external defibrillator (AED). Which of the following is the most appropriate next step? (Q793901)

A. Continue 5 rounds of CPR @ 30:2 followed by application of AED

B. Continue CPR while the team applies the AED paddles

C. Stop CPR and let them apply paddles

D. Handover the patient and leave

Correct Answer: B. Continue CPR while the team applies the AED paddles

Explanation: Correct Option B) Continue CPR while the team applies the AED paddles CPR should be continued without interruption until the AED is ready to analyze rhythm or deliver a shock. Continuous chest compressions maintain blood flow to vital organs. Pause CPR only when the AED instructs for rhythm analysis or shock delivery. Incorrect Options: Option A - Continue 5 rounds of CPR @ 30:2 followed by application of AED: Do not wait to finish 5 cycles before using AED. Option C - Stop CPR and let them apply paddles: Stopping CPR delays perfusion. Option D - Handover the patient and leave: You must assist and continue CPR until the team takes over.

Prepladder Notes

↑ *Back to this question in Part A*

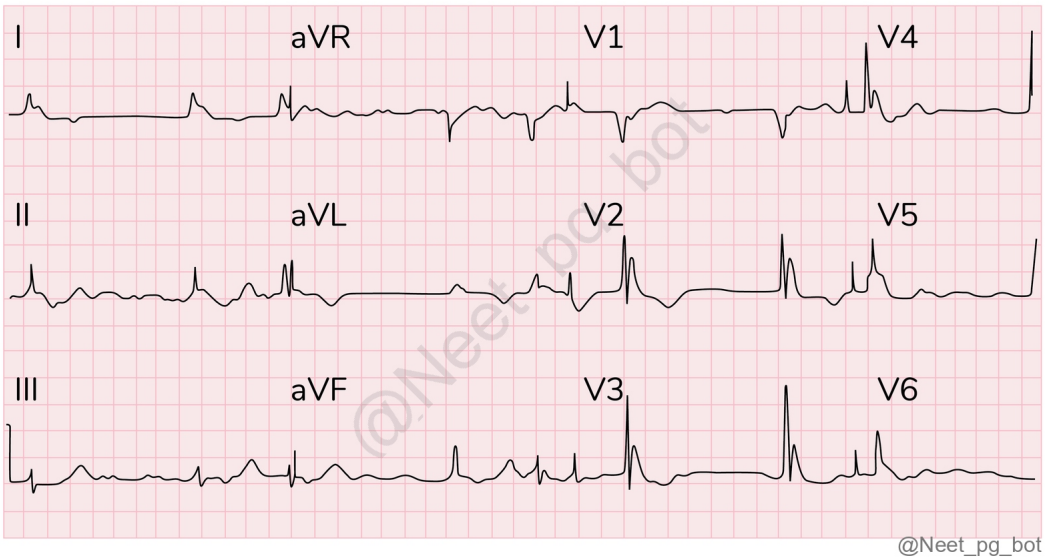
Q145: What is the probable diagnosis based on the ECG given below? (Q793909)

A. Hypokalemia

B. Hyperkalemia

C. Hypothermia

D. Hypocalcemia



Correct Answer: C. Hypothermia

Explanation: Hypothermia is a medical emergency that occurs when the body temperature drops below 35°C (95°F). As the body temperature drops, various physiological functions are affected, including heart function. The ECG changes seen in hypothermia are due to alterations in the electrical conduction system of the heart and are often reversible with rewarming. The ECG findings shown above indicate it to be hypothermia; it includes bradycardia, prolonged PR interval, widened QRS complex, and J waves/Osborn waves (shown with red arrows on the ECG). Osborn waves/J waves are positive deflections at the end of the QRS complex in the leads V3-V6 and are sometimes referred to as the "camel hump" sign. Option A - Hypokalemia: Hypokalemia is an electrolyte imbalance that can also affect the heart and cause ECG changes. Hypokalemia can cause flattened or inverted T waves, ST segment depression, and U waves. However, in this ECG, the findings are not consistent with either hypokalemia or hyperkalemia. Option B - Hyperkalemia: Hyperkalemia is also an electrolyte imbalance that can affect the heart and cause ECG changes. Hyperkalemia can cause peaked T waves, widened QRS complex, and a sine wave pattern. Option D - Hypocalcemia: Hypocalcemia can also cause ECG changes, such as QT prolongation and ST segment depression. However, these changes are not seen in the given ECG, making hypocalcemia an unlikely diagnosis.

ECG Changes with Potassium Imbalance

@Neet_pg_bot

Q146: A 19-year-old woman with no comorbidities presented with numbness and paraesthesia of the fingers along with the characteristic finding shown in the image below. She has no other illnesses, and she says these episodes occur when she is under excess stress or during cold temperatures . What is the most likely diagnosis ? (Q793945)

A. Primary Raynaud’s phenomenon

B. Secondary Raynaud’s phenomenon

C. Cold sores

D. Scleredema

Correct Answer: A. Primary Raynaud’s phenomenon

Explanation: Correct Option A - Primary Raynaud’s phenomenon: Primary Raynaud’s phenomenon is a condition in which the blood vessels in the fingers and toes narrow in response to cold temperatures or emotional stress. As a result, the fingers and toes may feel numb or cold and may turn white or blue. This condition occurs without any underlying disease and is more common in women than men. The patient in this case has no other comorbidities and has symptoms that are typical of Primary Raynaud's phenomenon. Incorrect Options: Options B, C, and D are incorrect.

References:

.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q147: Identify the false statement regarding management of NSTEMI (Q793962)

A. Aspirin loading dose should be initated immediately

B. ACC/AHA guidelines call for either a P2Y12 inhibitor (clopidogrel, prasugrel or ticagrelor) as a class I recommendation

C. Glycoprotein IIB/IIIA inhibitors are useful adjuncts

D. Fibrinolytic therapy is useful in acute coronary syndrome without ST-segment elevation

Correct Answer: D. Fibrinolytic therapy is useful in acute coronary syndrome without ST-segment elevation

Explanation: Correct Option D - Fibrinolytic therapy is useful in acute coronary syndrome without ST-segment elevation: Fibrinolytic therapy is not recommended for NSTEMI because the underlying cause of the condition is not a complete occlusion of a coronary artery by a blood clot. Fibrinolytic therapy is typically reserved for patients with STEMI (ST-segment elevation myocardial infarction) who have evidence of a complete occlusion of a coronary artery. Incorrect Options: Option A - Aspirin loading dose should be initiated immediately: True. Aspirin is a cornerstone of the treatment of NSTEMI, and a loading dose of 162-325 mg should be given immediately upon diagnosis. Option B - ACC/AHA guidelines call for either a P2Y12 inhibitor (clopidogrel, prasugrel, or ticagrelor) as a class I recommendation: True. P2Y12 inhibitors are recommended as part of the standard treatment for NSTEMI, as they help to prevent platelet aggregation and reduce the risk of further cardiac events. Option C - Glycoprotein IIB/IIIA inhibitors are useful adjuncts: True. Glycoprotein IIB/IIIA inhibitors are potent antiplatelet agents that can be used as adjunctive therapy in patients with NSTEMI who are at high risk for adverse cardiac events.

@Neet_pg_bot

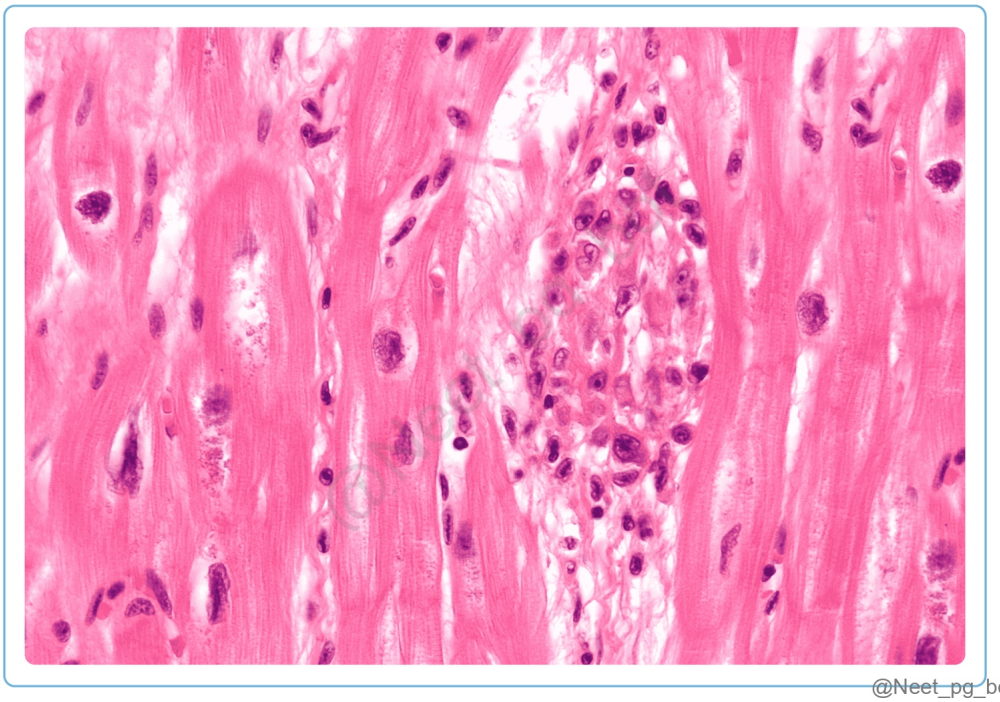
Q148: A 16-year-old female presents with recent episodes of palpitations and shortness of breath. On examination, she has a systolic murmur at the cardiac apex. Laboratory evaluation shows elevated anti-streptolysin O titers and erythrocyte sedimentation rate. An echocardiogram reveals moderate regurgitation in the mitral valve. A biopsy of her heart tissue is performed, and a pathology image is provided below. Which of the following statements about this pathology is not true? (Q828964)

A. Present in myocardium and endocardium only

B. Fibrinoid necrosis in the center

C. Uncommon in chronic stages

D. Anitschkow cells



Correct Answer: A. Present in myocardium and endocardium only

Explanation: Correct Option A - Present in myocardium and endocardium only: This patient's presentation, including elevated anti-streptolysin O titers and elevated ESR with heart valve involvement, suggests the diagnosis of acute rheumatic fever. The mitral and aortic valves are mostly involved, with resultant regurgitations in the acute stages of the disease. The pathology image shows a microscopic view of cardiac tissue stained with H&E (Hematoxylin and Eosin). Within the myocardium, there are characteristic Aschoff bodies, which appear as granulomatous nodules containing central fibrinoid necrosis, foci of T lymphocytes, occasional plasma cells, and plump activated macrophages. During acute RF, Aschoff bodies may be found in any of the three layers of the heart, resulting in pericarditis , myocarditis, or endocarditis (pancarditis). {{caption_text}} Incorrect Options: Option B - Fibrinoid necrosis in the center: Aschoff bodies typically show fibrinoid necrosis in the center. Option C - Uncommon in chronic stages: Aschoff bodies are rarely seen in patients with chronic RHD because of the long intervals between the initial insult and the development of valve deformity. They are most often seen only in patients with acute RF. Option D - Anitschkow cells: Aschoff bodies are indeed surrounded by Anitschkow cells, the plump activated macrophages that have abundant cytoplasm and central round-to-ovoid nuclei (occasionally binucleate) in which the chromatin condenses into a central, slender, wavy ribbon (hence the designation “caterpillar cells”).

@Neet_pg_bot

Q3: 65 year old patient with anterior wall MI develops asystole. Which of the following is the first step in management of this patient? (Q850937)

A. Asses for reversible causes

B. Check pulse

C. Chest compressions @30:2

D. 10 ml of 1:10,000 Epinephrine

Correct Answer: C. Chest compressions @30:2

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: hest compressions @30:2: Asystole is a non-shockable cardiac arrest rhythm. According to ACLS guidelines, once asystole is identified and cardiac arrest is confirmed, the first immediate step is to start high-quality CPR with chest compressions (30:2 if no advanced airway). Early, effective chest compressions

maintain cerebral and coronary perfusion while further management is organized. Assess for reversible causes (Option A): Reversible causes (5 H's and 5 T's) are evaluated after CPR has been initiated, not before starting life-saving measures. Check pulse (Option B): A pulse check is done before diagnosing cardiac arrest. Once asystole is identified, CPR should be started immediately. 10 ml of 1:10,000 Epinephrine (Option D): Epinephrine is indicated in asystole but is given after CPR has been started, not as the first step.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Blood pressure of a 65-year-old male in the ICU crashes. ECG tracing shows Ventricular fibrillation. 200 J biphasic shock is given to patient. Which of the following is next best step for management of this patient? (Q850940)

A. Amiodarone

B. Start CPR

C. Secure advanced airway

D. Epinephrine

Correct Answer: B. Start CPR

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Immediately after defibrillation, the rhythm takes some time to reset to normal. During this time, chest compressions must continue @30:2. Amiodarone (Option A): Given after CPR and defibrillation if VF persists. Secure advanced airway (Option C): Done during ongoing CPR if needed, but not the immediate next step. Epinephrine (Option D): Administered after the first CPR cycle, not immediately after shock.

@Neet_pg_bot

Q7: An alcoholic is admitted with diagnosis acute pancreatitis. On day 2 evening, he is shifted to ICU for Ventilator assistance for ARDS. Which of the following statements

is not correct regarding the management of this patient? (Q850941)

A. Set tidal volume of 12 mL/kg lean body weight

B. Prone positioning

C. Set FiO2 at 1.0 and then titrate down to maintain pO2 55- 80 mm Hg

D. Adjust Respiratory rate to keep pH > 7.3

Correct Answer: A. Set tidal volume of 12 mL/kg lean body weight

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Tidal volume should be kept at 6 ml per kg of lean body weight to enable. FiO2 (Fraction of Inspired Oxygen) is initially set at 1.0 (100% oxygen) and then reduced to the lowest level needed to maintain adequate oxygenation. Permissive hypercapnia is allowed, so keeping a pH of >7.3 is fine while adjusting the respiratory rate. Ventilator Settings for ARDS Parameter Recommended Setting Mode Volume Assist-Control (AC) or Pressure-Control Ventilation Tidal Volume (VT) 4-6 mL/kg of predicted body weight (PBW) - Prevents barotrauma/volutrauma Plateau Pressure ≤ 30 cm H 2 O - to reduce lung injury PEEP use PEEP -FiO 2 titration table (typically 5 -15 cm H 2 O, can go up to 20 in severe ARDS) FiO2 Strat with 100% (1.0), then titrate down to maintain SpO 2 88-95% or PaO 2 55-80 mmHg Respiratory Rate Adjust to maintain pH ≥ 7.30 (can be up to 35/min); permissive hypercapnia is allowed Driving Rate Keep <15 cm H 2 O - (Driving pressure = Plateau pressure - PEEP) I:E Ratio Typically 1:1 to 1:2 (can prolong expiration if needed) Prone Positioning Consider if PaO 2 /FiO 2 < 150 despite optimal settings

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Page 2230

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 58-year-old male patient with chronic obstructive pulmonary disease (COPD) is admitted to the hospital and placed on mechanical ventilation. His arterial blood gas analysis shows the following values: PaO2: 86 mmHg, PaCO2: 50 mmHg and pH: 7.32. Which of the following management strategies should be prioritized for this patient? (Q850942)

A. Decrease the tidal volume to improve ventilation.

B. Increase the FiO2 immediately to avoid oxygen toxicity.

C. Increase PEEP to improve oxygenation and maintain lung recruitment.

D. Increase the expiratory time to promote CO2 washout

Correct Answer: D. Increase the expiratory time to promote CO2 washout

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In a mechanically ventilated COPD patient, the most appropriate strategy is to increase expiratory time to enhance CO■ washout and prevent air trapping . These patients have prolonged airway resistance, and allowing insufficient expiratory time can lead to dynamic hyperinflation and auto-PEEP , worsening ventilation. Decreasing tidal volume (Option A) would reduce minute ventilation and worsen hypercapnia. Increasing FiO■ (Option B) is unnecessary as the patient's PaO■ is adequate, and excessive oxygen may depress respiratory drive in COPD. While increasing PEEP (Option C) may help alveolar recruitment in restrictive lung diseases, it must be used cautiously in COPD due to the risk of worsening air trapping. Therefore, optimizing expiratory time by reducing respiratory rate and adjusting the I: E ratio is the safest and most effective intervention in this scenario.

@Neet_pg_bot

Q9: A 35-year-old male with Guillain-Barré Syndrome develops progressive respiratory muscle weakness and is placed on mechanical ventilation. Which of the following ventilator modes is most appropriate in this setting? (Q850943)

A. Pressure Support Ventilation

B. Synchronized Intermittent Mandatory Ventilation

C. Assist-Control Mechanical Ventilation

D. Continuous Positive Airway Pressure

Correct Answer: C. Assist-Control Mechanical Ventilation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In Guillain-Barré syndrome with respiratory failure, Assist-Control ventilation provides full ventilatory support, ensuring adequate tidal volume and respiratory rate for patients with progressive muscle weakness . Pressure Support Ventilation (Option A): Requires spontaneous breathing, not suitable for severe weakness. Synchronized Intermittent Mandatory Ventilation (Option B): Provides partial support; may be insufficient in rapidly worsening paralysis. Continuous Positive Airway Pressure (Option D): Only maintains airway pressure in spontaneously breathing patients, not for full ventilation support.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 60-year-old male is on mechanical ventilation for acute hypoxemic respiratory failure (Type 1). His latest ABG shows: pH: 7.43, PaCO■: 38 mmHg, PaO■: 54 mmHg, HCO■■: 24 mEq/L. Which of the following changes should be made to improve his oxygenation? (Q850944)

A. Increase tidal volume

B. Increase FiO■

C. Decrease respiratory rate

D. Increase minute ventilation

Correct Answer: B. Increase FiO■

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has Type 1 respiratory failure (low PaO■ with normal PaCO■), indicating a pure oxygenation problem . Increasing FiO■ is the most direct and effective way to raise PaO■. It is also the latest and simplest way to improve oxygenation. It provides an immediate increase in alveolar oxygen concentration and thus

raises PaO■ quickly. Always titrate FiO■ up to 60% (0.6) before increasing PEEP. Increasing tidal volume (A) or minute ventilation (D) would reduce CO■, not help oxygenation. Decreasing RR (C) would worsen oxygenation by lowering minute ventilation and overall alveolar exposure to oxygen.

References:

pmc.ncbi.nlm.nih.gov/articles/PMC7782574/#

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 28-year-old male is admitted to the ICU after sustaining blunt chest trauma in a motor vehicle accident. Chest imaging reveals pulmonary contusions. After 48 hours, he develops severe hypoxemia with PaO■/FiO■ ratio of 110, bilateral infiltrates on chest X-ray, and no signs of left heart failure. What is the most appropriate next step in management? (Q850945)

A. Insert a wide-bore needle in the fifth intercostal space

B. Start intravenous furosemide to reduce pulmonary edema

C. Begin low tidal volume mechanical ventilation

D. Initiate high-flow nasal cannula oxygen therapy

Correct Answer: C. Begin low tidal volume mechanical ventilation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient has developed ARDS, likely secondary to pulmonary contusion, confirmed by bilateral infiltrates and low PaO■/FiO■ ratio. The cornerstone of ARDS management is lung-protective ventilation using low tidal volumes (4–6 mL/kg of predicted body weight) to prevent volutrauma and barotrauma. Wide-bore needle (Option A) is used for tension pneumothorax, which would present with absent breath sounds and hemodynamic compromise, not diffuse infiltrates. Lasix (Option B) may be harmful here, as ARDS is due to inflammatory alveolar damage, not fluid overload. HFNC (Option D) is insufficient in moderate-to-severe ARDS, where invasive ventilation is required to maintain oxygenation and protect lungs.

Harrison’s Principles of Internal Medicine, 21st Edition, Page 2231,2232

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 45-year-old male presents with acute shortness of breath, orthopnea, and bilateral pulmonary crackles. Work up shows elevated Pro-NT- BNP levels and ABG shows type 1 respiratory failure with pO2=60 mm Hg. Which of the following is best to improve his oxygenation status? (Q850946)

A. High-flow nasal cannula

B. Urgent intubation

C. Non-rebreather mask

D. NIV using Bi-PAP

Correct Answer: D. NIV using Bi-PAP

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has acute decompensated heart failure (orthopnea, crackles, elevated NT-proBNP) with Type 1 respiratory failure (hypoxemia without hypercapnia). BiPAP (Bilevel Positive Airway Pressure) helps by: Providing positive pressure during inspiration (IPAP) and expiration (EPAP) , improving oxygenation and offloading the failing left ventricle. Reducing preload and afterload , thus relieving pulmonary edema and improving gas exchange. HFNC (Option A) improves oxygenation but lacks the positive pressure support needed in pulmonary edema. Invasive ventilation (Option B) is reserved for severe respiratory distress, altered mental status, or failure of NIV. Non-rebreather mask (Option C): Delivers oxygen but offers no positive pressure support, less effective in pulmonary edema.

References:

https://www.ncbi.nlm.nih.gov/books/NBK482178/#

https://www.ncbi.nlm.nih.gov/books/NBK470429/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 68-year-old male with a history of COPD presents with increasing dyspnea, productive cough, and confusion. Arterial blood gas (ABG) shows pH 7.30, pCO■ 58 mmHg, and pO■ 55 mmHg. He is hemodynamically stable. What is the next best step in management? (Q850947)

A. Immediate endotracheal intubation

B. Noninvasive positive-pressure ventilation

C. Intravenous antibiotics only

D. High-flow nasal cannula oxygen therapy

Correct Answer: B. Noninvasive positive-pressure ventilation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient with COPD exacerbation shows moderate hypercarbia (pH 7.30, pCO■ 58 mmHg) and respiratory acidosis , which is an indication of NIV . NIV, such as BiPAP, can reduce the work of breathing, improve gas exchange, and prevent the need for intubation. Since the patient is hemodynamically stable and able to protect his airway, NIV is the appropriate next step. Immediate endotracheal intubation (Option A) : Reserved for severe respiratory acidosis (pH < 7.2) or failed NIV. This patient's pH is 7.30, indicating moderate acidosis. Intravenous antibiotics only (Option C) : While antibiotics may be needed, they do not address acute respiratory failure or hypercarbia. High-flow nasal cannula oxygen therapy (Option D) : Helps with oxygenation but does not manage hypercapnia or improve ventilation as NIV does in COPD exacerbations.

[02_Emergency Medicine] 011 Massive Transfusion Protocol Ards Snakebite Aha Updates Altitude Sickness — Quick Jump

Q1 (p. 1475)	*Q2 (p. 1476)*	*Q3 (p. 1477)*	*Q4 (p. 1477)*	*Q5 (p. 1479)*	*Q6 (p. 1480)*
Q7 (p. 1480)	*Q8 (p. 1481)*	*Q9 (p. 1482)*	*Q10 (p. 1483)*	*Q11 (p. 1484)*	*Q12 (p. 1485)*
Q13 (p. 1486)	*Q14 (p. 1487)*	*Q15 (p. 1488)*	*Q16 (p. 1488)*	*Q17 (p. 1489)*	*Q18 (p. 1490)*

Q1: A 60-year-old man collapses at a shopping mall. Bystanders start CPR and activate EMS. On arrival, paramedics find the patient unresponsive, pulseless, and in ventricular fibrillation on the monitor. What is the next best step for his managment? (Q850671)

A. Begin chest compressions and administer 1 mg epinephrine immediately, then attempt defibrillation

B. Deliver one shock with a biphasic defibrillator followed by immediate chest compressions, then secure airway

C. Deliver three stacked shocks followed by pulse check and atropine administration

D. Perform synchronized cardioversion followed by amiodarone if rhythm persists

Correct Answer: B. Deliver one shock with a biphasic defibrillator followed by immediate chest compressions, then secure airway

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient is in cardiac arrest with ventricular fibrillation (a shockable rhythm) . According to ACLS guidelines , the immediate next step is: Immediate defibrillation (one shock) Resume CPR for 2 minutes without pulse check Then consider airway and medications Chest compressions and administer 1 mg epinephrine immediately, then attempt defibrillation (Option A): Epinephrine is not first-line in shockable rhythms and should be given after the second defibrillation cycle. Stacked shocks followed by pulse check and atropine administration (Option C) refers to an outdated practice; stacked shocks are no longer recommended. Synchronized cardioversion followed by amiodarone if rhythm persists (Option D): Synchronized cardioversion is used for organized rhythms like SVT or VT with a pulse, not VF. Prompt defibrillation + CPR is the foundation of VF management in current guidelines.

@Neet_pg_bot

Q2: A 35-year-old male mountaineer plans a rapid ascent to an altitude of 4500 meters for a climbing expedition. He has a history of experiencing symptoms like fatigue, non-productive cough, and difficulty breathing during previous high-altitude trips. Based on the scenario, which of the following strategies should the mountaineer implement to effectively prevent symptoms, and what is the main treatment he should consider if symptoms develop? (Q850690)

A. Maintain an average altitude gain exceeding 300 m per day, and begin immediate treatment with acetazolamide

B. Ascend rapidly without acclimatization, and use supplemental oxygen if symptoms develop

C. Ascend slowly with a maximum altitude gain of 300 m per day, and prioritize descent of 1000 meters if symptoms occur

D. Use alcohol to relax during the ascent, and rely solely on portable hyperbaric chambers if symptoms arise

Correct Answer: C. Ascend slowly with a maximum altitude gain of 300 m per day, and prioritize descent of 1000 meters if symptoms occur

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The mountaineer is at risk of High Altitude Pulmonary Edema (HAPE) due to rapid ascent and previous symptoms, which include fatigue, cough, and dyspnea. Effective prevention involves a slow ascent with a maximum altitude gain of 300 m per day and the primary treatment for symptoms is immediate descent of 1000 meters to alleviate hypoxia and reduce pulmonary edema. Maintain an average altitude gain exceeding 300 m per day, and begin immediate treatment with acetazolamide. (Option A): This contradicts the recommendation to limit altitude gain to 300 m per day for prevention, and acetazolamide is not effective for HAPE treatment. Ascend rapidly without acclimatization, and use supplemental oxygen if symptoms develop. (Option B): Rapid ascent increases the risk of HAPE. While supplemental oxygen may help, it is not the primary treatment; immediate descent is crucial. Use alcohol to relax during the ascent, and rely solely on portable hyperbaric chambers if symptoms arise. (Option D): Alcohol should be avoided as it can worsen symptoms. Relying solely on hyperbaric chambers is not recommended without descent as a primary intervention.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 28-year-old male skier is found unresponsive in the snow with a core body temperature of 27°C (81°F). Which of the following is NOT a treatment approach for managing his hypothermia? (Q850682)

A. Administer warm intravenous fluids at 40-42°C

B. Utilize extracorporeal membrane oxygenation to provide rewarming and circulatory support

C. Use passive external rewarming by layering him with wet clothing

D. Perform active internal rewarming using warm saline lavage of body cavities

Correct Answer: C. Use passive external rewarming by layering him with wet clothing

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The skier's unresponsiveness and core body temperature of 27°C (81°F) indicate severe hypothermia, defined as a drop in core body temperature below 28°C. This condition disrupts the body's ability to maintain homeostasis, leading to potential organ failure and life-threatening complications. Layering with wet clothing can exacerbate heat loss, as wet materials conduct heat away from the body more efficiently than dry materials. Effective treatment for hypothermia requires removing wet clothing and using dry insulation to help retain body heat. Warm intravenous fluids at 40–42°C (Option A): Standard method for active internal rewarming. Extracorporeal membrane oxygenation (Option B): Used in severe hypothermia with cardiac instability. Active internal rewarming using warm saline lavage of body cavities (Option D): Effective core rewarming technique in severe cases.

References:

www.ncbi.nlm.nih.gov/books/NBK545239/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 40-year-old male fisherman is rescued after being exposed to cold water for several hours. Upon examination, his core body temperature is 29°C (84°F). He shows signs of lethargy, dilated pupils, and a slow heart rate. Which of the following statements about his condition is false? (Q850680)

A. Mild hypothermia typically presents with symptoms like shivering and increased muscle tone.

B. In moderate hypothermia shivering generally stops as the body temperature approaches 30°C.

C. Severe hypothermia can lead to unresponsiveness and increased risk of cardiac dysrhythmias.

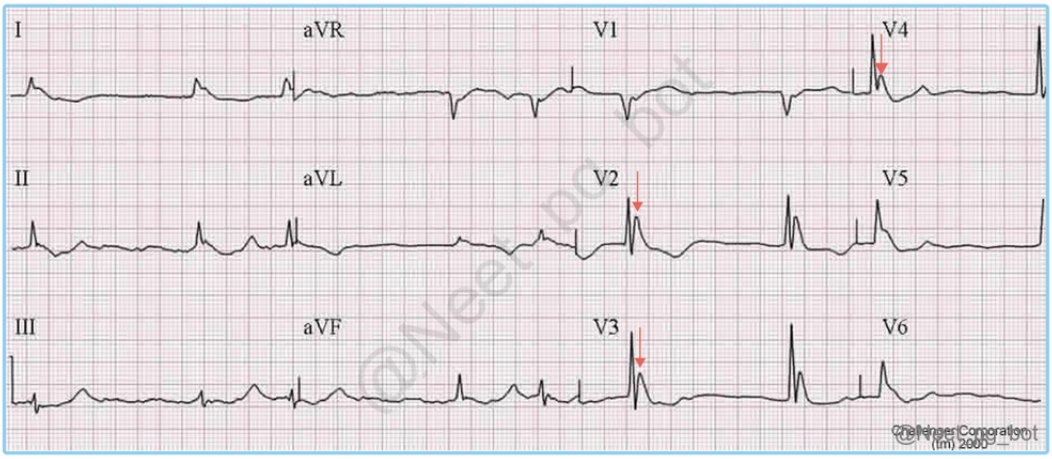
D. Osborn waves are typically absent in hypothermic patients with temperatures below 28°C.

Correct Answer: D. Osborn waves are typically absent in hypothermic patients with temperatures below 28°C.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient has hypothermia , characterized by a core body temperature of 29°C, leading to symptoms such as lethargy, dilated pupils, and bradycardia. This condition results from prolonged exposure to cold, affecting the body's ability to maintain normal temperature and function. Osborn (J) waves are often present in hypothermic patients and can indicate the severity of the condition. Mild hypothermia (32–35°C / 90–95°F) (Option A): Hunger, nausea, fatigue, shivering, pale/dry skin, ↑BP, HR, respiration, and muscle tone. Cognitive decline, memory impairment, ataxia, dysarthria. Shivering may stop if energy stores are low. Cold-induced diuresis. Moderate hypothermia (28–32°C / 82–90°F) (Option B): Lethargy, CNS depression (hyporeflexia, dilated pupils), shivering stops at 30–32°C, paradoxical undressing. ↑Risk of atrial fibrillation, hypotension, bradycardia, bradypnea. Severe hypothermia (<28°C / <82°F) (Option C): Unresponsiveness, ↓cerebral blood flow, hypotension, bradycardia, ↓cardiac output. Atrial/junctional dysrhythmias, pulmonary congestion, oliguria, areflexia. Risk of cardiorespiratory failure and death. {{caption_text}}



References:

www.ncbi.nlm.nih.gov/books/NBK545239/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 30-year-old male hiker ascends rapidly from sea level to an altitude of 4500 meters over 24 hours. Two days after his arrival, he begins to experience increasing fatigue, a non-productive cough, and difficulty breathing during physical activity. His oxygen saturation is 60% on examination, and he exhibits tachypnea and cyanosis. Based on the scenario, which factors do not contribute to the patient's clinical features? (Q850677)

A. Low hypoxic ventilatory response (HVR)

B. Use of sleep medications during ascent

C. Recent heavy physical exertion prior to ascent

D. Extended acclimatization period before ascent

Correct Answer: D. Extended acclimatization period before ascent

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient’s symptoms, including fatigue, cough, tachypnea, and low oxygen saturation, are characteristic of acute HAPE, a severe form of altitude sickness resulting from hypoxia and noncardiogenic pulmonary edema. An extended acclimatization period is protective against altitude sickness. It allows the body to adjust to lower oxygen levels gradually, thereby reducing the risk of developing HAPE (High altitude pulmonary edema). Low hypoxic ventilatory response (Option A) : A low HVR is a significant risk factor for developing altitude-related illnesses, including HAPE. It impairs the body's ability to respond to low oxygen levels, making it more likely for the patient to experience severe hypoxia and associated symptoms. Use of sleep medications during ascent (Option B) : Sleep medications can depress the respiratory drive, leading to a reduced HVR. This can worsen hypoxia at high altitudes, increasing the risk of HAPE and contributing to the patient's clinical features. Recent heavy physical exertion prior to ascent (Option C) : Engaging in heavy physical exertion can lead to fatigue and increased susceptibility to altitude sickness, including HAPE. This factor can contribute to the worsening of symptoms once at high altitude.

References:

www.ncbi.nlm.nih.gov/books/NBK430819/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 34-year-old woman, 36 weeks pregnant, is brought to the emergency department after collapsing at home. Upon arrival, she is unresponsive and in cardiac arrest. CPR is initiated immediately. The team begins advanced cardiac life support for pregnancy. Which of the following is the correct to optimize maternal and fetal outcomes? (Q850676)

A. Delay chest compressions to position the patient for cesarean section.

B. Perform left uterine displacement.

C. Administer 2 mg epinephrine IV every 5 minutes.

D. Delay defibrillation to avoid harm to the fetus.

Correct Answer: B. Perform left uterine displacement.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Relieving aortocaval compression is essential to improve venous return and cardiac output. Left uterine displacement (LUD) is crucial in pregnancy to optimize maternal resuscitation efforts. In cardiac arrest, CPR replaces the heart's pumping . CPR works only if enough blood returns to the chest . Pregnancy causes the uterus to compress the IVC , reducing venous return. Left uterine displacement relieves this compression. This improves venous return , making CPR more effective . Cardiac Arrest in Pregnancy Position: Full left lateral decubitus to relieve aortocaval compression. Oxygen: 100% via face mask. IV Access: Above diaphragm. Treat Causes: Identify and address precipitating factors. Location: Do not transport for cesarean ; manage on site. (Option A) CPR: ≥100/min, depth ≥5 cm, full recoil; limit interruptions. Uterus: Continuous manual LUD if ≥umbilicus. Defibrillation: Same as nonpregnant, biphasic 120–200 J. (Option D) Drugs: Amiodarone 300 mg IV for refractory VF/VT; repeat 150 mg as needed. Epinephrine 1 mg IV/IO q3–5 min preferred over vasopressin. (Option C) Cesarean: If resuscitation fails and GA >23 weeks, deliver within 4 min. Fetal survival: Best if delivery within 5 min of arrest.

www.ahajournals.org/doi/full/10.1161/cir.0000000000000300

pmc.ncbi.nlm.nih.gov/articles/PMC2700584/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 58-year-old man suffers a witnessed cardiac arrest in the emergency room. After 3 cycles of CPR , iv epinephrine, 2 defibrillation shocks, he achieves return of

spontaneous circulation (ROSC). He is now unresponsive, with a blood pressure of 88/50 mmHg and SpO■ of 92% on 10 L/min oxygen by face mask. Which of the following is the most appropriate next step in management? (Q850674)

A. Administer 1 mg epinephrine IV every 3–5 minutes and continue chest compressions

B. Perform immediate coronary angiography and stenting regardless of ECG findings

C. Optimize oxygenation and ventilation, and assess for need of vasopressors and targeted temperature management

D. Discontinue resuscitation efforts and observe, as ROSC has been achieved

Correct Answer: C. Optimize oxygenation and ventilation, and assess for need of vasopressors and targeted temperature management

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Once ROSC is achieved, the next priority is post-cardiac arrest care, which includes ensuring adequate oxygenation (SpO■ >94%), avoiding hyperoxia, supporting blood pressure (e.g., fluids, vasopressors if MAP <65 mmHg), and considering targeted temperature management (TTM) if the patient is comatose. The American Heart Association (AHA)–compliant post-ROSC bundle includes optimizing oxygenation and ventilation, assessing the need for vasopressors, and implementing targeted temperature management. Epinephrine administrations and chest compressions (Option A) is incorrect because epinephrine and CPR are no longer indicated after ROSC. Immediate coronary angiography and stenting (Option B) is premature unless STEMI is evident on ECG. Discontinue resuscitation efforts and observe, as ROSC has been achieved (Option D) ignores the fact that ROSC patients remain critically ill and need intensive support.

cpr.heart.org/en/resuscitation-science/cpr-and-ecc-guidelines/algorithms#pediatrics

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: 4-year-old child is found unresponsive at home. The parents initiate CPR, and the child is transported to the emergency department. Upon arrival, the medical team begins CPR and attaches a defibrillator. The rhythm check shows asystole. What is the next step in managing this child according to the Pediatric cardiac arrest Algorithm? (Q850672)

A. Deliver a shock immediately

B. Administer Amiodarone IV/IO

C. Administer Epinephrine and continue CPR

D. Administer Lidocaine IV/IO

Correct Answer: C. Administer Epinephrine and continue CPR

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In the pediatric cardiac arrest algorithm, asystole is a non-shockable rhythm. The appropriate treatment involves continuing CPR and administering Epinephrine as soon as possible. Defibrillation (shock) (Option A) is not indicated for asystole or pulseless electrical activity (PEA), which are non-shockable rhythms. Amiodarone (Option B) : Used in VF/pVT. Begin with 300 mg IV/IO; a follow-up dose of 150 mg IV/IO may be administered if needed. An alternative dose is 5 mg/kg IV. Lidocaine (Option D) : Used in VF/pVT. Start with 1-1.5 mg/kg IV. If ventricular fibrillation (VF) or pulseless ventricular tachycardia (VT) persists, administer 0.5-0.75 mg/kg IV every 5-10 minutes, up to a maximum of 3 mg/kg.

cpr.heart.org/en/resuscitation-science/cpr-and-ecc-guidelines/algorithms#pediatrics

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Which of the following statements about massive transfusion is not correct? (Q850645)

A. PRBC should be administered first to address hypoxia and acidosis in bleeding patient

B. 1:1:0.25 ratio of PRBC: FFP: SDP

C. Blood products should be warmed before infusion to prevent coaguloapthy

D. ABO grouping is not required for platelet transfusion

Correct Answer: D. ABO grouping is not required for platelet transfusion

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Even in massive transfusion, ABO grouping for platelets is relevant and preferred. The statement "ABO matching is not required" is still incorrect, although relaxed in emergencies under strict protocols. In the massive transfusion protocol, PRBC must be administered first (Option A) because, in a bleeding patient, blood loss causes hypoxia and acidosis. PRBC carries oxygen and helps neutralize the acidosis component.. Platelets should not be given first, as their function would be impaired by acidosis. The ratio of PRBC:FFP: PRP should be maintained at 1:1:1 (Option B), but for SDP is 1:1:0.25. Warming of blood products (Option C) is essential during rapid transfusion to prevent hypothermia, which is a significant risk in trauma patients receiving large volumes of cold blood products. Hypothermia can lead to coagulopathy, worsening the bleeding.

@Neet_pg_bot

Q11: A 35-year-old farmer is brought to ER 2 hours after being bitten by a snake on his left ankle. He has severe swelling of the left leg, gingival bleeding, and incoagulable blood on the 20-minute whole blood clotting time test. You decide to administer ASV . Twenty minutes after starting the ASV infusion, the patient develops urticaria, cough, and abdominal pain. His blood pressure drops to 85/50 mmHg. Which of the following is the most appropriate next step in management? (Q850669)

A. Discontinue ASV infusion permanently

B. Continue ASV infusion and administer corticosteroids

C. Stop ASV infusion temporarily and treat with epinephrine

D. Administer heparin to counteract coagulopathy

Correct Answer: C. Stop ASV infusion temporarily and treat with epinephrine

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In this case, the patient is developing an early (anaphylactic) reaction to the ASV , which occurs within 10-180 minutes of starting treatment. The symptoms presented (urticaria, cough, abdominal pain, and hypotension) are typical of this reaction. The correct management for an early ASV reaction is as follows: Stop the ASV infusion immediately. Administer epinephrine (adrenaline) intramuscularly or subcutaneously. Give antihistamines and corticosteroids. Treat shock if present (IV fluids, oxygen). Once symptoms have subsided, resume ASV administration at a slower rate. Discontinue ASV infusion permanently (Option A) is incorrect because ASV is crucial for treating severe envenomation. After managing the reaction, ASV should be restarted. Continuing ASV infusion and administering corticosteroids (Option B) is incorrect because continuing the infusion during an anaphylactic reaction can worsen the patient's condition. The infusion should be stopped first. Administer heparin (Option D) is incorrect and potentially dangerous. Heparin is contraindicated in snake bite-induced coagulopathy and would not address the anaphylactic reaction.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 28-year-old farmer is brought to the ER 30 minutes after being bitten by a snake on his right leg. He presents with severe pain and swelling at the bite site, and examination reveals two puncture wounds. His blood pressure is 90/60 mmHg and he has gingival bleeding. The 20-minute whole blood clotting time test shows that the blood is incoagulable. Which of the following is the most appropriate next step in management? (Q850666)

A. Administer crypoprecipitate

B. Administer 150-200 ml of polyvalent antivenom

C. Apply a tight tourniquet above the bite site

D. Administer heparin to manage coagulopathy

Correct Answer: B. Administer 150-200 ml of polyvalent antivenom

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In this case, the patient shows signs of severe envenomation: Severe pain and swelling at the bite site Hypotension (BP 90/60 mmHg) Gingival bleeding Incoagulable blood on the 20-minute whole blood clotting time test These symptoms strongly suggest a viper bite with significant systemic effects. According to the management guide, for severe poisoning with rapidly progressive or overt hemolysis or coagulopathy, the recommended antivenom dose is 150-200 ml. Administer cryoprecipitate (Option A): Supportive, but antivenom is needed first to

stop ongoing venom-induced coagulopathy. Apply a tight tourniquet above the bite site (Option C): Not recommended as it can worsen local tissue damage. Administer heparin to manage coagulopathy (Option D): Contraindicated as coagulopathy is due to venom, not thrombosis.

pmc.ncbi.nlm.nih.gov/articles/PMC4925324/

snakehelpline.com/snake-bite/first-aid/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 32-year-old farmer is brought to the emergency department after being bitten by a snake while working in his field in rural India. He presents with severe local pain, swelling, and gum bleeding. Within 2 hours, he develops diplopia, dysphagia, and progressive weakness in his limbs. Laboratory tests show prolonged prothrombin time and decreased fibrinogen levels. Which of the following snakes is most likely responsible for this envenomation? (Q850661)

A. Cobra

B. Russell's viper

C. Saw-scaled viper

D. Krait

Correct Answer: B. Russell's viper

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's symptoms and laboratory findings suggest a combination of hemotoxic and neurotoxic effects: Hemotoxic: Severe local pain and swelling, gum bleeding, prolonged prothrombin time, and decreased fibrinogen levels. Neurotoxic: Diplopia, dysphagia, and progressive limb weakness. This combination of hemotoxic and neurotoxic effects is characteristic of Russell's viper envenomation . Cobra (Option A): Mainly neurotoxic, rarely causes coagulopathy. Saw-scaled viper (Option C): Typically causes local tissue damage and mild coagulopathy, not prominent neurotoxicity. Krait (Option D): Neurotoxic only, minimal local swelling or coagulopathy.

References:

1. Davidson’s Principle and Practice of Medicine, 24th Edition, Page 152, 153, 154, 155, 156, 157, 158 2. pmc.ncbi.nlm.nih.gov/articles/PMC9278408/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 60-year-old woman is admitted to the ICU with sepsis secondary to a urinary tract infection. After 48 hours, she develops acute hypoxemic respiratory failure. Her chest X-ray shows bilateral infiltrates, and her PaO2/FiO2 ratio is 180 mmHg on PEEP of 8 cm H2O. An echocardiogram shows normal cardiac function. Which of the following is the most appropriate next step in management? (Q850660)

A. Initiate high-frequency oscillatory ventilation

B. Start inhaled nitric oxide therapy

C. Begin low tidal volume ventilation with 6 mL/kg lean body weight

D. Administer high-dose corticosteroids

Correct Answer: C. Begin low tidal volume ventilation with 6 mL/kg lean body weight

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient meets the Berlin criteria for ARDS: Timing: Within 1 week of known clinical insult (sepsis) Chest imaging: Bilateral infiltrates Origin of edema: Not due to cardiac failure (confirmed by echocardiogram) Oxygenation: PaO2/FiO2 ratio of 180 mmHg (indicating moderate ARDS: 100 mmHg < PaO2/FiO2 ≤ 200 mmHg) For moderate ARDS, the next best management option is low tidal volume ventilation with a predicted body weight of 6 mL/kg. ARDS: Management Grade Severity (PaO■/FiO■) Key Management Strategies Grade A (Mild) 200 mmHg < PaO■/FiO■ ≤ 300 mmHg (with PEEP or CPAP ≥ 5 cm H■O) Low tidal volume ventilation (4–8 ml/kg predicted body weight) and lower inspiratory pressures (plateau pressure < 30 cm H■O) Grade B (Moderate) 100 mmHg < PaO■/FiO■ ≤ 200 mmHg Minimized plateau and driving pressures; High PEEP (35–50 cmH■O for 20–40 s); Prone positioning; Recruitment maneuvers; ECMO in selected patients Grade C (Severe) PaO■/FiO■ ≤ 100 mmHg Neuromuscular blockade in early ARDS; Conservative fluid management; Inhaled vasodilators as rescue therapy; Avoid routine use of pulmonary artery catheter Grade D (Severe) PaO■/FiO■ ≤ 100 mmHg Avoid high-frequency oscillatory ventilation; Avoid β■-agonists for improving outcomes

Harrison’s Principles of Internal Medicine, 21st Edition, Page 2227, 2228, 2229

pmc.ncbi.nlm.nih.gov/articles/PMC7997862/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 45-year-old man is admitted to the ICU with severe pneumonia. He develops worsening respiratory symptoms and bilateral infiltrates on chest X-ray within 5 days. Which of the following best describes the pathophysiological mechanism occurring in the alveoli during the early phase of this patient's condition? (Q850655)

A. Increased surfactant production

B. Thickening of the alveolar basement membrane

C. Accumulation of protein-rich edema fluid

D. Fibrosis of the alveolar walls

Correct Answer: C. Accumulation of protein-rich edema fluid

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Rapid deterioration in a case of pneumonia indicates development of acute respiratory distress syndrome. The key pathophysiological mechanism in the early exudative phase of ARDS accumulation of protein-rich edema fluid. This occurs due to increased capillary permeability resulting from injury to the alveolar-capillary membrane. Increased surfactant production (Option A): ARDS leads to reduced surfactant dysfunction, not increased production. Thickening of the alveolar basement membrane (Option B): While this may occur later in ARDS, it's not a primary mechanism in the early phase. This is also seen in bronchial asthma. Fibrosis of the alveolar walls (Option D): This is a feature of the late (fibrotic) phase of ARDS, not the early phase.

References:

Harrison’s Principles of Internal Medicine Edition 21st Page 2225, 2226, 2227

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 55 year-old male presents to the emergency department with fever, tachypnea, and altered mental status. BP is 100/60 mm Hg Laboratory results show: WBC: 14,000/μL Serum lactate: 1.8 mmol/L Creatinine: 1.8 mg/dL (baseline 0.9 mg/dL) Chest X-ray reveals a right lower lobe infiltrate. The patient requires 6 L/min of oxygen to maintain pO2 of 90 mm Hg. Which of the following is the most accurate diagnosis for this patient? (Q850652)

A. Systemic Inflammatory Response Syndrome

B. Sepsis

C. Acute Tubular necrosis

D. Septic shock

Correct Answer: B. Sepsis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: According to Sepsis-3 , sepsis is life-threatening organ dysfunction caused by a dysregulated host response to infection. This patient has pneumonia (infection) with organ dysfunction: Respiratory: PaO■/FiO■ = 90/0.45 = 200 → indicates hypoxemia Renal: Creatinine rise from 0.9 to 1.8 mg/dL → acute kidney injury → Thus, SOFA score ≥2 , confirming sepsis . Systemic Inflammatory Response Syndrome (SIRS) (Option A): Infection or organ dysfunction not mandatory by criteria. Acute Tubular Necrosis (Option C): Explains renal injury only, not systemic infection or multi-organ dysfunction. Septic shock (Option D): Requires hypotension despite fluids and lactate ≥2 mmol/L, which are absent here.

References:

Harrison's Principles of Internal Medicine, 21st Edition, Volume I, Page.2241, 2242.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 30-year-old trauma patient underwent massive transfusion protocol after a road traffic accident. Six hours later, he develops acute onset dyspnea, hypoxia, and bilateral pulmonary infiltrates on chest X-ray. He is afebrile, Pulse 100/min with BP 124/ 80 mm Hg. JVP is normal and pro NT BNP levels are normal. What is the most likely diagnosis? (Q850648)

A. Transfusion-associated circulatory overload

B. Transfusion-related acute lung injury

C. Mismatched blood transfusion

D. Laryngospasm due to citrate induced hypocalcemia

Correct Answer: B. Transfusion-related acute lung injury

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Since BP is normal, neck veins are not distended, and Pro-NT-BNP levels are normal, it indicates TRALI developing after blood transfusion. TRALI presents within 6 hours of transfusion with acute hypoxemia and bilateral pulmonary infiltrates due to donor anti-leukocyte antibodies causing non-cardiogenic pulmonary edema. Transfusion-associated circulatory overload (TACO) (Option A): Shows elevated JVP and raised pro-BNP, unlike this case. Mismatched blood transfusion (Option C): Causes fever, chills, back pain, and hemoglobinuria, not isolated respiratory distress. Laryngospasm due to citrate-induced hypocalcemia (Option D): Leads to tetany or arrhythmias, not bilateral pulmonary infiltrates.

References:

Harrison's Principles of Internal Medicine,21st Edition, Volume I, Page. 894, 895.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 28-year-old male is brought to the trauma center following a motorcycle accident. He is unconscious BP 70/40 mmHg and shows signs of active bleeding. Massive transfusion protocol is initiated. After receiving 4 units of PRBCs rapidly, he develops muscle twitching. ABG shows metabolic alkalosis. ECG shows normal sinus rythm with QT prolongation. What is the most appropriate immediate next step in his management? (Q850646)

A. Administer intravenous calcium gluconate to correct citrate-induced hypocalcemia, which is causing neuromuscular irritability and QT prolongation.

B. Start platelet transfusion immediately to correct dilutional thrombocytopenia, as prolonged transfusion leads to bleeding due to thrombocytopenia.

C. Give sodium bicarbonate to treat the developing metabolic alkalosis resulting from massive transfusion.

D. Transfuse cryoprecipitate to correct fibrinogen deficiency and prevent DIC-like picture often seen after >10 units of PRBC.

Correct Answer: A. Administer intravenous calcium gluconate to correct citrate-induced hypocalcemia, which is causing neuromuscular irritability and QT prolongation.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: After rapid transfusion of multiple units of PRBCs, citrate toxicity can occur, leading to hypocalcemia , which presents with muscle twitching, paresthesia and prolonged QT interval . Hence, IV calcium gluconate is the most immediate and appropriate step . Platelet transfusion (Option B) is important later in MTP, but not the priority here, as the clinical picture suggests an electrolyte imbalance, not active coagulopathy. Sodium

bicarbonate (Option C) is incorrect because metabolic alkalosis seen post-transfusion is usually mild and self-limiting due to metabolism of citrate to bicarbonate; treating it with sodium bicarbonate can worsen alkalosis and is not first-line. Cryoprecipitate (Option D) , while relevant in ongoing transfusions, is not the immediate response to the described ECG

[02_Emergency Medicine] 012 Previous Year Questions — Quick Jump

Q1 (p. 1492) *Q2 (p. 1492)* *Q3 (p. 1493)* *Q4 (p. 1494)* *Q5 (p. 1494)* *Q6 (p. 1495)*
Q7 (p. 1496) *Q8 (p. 1497)* *Q9 (p. 1497)* *Q10 (p. 1498)* *Q11 (p. 1499)* *Q12 (p. 1499)*
Q13 (p. 1500)

Q1: An RTA patient has received 4 packed RBC within a few hours. Which of the following will be seen? (Q866789)

A. Hypernatremia

B. Hyponatremia

C. Hypocalcemia

D. Hyperkalemia

Correct Answer: C. Hypocalcemia

Explanation: Stored packed RBCs contain citrate as an anticoagulant. Rapid transfusion leads to citrate binding ionized calcium in the recipient's blood, causing acute hypocalcemia. Citrate toxicity is more likely when large volumes of blood are transfused rapidly, as in massive transfusion protocols. The liver normally metabolizes citrate, but in shock or hypothermia this clearance is impaired. Clinical signs: Perioral numbness, paresthesia, muscle cramps, tetany, hypotension, and prolonged QT interval on ECG. Massive Blood Transfusion: Definition: Replacement of blood volume exceeding patient's total blood volume within 24 hrs (or >10 units of PRBC). Acute complications: Metabolic: Hypocalcemia (citrate toxicity), hypomagnesemia, hyperkalemia (from hemolysis), hypothermia, metabolic alkalosis. Coagulopathy: Due to dilution of platelets and clotting factors. Volume overload & ARDS. Prevention: Warm blood before transfusion, monitor electrolytes, give calcium gluconate if needed, replace platelets & FFP in balanced ratios. Key electrolyte changes in massive transfusion: Electrolyte Cause Change Calcium Citrate binding ↓ (Hypocalcemia) Potassium Leakage from stored RBCs ↑ (Hyperkalemia) Magnesium Citrate binding ↓ (Hypomagnesemia) Sodium Usually normal; slight ↑ if using older preservatives — Incorrect Options: Hypernatremia (Option A) – Not a major finding; sodium content in stored blood is minimal. Hyponatremia (Option B) – Not typically caused by transfusion. Hyperkalemia (Option D) – Possible in prolonged storage, but acute citrate-induced hypocalcemia is more characteristic in rapid large transfusions.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which is the best confirmatory method to ensure the central line is in the jugular vein? (Q866816)

A. Chest x-ray

B. Blood pH

C. Blood color

D. ETCO2

Correct Answer: A. Chest x-ray

Explanation: Importance of Chest X-ray in Central Line Placement Initial Assessment: A chest X-ray should be performed immediately after internal jugular and subclavian line placement to confirm correct catheter placement and rule out iatrogenic pneumothorax. Post-Procedure Verification: It is crucial to verify catheter placement and ensure no complications, like pneumothorax, following the procedure. Ipsilateral Side Approach: If the internal jugular central venous line (CVL) insertion fails, move to the ipsilateral subclavian vein. A chest X-ray or ultrasound should be performed before attempting the opposite side to prevent bilateral pneumothoraces. Options B, C, and D are incorrect.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Young male has sustained Femur shaft fracture after RTA and internal fixation was done. 2 days later he develops shortness of breath with confusion and petechial rash. Diagnosis is? (Q866513)

A. FES

B. ARDS

C. Pulmonary embolism

D. Pleural effusion

Correct Answer: A. FES

Explanation: This patient has the classic triad of Fat Embolism Syndrome following a long bone fracture and orthopedic surgery: Respiratory distress (shortness of breath) Neurological symptoms (confusion, altered sensorium) Petechial rash (typically on upper chest, axillae, and conjunctiva) Fat emboli enter the circulation from bone marrow after trauma or fixation and lodge in pulmonary and systemic microvasculature, producing respiratory compromise, brain dysfunction, and a petechial rash due to dermal capillary occlusion. ARDS (Option B) : Can occur after trauma but doesn’t present with the petechial rash; onset is usually a bit later and is related to

widespread inflammatory lung injury. Pulmonary embolism (Option C) : Causes acute dyspnea and hypoxia but usually lacks neurologic signs and rash; most often from DVT. Pleural effusion (Option D) : Would present with unilateral decreased breath sounds, not acute neuro changes or rash.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following is not part of the clinical criteria for anaphylaxis? Urticaria, lip/tongue edema Wheeze and respiratory distress Abdominal cramps and vomiting Hypertension (Q840144)

A. 1, 2, and 3

B. 1 and 2

C. 2 and 3

D. 4

Correct Answer: D. 4

Explanation: While urticaria, respiratory distress, and GI symptoms are common, hypertension is not a feature of anaphylaxis. Anaphylaxis causes hypotension due to vasodilation and increased vascular permeability . Anaphylaxis is a severe, rapid-onset, multisystem allergic reaction . The clinical criteria include: Skin/Mucosal: Urticaria, angioedema, lip/tongue swelling, rash Respiratory: Wheezing, stridor, dyspnea Cardiovascular: Hypotension or shock , not hypertension Gastrointestinal: Abdominal cramps, vomiting, diarrhea

References:

.

@Neet_pg_bot

Q5: A 65-year-old patient with type 2 diabetes mellitus experiences hypoglycemia and falls, resulting in incoherent speech. CT scan reveals a large acute subdural hematoma (SDH) >30 cc. What is the most appropriate immediate management? (Q860237)

A. Administer intravenous mannitol and observe

B. Start dual antiplatelet therapy (aspirin + clopidogrel)

C. Emergent surgical evacuation (craniotomy or burr hole)

D. Stabilize the patient and schedule routine neurosurgical consultation

Correct Answer: C. Emergent surgical evacuation (craniotomy or burr hole)

Explanation: Large acute SDH (>30 cc) with neurological deficits is a surgical emergency . Immediate evacuation relieves mass effect, prevents herniation, and improves outcomes. Administer intravenous mannitol and observe (Option A): Temporarily reduces ICP but does not remove the hematoma → insufficient. Start dual antiplatelet therapy (aspirin + clopidogrel) (Option B): Antiplatelets increase bleeding risk and are contraindicated in acute SDH. Stabilize the patient and schedule routine neurosurgical consultation(Option D): While stabilization is important (airway, breathing, circulation), delaying surgery for routine consultation is dangerous. Large symptomatic SDH needs urgent neurosurgical intervention , not a routine referral.

Harrison's Principle of Internal Medicine 21st Edition Page 3457, 3458

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: What medication can be administered to a patient who experiences altered consciousness, sweating, rapid heartbeat, persistent erection, and increased saliva production, with a blood pressure reading of 150/90 mm Hg after visiting a temple with their grandmother? (Q854658)

A. ASV

B. Adrenaline

C. Steroid

D. Prazosin

Correct Answer: D. Prazosin

Explanation: The patient might be suffering from a scorpion sting cardiotoxicity as per his symptoms and the best choice of medication here is Prazosin . Treatment of scorpion sting: Identification of the scorpion species is essential for determining treatment, as stings from non-lethal species typically only require basic care. Non-lethal stings : Most stings cause local discomfort and can be managed at home with ice packs, analgesics, or antihistamines. Patients should return to the emergency department if cranial-nerve or neuromuscular symptoms develop. Severe envenomations : Aggressive supportive care and careful use of antivenom can prevent deaths from more dangerous stings. Initial measures : Keeping the patient calm, applying pressure dressings, and using cold packs can reduce venom absorption. Treatment for symptoms : Continuous IV infusion of midazolam can control agitation and muscle movements, but close monitoring is needed due to the risk of respiratory arrest,

especially when sedatives or narcotics are used. Management of complications : Hypertension and Pulmonary oedema : Managed with Nifedipine, Nitroprusside, Hydralazine, or Prazosin . Bradycardia : Managed with atropine. Antivenin : FDA-approved antivenin (C. sculpturatus IgG F(ab')2 in horse serum) is available in some countries and can rapidly reverse cranial-nerve dysfunction and muscular symptoms when administered intravenously. Incorrect Options: Anti-snake venom (Option A) is a specific treatment used for snakebite envenomation and is not indicated in the given scenario. Adrenaline (Option B) is commonly used in emergencies to treat severe allergic reactions and cardiac arrest. Steroids (Option C) , such as corticosteroids have anti-inflammatory and immunosuppressive effects. They are generally used in allergic reactions, autoimmune disorders, and asthma. However, these are not preferred in the given scenario.

Harrison's Principles of Internal Medicine, 21st Edition, Page: 3613.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A patient was being treated in ICU for sepsis. The initial ABG shows pH= 6.9, pO 2 = 80 mm Hg. pCO 2 = 55 mmHg, HCO 3 = 10 meq/L. A repeat ABG after 2 hours shows pH=7.1, pCO 2 = 20 mmHg, pO 2 = 140 mm Hg, and HCO 3 = 10 meq/L. Which is most plausible to explain the change seen in the ABG report? (Q854662)

A. Excessive air and less heparin in the ABG sample

B. Excess air and more heparin in the ABG sample

C. Less air and more heparin in the ABG sample

D. Less air and less heparin in the ABG sample

Correct Answer: B. Excess air and more heparin in the ABG sample

Explanation: The change in the pH without a change in the bicarbonate level indicates excess heparinization . The increased pO 2 shows excess air . Effects of excess heparin: Heparin is a sulfated mucopolysaccharide with acidic properties. The excess of heparin in the ABG syringe can have the following effects: Effect on pH: If the pH is normal or alkaline (high) to begin with, acidemia increases i.e., the pH will fall on contact with the acidic heparin. If the pH is very acidic to begin with, acidemia decreases i.e., the pH will rise as the mildly acidic heparin reduces the greater acidity of the blood. Delusional effect: The PaO 2 and PaCO 2 can also be falsely lowered by dilution.

https://pubmed.ncbi.nlm.nih.gov/3919622/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following statements regarding the management of frostbite is incorrect? (Q855609)

A. Amputation in severe cases

B. Rewarming is done

C. Antibiotics and analgesics not used

D. The area is dried and cleaned

Correct Answer: C. Antibiotics and analgesics not used

Explanation: Antibiotics are commonly prescribed in the management of frostbite to prevent or treat secondary bacterial infections that can occur as a result of damaged tissue. Analgesics, such as nonsteroidal anti-inflammatory drugs (NSAIDs) or opioids, may be used to manage pain. In severe cases of frostbite where tissue damage is extensive and irreversible, amputation may be necessary to remove dead or gangrenous tissue (Option A) and prevent the spread of infection. Therefore, amputation can be a part of the management in severe cases. Rewarming the affected area (Option B) is a critical step in the management of frostbite. It should be done using warm water (not hot) or by placing the affected area in a warm environment. Rewarming helps to restore blood flow and prevent further tissue damage. After rewarming, the affected area should be gently dried and cleaned to prevent infection. (Option D) Cleaning helps remove any debris or contaminants from the damaged tissue.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: During a scorching summer afternoon, a man, who had been toiling in a field, unexpectedly collapsed. Upon examination, there were no apparent physical indications of dehydration, although his radial pulse was detectable. The doctor determined that the man's serum electrolyte levels were within the normal range. Shockingly, the man's body temperature measured 106 degrees Fahrenheit. Considering these circumstances, which of the following should be administered as an initial form of immediate assistance? (Q857001)

A. Inject epinephrine immediately

B. Cover with hot damp sheets

C. Cover with cool damp sheets

D. Start CPR

Correct Answer: C. Cover with cool damp sheets

Explanation: The above patient seems to be suffering from a heat stroke. There are no signs of dehydration and the body temperature is quite high and the radial pulse is present. The next best step is to cover the body with cool damp sheets. Epinephrine injection (Option A) can be fatal for the patient. CPR (Option D) is not required as a steady radial pulse is perceived and the patient is not in shock.

@Neet_pg_bot

Q10: According to the ABCD2 scoring, which factors indicate a greater likelihood of a patient with TIA experiencing a future stroke? (Q856931)

A. Age <60 years

B. SBP>140 mm Hg and DBP <90 mmHg

C. Duration of TIA >5 mins

D. Diabetes

Correct Answer: D. Diabetes

Explanation: Presence of diabetes indicates higher risk of stroke following TIA. ABCD2 Score for TIA (Transient Ischemic Attack): The Risk of Stroke Parameter Criteria Points Age > 60 years (Option A) 1 point Blood Pressure BP ≥ 140/90 (Option B) 1 point Clinical Features Speech disturbance without weakness 1 point Unilateral leg weakness 2 points Duration 10–59 minutes (Option C) 1 point ≥ 60 minutes 2 points Diabetes Presence of diabetes 1 point Stroke Risk Based on Score: Score Stroke Risk Day 2 Day 7 Day 90 0–3 1% 1.2% 3.1% 4–5 4.1% 5.9% 9.8% 6–7 8.1% 11.7% 17.8%

https://www.ncbi.nlm.nih.gov/books/NBK459143/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: The recommended temperature of a water bath for a patient with frostbite is (Q858462)

A. 37 degree C

B. 42 degree C

C. 32 degree C

D. 30 degree C

Correct Answer: A. 37 degree C

Explanation: The recommended temperature of a water bath for a patient with frostbite is 37 degree C. Frostbite: Pathophysiology: Tissue freezes below 0°C (32°F), leading to the ice-crystal formation that destroys the cellular structure. Vascular endothelial damage causes stasis, microvascular thrombosis, and progressive dermal ischemia. Thrombosis, ischemia, and necrosis lead to mummification and demarcation over weeks to months. Clinical Presentation: Symptoms: Sensory deficits (light touch, pain, or temperature perception); "chunk of wood" sensation in extremities. Signs: Superficial frostbite: Anesthesia, erythema, pliable subcutaneous tissue, and no tissue loss. Deep frostbite: Waxy, mottled, violaceous-white tissue; hemorrhagic vesicles indicate severe injury. Treatment: Rewarming: Immerse frozen tissue in circulating water at 37°- 40°C (99°-104°F) for 30-60 minutes. Avoid premature termination of thawing despite the pain. Medical Management: Prostacyclin analogs (e.g., iloprost) within 48 hours. Thrombolysis (rt-PA) and heparin for deep frostbite within 24 hours to reduce amputation risk. Surgical Considerations: Delay debridement or amputation until demarcation.

Harrison’s Principles of Internal Medicine, 21st Edition, Page 3633,3634

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: All of the following is used in the management of breathless patients at a high altitude of 3000 mts except. (Q858463)

A. Intravenous digoxin

B. Oxygen supplementation

C. Immediate descent

D. Acetazolamide

Correct Answer: A. Intravenous digoxin

Explanation: A breathless patient at a high altitude of 3000 meters suggests High-Altitude Pulmonary Edema (HAPE) , and intravenous digoxin is not used in its management. High-Altitude Pulmonary Edema (HAPE): Risk Factors: Rapid ascent, history of HAPE, respiratory infections, cold temperatures. Cardiopulmonary abnormalities (e.g., mitral stenosis, primary pulmonary hypertension) increase risk, even at moderate altitudes. Clinical Features: Reduced exercise tolerance greater than expected at altitude. Dry cough may precede, followed by blood-tinged sputum. Tachypnea, tachycardia, crackles on auscultation. Hypoxemia and respiratory alkalosis are present unless on acetazolamide (which may cause metabolic acidosis). Investigation: Chest X-ray: Patchy or streaky interstitial edema. Electrocardiograms: Right ventricular strain or hypertrophy. Prevention: Gradual ascent is key to acclimatization. Sustained-release nifedipine (30 mg twice daily) prevents HAPE in those ascending rapidly or with a history of HAPE. Acetazolamide (Option D) and dexamethasone are potential options, though their roles require careful monitoring. Treatment: Immediate descent (Option C) and supplemental oxygen (Option B) (targeting >90% saturation) are the most effective treatments. Maintain rest, warmth, and limit exertion. Hyperbaric therapy (portable altitude chamber) may be lifesaving if descent is not possible. Oral nifedipine as adjunctive therapy.

Harrison’s Principle of Internal Medicine, 21st Edition, Page 3619,3620

↑ *Back to this question in Part A*

@Neet_pg_bot

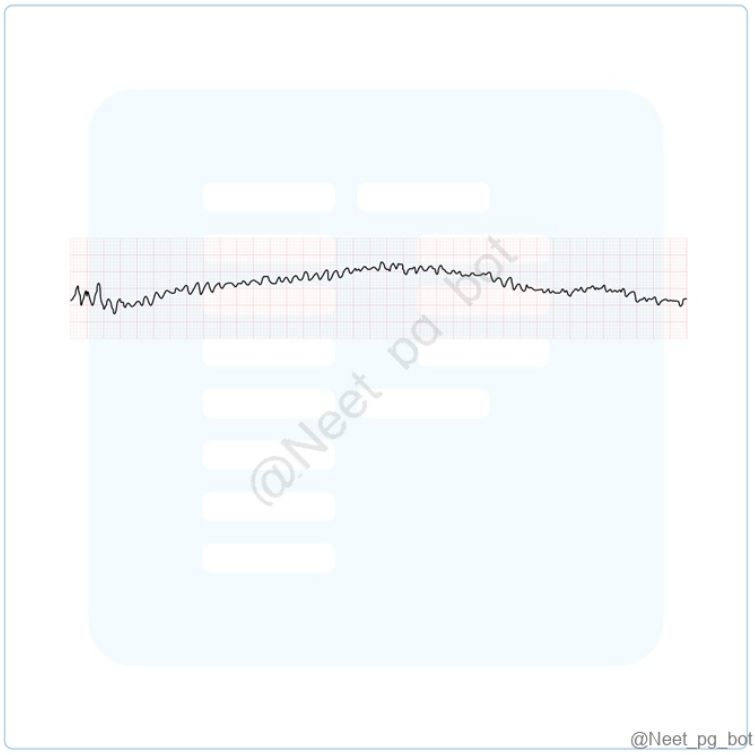
Q13: A 47-year-old woman was brought to the casualty in an unconscious state after having suddenly collapsed. As there was no pulse, cardiopulmonary resuscitation was started and the monitor showed the following rhythm. What is the next step? (Q859792)

A. Defibrillation

B. Synchronized cardioversion

C. 1mg epinephrine

D. 0.5mg atropine



Correct Answer: A. Defibrillation

Explanation: The given ECG shows ventricular fibrillation and the next step of management is defibrillation since this is a shockable rhythm. Shockable Conditions Non-Shockable Conditions Ventricular Fibrillation Asystole Ventricular Tachycardia Pulseless Electrical Activity Shockable Conditions Non-Shockable Conditions Immediate Recognition Identify Shockable Rhythm: Recognize VF or pulseless VT. Activate Emergency Response: Call for advanced life support. ↓ Initiate CPR Start High-Quality CPR: Perform chest compressions at a rate of 100-120/min, with a depth of 5-6 cm. Continue CPR for 2 minutes. ↓ Defibrillation (Option A) After 2 minutes of CPR, deliver a Non-Synchronized DC Shock to restore normal rhythm. If no change, administer a second shock immediately. ↓ Continue CPR Resume CPR for 2 Minutes Place an intravenous or intraosseous line for drug administration. ↓ Administer Epinephrine Epinephrine 1 mg (Option C) (1:10,000): Given IV/IO after 2 minutes of CPR to enhance coronary perfusion pressure. ↓ Advanced Airway Management Secure Airway: Perform endotracheal intubation if necessary. Capnography: Monitor end-tidal CO2 levels. Ventilation: Provide 1 breath every 6 seconds post-intubation. ↓ Further Defibrillation Third Shock: If VF or pulseless VT persists, deliver a third non-synchronized shock. Continue CPR for 2 More Minutes: Follow with additional CPR. ↓ Administer Antiarrhythmic Medication Amiodarone 300 mg IV: Administer for shock-refractory VT to stabilize heart rhythm. ↓ Identify and Treat Reversible Causes Immediate Recognition Identify Non-Shockable Rhythm: Recognize asystole or pulseless electrical activity (PEA). Activate Emergency Response: Call for advanced life support. ↓ Initiate CPR Start High-Quality CPR: Perform chest compressions at a rate of 100-120/min, with a depth of 5-6 cm. Continue CPR for 2 minutes. ↓ Establish intravenous or intraosseous lines for medication administration. ↓ Administer Epinephrine Epinephrine 1 mg (1:10,000): Administer IV/IO after the first 2 minutes of CPR. ↓ Identify Rhythm Non-Shockable Rhythm: Continue CPR and administer epinephrine every 3-5 minutes. Goal: To increase the likelihood of developing a shockable rhythm, such as ventricular fibrillation (VF), which is necessary for effective defibrillation. Shockable Rhythm: Administer a Non-Synchronized DC Shock to restore normal rhythm. ↓ Advanced Airway Management Airway: Secure the airway with endotracheal intubation if necessary.

Capnography: Monitor end-tidal CO2 levels. Ventilation: Provide 1 breath every 6 seconds post-intubation for adequate oxygenation. ↓ Continue CPR Resume chest compressions for 2 minutes. ↓ Identify and Treat Reversible Causes Primary Focus: Address reversible causes, especially hypothermia. ↓ Repeat CPR and Epinephrine Cycle: Continue repeating CPR and epinephrine administration every 3-5 minutes. Synchronized cardioversion (Option B) is used to reset the abnormal heart rhythm and is given in synchronisation with the R wave in the ECG (delivered at the peak of the R wave). It is performed in arrhythmias where the heart is still contracting but irregularly, such as Paroxysmal Supraventricular Tachycardia (PSVT), Atrial Fibrillation (AF), and Atrial Flutter. 0.5 mg atropine (Option D) is indicated for symptomatic bradycardia and not in a pulseless patient.

Q19 (p. 1518)

Q1: You are a doctor in armed forces and are tasked with doing medical examination of new recruits. Your next candidate has a blood report that mentions a FBS of 116 mg/dl. Which of the following terms will you use to describe this blood report? (Q850583)

A. Impaired fasting glucose

B. Impaired glucose tolerance

C. Diabetes mellitus

D. Secondary diabetes

Correct Answer: A. Impaired fasting glucose

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Impaired Fasting Glucose (IFG) term is used when FBS is 100-125 mg/dl Impaired Glucose Tolerance (IGT) (Option B) is used when the 2-hour value is between 140-199 mg/dl Diabetes mellitus (Option C): Requires FBS ≥126 mg/dL or other diagnostic criteria. Secondary diabetes (Option D): Occurs due to underlying conditions like pancreatitis or Cushing's syndrome.

@Neet_pg_bot

Q2: In type 1 DM, stage III of beta cell destruction presents as which of the following? (Q850609)

A. Autoimmune - , Symptomatic, Dysglycemia

B. ■■■■Autoimmune +, Symptomatic, Hyperglycemia

C. Autoimmune - , Asymptomatic, Normoglycemia

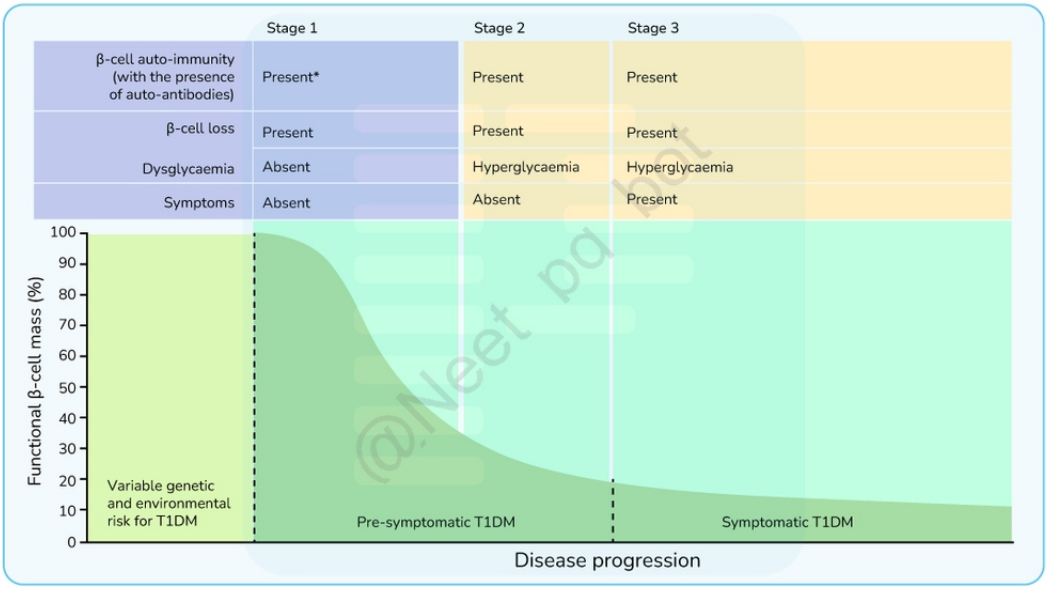
D. Autoimmune + , Asymptomatic, Normoglycemia

Correct Answer: B. ■■■■Autoimmune +, Symptomatic, Hyperglycemia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Type 1 diabetes mellitus is autoimmune in etiology due to islet cell antibodies. The stages of evolution of disease are as follows: Stage 1: Asymptomatic, Normoglycemia Stage 2 : Asymptomatic, Dysglycemia (progressive beta cell dysfunction) Stage 3: Symptomatic, Hyperglycemia



References:

JDRF–Endocrine Society–ADA consensus and published in Lancet Diabetes & Endocrinology and Diabetes Care.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which of the following insulin preparations need to given once a week? (Q850608)

A. Icodec

B. Glargine

C. Degludec

D. Determir

Correct Answer: A. Icodec

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Icodec is a once-weekly basal insulin with the longest duration (~7 days) among all insulins. It binds reversibly to albumin and is gradually released into the circulation. Among the given options, Icodec is the only insulin approved for once-weekly injection. Glargine (Option B) is a long-acting insulin (24 hours) used once daily for basal coverage. Degludec (Option C) is an ultra-long-acting insulin (>42 hours) that allows flexible dosing. Detemir (Option D) lasts 16–20 hours and often requires twice-daily dosing.

References:

https://pmc.ncbi.nlm.nih.gov/articles/PMC10258611/

https://pmc.ncbi.nlm.nih.gov/articles/PMC12048741/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following dermatological diseases is most specific to a patient of diabetes mellitus with RBS of 220 mg/dl and RIA showing low fasting insulin levels? (Q850604)

A. Necrobiosis lipoidica diabeticorum

B. Acanthosis nigricans

C. Diabetic dermopathy

D. Intertriginous candidiasis

Correct Answer: A. Necrobiosis lipoidica diabeticorum

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Necrobiosis lipoidica diabeticorum (NLD) is a rare, specific skin manifestation of diabetes, often seen in patients with long-standing or poorly controlled diabetes. It presents as well-defined, shiny plaques on the shins. Low fasting insulin and hyperglycemia suggest insulin deficiency rather than resistance , which correlates with NLD. Acanthosis nigricans (Option B): Associated with insulin resistance and hyperinsulinemia, not low insulin. Diabetic dermopathy (Option C): Common, but nonspecific “shin spots” seen in many diabetic patients. Intertriginous candidiasis (Option D): Opportunistic infection, not specific to diabetes.

References:

.

@Neet_pg_bot

Q5: A 17-year-old male with thalassemia major presents with fatigue, hyperpigmented skin, and recently diagnosed diabetes mellitus. He has been receiving regular blood transfusions since early childhood. On examination, he has discoloration of the skin shown below, mild hepatomegaly, and lab reports show elevated serum ferritin and fasting blood glucose of 180 mg/dL.Which of the following should not be done in the initial management of this patient? (Q850597)

A. Start basal bolus insulin

B. Start iron chelation therapy

C. Phlebotomy

D. Monitor for cardiac iron overload with MRI T2

@Neet_pg_bot

Correct Answer: C. Phlebotomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has Bronze Diabetes, a form of diabetes associated with iron overload due to repeated blood transfusions in thalassemia major. This condition leads to impaired insulin secretion, resulting in hyperglycemia and characteristic skin changes. In a thalassemia major patient with bronze diabetes, insulin therapy is essential to control hyperglycemia due to iron-induced β-cell damage. Iron chelation with agents like deferasirox is the appropriate method to reduce iron overload, as phlebotomy is contraindicated in such anemic patients. Monitoring for cardiac iron overload with MRI T2* is crucial due to the risk of siderotic cardiomyopathy. Start basal bolus insulin (Option A): Required to control hyperglycemia due to pancreatic iron deposition. Start iron chelation therapy (Option B): Essential to reduce iron overload and prevent organ damage. Monitor for cardiac iron overload with MRI T2 (Option D): Important to assess for cardiac siderosis and guide chelation therapy.

References:

https://pmc.ncbi.nlm.nih.gov/articles/PMC4437060/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Which of the following genetic factors is most strongly associated with an increased risk of developing Type 1 Diabetes Mellitus? (Q850595)

A. HLA-B27

B. HLA-DR3 DR4

C. HLA DR2

D. HLA DR 5

Correct Answer: B. HLA-DR3 DR4

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: HLA- DR3/DR4 haplotypes are strongly linked to increased susceptibility to T1DM. Mechanism: Loss of immune tolerance and progressive β-cell apoptosis in the pancreas by self-CD4 cells. HLA-B27 (Option A): Associated with ankylosing spondylitis and other spondyloarthropathies, not T1DM. HLA-DR2 (Option C): Associated with multiple sclerosis and protection against T1DM. HLA-DR5 (Option D): Less commonly associated; not a major risk factor for T1DM.

References:

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 728, 729

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: 25-year-old thin asymptomatic male is found to have fasting hyperglycemia during a routine checkup. His father and grandmother were diabetics.Genetic testing confirms a glucokinase mutation, consistent with MODY type 2. Which is correct management? (Q850593)

A. Start insulin

B. Start Metformin

C. Start semaglutide

D. No treatment required

Correct Answer: D. No treatment required

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: MODY2 is characterized by mutations in the GCK gene, leading to stable mild hyperglycemia without requiring treatment. Patients with this subtype typically maintain normal renal function and do not experience significant progression of diabetes. In contrast in MC subtype MODY 3 that occurs due to HNF1A mutation, treatment is given with glipizide. Insulin (Option A): Not required; hyperglycemia is mild and stable. Metformin (Option B): Usually ineffective in GCK-MODY. Semaglutide (Option C): Not indicated; MODY2 rarely benefits from pharmacotherapy.

Davidson's Principles and Practice of Medicine, 24th Edition, Page 733

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following is most important intervention to reduce the progression of macrovascular complications of diabetes mellitus (Q850591)

A. Tight glycaemic control with HbA1c < 7%

B. Tight BP control and statins

C. Cessation of smoking

D. Limitation of sedentary activities

Correct Answer: B. Tight BP control and statins

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Strict BP control and control of dyslipidemia are main interventions to reduce macrovascular complications in diabetes, such as myocardial infarction and stroke. Statin therapy is essential to lower LDL cholesterol. Target BP is <130/80 mm Hg and Target LDL is < 70 mg/dl. Macrovascular Complications of Diabetes Mellitus: Coronary circulation: Myocardial ischemia/infarction. Cerebral circulation: Transient ischemic attack, stroke. Peripheral circulation: Claudication, ischemia. Tight glycemic control with HbA1c <7% (Option A): Primarily reduces microvascular complications, less impact on macrovascular disease. Cessation of smoking (Option C): Important lifestyle measure, supportive but not as potent as BP/statin control. Limitation of sedentary activities (Option D): Helpful adjunct for overall cardiovascular health, but less direct impact on macrovascular outcomes.

References:

Davidson's Principles and Practice of Medicine, 24th Edition, Page 743, 755, 756, 757

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Which of the following is not a microvascular complication of diabetes mellitus? (Q850587)

A. Diabetic retinopathy

B. Diabetic neuropathy

C. Diabetic foot

D. Diabetic nephropathy

Correct Answer: C. Diabetic foot

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Diabetic foot is primarily a macrovascular complication resulting from peripheral artery disease and neuropathy. Diabetic Microvascular Complications Diabetic retinopathy Diabetic nephropathy Diabetic neuropathy (overall most common complication of DM)

References:

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 756- 762

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Which of the following is most important intervention for a newly diagnosed type 2 diabetes mellitus patient with HbA1c of 7%? (Q850586)

A. Hypocaloric diet

B. Carbohydrate counting

C. Light aerobic activity

D. Start cereals with low glycemic index

Correct Answer: A. Hypocaloric diet

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Lifestyle modifications like hypocaloric diet(500 Kcal restriction per day) is single most important intervention in newly diagnosed type 2DM. Carbohydrate counting is done for T1DM. Consumption of cereals with low glycemic index is universal intervention in all diabetics to prevent post prandial spikes. Even a 5–10% weight loss through calorie restriction can dramatically improve insulin sensitivity, reduce HbA1c, and potentially lead to diabetes remission in early T2DM. Carbohydrate counting (Option B): Mainly used in Type 1 DM for insulin dose adjustment. Light aerobic activity (Option C): Helpful adjunct but dietary control is the most crucial first intervention. Start cereals with low glycemic index (Option D): Supportive dietary advice, not the primary intervention.

References:

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 722, 726, 727, 728, 743, 744, 745.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 12-year-old girl presents with abdominal pain, vomitting and prostration for past one day. O/E: pulse:100/min, BP: 100/60 mm Hg and RR=20/min with a fruity-smelling breath. Work up shows plasma glucose level of 350 mg/dL and a positive urine ketone test. Which of the following is next step for managment of this patient? (Q850540)

A. Start regular insulin drip at 0.05–0.1 U/kg/hr

B. Give normal saline bolus

C. Perform ABG

D. Check serum electrolytes

Correct Answer: C. Perform ABG

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This child is having presentation of diabetic ketoacidosis on clinical grounds. However, the triad of DKA is not satisfied. Without a complete diagnosis we don't start treatment. RBS is > 200 mg/dl with symptoms, Urine ketones are present Acidosis report is not given in case presentation. We should first perform ABG to demonstrate low bicarbonate and low pH. It would take not more than few minutes and hence delay in treatment would not change the course of illness. Also note that vitals are decent and patient does not need bolus IV fluids. If this patient was having crashing vitals then giving fluid bolus would have given been preference over all others. The sequence in management of this patient will be Perform ABG (check lactate levels for possibility of lactic acidosis or sepsis and check potassium levels) IV Fluid saline over 1 hour to correct dehydration + KCL added to

IV fluid bottle Once K+ is ≥3.3 mEq/L and at least 1–2 hours of fluid therapy has been given, start regular insulin infusion at 0.05–0.1 U/kg/hr If blood sugar falls to below 250 mg/dl change IV fluid to N/2 in 5%D Transition to subcutaneous insulin once patient is alert, eating, and metabolic parameters (AG, pH, bicarb) normalize

References:

Harrison's Principle of Internal Medicine, 21st Edition, Page 3095

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 50-year-old woman presents for a routine check-up. She has no family history of diabetes or hypertension. According to the American Diabetes Association (ADA) guidelines, what is the most appropriate screening recommendation for her? (Q850568)

A. No screening is necessary until age 60

B. Screen now and re-screen every 3 years if normal

C. Screen every year regardless of results

D. Screen only if symptoms of diabetes appear

Correct Answer: B. Screen now and re-screen every 3 years if normal

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The American Diabetes Association recommends that adults aged 45 and older undergo screening for diabetes, regardless of risk factors. Since the patient is 50 years old, she should be screened now, with re-screening every 3 years if the results are normal, ensuring early detection and intervention if necessary. Summary of Screening Guidelines Population First Screening Age Rescreening Frequency General Adults 45 years Every 3 years, if normal Overweight/Obese Adults Any age Based on individual risk factors Individuals with Prediabetes N/A Annually High-Risk Ethnic Groups <45 years Every 3 years, if normal Pregnant Women During pregnancy As needed, based on risk factors

https://www.ncbi.nlm.nih.gov/books/NBK574060/

https://www.ncbi.nlm.nih.gov/books/NBK554615/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following is best for monitoring of diabetes mellitus? (Q850566)

A. Continous glucose monitoring

B. HbA1c

C. Post prandial blood glucose

D. Self monitoring of blood glucose

Correct Answer: A. Continous glucose monitoring

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Continuous glucose monitoring measures real-time glucose trends. It can detect nocturnal and silent hypoglycemia. It is unaffected by hemoglobinopathy and anemia. The biggest advantage is, it gives an immediate therapy adjustment opportunity. HbA1c (Option B) can be affected by hemoglobinopathies, anemia and does not detect hypoglycemic episodes that occur in diabetics. Postprandial blood glucose (Option C) is too variable-dependent on meal timing and composition Self-monitoring of blood (Option D) glucose is usually avoided by diabetics due to the hassle of pricking self.

References:

Davidson's Principles and Practice of Medicine, 24th Edition, Page 724, 727

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: Which of the following tests is the most appropriate for short-term monitoring of glycemic control in a diabetic patient ? (Q850563)

A. HbA1c

B. Fructosamine

C. Fasting Blood Glucose

D. Oral Glucose Tolerance Test (OGTT)

Correct Answer: B. Fructosamine

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Fructosamine is the best choice for short-term glycemic control monitoring because it reflects average blood glucose levels over the past 2-3 weeks , allowing for timely adjustments in diabetes management. This is crucial when monitoring changes after medication adjustments, unlike HbA1c (Option A), which indicates longer-term control over 2-3 months. Fasting, Postprandial Plasma Glucose and OGTT (Options C & D) provide only single-time-point results.

References:

www.ncbi.nlm.nih.gov/pmc/articles/PMC4604592/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: Glycosylated Hemoglobin is not reliable in diagnosis of which of the following types of diabetes mellitus? (Q850560)

A. Bronze diabetes

B. Type 1 Diabetes mellitus

C. Type 1.5 Diabetes mellitus

D. Type 2 Diabetes mellitus

Correct Answer: A. Bronze diabetes

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Glycated Hemoglobin (HbA1c) effectively assesses overall glycemic control and is suitable for diagnosing diabetes in asymptomatic individuals. Bronze diabetes is seen in transfusion-dependent thalassemia patients. They develop hemochromatosis, and iron excess damages the beta cells of the pancreas, leading to insulinopenia. Thalassemia patients have low HbA, which will cause falsely low HbA1c. Causes of falsely low or normal HbA1c (due to decreased RBC turnover) Causes of falsely elevated HbA1c Hemolytic anemia Acute blood loss Chronic liver disease Reticulocytosis B-12/Folate deficiency Iron deficiency anemia

References:

Davidson’s Principles and Practice of Medicine, 24th Edition, Pages 722, 726, 727, 728

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: Which of the following values is not used for diagnosis of diabetes mellitus? (Q850556)

A. Random Blood sugar of 250 mg/dl with classic symptoms

B. Post prandial value of 200 mg/dl

C. Fasting blood sugar of 140 mg/dl in an asymptomatic patient

D. HbA1c value of 7.8% in asymptomatic patient

Correct Answer: B. Post prandial value of 200 mg/dl

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Post-prandial value is used for monitoring and follow-up, and not for diagnosis. In the ADA diagnosis table, is 2-hour value > 200 mg/dl is used for diagnosis. The 2-hour value is taken after a glucose challenge of 75gm glucose and is not the same as the post-prandial value. PP value can be influenced by the type of meal taken. Random blood sugar> 200 mg/dl with classic symptoms, fasting blood sugar of 140 mg/dl in an asymptomatic patient, and HbA1c value of 7.8% in an asymptomatic patient are all used for the diagnosis of diabetes mellitus.

References:

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 722, 726, 727, 728.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: Which of the following drugs is most likely to cause drug-induced diabetes by impairing insulin secretion from the pancreas? (Q850550)

A. Glucocorticoids

B. Thiazide diuretics

C. Phenytoin

D. β-lactam antibiotics

Correct Answer: B. Thiazide diuretics

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Thiazide diuretics are known to impair insulin secretion from the pancreas (possibly secondary to the hypokalemia induced by the thiazide diuretics), leading to increased blood glucose levels and a higher risk of developing diabetes. Drugs Causing Diabetes Drugs Affecting Glucose levels (Not Causing DM) Glucocorticoids – Increase insulin resistance (Option A); can cause temporary or type 2 diabetes β-lactam antibiotics – Interfere with urine glucose tests (Option D) Thiazide diuretics – Impair insulin secretion (Option B); used for hypertension Levodopa – May cause false-positive glucose results Phenytoin – Possible liver-related mechanism (Option C); anticonvulsant Salicylates – Affect glucose measurements in urine

References:

Davidson's Principles and Practice of Medicine, 24th Edition, Page 725, 728, 733

KD Tripathi, Essentials of Medical Pharmacology, 8th edition, Page 606.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: An 8-year-old boy is brought to ER with a 2-day history of vomiting, abdominal pain and prostration. On examination, he is drowsy, with sunken eyes, dry tongue, cold extremities, a thready pulse of 140/min, BP of 80/50 mmHg and RR =30/min. His RBS : 460 mg/dL, urine shows 4+ ketones and ABG shows pH= 7.2 , pC02 =20 mm Hg and HCO3 = 5 meq/L. What is the most appropriate next step in management? (Q850548)

A. Start IV insulin infusion at 0.1 U/kg/hr

B. Start normal saline with insulin drip

C. Give bolus of normal saline

D. Normal saline with insulin bolus followed insulin drip

Correct Answer: C. Give bolus of normal saline

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This child has severe DKA with hypovolemic shock. In DKA with shock, the FIRST and most urgent step is fluid resuscitation. Administer 10–20 mL/kg of 0.9% normal saline over 30–60 minutes , repeating as needed until perfusion improves. This restores circulating volume, improves tissue perfusion, and helps correct acidosis. Start IV insulin immediately (Option A): Insulin before fluids can cause cerebral edema and worsen hypokalemia. Bolus of insulin has been discontinued as per the latest ISPAD guidelines Start bicarbonate infusion (Option B): Bicarbonate is avoided unless pH < 6.9. Raises risk of cerebral edema and offers no benefit here. Start maintenance IV fluids (Option D): Too slow for a child in shock. Must give rapid NS bolus, not maintenance rates.

References:

ISPAD guidelines

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: Which of the following statements about Type 1.5 Diabetes Mellitus is incorrect? (Q850545)

A. Characterized by autoimmune destruction of beta cells

B. Start basal bolus insulin if C- peptide > 0.8 ng/ml

C. It is often misdiagnosed as Type 2 DM

D. Avoid use of sulfonlyureas

Correct Answer: B. Start basal bolus insulin if C- peptide > 0.8 ng/ml

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Type 1.5 DM or Latent Autoimmune Diabetes in Adults (LADA) is usually diagnosed in adults, often in their 20s to 30s, distinguishing it from Type 1 DM which commonly presents in childhood. If C-peptide > 0.8 ng/mL (Preserved Function): Start metformin or DPP-4 inhibitors or GLP-1 agonists. Avoid sulfonylureas as they deplete beta cells faster If C-peptide = 0.3–0.8 ng/mL (Moderate dysfunction): Use Basal insulin + metformin or DPP-4i If C-peptide < 0.3 ng/mL (Severe deficiency):Start basal-bolus or basal + mealtime insulin Autoimmune β-cell destruction (Option A): True; LADA is an autoimmune diabetes similar to Type 1 but with slower progression. Often misdiagnosed as Type 2 DM (Option C): True; adults initially appear like T2DM but progressively lose β-cell function. Avoid sulfonylureas (Option D): True; they accelerate β-cell exhaustion and worsen progression in LADA.

Q13 (p. 1528) *Q14 (p. 1529)* *Q15 (p. 1529)* *Q16 (p. 1530)* *Q17 (p. 1531)* *Q18 (p. 1531)*
Q19 (p. 1532)

Q1: A 22-year-old female with newly diagnosed Type 1 Diabetes Mellitus is struggling to maintain postprandial glucose levels despite basal-bolus insulin therapy. Her endocrinologist decides to add an adjunctive medication approved for both type 1 and type 2 diabetes mellitus. Which of the following drugs fits this indication? (Q850634)

A. Empagliflozin

B. Linagliptin

C. Pramlintide

D. Semaglutide

Correct Answer: C. Pramlintide

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Pramlintide is an amylin analog, approved for use in both type 1 and type 2 diabetes mellitus, in patients already on insulin. It slows gastric emptying, suppresses postprandial glucagon, and promotes satiety, helping improve postprandial glucose control. Empagliflozin (Option A) (SGLT2 inhibitor) is used only in type 2 DM, not type 1 due to DKA risk. Linagliptin (Option B) is a DPP-4 inhibitor. Semagutide (Option D) is not approved for use in type 1 DM as it needs some beta cell reserve to be able to produce insulin by incretin effect

References:

Harrison’s Principle of Internal Medicine, 21st Edition, Page 3111

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 65-year-old woman with poorly controlled diabetes mellitus presents to the emergency department with fever, facial pain, and a black necrotic eschar on her nasal turbinates. A CT scan shows sinus involvement and extension to the brain. What is the most appropriate initial management for this patient? (Q850781)

A. Fluconazole

B. Immediate surgical debridement and intravenous amphotericin B

C. Doxycyline and Azithromycin

D. Piperacillin Tazobactum

Correct Answer: B. Immediate surgical debridement and intravenous amphotericin B

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In cases of rhino-cerebral mucormycosis, especially with signs of significant tissue necrosis and possible central nervous system involvement, immediate surgical debridement is essential to remove necrotic tissue and control the infection. Intravenous amphotericin B is the first-line antifungal treatment that targets the causative organisms, significantly improving the patient's chances of survival.

https://www.ncbi.nlm.nih.gov/books/NBK557429/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 55-year-old woman with a 10-year history of type 2 diabetes presents for a routine eye examination with compliants of visual loss. On examination, she is found to have microaneurysms, retinal haemorrhages, cotton wool spots and macular edema. What is the most effective management option for her symptomatic foveal oedema? (Q850780)

A. Pan-retinal laser photocoagulation

B. Intravitreal anti-VEGF injections

C. Corticosteroid injections

D. Routine observation and follow-up

Correct Answer: B. Intravitreal anti-VEGF injections

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient likely has diabetic macular oedema, a complication of diabetic retinopathy characterized by retinal thickening and fluid accumulation in the macula. This condition can lead to visual impairment and requires prompt treatment to preserve vision. Anti-VEGF therapy has been shown to be more effective than laser treatment for symptomatic foveal oedema in diabetic macular oedema. Pan-retinal laser photocoagulation (Option A) : While effective for proliferative diabetic retinopathy, it is not the first-line treatment for symptomatic foveal oedema. Corticosteroid injections (Option C) : While they may have some benefit, anti-VEGF injections are typically preferred in current clinical practice for treating diabetic macular oedema. Routine observation and follow-up (Option D) : This option is not appropriate for symptomatic foveal oedema, as timely intervention is necessary to prevent vision loss.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Best screening test for evaluation of diabetic nephropathy is (Q850779)

A. HbA1c

B. BUN: Creatinine ratio

C. Creatinine clearance

D. Urinary protein to creatinine ratio

Correct Answer: D. Urinary protein to creatinine ratio

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Serum creatinine and creatinine clearance rise only after significant nephron loss (≥50%) , so they miss early kidney damage like microalbuminuria. They are late markers and poor indicators for early diabetic nephropathy screening . Diabetic nephropathy begins with microalbuminuria (30–300 mg/day). uPCR can detect even small increases in albumin accurately. Most important is that it is a quantitative test and not qualitative test. By using creatinine as a reference, uPCR corrects for variations in urine concentration. It r equires only a random spot urine sample, not cumbersome 24-hour urine collection. Improves patient compliance. More consistent and less expensive than repeated 24h urine collections. Useful for routine diabetic follow-up HbA1c (Option A): Reflects long-term glycemic control but does not assess kidney damage or albuminuria. BUN:Creatinine ratio (Option B): Useful for differentiating pre-renal vs intrinsic renal failure, not for screening diabetic nephropathy. Creatinine clearance (Option C): Detects later decline in GFR; not sensitive for early microalbuminuria in diabetic

nephropathy.

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 757-759

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: All of the following are correct about diabetic neuropathy except? (Q850778)

A. Affects unmyelinated type C fibers

B. Third nerve palsy presents with pupillary involvement

C. Orthostatic hypotension occurs due to involvement of type B fibers

D. Clonidine is used for management of diabetic diarrhea

Correct Answer: B. Third nerve palsy presents with pupillary involvement

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Most common cranial nerve affected in DM is occulomotor nerve with pupillary sparing. Microvascular ischemia affects the central core of the nerve where the somatic motor fibers are located . Thus EOM palsy will occur causing ptosis and eye being down and out. Peripheral parasympathetic fibers are spared because they are supplied by pial blood vessels on the nerve’s surface. Diabetic neuropathy affects unmyelinated type C fibers, causing burning pain and autonomic symptoms because these fibers are most vulnerable to chronic hyperglycemia-induced oxidative stress. (Option A) Orthostatic hypotension arises from damage to lightly myelinated type B preganglionic fibers, as ischemia impairs sympathetic vasoconstriction needed to maintain BP upon standing. (Option C) Clonidine, an α2-agonist, helps in diabetic diarrhea by reducing intestinal secretions through inhibition of sympathetic outflow to the gut. (Option D)

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 758-761.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Which of the following is not correct about Type 2 diabetes mellitus? (Q850776)

A. Polygenic inheritance

B. Increased insulin levels

C. Beta cell exhaustion

D. Increased PPAR-γ activity

Correct Answer: D. Increased PPAR-γ activity

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Type 2 diabetes mellitus is characterized by insulin resistance and β-cell dysfunction. PPAR-γ is a nuclear receptor that improves insulin sensitivity when activated. In T2DM, endogenous PPAR-γ activity is not increased; instead, insulin resistance predominates. Reduced or dysfunctional PPAR-γ signaling is more consistent with the metabolic state of T2DM. Drugs like Thiazolidinediones (TZDs) intentionally activate PPAR-γ to treat insulin resistance. Therefore, increased PPAR-γ activity is not a pathological feature of T2DM. Incorrect Options: Option A) Polygenic inheritance - Correct : T2DM has a strong genetic basis involving multiple genes . Shows familial clustering. Option B) Increased insulin levels - Correct (early phase) : Due to insulin resistance, the pancreas initially compensates with hyperinsulinemia . Insulin levels fall later as β-cells fail. Option C) Beta-cell exhaustion - Correct . Chronic overwork of β-cells leads to β-cell dysfunction and failure , producing sustained hyperglycemia.

References:

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 730, 731, 743

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Which of the following is correct about mechanism of action of Acarbose? (Q850774)

A. Increases insulin secretion from pancreatic beta cells

B. Inhibits α-glucosidase in intestinal brush border

C. Increases glucose uptake in peripheral tissues

D. Enhances insulin sensitivity in peripheral tissues

Correct Answer: B. Inhibits α-glucosidase in intestinal brush border

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Acarbose inhibits alpha-glucosidase enzymes in the gut, slowing the digestion of carbohydrates and reducing post-meal glucose spikes. It is taken with each meal to reduce post-prandial blood glucose and modestly improve glycemic control.

References:

Davidson’s Principles and Practice of Medicine, 24th Edition, Page 747

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following is not correct about complications seen in Diabetes mellitus? (Q850640)

A. Blindness incidence is increased by 25 times

B. Foot gangrene and amputation risk is increased by 100 times

C. Most common site of diabetic foot ulcer is heel

D. Diabetic nephropathy is leading cause of Chronic kidney disease

Correct Answer: C. Most common site of diabetic foot ulcer is heel

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A diabetic foot ulcer is usually seen on the toes or metatarsal heads, not heels Risk of blindness in diabetics is up to 25 times higher than in the normal population due to neovascularization. It can lead to retinal detachment and vitreous hemorrhage. Diabetic nephropathy leads to diffuse glomerulosclerosis that causes progressive decline of eGFR. At values less < 30 ml /min, either Hemodialysis or kidney transplantation decision-making has to be done. Due to the combination of neuropathy and angiopathy, the risk of critical limb ischemia, non-healing ulcers, and ultimately digital gangrene or limb amputation is much higher, reaching up to 40-100x times more than the normal population.

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Page 3113

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: Which of the following is not correct about SGLT2i (Q850638)

A. Lowering of SBP

B. Used in HFreEF in non diabetic population

C. Cause afferent arteriolar dilatation

D. Increased risk of mycotic genital infections

Correct Answer: C. Cause afferent arteriolar dilatation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: SGLT2i will cause salt loss in urine. It will increase sodium at macula densa and cause afferent constriction. This reduces intraglomerular pressure. Thus it reduces progression of diabetic nephropathy Salt loss in urine also lowers SBP by 5 mm Hg and explains the cardiovascular benefit without causing orthostatic hypotension Increased sugar levels in urine explains the risk of mycotic genital infections and UTI.

References:

Harrison's Principle of Internal Medicine, 21st Edition, Page 3112

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Which of the following is the earliest renal abnormality in diabetic nephropathy? (Q850636)

A. Microalbuminuria

B. Nodular glomerulosclerosis

C. Increased glomerular filtration rate

D. Proteinuria (>300 mg/day)

Correct Answer: C. Increased glomerular filtration rate

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The earliest functional change in diabetic nephropathy is glomerular hyperfiltration, seen as an increased GFR due to afferent arteriolar dilation resulting from altered tubuloglomerular feedback. This precedes microalbuminuria, which marks the first clinical stage. Structural changes like Kimmelstiel–Wilson nodules occur much later.

References:

Brenner & Rector’s The Kidney (11th Ed)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: 50-year-old man with T2DM presents with consistently elevated early morning blood glucose levels. His continous glucose monitoring does not show any noctural hypoglycemia. His current insulin regimen includes twice-daily intermediate-acting insulin. Which of the following is the most likely explanation for his fasting hyperglycaemia? (Q850615)

A. Excess dose of insulin given the day before

B. Increased insulin sensitivity between 4 am to 8 am

C. Inreased insulin resistance between 4 am to 8 am

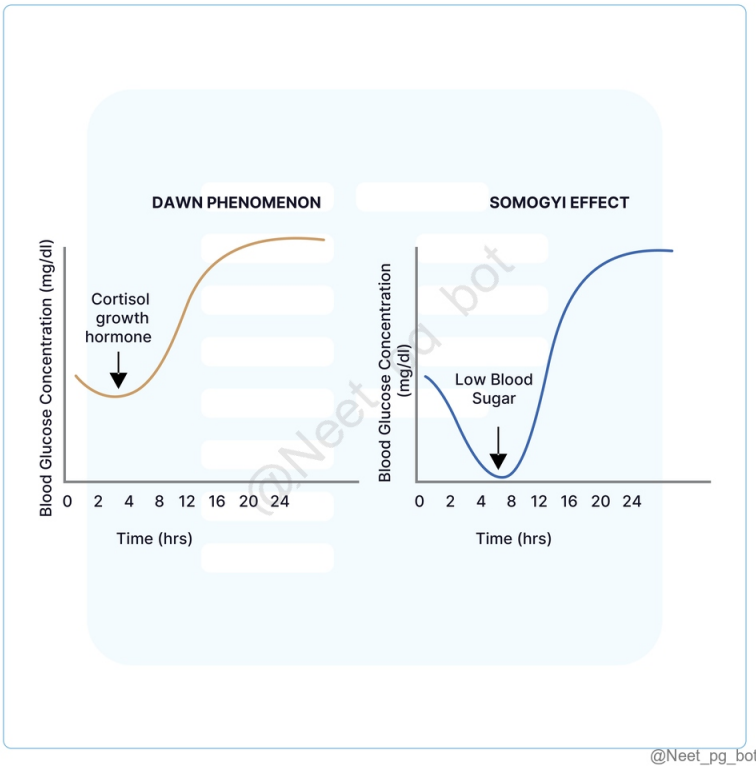
D. Beta cell exhausation

Correct Answer: C. Inreased insulin resistance between 4 am to 8 am

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has dawn phenomenon , where early morning hyperglycemia results from increased insulin resistance between 4 am to 8 am. The lack of preceding nocturnal hypoglycemia rules out somogyi phenomenon. Somogyi phenomenon : Hormones involved are catecholamines, cortisol, glucagon and GH Dawn phenomenon : Hormones involved are cortisol and GH {{caption_text}}



@Neet_pg_bot

@Neet_pg_bot

Q12: Which of the following drugs slows the progression of diabetic nephropathy and is an aldosterone antagonist? (Q850632)

A. Finrenone

B. Empagliflozin

C. Linagliptin

D. ACEi

Correct Answer: A. Finrenone

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Drugs that slow the progression of CKD in diabetic nephropathy ACEi or ARB Finrenone SGLT2i - Empagliflozin GLP1RA Drugs to avoid in diabetic nephropathy NSAIDS Metformin Dual RAAS blockade with ACEi and ARB

References:

Harrison's Principle of Internal Medicine, 21st Edition, Page 3111

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 52-year-old obese male with poorly controlled Type 2 Diabetes Mellitus is started on semaglutide. Which of the following statements is not true regarding this drug? (Q850629)

A. It acts via GLP-1 receptor agonism, enhancing glucose-dependent insulin secretion

B. It may cause abdominal pain and elevated serum amylase levels suggestive of pancreatitis

C. It can cause transient worsening of diabetic retinopathy, especially in patients with rapid glycemic improvement

D. It commonly causes fluid retention and weight gain due to PPAR-γ activation

Correct Answer: D. It commonly causes fluid retention and weight gain due to PPAR-γ activation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Fluid retention and weight gain are side effects of thiazolidinediones like pioglitazone which act via PPAR-γ – not seen with semaglutide. Semaglutide carries a black box warning for Risk of thyroid C-cell tumors, including medullary thyroid carcinoma (MTC) based on studies on rodents. So contraindicated in patients with MEN 2 Semaglutide is a GLP-1 receptor agonist, increases insulin release in a glucose-dependent manner. (Option A) Semaglutide is associated with pancreatitis; patients may show raised amylase/lipase. (Option B) Rapid correction of chronic hyperglycemia by semaglutide and even intensive insulin therapy causes sudden shift in retinal perfusion , altered retinal blood flow and endothelial function causing transient worsening of pre-existing microvascular damage. (Option C)

References:

Harrison's Principle of Internal Medicine, 21st Edition, Page 3110

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 50-year-old woman with Type 2 diabetes mellitus presents with extreme fatigue and thirst. She is non-compliant with her medications. Her blood pressure is 170/100 mmHg, and labs show: Random plasma glucose: 286 mg/dL HbA1c: 11.2% Urine glucose: +++ Serum creatinine: 2 mg/dL eGFR: 25 mL/min Serum potassium: 6.5 mEq/L Which of the following is NOT appropriate for managing this patient? (Q850628)

A. Monitor urine albumin creatinine ratio

B. Start Metformin with Sitagliptin

C. Start Amlodipine

D. Start Empagliflozin

Correct Answer: B. Start Metformin with Sitagliptin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Metformin is contraindicated in patients with eGFR <30 mL/min due to the risk of lactic acidosis . Sitagliptin is renally excreted and requires dose adjustment in CKD stage 4; starting standard doses is not appropriate . Monitor urine albumin-to-creatinine ratio (Option A): Essential for tracking progression of diabetic nephropathy. Start Amlodipine (Option C): Calcium channel blockers are safe for hypertension in CKD. Preferred when serum potassium is high , since ACE inhibitors/ARBs may worsen hyperkalemia. Start Empagliflozin (Option D) : SGLT2 inhibitors provide cardiorenal benefits : lower blood pressure, reduce proteinuria, and slow CKD progression. Can be used cautiously in patients with eGFR 25 mL/min , though glucose-lowering efficacy decreases at lower eGFR.

Harrison’s Principle of Internal Medicine, 21st Edition, Page 3110

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: You are educating a mother of 8-year-old girl with type 1 Diabetes Mellitus about insulin administration techniques. Which of the following statements is incorrect regarding insulin delivery? (Q850626)

A. The preferred site for subcutaneous insulin injection is the anterior abdominal wall.

B. Insulin pens should be held at a 90° angle to the skin for optimal delivery

C. Repeated insulin injections at the same site can cause lipohypertrophy

D. Repeat the insulin injection spot after 5-7 days

Correct Answer: D. Repeat the insulin injection spot after 5-7 days

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Repeating the same injection spot should be avoided for at least 2 weeks to allow tissue healing and reduce lipodystrophy risk. Repeated use of the same site may cause lipodystrophy. Lipohypertrophy is more common and is seen due to the anabolic effects of insulin. The anterior abdominal wall is the preferred site due to consistent absorption. 90° angle ensures proper SC delivery using insulin pens or syringes.

Harrison's Principle of Internal Medicine, Edition 21st- Page 3108, 3106.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 60-year-old diabetic patient collapsed in the bathroom in the morning and died. She was on metformin and glipizide for the last 10 years. Her latest HbA1c was 11%. What can be a possible cause of this event? (Q850623)

A. Autonomic neuropathy

B. Congestive chronic heart failure

C. Pericardial tamponade

D. Catastrophic CNS hemorrhage

Correct Answer: A. Autonomic neuropathy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Uncontrolled diabetes with a 10-year duration will have an increased risk of cardiac autonomic neuropathy. It can cause silent myocardial ischemia, arrhythmias, nocturnal bradycardia, or QT prolongation, leading to sudden death, especially overnight or early morning (bathroom collapse is classic). HbA1c: 11% indicates suboptimal control, further increasing microvascular and autonomic complications. Congestive chronic heart failure (Option B) causes gradual decompensation, not sudden collapse unless massive arrhythmia.

Pericardial tamponade (Option C) : There is no history suggestive of cardiac tamponade. CNS bleed (Option D) w ould present with headache, focal neuro deficits, and may not cause instant death unless massive

Harrison's Principle of Internal Medicine, 21st Edition, Page 3108, 3109

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 55-year-old man with T2DM is brought to ER in unconcious state. Work up shows ABG pH=7.38, pCO2 40 mm Hg HCO3 = 26 meq/L, Sodium 140 meq/L , K =5.5 meq/L urine ketostix is negative, RBS : 150 mg/dl and serum lactate is normal. Which of the following is correct about next step in managment of this patient? (Q850621)

A. NCCT head

B. Normal saline followed by insulin drip

C. Administer 50% dextrose

D. Draw blood culture and start empirical antimicrobials

Correct Answer: A. NCCT head

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Presentation given is of a diabetic patient with normal glucose, no acidosis, no ketones, and normal lactate, the most likely cause of sudden unconsciousness should trigger an evaluation for neurological causes (e.g., stroke or seizure). Based on lab reports hypoglycemia, DKA, hyperosmolar hyperglycemic state and sepsis are ruled out. Hence we will perform NCCT head to evaluate for CNS event like stroke.

Harrison's Principle of Internal Medicine, 21st Edition, Page 3134, 3135.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: Which of the following drug will worsen cardiovascular mortality in a diabetic patient who underwent a CABG? (Q850618)

A. Semaglutide

B. Empagliflozin

C. Rosiglitazone

D. Tirzepatide

Correct Answer: C. Rosiglitazone

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Rosiglitazone, a thiazolidinedione , has been associated with an increased risk of cardiovascular events, particularly myocardial infarction and heart failure, especially in patients with existing cardiovascular disease or those who have undergone procedures like CABG. Antidiabetic drugs proven to reduce cardiovascular mortality in T2DM: SGLT2 inhibitors Empagliflozin, Canagliflozin, Dapagliflozin Proven to reduce CV death , hospitalization for heart failure , and renal outcomes Especially useful in T2DM with HF or CKD GLP-1 receptor agonists Semaglutide, Liraglutide, Dulaglutide Reduce major adverse cardiovascular events (MACE) in atherosclerotic CV disease Tirzepatide A dual GLP-1 + GIP agonist

Harrison’s Principle of Internal Medicine, 21st Edition, Page 3106

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: Which form of insulin is used for basal delivery in basal bolus regimen? (Q850617)

A. Lispro

B. N.P.H

C. Glargine

D. Glulisine

Correct Answer: C. Glargine

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In the basal–bolus insulin regimen, basal insulin is used to provide a continuous, peakless insulin level to control fasting and between-meal glucose. Insulin glargine is a long-acting insulin analog with a duration of ~24 hours and no pronounced peak, making it ideal for basal delivery. This regimen closely mimics physiological insulin secretion. Lispro (Option A): Lispro is a rapid-acting insulin used for prandial (bolus) coverage, not for basal insulin requirements. N.P.H (Option B): NPH is an intermediate-acting insulin with a definite peak, increasing the risk of hypoglycemia, and is less preferred for basal–bolus regimens. Glulisine (Option D): Glulisine is a rapid-acting insulin analog used for mealtime glucose control, not basal insulin delivery.

Q1: A 45-year-old man comes with recurrent episodes of loss of consciousness, tremors, excessive sweating, and confusion. A tumour of the pancreas is suspected, and the serum proinsulin level (on a 72-hour fasting test) is raised. Which of the following investigations would be most preferred? (Q850664)

A. Computed tomography

B. MRI

C. Manual Palpation and Intraoperative Ultrasound

D. Endoscopic Ultrasound (EUS)

Correct Answer: D. Endoscopic Ultrasound (EUS)

Explanation: The clinical scenario points to insulinoma for which the main investigation of choice to confirm the diagnosis is endoscopic ultrasound. EUS is highly sensitive for detecting small insulinomas in the pancreas and allows precise localization before surgery. It is highly sensitive for small pancreatic neuroendocrine tumors (<2 cm) and allows fine-needle aspiration if needed. CT scan (Option A): Useful for larger pancreatic masses but less sensitive for detecting small insulinomas (<2 cm). MRI (Option B): Good soft tissue resolution but less sensitive than EUS for tiny lesions. Manual palpation and intraoperative ultrasound (Option C): Used during surgery, not as an initial preferred diagnostic tool.

@Neet_pg_bot

Q2: A 48-year-old woman presents with a 6-month history of recurrent diarrhoea, weight loss, and intermittent abdominal pain. She also reports flushing and has recently developed diabetes without prior risk factors. Examination shows steatorrhea and a mild erythematous rash. Blood tests reveal elevated fasting plasma glucose. A pancreatic somatostatinoma is suspected.Which of the following investigations is NOT routinely used in the initial diagnosis of this condition? (Q850691)

A. Measurement of fasting somatostatin levels

B. CT/MRI imaging

C. Somatostatin receptor imaging

D. Biopsy with immunohistochemistry

Correct Answer: C. Somatostatin receptor imaging

Explanation: Somatostatinoma is a rare pancreatic neuroendocrine tumour characterised by: Diabetes Steatorrhea Gallstones Abdominal pain, diarrhoea, and occasional flushing Sometimes a necrolytic erythema-like rash Somatostatin receptor imaging (SRI) such as Octreotide scans or Ga-68 DOTATATE PET is not required for the initial diagnosis . It is mainly used for: Staging Assessing tumour burden Detecting metastases Evaluating somatostatin receptor expression for therapeutic planning Elevated fasting plasma somatostatin levels (Option A): Essential for diagnosis. CT/MRI imaging (Option B): These are first-line imaging modalities used to localize the pancreatic tumour; hence, routinely required. Biopsy and immunohistochemistry (Option D): Confirms the tumor histologically.

@Neet_pg_bot

Q3: Assertion : In diabetic ketoacidosis (DKA), potassium levels can appear normal or even elevated initially despite a total body potassium deficiency. Reason : Potassium shifts from the intracellular to the extracellular space due to insulin deficiency and acidosis, temporarily raising serum potassium levels. (Q850688)

A. Both assertion and reason are correct, and the reason correctly explains the assertion.

B. Both assertion and reason are correct, but the reason does not correctly explain the assertion.

C. The assertion is correct, but the reason is incorrect.

D. The assertion is incorrect, but the reason is correct.

Correct Answer: A. Both assertion and reason are correct, and the reason correctly explains the assertion.

Explanation: In DKA , total body potassium is depleted due to osmotic diuresis, vomiting, and urinary losses. However, serum potassium may appear normal or elevated because insulin deficiency and acidosis cause potassium to shift from cells into the extracellular space , temporarily raising serum levels.

@Neet_pg_bot

Q4: A 45-year-old male with type 1 diabetes presents with increased thirst, frequent urination, nausea, vomiting, and abdominal pain. On examination, he has dry mucous membranes, tachypnea, and a fruity odour to his breath. His blood pressure is 90/60 mmHg. Labs show blood glucose of 450 mg/dL, bicarbonate of 18 mEq/L, and pH of 7.28. Which of the following statements is FALSE? (Q850686)

A. Kussmaul breathing is deep, laboured, and rapid.

B. Fruity odour on the breath is caused by acetone.

C. Dehydration in DKA is associated with dry mucous membranes and poor capillary refill.

D. Fever is always present in DKA and indicates infection.

Correct Answer: D. Fever is always present in DKA and indicates infection.

Explanation: Fever is not always present in DKA ; its presence may suggest an underlying infection but is not a defining feature of DKA. Kussmaul breathing (Option A): It is deep, laboured, and rapid to compensate for metabolic acidosis. Fruity odour (Option B): Caused by acetone from ketone metabolism. Dehydration (Option C): Presents with dry mucous membranes and poor capillary refill .

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Page 3114,3115

@Neet_pg_bot

Q5: A 23-year-old male with Type 1 Diabetes Mellitus presents to the emergency department with nausea, vomiting, and abdominal pain. He reports that he has not taken his insulin for the past two days. On examination, he appears dehydrated, with deep and rapid breathing. Laboratory tests reveal high blood glucose, ketonemia, and metabolic acidosis. Which of the following statements about the pathophysiology of the patient’s condition is TRUE? (Q850684)

A. Insulin deficiency leads to increased glucose utilization by the cells.

B. Elevated counterregulatory hormones increase glycogen synthesis, reducing blood glucose levels.

C. Lipolysis increases free fatty acids (FFA) in the liver, leading to ketogenesis.

D. Increased glucose utilization prevents hyperglycemia and osmotic diuresis.

Correct Answer: C. Lipolysis increases free fatty acids (FFA) in the liver, leading to ketogenesis.

Explanation: In diabetic ketoacidosis (DKA) , insulin deficiency and elevated counterregulatory hormones promote lipolysis , increasing FFAs, which the liver converts to ketone bodies , causing metabolic acidosis. A) Increased glucose utilization (Option A): Insulin deficiency actually reduces glucose uptake , causing hyperglycemia. B) Glycogen synthesis reduces glucose (Option B): Counterregulatory hormones increase glycogenolysis and gluconeogenesis , raising glucose. D) Increased glucose utilization prevents hyperglycemia (Option D): Hyperglycemia occurs due to reduced utilization and increased production .

@Neet_pg_bot

Q6: A 35-year-old patient presents to the clinic with persistent diarrhoea, which has led to significant dehydration. After evaluation, it is determined that the diarrhoea is secretory. The patient has a history of diabetes, which is uncontrolled. Which of the following statements best describes the management and mechanisms associated with secretory diarrhoea in this patient? (Q850683)

A. Secretory diarrhoea primarily results from the malabsorption of nutrients

B. The main goal of management is reducing intestinal secretion

C. Antisecretory agents like Racecadotril and Crofelemer may help reduce fluid loss

D. Secretory diarrhoea shows a high osmotic gap that is not related to food intake

Correct Answer: C. Antisecretory agents like Racecadotril and Crofelemer may help reduce fluid loss

Explanation: The clinical scenario is of secretory diarrhoea associated with uncontrolled diabetes mellitus, and antisecretory agents like Racecadotril and Crofelemer help reduce fluid loss. Malabsorption of nutrients (Option A): This causes osmotic diarrhea , not secretory diarrhea. Main goal is reducing intestinal secretion (Option B): Supportive care with fluid and electrolyte replacement is the priority; secretion control is adjunctive. High osmotic gap unrelated to food (Option D): Secretory diarrhea actually has a low osmotic gap and occurs even during fasting .

@Neet_pg_bot

Q7: Which of the following toxin-producing bacteria does a VIPoma mimic? (Q850679)

A. Shigella dysenteriae

B. Vibrio cholerae

C. Corynebacterium diphtheriae

D. Bordetella pertussis

Correct Answer: B. Vibrio cholerae

Explanation: VIPoma secretes vasoactive intestinal peptide (VIP) , causing profuse watery diarrhea, hypokalemia, and dehydration , similar to the cholera toxin effect . Shigella dysenteriae (Option A): Causes dysentery with bloody diarrhea, not watery diarrhea. Corynebacterium diphtheriae (Option C): Causes respiratory diphtheria , not secretory diarrhea. Bordetella pertussis (Option D): Causes whooping cough , unrelated to VIP effects.

References:

Harrison’s Principles of Internal Medicine, 21st edition, Page: 665.

@Neet_pg_bot

Q8: Identify the true statement about the condition where the patient presents with high plasma somatostatin levels, steatorrhea, hypochlorhydria, and diabetes mellitus due to a tumour. (Q850675)

A. The tumour primarily occurs in the stomach

B. This is usually a small tumour that often goes unnoticed

C. This is rarely associated with MEN 1 syndrome

D. Metastasis is rare and is treated using chemotherapy for localized disease

Correct Answer: C. This is rarely associated with MEN 1 syndrome

Explanation: Somatostatinomas are rare pancreatic or duodenal neuroendocrine tumors, and unlike other pancreatic NETs, they are infrequently associated with MEN 1 syndrome . Tumor primarily in the stomach (Option A): Usually occurs in the duodenum or pancreas , not stomach. Small tumor often goes unnoticed (Option B): They are often large at diagnosis due to nonspecific symptoms. Metastasis rare / treated with chemo (Option D): Many are malignant and may metastasize , requiring surgical management.

References:

Harrison's Principles of Internal Medicine, 21st edition, Page: 665, 2987.

www.ncbi.nlm.nih.gov/books/NBK279034/

↑ *Back to this question in Part A*

@Neet_pg_bot

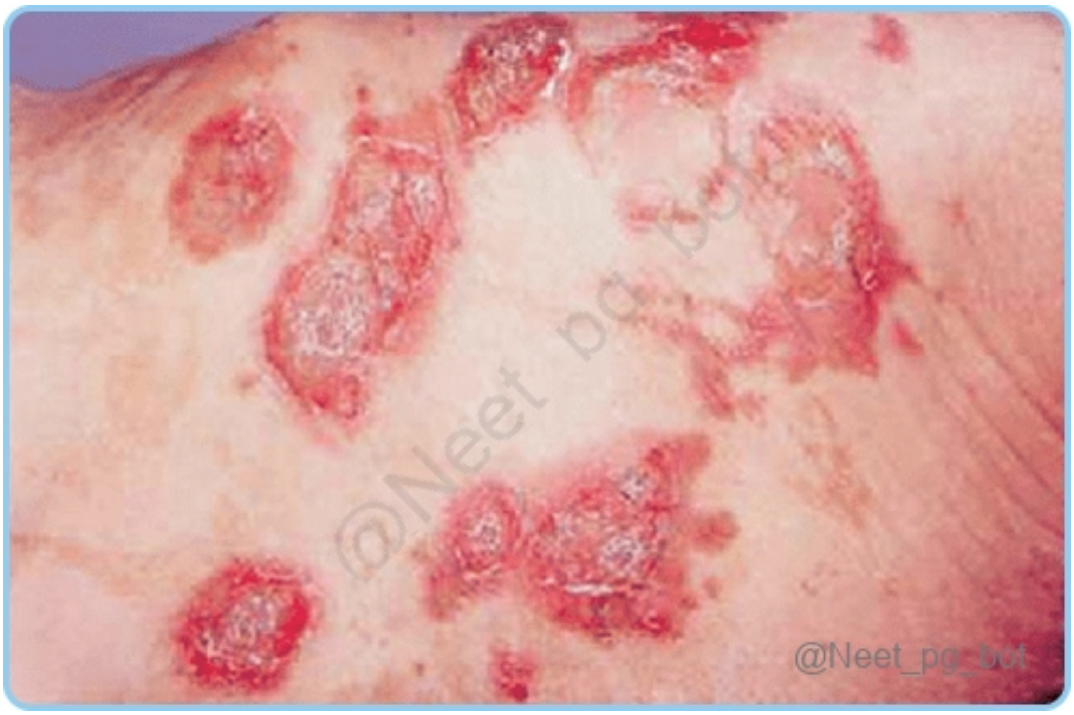
Q9: A 54-year-old female presents with significant weight loss and a characteristic rash as in the image. Blood tests reveal elevated plasma glucagon levels exceeding 1000 pg/mL. A CT scan shows a large mass in the tail of the pancreas. Which of the following statements regarding her condition is correct? (Q850667)

A. The mass is commonly found in the head of the pancreas

B. The initial treatment includes antibiotics and steroids

C. The rash seen is necrolytic migratory erythema

D. Surgical resection is the treatment option for this condition



Correct Answer: C. The rash seen is necrolytic migratory erythema

Explanation: The scenario here is of the diagnosis of glucagonoma, which is characterized by elevated plasma glucagon levels exceeding 1000 pg/mL and the typical rash found in this condition called necrolytic migratory erythema. Mass in the head of the pancreas (Option A): Glucagonomas are most commonly found in the tail . Antibiotics and steroids (Option B): Do not treat the tumor or associated syndrome. Surgical resection (Option D): Curative option for a small percentage of patients with localized tumors.

@Neet_pg_bot

Q10: A 65-year-old female with type 2 diabetes on SGLT2 inhibitors is brought to the emergency department unconscious. Lab results show pH 7.2, $HCO3^-$ 15 mEq/L, RBS 210 mg/dl, and plasma beta-hydroxybutyrate 2.8 mmol/L with normal lactate. Urine analysis reveals the presence of ketones. What condition is most consistent with these findings? (Q850639)

A. Lactic Acidosis

B. Diabetic Ketoacidosis

C. Euglycemic Diabetic Ketoacidosis

D. Hyperglycemic Hyperosmolar State

Correct Answer: C. Euglycemic Diabetic Ketoacidosis

Explanation: SGLT2 inhibitors can cause ketoacidosis with only mildly elevated or normal glucose levels; here, metabolic acidosis with ketones and glucose 210 mg/dl fits Euglycemic Diabetic Ketoacidosis (EDKA). Lactic Acidosis (Option A): Ruled out as lactate is normal. Diabetic Ketoacidosis (Option B): Typical DKA presents with marked hyperglycemia (>250–300 mg/dl). Hyperglycemic Hyperosmolar State (Option D): Characterized by severe hyperglycemia (>600 mg/dl), absent here.

@Neet_pg_bot

Q11: A 40-year-old male comes to the clinic with recurrent episodes of hypoglycemia and loss of consciousness. On further evaluation, he is found to have a tumour on the pancreas. Which of the following is not a component of Whipple’s triad to suspect insulinoma? (Q850662)

A. Symptoms of hypoglycemia

B. Low plasma glucose concentration

C. Subsequent improvement of symptoms with the use of glucose treatment

D. Elevated fasting insulin levels

Correct Answer: D. Elevated fasting insulin levels

Explanation: Whipple's triad includes: Symptoms of hypoglycemia (Emotional outburst) Low plasma glucose measured during symptoms <45 mg/dl Relief of symptoms after glucose administration.

References:

Harrison's Principles of Internal Medicine, 21st edition, Page: 664, 665.

www.ncbi.nlm.nih.gov/books/NBK544299/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 45-year-old woman with diabetes presents to the emergency department with confusion, fatigue, dizziness, palpitations, sweating, and tremors. Her blood glucose is 48 mg/dL. Which of the following is least likely to cause hypoglycemia in this patient? (Q850658)

A. Insulin

B. Sulfonylureas

C. Metformin

D. Meglitinides

Correct Answer: C. Metformin

Explanation: Metformin rarely causes hypoglycemia when used alone. Its primary action is to reduce hepatic glucose production and improve peripheral glucose uptake , without directly stimulating insulin secretion , which is why blood glucose rarely drops below normal . Insulin (Option A) directly lowers blood glucose and is a common cause of hypoglycemia. Sulfonylureas (Option B) stimulate insulin release , increasing the risk of hypoglycemia. Meglitinide s (Option D) also stimulate insulin secretion , so hypoglycemia is a potential complication.

References:

Harrison's Principles of Internal Medicine, 21st edition, Page: 3129, 3130.

www.ncbi.nlm.nih.gov/books/NBK534841/

www.endocrine.org/patient-engagement/endocrine-library/severe-hypoglycemia

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 55-year-old man presents with persistent abdominal pain and unintentional weight loss over the past 3 months. He reports no significant past medical history and denies any changes in bowel habits. A CT scan of the abdomen reveals a well-circumscribed mass in the pancreas. Laboratory tests show elevated serum glucose levels but normal levels of other pancreatic hormones. Which of the following is the most likely diagnosis for this patient? (Q850654)

A. Insulinoma

B. Gastrinoma

C. Non-functioning pancreatic NET

D. Glucagonoma

Correct Answer: C. Non-functioning pancreatic NET

Explanation: The patient has a pancreatic mass with hyperglycemia but no hormone-related symptoms , which is typical for non-functioning NETs that present due to mass effect or incidental findings. Insulinoma (Option A): Causes hypoglycemia , not high glucose. Symptoms: confusion, sweating, tremors, Whipple's triad. Not consistent. Gastrinoma (Option B): Causes refractory peptic ulcers, diarrhea , and high gastrin. CT may show tumors in the gastrinoma triangle. No ulcers, no gastrin elevation. Glucagonoma (Option D): Causes severe hyperglycemia + classic rash (necrolytic migratory erythema. Also, weight loss and anemia. Rash is absent; hormone levels are normal.

References:

Harrison's Principles of Internal Medicine 21st edition Page 664.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 75-year-old man with poorly controlled type 2 diabetes presents to the emergency department with confusion and increased thirst over the past week. On examination, he has dry mucous membranes, a weak pulse, and a blood pressure of 85/50 mmHg. Laboratory tests show: (Plasma glucose: 1000 mg/dL, Serum osmolality: 360 mOsm/kg, Serum sodium: 130 mEq/L, Arterial blood gas: pH 7.38, bicarbonate

18 mEq/L). Which of the following is the most appropriate initial treatment for this patient? (Q850653)

A. Administer IV Ringer Lactate

B. Administer IV 0.9% normal saline

C. Start IV insulin bolus of 1 unit/kg with IV Potassium

D. Administer oral hypoglycemic agents

Correct Answer: B. Administer IV 0.9% normal saline

Explanation: This patient has Hyperglycemic Hyperosmolar State (HHS) : very high plasma glucose (>600 mg/dL), elevated osmolality, dehydration, and no significant acidosis (pH normal, HCO■■ >18). The initial and most critical step is aggressive fluid resuscitation with isotonic saline (0.9% NaCl) to restore intravascular volume and perfusion before starting insulin. Ringer Lactate (Option A) Contains lactate and is not the first-choice fluid for HHS; normal saline is preferred. IV insulin bolus with potassium (Option C) Insulin is started only after initial fluid resuscitation; otherwise, it can worsen shock and electrolyte shifts. Oral hypoglycemic agents (Option D) Ineffective and unsafe in this acute emergency.

References:

Harrison’s Principles of Internal Medicine 21st edition Page 3117

recapem.com/resuscitation-of-adult-diabetic-ketoacidosis/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 70-year-old woman with type 2 diabetes is admitted for confusion and severe dehydration. Her blood glucose is 900 mg/dL, and serum osmolality is elevated. Arterial blood gas reveals a normal pH and bicarbonate. Which of the following clinical signs would NOT be expected in this patient? (Q850650)

A. Hypotension

B. Tachycardia

C. Kussmaul breathing

D. Fever

Correct Answer: C. Kussmaul breathing

Explanation: This patient has Hyperglycemic Hyperosmolar State (HHS) : severe hyperglycemia, high osmolality, dehydration, but no ketoacidosis (normal pH and bicarbonate). Kussmaul breathing is characteristic of DKA , not HHS. Hypotension (Option A): Expected due to severe dehydration. Tachycardia (Option B): Common compensatory response to volume loss. Fever (Option D): May occur if infection precipitated HHS.

References:

Harrison's Principles of Internal Medicine 21st edition Page 3117

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 28-year-old female with type 1 diabetes presents to the emergency department with increased thirst, frequent urination, nausea, abdominal pain, and signs of dehydration, including dry mucous membranes, tachycardia, and hypotension (BP: 98/60 mmHg). On examination, her vital signs include a heart rate of 110 bpm, respiratory rate of 22 breaths/min, and a blood pressure of 98/60 mmHg. Laboratory results show a blood glucose level of 350 mg/dL, serum bicarbonate of 18 mEq/L, and a pH of 7.30. What is the next step in management based on the ISPAD 2022 guidelines? (Q850647)

A. Start intravenous fluids and initiate insulin therapy

B. Administer subcutaneous insulin and monitor glucose

C. Provide oral hydration and adjust the diet accordingly

D. Ensure airway patency and consider nasogastric tube insertion

Correct Answer: A. Start intravenous fluids and initiate insulin therapy

Explanation: According to ISPAD 2022 guidelines , this patient has mild DKA (pH 7.25–7.30, HCO■■ 15–18, glucose >250 mg/dl, dehydration). The first step in management is IV fluid resuscitation to restore intravascular volume, followed by insulin infusion after initial fluid replacement. Subcutaneous insulin (Option B) Used only in selected mild/moderate DKA cases when IV insulin is not feasible. Oral hydration/diet (Option C) Inadequate for DKA, as patient has dehydration and acidosis. Airway patency/NG tube (Option D) Not indicated unless patient is comatose or vomiting with risk of aspiration.

Adult Diabetic Ketoacidosis - StatPearls - NCBI Bookshelf

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 28-year-old male presents with tachycardia, hypotension, and drowsiness. He has a sweet smell of acetone on his breath. Laboratory results show a random blood sugar of 400 mg/dL, serum bicarbonate level of 12 mEq/L, arterial pH of 7.1, and serum β-hydroxybutyrate level of 6 mmol/L. What diagnosis is most consistent with this patient's condition? (Q850644)

A. Mild Diabetic Ketoacidosis

B. Moderate Diabetic Ketoacidosis

C. Severe Diabetic Ketoacidosis

D. Hyperglycemic Hyperosmolar State

Correct Answer: B. Moderate Diabetic Ketoacidosis

Explanation: The patient has pH 7.1 , serum bicarbonate 12 mEq/L , and is drowsy , which fall into the criteria for moderate DKA (pH 7.00–7.24, HCO■■ 10–15, altered sensorium) . Mild DKA (Option A): pH 7.25–7.30 and HCO■■ 15–18 with patient alert; not seen here. Severe DKA (Option C): pH <7.0 and HCO■■ <10 with stupor/coma; criteria not met. Hyperglycemic Hyperosmolar State (Option D): Glucose usually >600 mg/dL with little/no ketosis; does not match this case.

Q18: A 40-year-old male with poorly controlled type 1 diabetes presents with vomiting and shortness of breath. He appears dehydrated and tachycardic, with a fruity odour on his breath. His lab results show elevated blood glucose and ketones. Which of the following is not a risk factor for his condition? (Q850642)

A. Infection

B. Pancreatitis

C. Hypothyroidism

D. Inadequate insulin administration

Correct Answer: C. Hypothyroidism

Explanation: Diabetic ketoacidosis (DKA) is commonly precipitated by infection, pancreatitis, myocardial infarction, and inadequate insulin administration . Hypothyroidism is not a recognized risk factor. Precipitating Factors: Inadequate insulin administration (Option D) Infection (pneumonia/UTI/gastroenteritis/sepsis) (Option A) Infarction (cerebral, coronary, mesenteric, peripheral) Pancreatitis (Option B) Drugs (cocaine) Pregnancy

Q19 (p. 1563)	*Q20 (p. 1564)*	*Q21 (p. 1565)*			

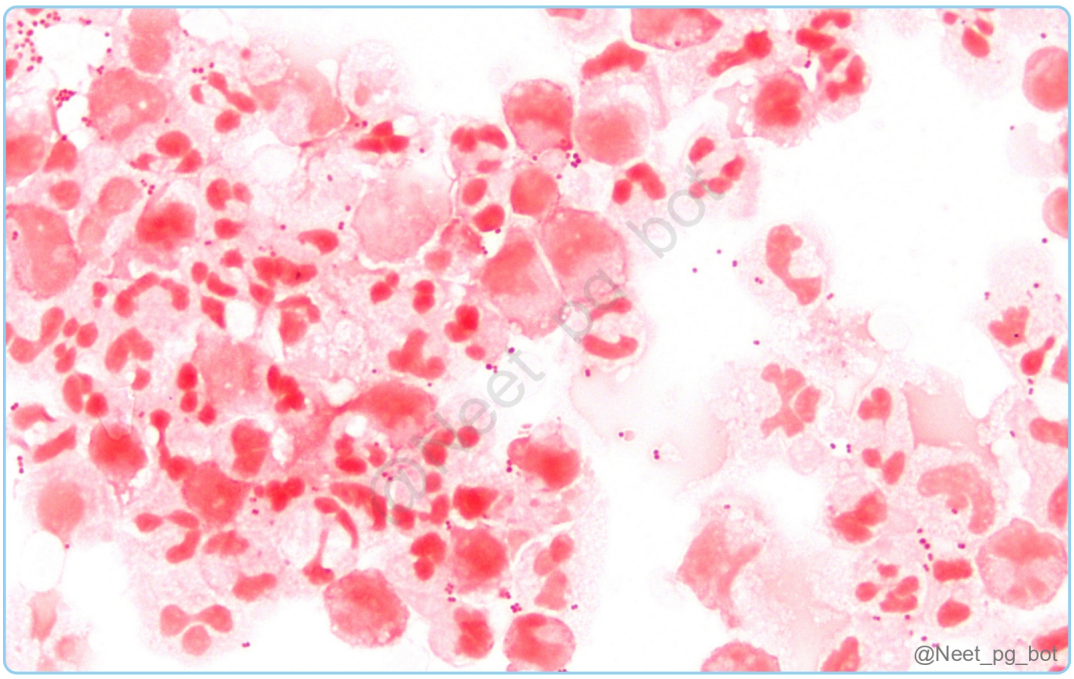
Q1: 16-year-old boy is brought to the ER due to fever, vomiting, and irritability for 2 days. Vitals are thready pulse 120/min, BP is 80/60 mm Hg with cold clammy extremities. General physical examination shows petechiae on extremities, CNS examination shows nuchal rigidity and kernig sign. CBC show TLC of 25000 cells/ cu.mm and platelet count of 15,000/cu.mm Gram stain of CSF is shown and rest of the lab report is awaited. Which of the following is not correct about managment of this patient? {{caption_text}} (Q850558)

A. Normal saline bolus

B. Hydrocortisone

C. Ceftriaxone and Vancomycin

D. Fludrocortisone



Correct Answer: D. Fludrocortisone

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient is criticially sick and going into addisonian crisis due to Waterhouse-Friderichsen Syndrome Gram stain reveals gram negative diploccoci which is neisseria meningitidis. The ongoing sepsis has caused DIC as suggested by low platelet count Give Fluid boluses till pulse comes back to normal followed by 1L over next 1-2 hours which will restore the circulation of this patient. IV hydrocortisone is DOC for addisonian crisis. IV ceftriaxone and vancomycin will be given to treat the sepsis Fludrocortisone is an oral tablet used in primary chronic adrenal insufficiency . Management: Management Aspect Clinical Action & Details Duration Fluid Resuscitation Normal saline boluses (Aggressive resuscitation to maintain cardiac output). If shock persists after 40 mL/kg, elective intubation is recommended. Acute Phase (until hemodynamically stable). Empirical Antibiotics Ceftriaxone (75 - 100 mg/kg/d) + Vancomycin (40 - 60 mg/kg/d) to cover resistant bacteria. 7 days (Standard); 3–5 days may be effective. Adjunctive Steroids Hydrocortisone (Replacement doses for refractory shock with impaired adrenal responsiveness). During Refractory Shock period. Metabolic Support Correct hypoglycemia, acidosis, and electrolyte imbalances (K, Ca, Mg, PO 4). Continuous monitoring until resolved. Post-Inflammatory NSAIDs for immune-complex inflammatory syndrome. Until spontaneous resolution .

https://www.ncbi.nlm.nih.gov/books/NBK551510/

Harrison’s Principle of Internal Medicine, 21st Edition, Page 1249-1250

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 30-year-old male presents to the clinic with complaints of hyperpigmented skin, lethargy, and abdominal pain occasionally. His vitals are blood pressure of 158/90mmHg, heart rate of 102/min, and a temperature of 98 ° F (37 ° C). Keeping in view the suspicion of primary hyperaldosteronism, which of the following set of metabolic findings correlates with this diagnosis? (Q876269)

A. Hyperkalaemia, hyponatremia, and normal renin

B. Hyponatremia only

C. Hypernatremia, hypokalaemia, and low renin

D. Hypercalcemia only

Correct Answer: C. Hypernatremia, hypokalaemia, and low renin

Explanation: Correct Option C - Hypernatremia, hypokalaemia, and low renin: Primary hyperaldosteronism (also known as Conn's syndrome) is caused by a benign tumour (adenoma) in one of the adrenal glands. Secondary hyperaldosteronism, on the other hand, is usually caused by an underlying condition that stimulates the adrenal glands to produce more aldosterone, such as renal artery stenosis, heart failure, or cirrhosis. Clinical findings of hyperaldosteronism may include: Hypertension (high blood pressure) Hypokalemia (low levels of potassium in the blood) Muscle weakness and fatigue Polyuria (increased urine production) Polydipsia (increased thirst) Headaches Visual disturbances Palpitations Numbness or tingling in the extremities Diagnosis Screening for mineralocorticoid excess is not currently recommended for all patients with hypertension, but drug-resistive hypertensive patients should be screened for mineralocorticoid excess. For this, different levels of hormones should be monitored. Detect Plasma renin level. Detect Plasma aldosterone Measure Aldosterone renin ratio Lab findings Hypernatremia Hypokalaemia Low renin Treatment The goal of treatment is to manage hypokalaemia and hypertension. Calcium channel blockers, particularly nifedipine, have been administered to treat hypertension. Spironolactone and other mineralocorticoid antagonists may also be used to treat this condition. A combination of diuretics, such as thiazide and spironolactone, may also alleviate the hypertensive crisis. Other therapeutic possibilities include ARBs and ACE inhibitors. Incorrect Options: Option A - Hyperkalaemia, hyponatremia, normal renin: These are the findings of adrenal insufficiency Low aldosterone levels are characterized by hyperkalemia and hyponatremia. Option B - Hyponatremia only: Hyponatremia does not occur in the primary aldosteronism Hyponatremia occurs in various medical disorders, such as Syndrome of inappropriate anti-diuretic hormone Chronic vomiting Heart failure Option D - Hypercalcemia only: In primary aldosteronism, hypercalcemia does not occur It is of the excess parathyroid hormone secretion

References:

Harrison's principle of internal medicine, 21st edition, Page no. 2731-2734

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: 40-year-old woman diagnosed with cushing syndrome presents with headaches and increased skin pigmentation over the past few months. She underwent a bilateral adrenalectomy six months ago. Which of the following is false about her condition? (Q850612)

A. Rapid expansion of pituitary tumor

B. Low ACTH level

C. Prevented by prophylactic radiation therapy before adrenalectomy

D. Occurs due to lack of negative feedback

Correct Answer: B. Low ACTH level

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ACTH levels are very high in Nelson syndrome since both adrenal glands have been resected leading to loss of negative feedback control. It can occur in patient with cushing disease refractory to surgery. The pre-existing corticotrope adenoma will expand in size to loss of check mechanism and will produce mass effects explaining the presenting complaints of this patient.

References:

Harrison's Principles of Internal Medicine, 21st edition, Page 2916

https://www.ncbi.nlm.nih.gov/books/NBK560755/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following is first investigation to be performed in patient with ACTH dependant cushing syndrome? (Q850606)

A. MRI Pituitary

B. High dose dexamethasone suppression test

C. Low dose dexamethasone suppression test

D. Inferior petrosal sinus sampling

Correct Answer: A. MRI Pituitary

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: First investigation to be done in ACTH dependant cushing syndrome is MRI pituitary Elevated ACTH and elevated cortisol implies either endogenous cause or ectopic cause. MRI pituitary along with CRH test will help in identifying a pituitary adenoma High dose dexamethasone suppression test helps to differentiate endogenous or ectopic cause. Failure to suppress cortisol production will imply ectopic source (Option B) Low dose dexamethasone is a screening test for cushing syndrome (Option C) Inferior petrosal sinus sampling petrosal/ peripheral ratio > 2 indicates endogenous cause (Option D) First investigation to be done in ACTH independant cushing syndrome is CT abdomen

References:

Harrison's Principles of Internal Medicine, 21st Edition, Page 2962

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which of the following is not a clinical feature of Cushing syndrome? (Q850600)

A. Hypokalemia

B. Increased susceptibility to infections

C. Menorrhagia

D. Wasting of gluteal musculature

Correct Answer: C. Menorrhagia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ushing syndrome results from chronic excess glucocorticoids and is characterized by catabolic effects, immunosuppression, and mineralocorticoid activity. Typical features include hypokalemia (due to mineralocorticoid action), increased susceptibility to infections, and proximal muscle wasting, including gluteal muscle wasting. Menstrual irregularities are common, but they usually present as amenorrhea or oligomenorrhea, not menorrhagia. Incorrect Options: Option A – Hypokalemia: Excess cortisol can activate mineralocorticoid receptors, leading to renal potassium loss and hypokalemia, especially in ectopic ACTH syndrome. Option B - Increased susceptibility to infections: Glucocorticoids cause immunosuppression, predisposing patients to bacterial, fungal, and opportunistic infections. Option D - Wasting of gluteal musculature: Cortisol causes protein catabolism, leading to proximal muscle weakness and wasting, particularly involving the pelvic girdle and gluteal muscles.

Harrison's principles of internal medicine, 21st Edition, Page 2961

↑ *Back to this question in Part A*

@Neet_pg_bot

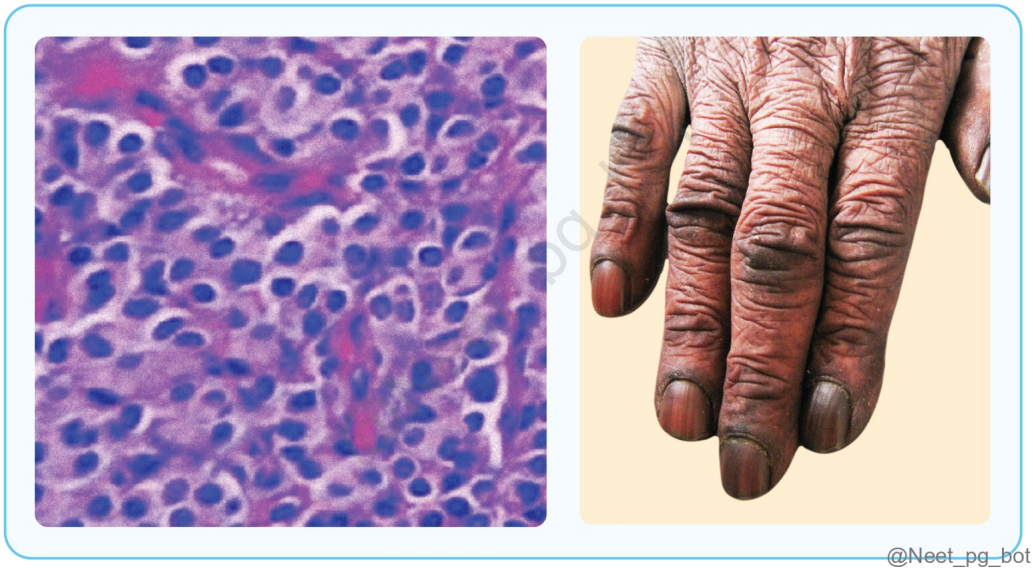
Q6: 50-year-old man presents with severe cough for 3 months and hemoptysis episodes for past 3 days. Physical examination shows hypertension, purple abdominal wall striae, changes in hands as shown. Endobronchial lung biopsy is shown below. Which of the following is the most likely cause in this patient? (Q850594)

A. Carcinoid tumor

B. Oat cell cancer of lung

C. Squamous cell cancer of lung

D. Large cell cancer of lung



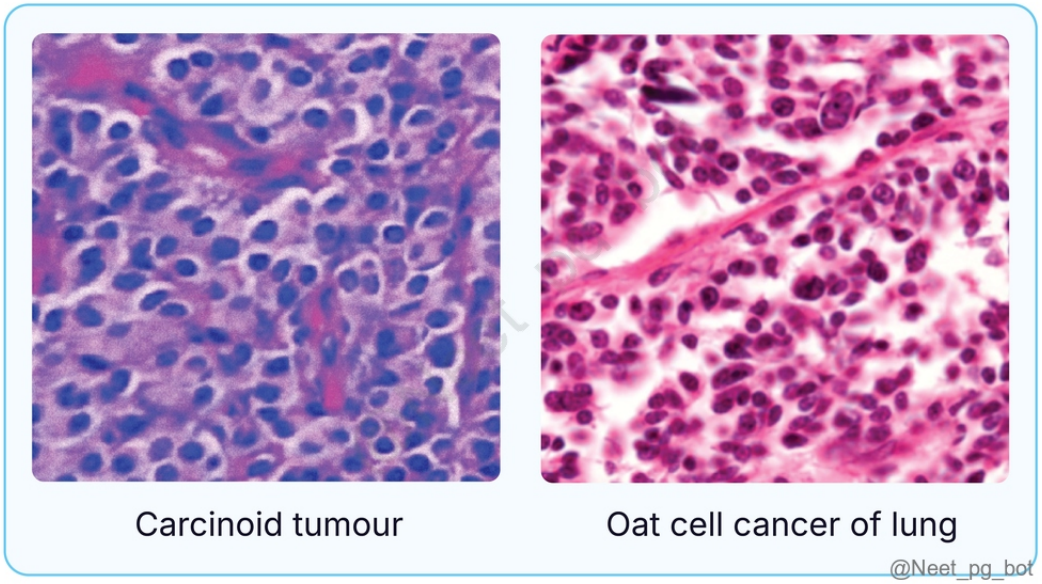
Correct Answer: A. Carcinoid tumor

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Carcinoid tumor Clinical history points to diagnosis of cushing syndrome due to ectopic source. Cushing features are hyperpigmentation of knuckes and IP joints with purpule striae on anterior abdominal wall, hypertension and centripetal obesity. Endobronchial biopsy report shows organoid nests of uniform cells and the nuclei with “salt and pepper” chromatin. Oat cell cancer cells will be disorganised mass of cells with nuclei that will always looked crushed and squeezed. Carcinoid Tumor (Left Slide) Uniform cells with abundant cytoplasm , round nuclei , and “salt and pepper” chromatin pattern. Cells arranged in nesting or trabecular pattern with minimal mitosis and necrosis. Oat Cell Cancer / Small Cell Lung Carcinoma (Right Slide) Small round cells with

scant cytoplasm , hyperchromatic nuclei , and nuclear molding . Shows high mitotic activity , frequent necrosis , and crush artifacts due to fragile cells.



References:

Harrison's Principles of Internal Medicine, 21st Edition, Page 3000- 3008

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: 35 year old bollywood actor develops flushing episodes, asthma like symptoms and frequent episodes of watery diarrhea . 24 hour urinary 5 HIAA levels are elevated. Which of the following drugs will be suitable for managment of GI complaints of this patient? (Q850588)

A. Loperamide

B. Telotristat ethyl

C. Somatostatin analogues

D. Racecadotril

Correct Answer: C. Somatostatin analogues

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Somatostatin analogues are the first-line treatment for carcinoid syndrome. They inhibit secretion of serotonin and other vasoactive peptides , thereby controlling flushing, diarrhea, and wheezing Telotristat ethyl (Option A) blocks serotonin production by inhibiting tryptophan hydroxylase ; used as adjunctive therapy for patients who don't fully respond to somatostatin analogues Loperamide (Option B) acts on μ-opioid receptors in gut → ↓ motility, ↑ transit time. It works well in motility-driven diarrhea like IBS-D and travelers' diarrhea. Racecadotril (Option D) is an enkephalinase inhibitor → ↑ endogenous enkephalins → ↓ cAMP-mediated secretion. It is useful in acute infectious diarrhea , but serotonin-mediated secretion in carcinoid is too strong , so inhibition is inadequate.

@Neet_pg_bot

Q8: 30 year old patient with pheochromocytoma is undergoing surgery for tumor resection. Which drug should be prepared by anaesthesiologist as a standy infusion and will not cause post operative hypotension? (Q850585)

A. Labetalol

B. Phenoxybenzamine

C. Nitroprusside

D. Phentolamine

Correct Answer: C. Nitroprusside

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: During pheochromocytoma surgery, a short-acting, easily titratable IV agent is needed to manage sudden hypertensive surges. Nitroprusside acts within seconds and stops acting within minutes, so it provides excellent intraoperative control without causing postoperative hypotension . Phenoxybenzamine (Option A): long-acting; causes prolonged postoperative hypotension. Phentolamine (Option B): alpha-blocker; may cause postoperative hypotension. Labetalol (Option D): not ideal for acute hypertensive crises; beta-blockade can worsen BP if unopposed.

@Neet_pg_bot

Q10: Which of the following drugs is used for managment of pre-operative hypertension in pheochromocytoma (Q850575)

A. Selective beta-blocker alone before surgery

B. Phenoxybenzamine + Phentolamine

C. Phenoxybenzamine + Propranolol

D. Propranolol and Phentolamine

Correct Answer: C. Phenoxybenzamine + Propranolol

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Managing pheochromocytoma before surgery is critical to prevent life-threatening hypertensive crises during tumor manipulation. The standard approach includes: 1. Alpha-Blockade (FIRST and MANDATORY) Drug: Phenoxybenzamine (non-selective, irreversible α-blocker) Start: 10–14 days before surgery 2. Volume Expansion Liberal salt and fluid intake (especially after adequate α-blockade) Prevents postoperative hypotension 3. Beta-Blockade (Never give before α-blockade – may precipitate hypertensive crisis by unopposed α-adrenergic action) Indication: If patient has persistent tachycardia or arrhythmias Drug: Propranolol or atenolol

Harrison's Principles of Internal Medicine, 21st edition, Pages 2976-2979.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: Which of the following is imaging modality of choice for pheochromocytoma? (Q850567)

A. MRI abdomen

B. Gallium 68 dotatate PET/CT

C. MIBG scan

D. Somatostatin receptor Scinitgraphy

Correct Answer: B. Gallium 68 dotatate PET/CT

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Imaging modality with > 95% diagnostic sensitivity and specificity for pheochromocytoma is Gallium 68 dotatate PET/CT. Another test with similar diagnostic accuracy is 18Fluoro-DOPA PET/CT. The remaining options are stars of older years.

References:

Harrison's Principles of Internal Medicine, 21st edition, Pages 2977

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 45-year-old woman presents with persistent hypertension, weight gain, and muscle weakness. Lab results reveal elevated cortisol levels and suppressed ACTH. Which of the following is the next best investigation for work up of this patient? (Q850525)

A. High dose dexamethasone suppresion test

B. Low dose dexamethasone suppression test

C. CT abdomen

D. MRI pituitary

Correct Answer: C. CT abdomen

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's clinical presentation, including elevated cortisol, suppressed ACTH, indicates an autonomous source of cortisol. Since we are suspecting adrenal adenoma / ACTH independant cushing syndrome , CT abdomen will be done. MRI pituitary and High dose dexamethasone suppression test is done in ACTH dependant cushing syndome. Low dose dexamethasone is done for confirmation of diagnosis but in this case the diagnosis is already made.

@Neet_pg_bot

Q13: Which of the following statements is incorrect regarding a patient with mineralocorticoid excess? (Q850552)

A. Excess aldosterone causes hypokalemic metabolic alkalosis

B. Serum sodium may remain normal despite total body sodium overload

C. Long-standing hypokalemia can lead to proximal muscle weakness

D. ACE inhibitors can falsely elevate aldosterone levels

Correct Answer: D. ACE inhibitors can falsely elevate aldosterone levels

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ACE inhibitors actually suppress aldosterone , leading to falsely low aldosterone levels and low aldosterone-to-renin ratio (ARR) . They do not elevate aldosterone , so they must be stopped before testing. Excess aldosterone causes hypokalemic metabolic alkalosis (Option A) : Excess aldosterone increases renal excretion of potassium and hydrogen ions , causing hypokalemic metabolic alkalosis Serum sodium may remain normal despite total body sodium overload■■■■■■■ (Option B) : Although total body sodium is high, serum sodium may appear normal due to dilution from fluid retention ■■■■■■■Long-standing hypokalemia can lead to proximal muscle weakness (Option C) : Chronic hypokalemia can impair muscle function, leading to proximal myopathy

References:

Harrison’s Principles of Internal Medicine, 21st edition, Page 2966-65

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: Which of the following is not correct about primary addison disease? (Q850546)

A. Increased Serum creatinine

B. Orthostatic hypotension

C. Skin color changes to pale alabaster

D. Hyperkalemia

Correct Answer: C. Skin color changes to pale alabaster

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Addison disease has salt wasting and volume depletion. This can lead to incresed serum creatinine (Option A) Salt wasting explains orthostatic hypotension (Option B) Low aldosterone explains hyponatermia with hyperkalemia. Remember aldosterone and potassium have inverse relation (Option D) In primary addison disease, ACTH will rise due to feedback mechanism and will cause hyperpigmentation of skin. In contrast pale alabaster skin is seen in secondary addison disease.

References:

Davidson's Principles and Practice of Medicine 24th edition, pages 672-673

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: Which of the following is not a clinical feature of glucocorticoid deficiency (Q850543)

A. Hypoglycemia

B. Eosinopenia

C. Orthostatic hypotension

D. Hyponatremia

Correct Answer: B. Eosinopenia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Low glucocorticoids will cause hypoglycemia attacks. Cortisol values and eosinophil count has inverse relation. Low cortisol is associated with high eosinophil count and vice versa. Lack of cortisol causes loss of feedback inhibition of ADH release . This causes more ADH and resultant dilutional hyponatermia. Cortisol has partial aldosterone like activity. Less cortisol will cause low BP

References:

Davidson's Principles and Practice of Medicine, 24th edition, pages 671-672

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: Which part of the nephron is affected in Gordon syndrome? (Q850541)

A. Distal convoluted tubule

B. Proximal nephron

C. Ascending limb of the loop of Henle

D. Descending limb of the loop of Henle

Correct Answer: A. Distal convoluted tubule

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Gordon syndrome affects DCT. It is caused by mutations that increase sodium-chloride reabsorption via the NCC (Na■/Cl■ cotransporter) in the DCT. this leads to low alosterone levels and hence it is also called Pseudohypoaldosteronism type IIA. It leads to: 1. Hypertension (due to volume expansion) 2. Hyperkalemia (due to reduced potassium excretion) 3. Metabolic acidosis 4. Low renin and aldosterone levels It is the opposite phenotype of Gitelman syndrome , which also involves the DCT but causes hypokalemia and metabolic alkalosis. Inheritance Autosomal dominant (mostly) Pathogenesis Mutations in the WNK1, WNK4, CUL3, or KLHL3 genes result in abnormalities in serine/threonine kinases that dysregulate the thiazide-sensitive sodium-chloride cotransporter (NCC) in the distal nephron (Option A). This leads to increased sodium and chloride reabsorption, causing extracellular volume expansion and subsequent hypertension. Clinical Presentation Non-specific symptoms like muscle weakness, fatigue, hypertension (not always) Laboratory Findings Hyperkalemia Hyperchloremic metabolic acidosis Hypercalciuria Low or low-normal plasma renin activity Low serum aldosterone levels (relative to hyperkalemia) Normal kidney function/normal glomerular filtration Management Correction of electrolyte abnormalities Salt restriction Thiazide diuretics

References:

https://www.ncbi.nlm.nih.gov/pmc/articles/PMC10874887/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: All of the following are clinical manifestations of Liddle’s syndrome except? (Q850537)

A. Hypokalemia

B. Hyporeninemia

C. Hypertension

D. Hyperaldosteronism

Correct Answer: D. Hyperaldosteronism

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Aldosterone levels are suppressed in Liddle’s syndrome. Liddle’s syndrome (pseudohyperaldosteronism): Definition An autosomal dominant genetic disorder characterized by hypertension with hypokalemic metabolic alkalosis, hyporeninemia, and suppressed aldosterone secretion Pathophysiology Mutations in SCNN1A, SCNN1B, and SCNN1G genes → α, β, and γ subunits of ENaC (Epithelial Sodium Channel) altered → Increased Epithelial Sodium Channel activity→Elevated sodium reabsorption in the distal nephron → Sodium retention Clinical features Early-onset hypertension (as early as 2 years of age) (Option C ruled out) Hypokalemia (Option A ruled out) and metabolic alkalosis Suppressed plasma renin (Option B ruled

out) and aldosterone levels (Option D) Fatigue, muscle weakness, dizziness, and vision changes Management Potassium-sparing diuretics: Amiloride or Triamterene Salt restriction

References:

https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6731958/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: 45-year-old woman presents to the clinic with complaints of persistent high blood pressure despite medication and muscle weakness. On examination BP is 170/100 mmHg. Work up shows results pH= 7.46, serum potassium: 3.2 mEq/L, serum sodium: 142 mEq/L and increased aldosterone levels. CT abdomen shows adrenal mass size of 2cm. Which of the following test is used to confirm the diagnosis? (Q850535)

A. Plasma renin activity

B. Saline infusion test

C. ACTH stimulation test

D. Petrosal sinus sampling

Correct Answer: B. Saline infusion test

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Diagnosis based on hypertension with hypokalemic alkalosis is primary hyperaldosteronism. Since CT shows an adrenal mass, it would be conn syndrome. ARR is the correct initial test to screen for hyperaldosteronism and saline infusion test is a confirmatory test for diagnosis of Primary Hyperaldosteronism. ACTH stimulation test (Option C) is used for adrenal insufficiency/ Addison disease. Dexamethasone suppression test evaluates cortisol excess (Cushing’s syndrome).

References:

Davidson's Principles and Practice of Medicine, 24th edition, pages 673-674

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: 50-year-old hypertensive male presents with muscle weakness and frequent headaches. Work up shows hypokalemic metabolic alkalosis with low plasma aldosterone and low renin. Which of the following is the most likely diagnosis? (Q850531)

A. Liddle syndrome

B. Conn syndrome

C. Addison disease

D. Bilateral adrenal hyperplasia

Correct Answer: A. Liddle syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Liddle syndrome This patient has hypertension, hypokalemia, and metabolic alkalosis — a triad suggesting mineralocorticoid excess. However, both plasma aldosterone and renin are low, ruling out primary (Conn syndrome) and secondary hyperaldosteronism . (Option B and D ruled out) . This points toward a condition that mimics aldosterone's action despite its suppression. Liddle syndrome fits this profile: it is a genetic disorder where mutated ENaC channels in the distal nephron stay overactive, causing sodium retention and potassium loss, independent of aldosterone. Addison disease has hypotension and salt wasting and hence is ruled out. (Option C)

References:

Harrison's Principles of Internal Medicine, 21st Edition, Page 2078-79

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: 30 year old patient presents with hypertension and hypokalemic metabolic alkalosis. CT scan shows mass over the kidney of size 1.5 cm with elevated ARR. What is the next best step for management of this patient? (Q850528)

A. Spironolactone on life-long basis

B. Adrenalectomy

C. Adrenal venous sampling

D. Dexamethasone suppression test

Correct Answer: C. Adrenal venous sampling

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Adrenal venous sampling Diagnosis is Conn syndrome as elevated aldosterone renin ratio is given in patient with adrenal mass with Hypertension Even if a CT scan shows an adrenal mass, AVS (adrenal venous sampling) is needed to confirm lateralization of aldosterone production before surgery because: Coexistent non-functioning adrenal adenomas (incidentalomas) are common, especially in older adults. The CT might show a mass, but it may not be the one producing aldosterone — and sometimes both glands are involved (bilateral hyperplasia). AVS helps to differentiate between Unilateral disease → candidate for adrenalectomy Bilateral disease → treated medically (e.g. with mineralocorticoid receptor antagonists like spironolactone or eplerenone)

References:

Harrison's Principles of Internal Medicine, 21st Edition, Page 349, 350, 365, 2078, 2079, 2965, 2987, 3162, 3165.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 35-year-old man presents with episodic headaches, palpitations, and excessive sweating. He is found to have labile hypertension and an adrenal mass on testing. Genetic testing confirms a ret proto-oncogene mutation, and ultrasound shows bilateral thyroid nodules. Which of the following is the major catecholamine produced by this tumor? (Q850527)

A. Epinephrine

B. Nor epinephrine

C. Dopamine

D. Metanephrine

Correct Answer: A. Epinephrine

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Majority of pheochromocytoma are NE producing (80%) but in this question due to association with MEN 2/ Sipple syndrome the answer is epinephrine producing . The presence of ret gene and thyoid masses indictate a medullary carcinoma of thyroid that could be present. Pheochromocytomas arise from chromaffin cells of the adrenal medulla (or extra-adrenal paraganglia). These tumors lack cortisol exposure needed to activate the enzyme phenylethanolamine N-methyltransferase (PNMT) , which converts norepinephrine to epinephrine. Hence, overall norepinephrine is the predominant secretion in ~80% of pheochromocytomas. Norepinephrine (Option B):

Predominant in noradrenergic pheochromocytomas (e.g., VHL syndrome or sporadic extra-adrenal paragangliomas), where PNMT is absent. In MEN2, norepinephrine is mostly converted to epinephrine, so it's not the major product. Dopamine (Option C): This is rarely the major product and is more commonly seen in rare, malignant paragangliomas. Metanephrine (Option D): This is the O-methylated metabolite of epinephrine (via COMT), not a catecholamine itself. Plasma free metanephrines are key for diagnosis, but the tumor primarily produces epinephrine.

Q1: An elderly woman is brought to the emergency department with altered behavior after a week of poor oral intake. She has a known history of hypothyroidism and has been irregular with her medications. On examination, she is bradycardic and hypotensive. Arterial blood gas analysis reveals respiratory acidosis, and serum sodium levels are low. Which of the following findings is least likely to be present in this patient? (Q884031)

A. Hypoglycemia

B. Hyperthermia

C. Rhabdomyolysis

D. Hypercapnia

Correct Answer: B. Hyperthermia

Explanation: Myxedema coma is the life-threatening extreme of hypothyroidism and carries a 20-40% mortality rate , even with intensive treatment. Importantly, clinical outcomes are independent of serum T4 and TSH levels. Clinical manifestations include: Reduced level of consciousness ranging from confusion → somnolence → coma Seizures and other abnormal CNS signs Profound hypothermia (may reach 23°C) Hypoventilation leading to hypercapnia (Option D) and hypoxemia Hyponatremia Hypoglycemia (Option A) due to impaired gluconeogenesis and cortisol deficiency Bradycardia and hypotension Rhabdomyolysis (Option C) and acute kidney injury

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3032

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 64-year-old woman from an iodine-deficient region has had a slowly progressive multinodular thyroid enlargement for 18 years. She was asymptomatic and euthyroid until recently. She now presents with palpitations, weight loss, and tremors. Investigations show: TSH - Suppressed Free T4 - Normal T3 - Disproportionately elevated Thyroid scintigraphy - Heterogeneous uptake with multiple hot and cold areas FNAC from different nodules shows mixed polyclonal and monoclonal populations Which of the following represents the most important pathophysiological change responsible for her current disease state? (Q884023)

A. Development of autoimmune TSH-receptor antibodies

B. Emergence of nodules with functional autonomy

C. Progressive iodine deficiency causing diffuse hyperplasia

D. Malignant transformation of polyclonal nodules

Correct Answer: B. Emergence of nodules with functional autonomy

Explanation: Initially, she had Nontoxic Multinodular Goitre (NT-MNG) presenting as euthyroid, predominantly polyclonal hyperplastic nodules with normal TSH, which represents a hyperplastic response to growth factors & cytokines. But over time, some nodules acquire functional autonomy, and they begin secreting thyroid hormone independent of TSH. This converts NT-MNG to Toxic MNG, whose defining pathophysiologic feature is functional autonomy. This explains the low TSH, T3-predominant thyrotoxicosis, heterogeneous uptake and clinical symptoms of AF, palpitations, and weight loss; precipitated by iodine exposure (Jod-Basedow phenomenon). Autoimmune TSH-receptor antibodies (Option A): This is the mechanism of Graves' disease, causing diffuse toxic goitre, not toxic multinodular goitre. Progressive iodine deficiency (Option C): Iodine deficiency causes diffuse or multinodular goitre formation, but does not explain the development of thyrotoxicosis in multinodular goitre. Malignant transformation of polyclonal nodules (Option D): Malignancy may cause rapid enlargement, hoarseness or lymphadenopathy, but it does not produce thyroid hormone excess and therefore does not cause thyrotoxicosis.

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3041, 3042.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 32-year-old woman presents with a painless thyroid nodule. Ultrasound shows a hypoechoic solid lesion with microcalcifications and irregular margins. FNAC reveals nuclear grooves and intranuclear cytoplasmic inclusions. Which thyroid malignancy is most likely to account for the majority of thyroid cancers worldwide? (Q884024)

A. Follicular carcinoma

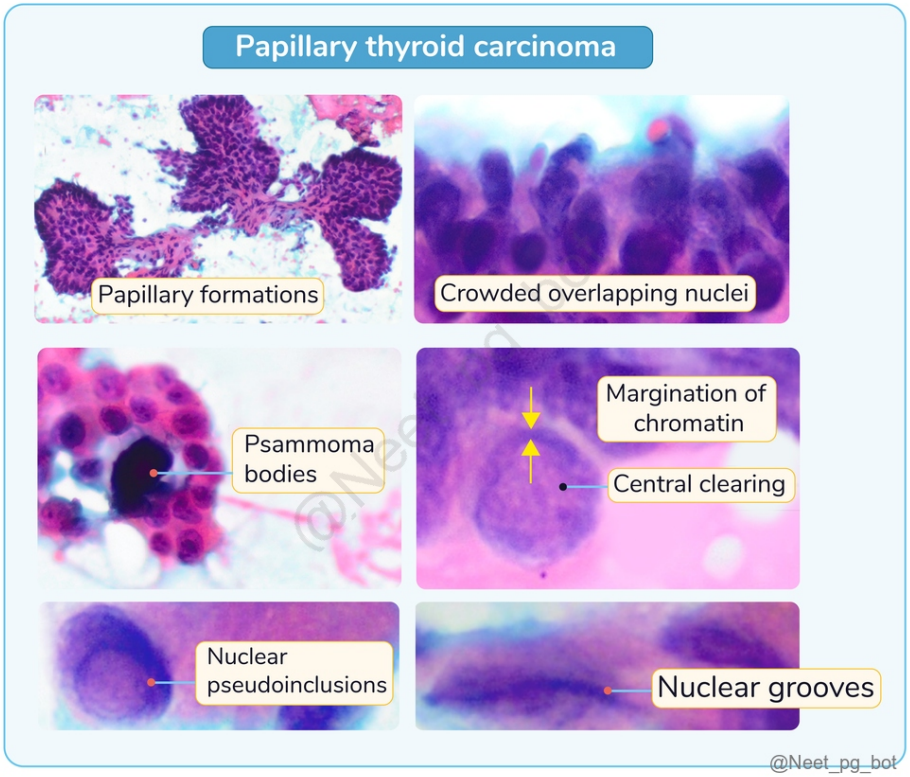
B. Papillary carcinoma

C. Medullary thyroid carcinoma

D. Anaplastic carcinoma

Correct Answer: B. Papillary carcinoma

Explanation: Papillary thyroid carcinoma (PTC) is the most common thyroid malignancy, accounting for ~80-90% of all thyroid cancers and 80-85% of well-differentiated thyroid malignancies. Microscopic PTC is found in up to 25% of thyroid glands at autopsy, but most are clinically insignificant microcarcinomas. Characteristic cytology: Orphan Annie eye nuclei Nuclear grooves Intranuclear cytoplasmic inclusions Spread: Predominantly lymphatic, but can metastasise hematogenously (lung, bone) Treatment: Total thyroidectomy (lobectomy only for low-risk microcarcinoma) with radioiodine ablation when indicated, followed by TSH-suppressive levothyroxine therapy. Follicular carcinoma (Option A): Accounts for only 5-10% of thyroid cancers and spreads mainly hematogenously. Medullary carcinoma (Option C): Comprises <10% of cases, arises from parafollicular C-cells, and is associated with MEN syndromes. Anaplastic carcinoma (Option D): Extremely aggressive but very rare (1-2%) and not the predominant thyroid malignancy.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3046.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following is/ are recognised risk factors for thyroid carcinoma in a patient presenting with a thyroid nodule? History of head and neck irradiation during childhood Male gender Slowly enlarging, mobile thyroid nodule in a middle-aged woman Hoarseness of voice or vocal cord paralysis PET-avid thyroid nodule on 18-FDG imaging (Q884025)

A. 1, 2, 4 and 5

B. 1 and 4 only

C. 1, 3 and 4

D. Only 1

Correct Answer: A. 1, 2, 4 and 5

Explanation: High-risk historical and examination features that increase malignancy probability include: Age <20 or >65 years Male gender (Statement 2) Nodule size >4 cm Rapidly enlarging or new neck mass Hoarseness / vocal cord paralysis (recurrent laryngeal nerve involvement) (Statement 4) Nodule fixed to adjacent structures Lateral cervical lymphadenopathy (ipsilateral nodes) Extrathyroidal extension Childhood head and neck irradiation (mantle radiation, cranial radiation, nuclear fallout exposure) (Statement 1) PET-avid nodules on 18-FDG or Ga-68 DOTATATE imaging Family history of papillary thyroid cancer in two or more first-degree relatives Genetic syndromes - MEN2, Cowden's, FAP, Carney complex, PTEN hamartoma tumour syndrome$f$ A slowly enlarging mobile thyroid nodule in a middle-aged woman is characteristic of benign disease and is not a malignancy risk factor. (Statement 3)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3045.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 19-year-old woman is evaluated for persistent biochemical thyrotoxicosis detected during routine screening. She has mild tachycardia but no weight loss, tremor, or ophthalmopathy. Her mother and maternal uncle are known to have "high thyroid hormone levels" but have never required treatment. Investigations show: Free T4 - High Free T3 - High TSH - Normal Which of the following best explains this patient's condition? (Q884026)

A. Activating mutation of the TSH receptor

B. Impaired feedback due to thyroid hormone receptor-β mutation

C. Autonomous hyperfunctioning thyroid nodules

D. TSH-secreting pituitary adenoma

Correct Answer: B. Impaired feedback due to thyroid hormone receptor-β mutation

Explanation: This is Resistance to Thyroid Hormone (RTH) . Key discriminator clues: Elevated T3 and T4 with non-suppressed TSH Minimal clinical hyperthyroidism Strong family history No ophthalmopathy No nodular goiter Classic RTH is caused by mutations in the TRβ gene , leading to impaired tissue sensitivity and loss of negative feedback at the pituitary , producing inappropriately normal or high TSH despite elevated thyroid hormones. Patients are often clinically euthyroid or mildly hyperthyroid and usually do not require antithyroid therapy Activating TSH receptor mutation (Option A): Produces true hyperthyroidism with suppressed TSH and overt symptoms. Autonomous nodules (Option C): TSH is suppressed due to intact pituitary feedback. TSH-secreting pituitary adenoma (Option D): TSH is frankly elevated, and patients have progressive

thyrotoxicosis, goitre, and mass-effect symptoms.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3025.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 27-year-old woman presents with weight loss, tremors and palpitations for 2 months. She has no neck pain or fever. Examination shows no goiter or thyroid tenderness. Laboratory evaluation shows: TSH - Suppressed Free T4 - Elevated ESR - Normal Thyroid radionuclide uptake - Very low Serum thyroglobulin - Normal Which of the following is the most likely diagnosis? (Q884027)

A. Subacute granulomatous thyroiditis

B. Graves’ disease

C. Thyrotoxicosis factitia

D. Toxic multinodular goitre

Correct Answer: C. Thyrotoxicosis factitia

Explanation: Serum thyroglobulin remains normal in thyrotoxicosis factitia (Exogenous thyroid hormone ingestion) because the excess thyroid hormone is self-administered , and the thyroid gland is not actively synthesising or releasing hormone. In Thyrotoxicosis Factitia: RAIU is suppressed because the thyroid gland is not synthesizing hormone. TSH is suppressed , but T3:T4 ratio is low (T4 predominance), unlike Graves where T3 predominates. Thyroid gland is normal-sized and non-tender (no goitre, no pain). No ophthalmopathy or dermopathy (unlike Graves’ disease). Anti-TPO and TRAb antibodies are negative. Serum thyroglobulin is normal or low - key discriminator. Treatment is cessation of exogenous hormone ± beta blockers In contrast, thyroglobulin is elevated in all endogenous causes of thyrotoxicosis. It is particularly high in thyroiditis , where follicular destruction causes leakage of stored thyroglobulin. The primary clinical use of thyroglobulin is in follow-up of differentiated thyroid carcinoma - after total thyroidectomy and radioiodine ablation, thyroglobulin should be undetectable . Detectable thyroglobulin (without anti-Tg antibodies) indicates residual or recurrent disease. Subacute granulomatous thyroiditis (Option A): Follicular destruction causes marked thyroglobulin elevation . Graves’ disease (Option B): Diffuse gland hyperfunction causes elevated thyroglobulin . Toxic multinodular goitre (Option D): Autonomous nodules actively synthesise hormone → elevated thyroglobulin .

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3026

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 38-year-old woman presents with weight gain, constipation, and cold intolerance. Laboratory evaluation shows low free T4 with elevated TSH. Which of the following conditions is least likely to produce this biochemical pattern? (Q884028)

A. Postpartum autoimmune thyroiditis

B. Lithium-induced thyroid dysfunction

C. Sheehan syndrome

D. Chronic autoimmune thyroiditis

Correct Answer: C. Sheehan syndrome

Explanation: The biochemical pattern shown is primary hypothyroidism (↓T4, ↑TSH). Causes of Primary Hypothyroidism Autoimmune destruction (Option D) - Hashimoto's thyroiditis, atrophic thyroiditis Iatrogenic - Post ^{131}I therapy, subtotal/total thyroidectomy, neck irradiation Drug-induced - Amiodarone, lithium (Option B), iodine excess (contrast), antithyroid drugs, interferon-α, tyrosine kinase inhibitors (e.g., sunitinib), immune checkpoint inhibitors (nivolumab, pembrolizumab, ipilimumab) Congenital - Thyroid dysgenesis, dyshormonogenesis, TSH-R mutation Iodine deficiency (most common cause worldwide) Infiltrative diseases - Amyloidosis, sarcoidosis, hemochromatosis, Riedel thyroiditis Transient forms - Postpartum thyroiditis (Option A) , subacute thyroiditis, withdrawal of excess thyroxine Sheehan syndrome is a cause of secondary hypothyroidism due to pituitary infarction. It causes low or inappropriately normal TSH with low T4 , not the elevated TSH seen in primary hypothyroidism - making it least consistent with the given biochemical pattern.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3027

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 2-month-old infant presents with persistent constipation, poor feeding, prolonged jaundice and hypotonia. Examination reveals macroglossia and no palpable thyroid gland in the neck. Laboratory evaluation shows: TSH - markedly elevated Free T4 - very low Which of the following statements regarding this condition is true? (Q884029)

A. Most cases are caused by defects in thyroid hormone synthesis

B. High circulating T4 levels are required to normalize TSH in early life

C. The disorder is more common in males

D. Thyroid hormone replacement can be delayed until 1 year of age

Correct Answer: B. High circulating T4 levels are required to normalize TSH in early life

Explanation: This infant has congenital hypothyroidism , most commonly due to thyroid gland dysgenesis . ≈85% of neonatal hypothyroidism is due to thyroid dysgenesis (Option A) (agenesis, ectopy, hypoplasia) Remaining cases are due to dyshormonogenesis (defective hormone synthesis) Females are affected twice as often as males (Option C) Classic features include: Prolonged jaundice Macroglossia Hypotonia Constipation Umbilical hernia Neonates require relatively high circulating T4 levels to suppress TSH and normalise neurodevelopment. This is why early high-dose levothyroxine is essential. Delay in therapy leads to irreversible intellectual disability (Option D)

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3027, 3028

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A patient with autoimmune thyroid disease is suspected to have autoimmune polyendocrine syndrome type 2 (APS-2). Which of the following pairs of additional diseases, when present together with autoimmune thyroid disease, would confirm the diagnosis of APS-2? (Q884030)

A. Hypoparathyroidism + Chronic mucocutaneous candidiasis

B. Addison's disease + Type 1 diabetes mellitus

C. Pernicious anemia + Vitiligo

D. Celiac disease + Sjögren syndrome

Correct Answer: B. Addison's disease + Type 1 diabetes mellitus

Explanation: Autoimmune Polyendocrine Syndrome Type 2 (APS-2) (Schmidt syndrome) is a polygenic autoimmune disorder characterized by a specific triad: Autoimmune thyroid disease - present in 70-75% of cases Type 1 diabetes mellitus - present in 40-60% of cases Addison disease - present in 40-50% of cases (mandatory component) Thus, in a patient who already has autoimmune thyroid disease, the coexistence of Addison disease and T1DM together confirms APS-2. Other associations of Autoimmune Hypothyroidism Vitiligo Pernicious anemia Alopecia areata Sjögren syndrome Myasthenia gravis Autoimmune hypoparathyroidism Primary hypogonadism Celiac disease Dermatitis herpetiformis Rheumatoid arthritis and SLE

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3030

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 61-year-old woman from an iodine-deficient region presents with a gradually enlarging neck mass for 16 years. She is clinically euthyroid. On raising both arms above her head, she develops facial flushing and venous congestion. Her CT scan shows substernal extension with mild tracheal narrowing. Thyroid ultrasound reveals multiple nodules of varying size. Which of the following statements regarding her condition is correct? (Q884022)

A. Most nodules represent monoclonal neoplastic transformation

B. Sudden onset of neck pain most commonly indicates malignant change

C. Radioiodine can reduce goitre volume by nearly half and ablate autonomous nodules

D. Thyroxine suppression therapy is the preferred long-term treatment

Correct Answer: C. Radioiodine can reduce goitre volume by nearly half and ablate autonomous nodules

Explanation: Non-toxic multinodular goitre (MNG) is more common in women, increases with age and is frequent in iodine-deficient regions. Most nodules are polyclonal hyperplastic lesions (Option A) , and patients are usually euthyroid and asymptomatic. Pemberton’s sign indicates thoracic inlet compression. Radioiodine therapy is used when surgery is contraindicated; it can reduce goitre size by ~40-50% and selectively ablate autonomous nodules. Sudden neck pain (Option B): Usually due to intranodular haemorrhage, not malignancy. Thyroxine suppression (Option D): Rarely effective and increases the risk of inducing thyrotoxicosis.

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3041, 3042, 3043.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: An elderly woman is brought to the emergency department in winter with progressive drowsiness for 2 days. On examination, she is hypothermic, bradycardic,

hypotensive, and has non-pitting facial puffiness. She is hypoventilating. Laboratory evaluation reveals hyponatremia, hypoglycemia, and hypercapnia. What is the most likely diagnosis? (Q884032)

A. Septic shock

B. Cardiogenic shock

C. Myxedema coma

D. Acute adrenal crisis

Correct Answer: C. Myxedema coma

Explanation: This presentation is classic for myxedema coma , the most severe and life-threatening manifestation of hypothyroidism. Myxedema coma represents the extreme end of the myxedema crisis spectrum and has a 20-40% mortality rate even with treatment. Clinical features present here: Altered mental status (drowsiness → coma) Profound hypothermia (can fall to ~23°C) Bradycardia and hypotension Hypoventilation → hypercapnia and hypoxemia Hyponatremia and hypoglycemia Non-pitting edema (myxedema) Common precipitants include: sedatives, antidepressants, anesthetics, opioids, infection, cold exposure, MI, and stroke. Septic shock (Option A): Characterized by fever, tachycardia, leukocytosis and an identifiable infective focus. Myxedema coma instead presents with profound hypothermia, bradycardia, and hypoventilation. Cardiogenic shock (Option B): Would show signs of left heart failure such as pitting pedal edema, raised JVP, pulmonary edema and dyspnea , not non-pitting myxedematous edema and hypothermia. Acute adrenal crisis (Option D): Causes hypotension and hypoglycemia, but does not produce hypothermia, bradycardia, hypoventilation, or myxedematous facial puffiness.

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3032

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 64-year-old man is admitted with severe community-acquired pneumonia requiring ICU care. He has no prior thyroid disease. Thyroid profile shows: Total T3 - Low Free T4 - Normal TSH - Normal Reverse T3 - Elevated What is the most appropriate interpretation of this thyroid profile? (Q884033)

A. Primary hypothyroidism

B. Secondary hypothyroidism

C. Sick euthyroid syndrome

D. Thyroid hormone resistance

Correct Answer: C. Sick euthyroid syndrome

Explanation: The most common hormone pattern seen in Sick Euthyroid Syndrome (SES) is a decrease in total and free T3 levels with normal T4 and TSH . This pattern is termed Low T3 syndrome . SES occurs in patients with acute or severe systemic illness without intrinsic thyroid disease . Acute severe illness suppresses peripheral 5′-deiodinase activity, leading to: Impaired conversion of T4 → T3 Increased conversion of T4 → rT3 Fall in biologically active T3 proportional to illness severity This represents an adaptive metabolic response to reduce energy expenditure. Thyroid hormone therapy is not indicated . In critically ill patients, both T4 and T3 may fall markedly - this is termed Low T4 syndrome , which is associated with poor prognosis . Primary hypothyroidism (Option A): Characterised by low T4 with elevated TSH due to failure of the thyroid gland. Reverse T3 is not elevated and the characteristic low-T3 pattern of SES is not seen. Secondary hypothyroidism (Option B) : Due to pituitary failure, showing low T4 with low or inappropriately normal TSH . This is a structural endocrine disorder, not a transient adaptive response to illness. Thyroid hormone resistance (Option D) : Shows elevated T3 and T4 with non-suppressed TSH due to impaired tissue sensitivity to thyroid hormone. It does not produce isolated low T3 levels.

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3039

↑ *Back to this question in Part A*

@Neet_pg_bot

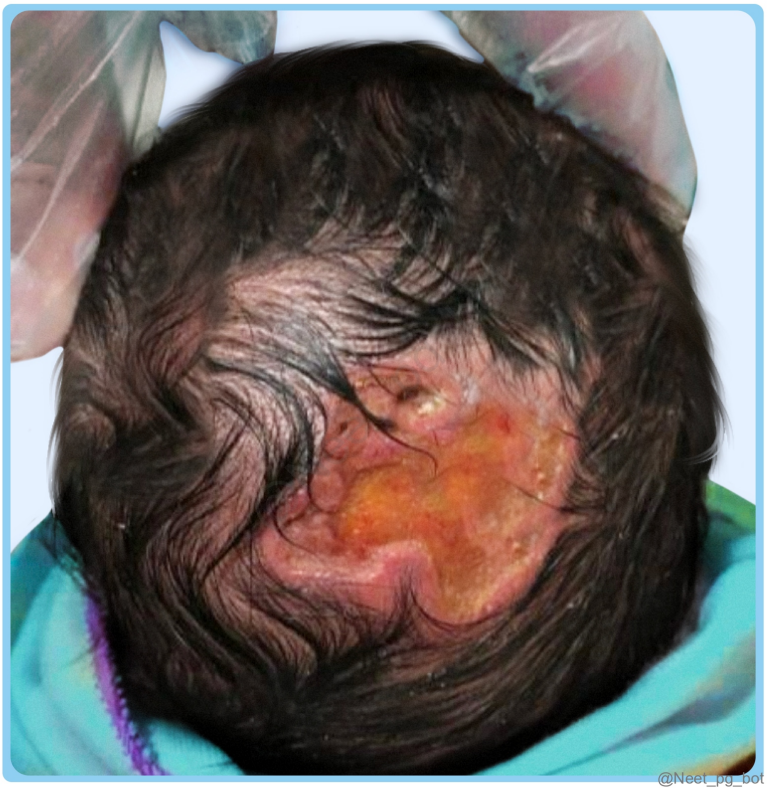
Q13: A neonate is born with a large scalp defect as shown. The mother had been treated for hyperthyroidism during early pregnancy. Which of the following drugs is most likely responsible for this congenital anomaly? (Q884034)

A. Propylthiouracil

B. Methimazole

C. Radioactive iodine

D. Levothyroxine



Correct Answer: B. Methimazole

Explanation: This neonate has aplasia cutis congenita , a scalp defect with absence of skin and underlying skull bone commonly over the vertex It is a characteristic teratogenic defect classically associated with methimazole / carbimazole exposure during the first trimester of pregnancy . Methimazole embryopathy includes: Aplasia cutis congenita Choanal atresia Tracheoesophageal fistula Esophageal atresia Facial anomalies Fetal goitre Because of this risk, propylthiouracil (PTU) is preferred in the first trimester , and methimazole is avoided. Propylthiouracil (Option A): Preferred antithyroid drug in the first trimester because it has much lower teratogenic risk . It is not associated with aplasia cutis congenita. Radioactive iodine (Option C): Causes fetal thyroid ablation leading to congenital hypothyroidism , not structural scalp defects like aplasia cutis. Levothyroxine (Option D): Synthetic thyroid hormone used to treat hypothyroidism and is safe in pregnancy . It does not cause any congenital malformations.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3036

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 32-year-old woman with Graves' disease has persistent hyperthyroidism despite 12 months of carbimazole therapy. She is a smoker and has mild

exophthalmos. She is not pregnant and is not breastfeeding. She wishes to conceive in the future. Which of the following is the most appropriate next step? (Q884035)

A. Radioiodine therapy without any additional medication

B. Radioiodine therapy with concurrent oral prednisone

C. Radioiodine therapy after immediate conception

D. Total thyroidectomy without further evaluation

Correct Answer: B. Radioiodine therapy with concurrent oral prednisone

Explanation: This patient has Graves disease with mild ophthalmopathy and is a smoker , which significantly increases the risk of worsening eye disease following radioiodine (RAI) therapy. Pregnancy and lactation are the only absolute contraindications to RAI - she has neither. RAI can be given in mild ophthalmopathy with steroid cover. Prednisone 0.2-0.5 mg/kg/day started at the time of RAI and tapered over 6-12 weeks reduces the risk of ophthalmopathy progression. Conception should be deferred for at least 6 months after RAI. Radioiodine therapy without steroid cover (Option A): Patients with Graves ophthalmopathy-especially smokers-have a high risk of worsening eye disease after radioiodine. Steroid prophylaxis is required to prevent progression. Radioiodine therapy followed by immediate conception (Option C): Conception is contraindicated for at least 6 months after radioiodine therapy due to risk of fetal thyroid ablation. Total thyroidectomy without further evaluation (Option D): Surgery is reserved for patients with large goiters, compressive symptoms, suspected malignancy, or moderate-to-severe ophthalmopathy. Mild ophthalmopathy can be safely managed with radioiodine plus steroid cover.

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3036

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 25-year-old primigravida at 9 weeks of gestation presents with palpitations, tremors and excessive sweating. Thyroid function tests confirm hyperthyroidism. Which is the most appropriate initial drug of choice? (Q884036)

A. Methimazole

B. Carbimazole

C. Propylthiouracil

D. Propranolol

Correct Answer: C. Propylthiouracil

Explanation: This patient is in the first trimester of pregnancy with thyrotoxicosis. Propylthiouracil (PTU) is the drug of choice in the first trimester because it has lower teratogenic risk compared to methimazole and carbimazole. Methimazole and carbimazole (Option A and B) are associated with characteristic embryopathy, including: Aplasia cutis congenita Choanal atresia Tracheoesophageal fistula Fetal goiter Omphalocele Therefore, they are avoided in early pregnancy. However, PTU is used only in the first trimester because prolonged use is associated with severe hepatotoxicity . Hence, after completion of the first trimester, patients are shifted to methimazole or carbimazole . Throughout pregnancy, the lowest effective dose of antithyroid drug should be used to maintain maternal free T4 in the upper limit of the non-pregnant reference range . Propranolol (Option D): Provides only symptomatic control and does not reduce thyroid hormone synthesis.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3036

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 42-year-old woman presents with a slowly progressive anterior neck swelling for 4 years. She has no palpitations, tremor, weight loss, or menstrual irregularities. Examination reveals a soft, symmetrically enlarged, non-tender thyroid gland with no palpable nodules. Thyroid function tests are normal. Which of the following best explains the pathogenesis of her condition? (Q884037)

A. Activating mutation of the TSH receptor

B. Chronic iodine deficiency causing diffuse follicular hyperplasia

C. Autoimmune destruction of thyroid follicles

D. Somatic mutations causing monoclonal nodular proliferation

Correct Answer: B. Chronic iodine deficiency causing diffuse follicular hyperplasia

Explanation: This patient has non-toxic diffuse (simple/colloid) goitre . It is most commonly caused by iodine deficiency Relative TSH stimulation due to impaired thyroid hormone synthesis → uniform follicular hyperplasia with colloid accumulation Gland is soft, symmetrical, non-tender, euthyroid and nodule-free Usually benign and asymptomatic TFTs are normal Surgery is rarely indicated - only for cosmetic reasons, tracheal compression, or thoracic inlet obstruction Large substernal goitres can show positive Pemberton's sign Early stages show diffuse hyperplasia; late stages may accumulate colloid. Activating mutation of the TSH receptor (Option A): Causes autonomous hormone production leading to toxic nodular goitre with suppressed TSH and clinical thyrotoxicosis - not a euthyroid diffuse enlargement. Autoimmune destruction of thyroid follicles (Option C): Represents Hashimoto's thyroiditis , which causes a firm irregular gland with hypothyroidism and positive anti-TPO antibodies - not a soft euthyroid diffuse goitre. Somatic mutations causing monoclonal nodular proliferation

(Option D): Seen in multinodular goitre , which produces nodular architecture rather than a uniform diffuse enlargement.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3040, 3041

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 29-year-old woman with no prior thyroid illness presents with intermittent tremors and heat intolerance for 10 days. She delivered her second child 5 months ago. There is no neck pain, fever, or sore throat. Examination shows a small, soft, non-tender thyroid gland. Investigations reveal: TSH - Suppressed Free T4 - Elevated ESR - Normal Anti-TPO antibodies - Positive 99mTc-pertechnetate uptake - Suppressed Which of the following best describes the expected course of this illness? (Q884038)

A. Progression to permanent thyrotoxicosis requiring radioiodine

B. Spontaneous resolution after a transient hypothyroid phase

C. Requirement of prolonged glucocorticoid therapy

D. Lifelong antithyroid drug therapy due to high relapse rate

Correct Answer: B. Spontaneous resolution after a transient hypothyroid phase

Explanation: This patient has silent (postpartum) thyroiditis , a painless autoimmune destructive thyroiditis occurring 3-6 months after delivery . Thyrotoxicosis results from release of preformed thyroid hormones , not increased synthesis-hence suppressed radionuclide uptake , normal ESR , and positive anti-TPO antibodies . The illness typically follows a self-limited course with a transient thyrotoxic phase , followed by a temporary hypothyroid phase , and then spontaneous recovery in most patients. Silent thyroiditis is an autoimmune destructive thyroiditis that: Occurs 3-6 months postpartum - Postpartum thyroiditis Is associated with positive TPO antibodies Has normal ESR Shows suppressed radionuclide uptake due to follicular destruction Is more common in women with autoimmune disease Clinical course: Transient thyrotoxic phase (2-4 weeks) Followed by hypothyroid phase (4-12 weeks) Then spontaneous recovery in most patients (Option A) ~20-30% may develop permanent hypothyroidism long-term Management: Only symptomatic therapy (β-blockers). Temporary thyroxine may be used during hypothyroid phase and withdrawn after 6-9 months. Annual follow-up is recommended as a proportion may develop permanent hypothyroidism and recurrence may occur in subsequent pregnancies. Prolonged glucocorticoids (Option C): Steroids are required in painful subacute thyroiditis, not in painless silent thyroiditis. Lifelong antithyroid therapy (Option D): Antithyroid drugs are ineffective because hormone excess is due to follicular destruction, not increased synthesis.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3038, 3039

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 29-year-old woman with known primary hypothyroidism is 11 weeks pregnant and is on regular levothyroxine therapy. She is clinically well. Which of the following is the recommended upper limit of serum TSH that should be maintained in her at this gestational age? (Q884039)

A. < 1.5 mIU/L

B. < 2.5 mIU/L

C. < 3.0 mIU/L

D. < 4.0 mIU/L

Correct Answer: B. < 2.5 mIU/L

Explanation: During the first trimester , maternal thyroxine is the sole source of thyroid hormone for fetal brain development. Even mild maternal hypothyroidism is associated with impaired fetal neurocognitive outcomes. Therefore, pregnancy-specific TSH targets are: 1st trimester: TSH < 2.5 mIU/L 2nd trimester: TSH < 3.0 mIU/L 3rd trimester: TSH < 3.0 mIU/L Thyroid function should be monitored by measuring TSH every 4 weeks in the first trimester , and less frequently after 20 weeks of gestation. Levothyroxine dose requirements increase during pregnancy due to increased thyroxine-binding globulin, placental deiodination, and increased maternal-fetal demand. → The dose often needs to be increased by up to 50% . Post-delivery levothyroxine doses are usually reduced back to pre-pregnancy levels , with repeat TSH monitoring to re-establish euthyroidism.

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3031, 3032

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: Which of the following is not a feature of hypothyroidism? (Q850927)

A. Pericardial efffusion

B. Pleural efffusion

C. Carpal tunnel syndrome

D. Diarrhea

Correct Answer: D. Diarrhea

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypothyroidism typically slows metabolism , leading to fluid accumulation (pericardial or pleural effusions) and neuropathies like carpal tunnel syndrome. Diarrhea is not a feature ; constipation is more common. Serous cavity effussions are seen in hypothyroidism due to myxedema. Myxedema reduces lymphatic outflow / drainage of Lymph that explains the development of both pericardial and pleural effusion (Options A and B) in these patients. Deposition of mucinous material of GAG in the transverse carpal ligament and surrounding soft tissues causes median nerve compression (Option C) and numbness, tingling, weakness in the hand.

Harrison’s Principles of Internal Medicine, 21st Edition, Volume I, Page 2933

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: Which of the following is the most appropriate preoperative management to prevent thyroid storm in a pateint of grave's disease who is scheduled for total thyroidectomy? (Q850785)

A. Start propranolol 7 days before and perform surgery once heart rate normalizes

B. Start methimazole and wait till acheiving euthyroid status

C. Start methimazole, potassium iodide, propranolol and wait till achieving euthyroid status

D. Take consent for high risk emergency surgery with careful intraoperative monitoing

Correct Answer: C. Start methimazole, potassium iodide, propranolol and wait till achieving euthyroid status

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: To prevent thyroid storm during thyroidectomy in a patient with severe hyperthyroidism due to Grave's disease, it is essential to render the patient euthyroid preoperatively. Methimazole is started to inhibit thyroid hormone synthesis, and once hormone levels begin to fall (typically after a few days), potassium iodide is added 7–10 days before surgery to inhibit hormone release (the Wolff-Chaikoff effect) and reduce gland

vascularity. Propranolol is used to control adrenergic symptoms and also slightly inhibits peripheral T4 to T3 conversion. The Burch-Wartofsky scoring system is used to help diagnose thyroid storm: Interpretation of Burch-Wartofsky score: ≥45 points: Highly suggestive of thyroid storm 25-44 points: Impending thyroid storm <25 points: Unlikely to represent thyroid storm

References:

Harrison's Principles of Internal Medicine, 21st Edition, Page 2942..

www.ncbi.nlm.nih.gov/books/NBK278927/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 45-year-old woman with a history of multinodular goitre undergoes a CT angiogram with iodinated contrast for suspected pulmonary embolism. Two weeks later, she presents with palpitations, heat intolerance, and weight loss. Her thyroid function tests show suppressed TSH and elevated T3 and T4. Which of the following best explains this patient's current condition? (Q850786)

A. Wolff-Chaikoff effect

B. Jod-Basedow effect

C. Thyroid storm

D. Hashitoxicosis

Correct Answer: B. Jod-Basedow effect

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient developed iodine-induced hyperthyroidism (Jod-Basedow phenomenon) after exposure to iodinated contrast, especially in the setting of pre-existing multinodular goitre. The sudden iodine load triggers excessive thyroid hormone synthesis in autonomous thyroid tissue. Wolff-Chaikoff effect (Option A): This is the opposite of Jod-Basedow. It is a protective mechanism where a large dose of iodine causes the thyroid to shut down hormone production temporarily. This would lead to hypothyroidism (high TSH, low T4), not hyperthyroidism. Thyroid storm (Option C): This is a life-threatening, extreme manifestation of hyperthyroidism (fever, delirium, cardiac failure). While this patient is symptomatic, "Thyroid storm" describes the severity of the state rather than the underlying mechanism requested by the question. Hashitoxicosis (Option D): This is the transient hyperthyroid phase of Hashimoto’s thyroiditis caused by the "leaking" of preformed hormones as the gland is destroyed. It is not triggered by iodine contrast.

References:

Harrison’s Principle of Internal Medicine, 21st Edition, Page 2945

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: A 52-year-old woman presents with a 2-week history of palpitations, anxiety, and weight loss. On examination, her heart rate is 110 bpm and regular, and she has a painful goitre. Thyroid function tests show decreased TSH level and elevated free T3 & T4 levels. A thyroid scan shows very low uptake. Which of the following is the most likely diagnosis? (Q850787)

A. Graves' disease

B. Toxic multinodular goiter

C. Subacute thyroiditis

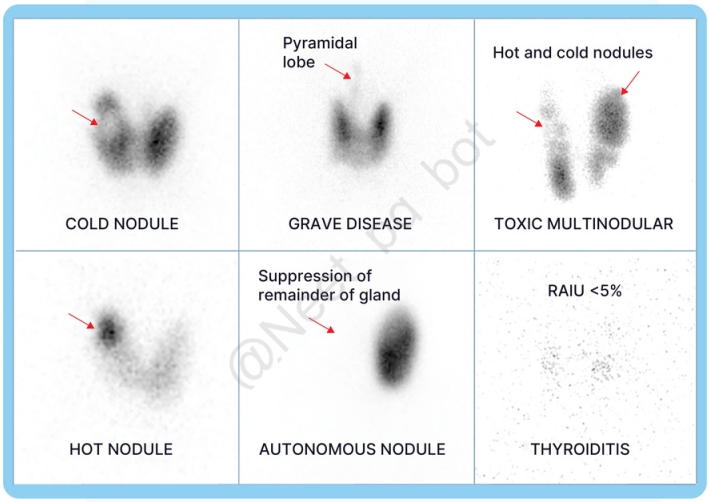
D. TSH-secreting pituitary adenoma

Correct Answer: C. Subacute thyroiditis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient presents with painful goitre, hyperthyroid symptoms, and low radioactive iodine uptake , which is characteristic of subacute (de Quervain) thyroiditis . The low uptake differentiates it from conditions caused by overproduction of hormone. {{caption_text}} Graves' disease (Option A) usually presents with diffuse, painless goitre and high radioactive iodine uptake. Toxic multinodular goiter (Option B) is typically painless with patchy increased uptake on scan. TSH-secreting pituitary adenoma (Option D) causes high TSH with high T3/T4, unlike the suppressed TSH seen here.



@Neet_pg_bot

References:

www.ncbi.nlm.nih.gov/books/NBK482216/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: 35-year-old woman presents with a history of weight loss, palpitations and heat intolerance. On examination, she has a diffuse goitre, ophthalmopathy and fine tremors in her outstretched hands. Her thyroid function tests show: TSH: < 0.01 mIU/L (normal range: 0.4-4.0 mIU/L) Free T4: 35 pmol/L (normal range: 10-20 pmol/L) Free T3: 12 pmol/L (normal range: 3.5-6.5 pmol/L) Which of the following is the most likely cause of her hyperthyroidism? (Q850790)

A. Toxic multinodular goiter

B. Graves' disease

C. TSH-secreting pituitary adenoma

D. Jod Basedow effect

Correct Answer: B. Graves' disease

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has diffuse goitre, ophthalmopathy, tremors, and suppressed TSH with elevated T3/T4 , which is characteristic of Graves' disease , an autoimmune hyperthyroidism. Toxic multinodular goiter (Option A) usually presents with nodular, asymmetric goitre without ophthalmopathy. TSH-secreting pituitary adenoma (Option C) causes elevated TSH despite high T3/T4, unlike the suppressed TSH seen here. Jod-Basedow effect (Option D) occurs after iodine exposure in susceptible patients and is usually not associated with ophthalmopathy.

Davidson's Principle and Practice of Medicine, 24th Edition, Page 634.

pmc.ncbi.nlm.nih.gov/articles/PMC5014602/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: 50 year old patient was diagnosed with atrial fibrillation. Diagnostic work up showed high T4, high T3 and high TSH. Which of the following is next best investigation for this patient? (Q850795)

A. MRI Head

B. USG neck

C. TSH receptor antibody titer

D. Radioactive thyroid scan

Correct Answer: A. MRI Head

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has high T4, high T3, and inappropriately high TSH , suggesting secondary hyperthyroidism due to a TSH-secreting pituitary adenoma . MRI of the pituitary is the next best investigation to localize the adenoma. USG neck (Option B) is used to assess thyroid nodules but cannot detect a pituitary source. TSH receptor antibody titer (Option C) is for Graves' disease, which presents with suppressed TSH, not elevated. Radioactive thyroid scan (Option D) evaluates thyroid uptake but cannot identify a pituitary cause.

References:

Davidson's Principle and Practice of Medicine, 24th Edition, Page 637.

pmc.ncbi.nlm.nih.gov/articles/PMC5014602/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: On the Thyroid function test, TSH is suppressed, Free T4 level is normal, and Free T3 is increased. Which of the following is the most likely diagnosis? (Q850796)

A. Subclinical hyperthyroidism

B. Euthyroid sick syndrome

C. Primary Hyperthyroidism

D. T3 thyrotoxicosis

Correct Answer: D. T3 thyrotoxicosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: T3 thyrotoxicosis is characterized by suppressed TSH, elevated T3, and normal T4 , often representing an early or mild form of hyperthyroidism where T3 rises first. Subclinical hyperthyroidism (Option A) shows suppressed TSH but normal T3 and T4. Euthyroid sick syndrome (Option B) usually shows low T3 with normal or low T4 and variable TSH. Primary hyperthyroidism (Option C) generally presents with suppressed TSH and elevated T4 (often T3 as well).

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Volume I, Page 2931, 2932.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q26: RAIU scan was performed for a 35 year old lady with hypertension and palpitations. Diagnosis is? (Q850925)

A. Toxic multinodular goiter

B. Graves' disease

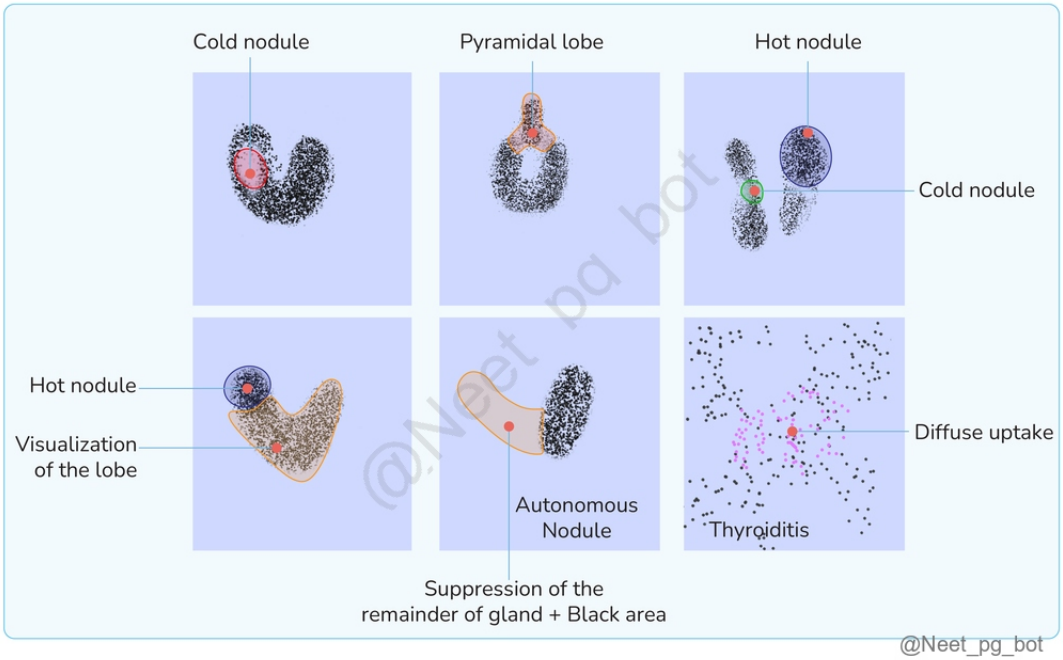
C. Thyroiditis

D. Thyroid adenoma

Correct Answer: B. Graves' disease

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Graves' disease typically shows diffusely increased uptake on a radioactive iodine uptake (RAIU) scan, correlating with hyperthyroidism and systemic symptoms like palpitations and hypertension. Toxic multinodular goiter (Option A) usually shows heterogeneous uptake with multiple “hot” nodules rather than diffuse uptake. Thyroiditis (Option C) shows low or negligible uptake due to release of preformed hormone rather than increased synthesis. Thyroid adenoma (Option D) presents as a single “hot” nodule on RAIU scan, not diffuse uptake.



References:

Harrison's Principles of Internal Medicine, 21st Edition, Volume I, Page. 2932.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q27: A 32-year-old woman presents with palpitations, weight loss, and heat intolerance for the past 3 months. On examination, she has a diffuse goitre and mild proptosis. Thyroid function tests show suppressed TSH and elevated free T4 and T3. Which of the following is the most appropriate next step in management? (Q850926)

A. Radioiodine ablation

B. Total thyroidectomy

C. Start propranolol and carbimazole

D. MRI Brain

Correct Answer: C. Start propranolol and carbimazole

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient has new-onset Graves' disease with symptomatic hyperthyroidism. Initial management includes beta-blockers (like propranolol) for symptom control and antithyroid drugs (like carbimazole) to reduce hormone synthesis. Radioiodine ablation (Option A) is considered later for definitive therapy, not first-line in new-onset disease. Total thyroidectomy (Option B) is reserved for large goiters, suspicion of malignancy, or intolerance to medications. MRI Brain (Option D) is not indicated as this is a primary thyroid disorder, not a central cause of hyperthyroidism.

References:

Harrison's Principles of Internal Medicine, 21st Edition, Page 2938, 2941

↑ *Back to this question in Part A*

@Neet_pg_bot

Q28: A 45-year-old woman presents with palpitations, vomiting, diarrhea and marked agitation following an abrupt discontinuation of her antithyroid medication following a UTI. On examination, she is diaphoretic with proptosis and diffuse neck swelling with prominent jugular pulsations . Vitals are pulse: 120/min, BP 160/100 mm Hg, RR 24/min Temp: 39 C. Which of the following is best drug for managment of this patient? (Q850784)

A. Saturated solution of potassium iodide

B. Propylthiouracil

C. Liothyronine

D. Propranolol

Correct Answer: B. Propylthiouracil

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hyperadrenergic symptoms like palpitations, tremors, sweating with hyperthermia in a grave's disease patient (diffusely enlarged thyroid with proptosis), and abrupt discontinuation of medication and infection point to Thyroid storm. The drug of choice for thyroid storm and initial treatment to be given is Propylthiouracil, which reduces peripheral T4 to T3 conversion. Saturated solution of potassium iodide (Option A) is used to acutely block thyroid hormone release, but only after thionamides are started. Liothyronine (Option C) is T3 supplementation and would worsen thyroid storm. Propranolol (Option D) should be given with extreme caution, as the finding of heart failure (prominent neck veins is mentioned).

References:

Harrison's Principles of Internal Medicine, 21st Edition, Page 2942

↑ *Back to this question in Part A*

@Neet_pg_bot

Q29: Which of the following is correct description of myxedema seen in patients with hypothyroidism? (Q850928)

A. Increased dermal collagen deposition

B. Accumulation of dermal glycosaminoglycans

C. Dermal saponification of fat

D. Dermal fibrosis

Correct Answer: B. Accumulation of dermal glycosaminoglycans

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's symptoms, including fatigue , weight gain , dry skin , and non-pitting edema (myxedema) , points to hypothyroidism. In hypothyroidism, there is an accumulation of glycosaminoglycans in the dermis that binds to water, leading to non-pitting edema of skin. Increased dermal collagen deposition (Option A) is not the primary mechanism of myxedema. Dermal saponification of fat (Option C) occurs in pancreatic fat necrosis, not hypothyroidism. Dermal fibrosis (Option D) refers to chronic scarring, which is not characteristic of myxedema.

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Volume I, Page 2935

↑ *Back to this question in Part A*

@Neet_pg_bot

Q30: A 45-year-old woman comes with complaints of extensive hair loss, menorrhagia and weight gain. Work up shows elevated TSH , low T3, low T4 levels and anti TPO antibody present status. She has no known cardiovascular disease. Which of the following is the most appropriate next step regarding this patient? (Q850929)

A. Start levothyroxine 25 µg daily

B. Start levothyroxine 100 µg daily

C. Start liothyronine (T3) 5 µg three times daily

D. Observe and repeat thyroid function tests in 3 months

Correct Answer: B. Start levothyroxine 100 µg daily

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Start levothyroxine 100 µg daily is approximately the full replacement dose (1.6ug/kg) for a healthy adult without cardiovascular disease. Levothyroxine increases oxygen consumption of heart and giving full dose in patients with coexistent heart disease can trigger angina. Levothyroxine 25 µg daily (Option A) is too low and is used for elderly or patients with heart disease to avoid precipitating arrhythmias or angina. Liothyronine (T3) 5 µg TID (Option C) is used in myxedema coma Observe and repeat in 3 months (Option D): We have to be proactive in this case

@Neet_pg_bot

Q31: A known case of autoimmune thyroiditis presents with confusion and seizures. EEG shows generalized slowing without epileptiform discharges. Vitals are pulse 60/min. BP 120/100 mm Hg and temp 37.2 C. Work up shows High TSH, low T4, low T3, blood counts and CRP is normal. Which of the following is correct about diagnosis and management? (Q851050)

A. Hashimoto's encephalopathy and Hydrocortisone

B. Myxedema coma and iv Liothyronine

C. Myxedema coma and iv Levothyroxine

D. Thyroid storm and NG tube Propylthiouracil

Correct Answer: A. Hashimoto's encephalopathy and Hydrocortisone

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient presents with neurological symptoms (confusion, seizures) in the context of autoimmune thyroiditis . Normal blood counts and CRP, along with high TSH and low T4/T3, support Hashimoto's encephalopathy , which responds to corticosteroids . Myxedema coma (Options B and C) usually presents with hypotension, hypothermia, and more severe systemic compromise. Thyroid storm and NG tube Propylthiouracil

(Option D): Thyroid storm is a hyperthyroid emergency, not seen with high TSH and low T4/T3.

www.ncbi.nlm.nih.gov/books/NBK545193/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q32: Most common cardiovascular finding in case of young female with Grave's disease is? (Q851051)

A. Sinus Tachycardia

B. Atrial fibrillation

C. Ejection systolic murmur

D. Widened pulse pressure

Correct Answer: A. Sinus Tachycardia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The increased sympathomimetic drive caused by an excess of thyroid hormones leads to sinus tachycardia as the most common feature. Atrial fibrillation is also seen, particularly in patients over 50 years of age, and resolves in more than 50% of cases when antithyroid medication is started. High cardiac output produces bounding pulses and widened pulse pressure , along with an aortic systolic murmur due to hyperdynamic circulation. This can worsen angina or heart failure in elderly patients.

Harrison 21st edition, page 2939

Davidson’s Principle and Practice of Medicine, 24th Edition,Page 642

↑ *Back to this question in Part A*

@Neet_pg_bot

Q33: Which of the following is not correct about Grave's associated ophthalmopathy? (Q851052)

A. Occurs in the absence of hyperthyroidism in 10% of patients

B. Earliest manifestation is proptosis and diplopia

C. Can cause loss of vision and papilledema

D. Lid lag can occur in causes other than grave' disease

Correct Answer: B. Earliest manifestation is proptosis and diplopia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: arliest manifestation is proptosis and diplopia: In Graves' ophthalmopathy (thyroid eye disease), the earliest and most common manifestation is lid retraction and lid lag, due to sympathetic overactivity and levator palpebrae involvement. Proptosis and diplopia occur later, as a result of orbital fibroblast activation, glycosaminoglycan deposition, and extraocular muscle enlargement. Hence, stating proptosis and diplopia as the earliest features is incorrect. Incorrect Options: Option A - Occurs in the absence of hyperthyroidism in 10% of patients: Graves' ophthalmopathy can occur in euthyroid or hypothyroid patients (euthyroid Graves' disease) in about 5–10% of cases. Option C - Can cause loss of vision and papilledema: Severe disease may lead to optic nerve compression, causing decreased vision, papilledema, or optic neuropathy. Option D - Lid lag can occur in causes other than Graves' disease: Lid lag is not specific to Graves' disease and may be seen in other causes of thyrotoxicosis and hyperadrenergic states.

Harrison's Principles of Internal Medicine, 21st Edition, Volume I, Page 2938.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q34: In a patient with suspected hyperthyroidism, what is the initial screening test to be considered? (Q851053)

A. TSH and free T4

B. TSH and unbound T3

C. TSH and ultrasound neck

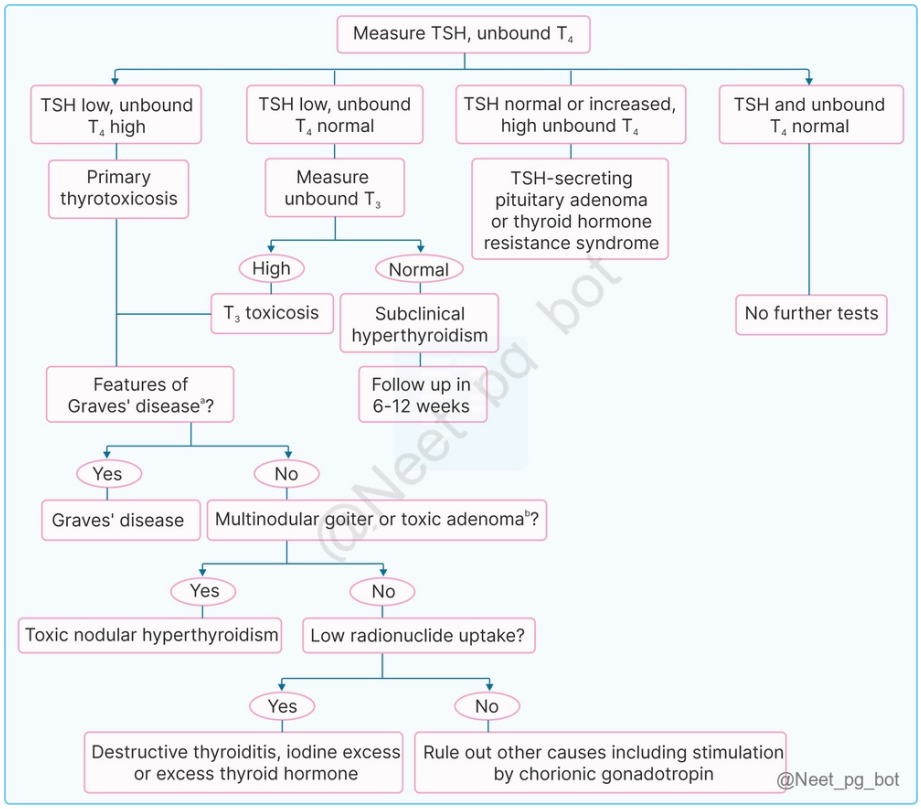
D. TSH and RAIU

Correct Answer: A. TSH and free T4

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: TSH and free T4 are the initial screening tests for suspected hyperthyroidism. Suppressed TSH with elevated free T4 confirms the diagnosis, guiding further evaluation. TSH and unbound T3 (Option B) is not routinely used for initial screening, as T3 may be normal in early hyperthyroidism. TSH and ultrasound neck (Option C) is used later to assess nodules or structural abnormalities, not for initial screening. TSH and RAIU (Option D) is used to differentiate causes of hyperthyroidism, not for first-line screening.



References:

Davidson’s Principle and Practice of Medicine, 24th Edition, Page 640, 641

↑ *Back to this question in Part A*

@Neet_pg_bot

Q35: A 68-year-old man with ischemic cardiomyopathy has been on amiodarone for 1 year. Routine screening reveals: TSH: 9.4 mIU/L (↑) Free T4: Low-normal Free T3: Normal He has no neck pain or thyroid tenderness. Which of the following thyroid disorders is least likely to be related to amiodarone therapy? (Q884019)

A. Failure to escape from the Wolff-Chaikoff effect

B. Iodine-induced hyperthyroidism due to autonomous nodules

C. Destructive thyroiditis-like thyrotoxicosis

D. Painless autoimmune thyroiditis (silent/postpartum)

Correct Answer: D. Painless autoimmune thyroiditis (silent/postpartum)

Explanation: Amiodarone, a type III antiarrhythmic agent, is structurally related to thyroid hormone and contains 39% iodine by weight. Thus, typical doses of amiodarone (200 mg/d) are associated with very high iodine intake, leading to greater than 40-fold increases in plasma and urinary iodine levels. Amiodarone has the following effects on thyroid function: Acute, transient suppression of thyroid function; Inhibition of T4 to T3 conversion causing either a euthyroid hyperthyroxinemia or increased dosage requirement in LT4-treated hypothyroid patients. Hypothyroidism in patients susceptible to the inhibitory effects of a high iodine load (Wolff-Chaikoff effect) (Option A) Thyrotoxicosis that may be caused by either a Jod-Basedow effect (Option B) from the iodine load, in the setting of MNG or incipient Graves' disease (Type 1 Amiodarone-induced Thyrotoxicosis (AIT)) , or a thyroiditis-like condition due to a toxic effect on thyroid follicular cells (Option C) (Type 2 Amiodarone-induced Thyrotoxicosis (AIT)). Painless autoimmune (Hashimoto-type) thyroiditis is an autoimmune thyroid disease and is not caused by amiodarone. Typically, patients have a brief phase of thyrotoxicosis lasting 2-4 weeks, followed by hypothyroidism for 4-12 weeks, and then resolution; often, however, only one phase is apparent The condition can occur in up to 5% of women 3-6 months after pregnancy and is then termed postpartum thyroiditis , and is usually associated with the presence of TPO antibodies in antepartum.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3039, 3040.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q36: A 61-year-old man with long-standing multinodular goitre has been on amiodarone for ventricular arrhythmia for the past 9 months. He presents with palpitations, weight loss and tremors. Thyroid function tests show suppressed TSH with elevated free T4 and T3. Colour Doppler ultrasound of the thyroid shows markedly increased vascularity. Which of the following statements is correct regarding his condition? (Q884020)

A. Thyrotoxicosis is due to drug-induced lysosomal destruction of thyroid follicles

B. Radioiodine uptake is typically very low due to follicular cell destruction

C. It results from iodine-induced autonomous hormone synthesis

D. First-line therapy is systemic glucocorticoids

Correct Answer: C. It results from iodine-induced autonomous hormone synthesis

Explanation: Type-1 Amiodarone-Induced Thyrotoxicosis (Type-1 AIT) occurs in patients with pre-existing thyroid disease such as multinodular goitre or latent Graves disease. The massive iodine load from amiodarone triggers the Jod-Basedow phenomenon , leading to excess autonomous thyroid hormone synthesis. It shows increased thyroid vascularity on colour Doppler. Feature Type-1 AIT Type-2 AIT Underlying thyroid disease Present Absent Mechanism Jod-Basedow hormone overproduction Lysosomal follicular destruction (Option A) Doppler flow Increased Decreased Primary treatment Thionamides ± perchlorate Glucocorticoids (Option D) Natural course Persistent May resolve spontaneously Low radioiodine uptake (Option B): Seen in Type-2 AIT because hormone excess is due to follicular destruction, not increased synthesis.

Q31 (p. 1628)	*Q32 (p. 1629)*				

Q1: A 64 y/o man presents with 1 week of confusion, lethargy, constipation, and polydipsia. He also has unintentional weight loss. Examination shows cachexia. Laboratory investigations: Serum calcium: 16.8 mg/dL, Serum albumin: 3.8 g/dL, Serum phosphorus: 2.1 mg/dL If this patient had metabolic alkalosis and a history of consuming large quantities of over-the-counter heartburn relief tablets, which of the following would be the most likely diagnosis? (Q890423)

A. Primary hyperparathyroidism

B. Familial hypocalciuric hypercalcemia

C. Milk-alkali syndrome

D. Vitamin D intoxication

Correct Answer: C. Milk-alkali syndrome

Explanation: This patient has severe hypercalcemia with hypophosphatemia and metabolic alkalosis , along with a history of consuming large amounts of over-the-counter heartburn tablets (typically calcium carbonate). This is suggestive of milk-alkali syndrome. Milk-alkali syndrome (also known as calcium-alkali syndrome) is caused by the ingestion of large amounts of calcium and absorbable alkali (like calcium carbonate). Classic triad: Hypercalcemia Metabolic alkalosis Acute kidney injury Now, a common cause of hypercalcemic crisis is widespread OTC calcium use Hypercalcemic crisis is defined as severe hypercalcemia (usually >14 mg/dL) with neurologic dysfunction, dehydration, and acute kidney injury The major causes (from Harrison) include: Malignancy-associated hypercalcemia (PTHrP, osteolytic metastases) Primary hyperparathyroidism Milk-alkali syndrome Vitamin D-mediated causes (intoxication, granulomatous disease) High bone turnover states (immobilisation) Primary hyperparathyroidism (Option A): Causes hypercalcemia via ↑ PTH → bone resorption

& renal Ca reabsorption. Familial hypocalciuric hypercalcemia (Option B): Due to a CaSR mutation, produces mild, lifelong, asymptomatic hypercalcemia. Vitamin D intoxication (Option D) : Causes hypercalcemia via ↑ intestinal Ca absorption. Typically associated with hyperphosphatemia.

Harrison's Principles of Internal Medicine, 22nd Edition, Pages 3282, 3283.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: Which of the following interventions is the initial therapy for a patient with severe, acute symptomatic hypocalcemia with tetany, laryngeal spasm, and seizures? (Q890445)

A. Oral calcium carbonate

B. Intravenous calcium infusion

C. Subcutaneous teriparatide

D. Intravenous bisphosphonates

Correct Answer: B. Intravenous calcium infusion

Explanation: Severe, symptomatic hypocalcemia is a medical emergency requiring rapid restoration of serum calcium. IV calcium (calcium gluconate preferred): Provides immediate calcium availability Rapidly reverses neuromuscular irritability Stabilises cardiac and neuronal membranes Indications for IV calcium: Tetany Laryngospasm Seizures Prolonged QT interval Typical approach: Bolus followed by continuous infusion Cardiac monitoring recommended Complete treatment framework for hypocalcemia: Acute symptomatic → IV calcium gluconate Chronic or mild → Oral calcium supplementation Hypoparathyroidism → Oral calcium + calcitriol Vitamin D deficiency → Vitamin D replacement Refractory hypocalcemia → Always correct hypomagnesemia Goal of therapy: Relieve symptoms Maintain calcium in the low-normal range Avoid hypercalciuria Oral calcium carbonate (Option A): Too slow for acute, life-threatening symptoms. Subcutaneous Teriparatide (Option C) : Used in chronic hypoparathyroidism, not emergency rescue. Intravenous Bisphosphonates (Option D) : Lower calcium and worsen hypocalcemia.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3279.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A physician taps the patient's face just anterior to the ear lobe, below the zygomatic arch. This produces the following characteristic finding. This physical sign is associated with which of the following electrolyte abnormalities? (Q890444)

A. Hypercalcemia

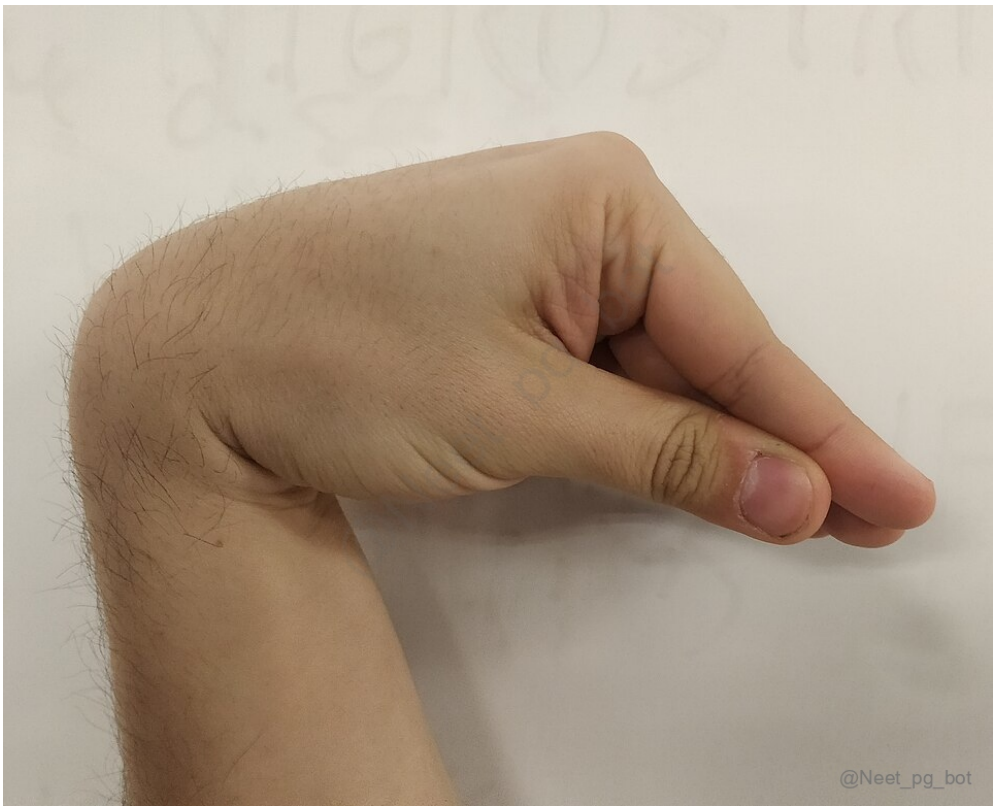
B. Hypocalcemia

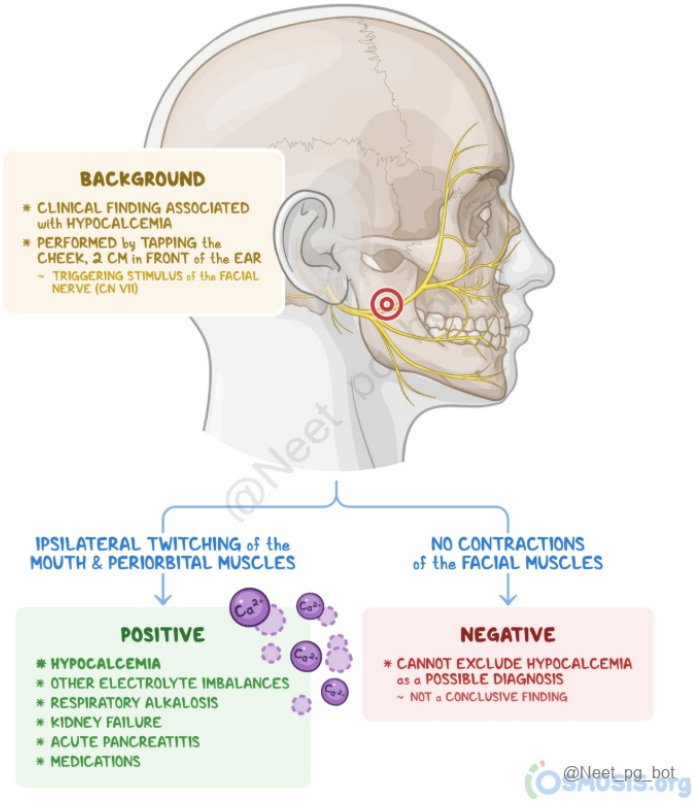
C. Hypermagnesemia

D. Hypokalemia

Correct Answer: B. Hypocalcemia

Explanation: Tapping the face just anterior to the ear lobe below the zygomatic arch producing facial muscle twitching is Chvostek sign. This occurs due to increased neuromuscular excitability from low serum calcium levels, commonly seen in hypocalcemia (e.g., hypoparathyroidism). Hypocalcemia increases neuromuscular excitability, leading to facial muscle twitching when the facial nerve is stimulated (Chvostek sign) Chvostek sign: Elicited by tapping the facial nerve Indicates latent tetany Classic bedside sign of chronic hypocalcemia Pathophysiology: Low extracellular calcium lowers the threshold for neuronal depolarisation Results in involuntary muscle contractions Key signs & symptoms of hypocalcemia: Chvostek sign Trousseau sign Tetany and carpopedal spasm Perioral numbness and tingling Seizures in severe cases ECG: prolonged QT interval Hypercalcemia (Option A): Decreases neuromuscular excitability → weakness, not twitching. Hypermagnesemia (Option C) : Causes neuromuscular blockade and hyporeflexia. Hypokalemia (Option D) : Causes muscle weakness and U waves on ECG.





References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3286.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: Which of the following ECG changes is characteristically associated with significant hypocalcemia? (Q890443)

A. Shortened QT interval

B. Prolonged QT interval

C. Prominent U waves

D. Peaked T waves

Correct Answer: B. Prolonged QT interval

Explanation: Hypocalcemia prolongs ventricular repolarisation, leading to ST-segment lengthening and a prolonged QT interval on ECG Pathophysiologic basis: Low serum calcium delays calcium-dependent phase 2 of the cardiac action potential Results in prolonged myocardial repolarisation ECG hallmark of hypocalcemia: Prolonged QT interval Opposite finding in hypercalcemia → shortened QT (Option A) Clinical features of hypocalcemia: Perioral numbness, tingling Tetany, carpopedal spasm Chvostek and Trousseau signs Seizures and arrhythmias in severe cases Common causes of hypocalcemia: Vitamin D deficiency (most common) Hypoparathyroidism Pseudohypoparathyroidism Chronic kidney disease Acute pancreatitis Hungry bone syndrome Prominent U waves (Option C): Prominent U waves are seen in hypokalemia. Peaked T waves (Option D) : Peaked T waves are characteristic of hyperkalemia.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Pages 3285, 3286.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: Which of the following is characteristic of a patient diagnosed with pseudopseudohypoparathyroidism (PPHP)? (Q890442)

A. Hypocalcemia, hyperphosphatemia, elevated PTH

B. Hypocalcemia, hypophosphatemia, elevated PTH

C. Hypercalcemia, hypophosphatemia, suppressed PTH

D. Normal calcium, normal phosphate, normal PTH

Correct Answer: D. Normal calcium, normal phosphate, normal PTH

Explanation: Pseudopseudohypoparathyroidism (PPHP) is defined by: Physical features of Albright hereditary osteodystrophy (AHO) Absence of parathyroid hormone resistance Biochemical hallmark of PPHP: Normal serum calcium (Option A, B, and C ruled out) Normal serum phosphate Normal PTH levels Pathophysiologic basis: Caused by paternal inheritance of a GNAS mutation PTH signalling in the kidney and bone is intact Therefore, no hypocalcemia or hyperphosphatemia Key contrast (high-yield): Maternal GNAS mutation → pseudohypoparathyroidism (PTH resistance) Paternal GNAS mutation → pseudopseudohypoparathyroidism (no resistance) Disorder AHO Ca PO■ PTH GNAS Inheritance PHP 1A Yes ↓ ↑ ↑ Maternal PHP 1B No ↓ ↑ ↑ Imprinting defect PHP 2 No ↓ ↑ ↑ Post-receptor PPHP Yes Normal Normal Normal Paternal PHP = Pseudohypoparathyroidism PPHP = Pseudopseudohypoparathyroidism

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Pages 3288-3290.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Which of the following disorders is characterised by hypocalcemia with hyperphosphatemia in the absence of renal failure? (Q890440)

A. Vitamin D deficiency

B. Pseudohypoparathyroidism

C. Hungry bone syndrome

D. Malabsorption syndrome

Correct Answer: B. Pseudohypoparathyroidism

Explanation: Hypocalcemia with hyperphosphatemia indicates absent or ineffective PTH action In the absence of renal failure, this biochemical pattern most strongly points to: Hypoparathyroidism Pseudohypoparathyroidism (PTH resistance) Pseudohypoparathyroidism (PHP): Characterised by end-organ resistance to PTH PTH levels are elevated, but the kidneys fail to respond Results in: ↓ Renal calcium reabsorption and ↓ 1,25-(OH)■D production → hypocalcemia ↓ Renal phosphate excretion → hyperphosphatemia Low calcium with high phosphate in the absence of renal failure almost invariably indicates hypoparathyroidism or PHP Key differential framework for hypocalcemia + hyperphosphatemia: Low PTH → hypoparathyroidism High PTH with resistance → pseudohypoparathyroidism Renal failure → phosphate retention. Vitamin D deficiency (Option A): Causes secondary hyperparathyroidism → phosphaturia, not hyperphosphatemia. Hungry bone syndrome (Option C): Causes hypocalcemia with low phosphate due to rapid skeletal uptake. Malabsorption syndrome (Option D) : Leads to vitamin D deficiency and secondary HPT → low/normal phosphate.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Pages 3290, 3291.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 68 y/o woman with chronic kidney disease presents with progressive confusion, lethargy, polyuria, and polydipsia. Examination shows severe dehydration. Laboratory results reveal: Serum calcium: 16.2 mg/dL, BUN: 52 mg/dL, Creatinine: 2.4 mg/dL. Which of the following is the most appropriate initial step in management? (Q890439)

A. Intravenous zoledronic acid

B. Intravenous hydration with normal saline

C. Intravenous furosemide

D. Subcutaneous calcitonin

Correct Answer: B. Intravenous hydration with normal saline

Explanation: This patient meets criteria for hypercalcemic crisis: Serum calcium >14 mg/dL Neurologic symptoms (confusion, obtundation) Acute kidney injury and profound dehydration The most appropriate initial step in management is IV hydration with normal saline Hypercalcemic crisis: Pathophysiologic basis of crisis: Hypercalcemia → nephrogenic diabetes insipidus Polyuria → volume depletion ↓ GFR → impaired renal calcium excretion → worsening hypercalcemia First and most critical step in management: Aggressive IV isotonic saline Restores intravascular volume Improves renal perfusion and GFR Enhances renal calcium clearance This step is mandatory regardless of aetiology (malignancy, PTH-mediated, vitamin D - mediated) Intravenous Zoledronic acid (Option A): Essential for malignancy-associated hypercalcemia, but onset is 24-48 hours. Intravenous furosemide (Option C): Only after adequate hydration; premature use worsens dehydration. Subcutaneous calcitonin (Option D) : Rapid but temporary effect; does not correct volume depletion.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3284, 3285.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following is the treatment of hypercalcemia caused by vitamin D intoxication, often leading to normalisation of serum calcium over several days? (Q890437)

A. Thiazide diuretics

B. Glucocorticoids

C. Lithium

D. Calcimimetics

Correct Answer: B. Glucocorticoids

Explanation: The treatment of hypercalcemia caused by vitamin D intoxication is with glucocorticoids. Vitamin D intoxication causes hypercalcemia primarily by: Increased intestinal calcium absorption Increased vitamin D - mediated bone resorption Glucocorticoids are specifically effective in this setting because they: Reduce intestinal calcium absorption Suppress vitamin D - dependent gene transcription Decrease in the conversion and action of active vitamin D metabolites Typical response: Serum calcium falls gradually over several days Commonly used agents include prednisone Core management principles for vitamin D - mediated hypercalcemia: Stop vitamin D and calcium intake IV isotonic saline for hydration Glucocorticoids as targeted therapy Bisphosphonates if hypercalcemia is severe or persistent Thiazide diuretics (Option A): Increase renal calcium reabsorption and worsen hypercalcemia. Lithium (Option C): Raises the PTH set-point and can cause hypercalcemia. Calcimimetics (Option D) : Used in PTH-mediated hypercalcemia, not vitamin D toxicity.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3281.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: The hand X-ray shown is most characteristic of which condition? (Q890435)

A. Rheumatoid arthritis

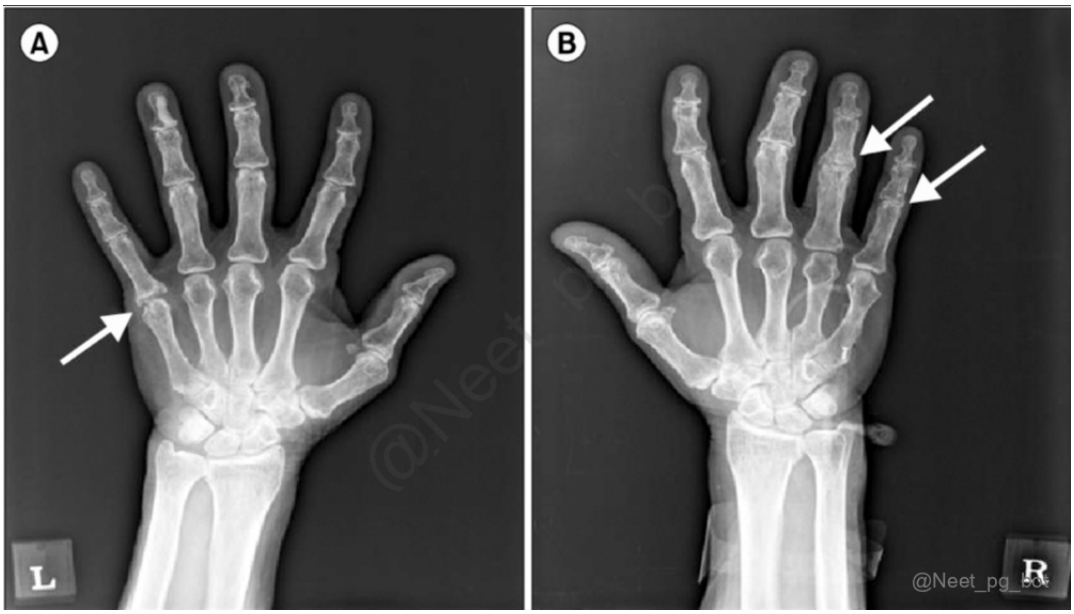
B. Acromegaly

C. Hyperparathyroidism

D. Osteoarthritis

Correct Answer: B. Acromegaly

Explanation: The image given shows widening, flattening, and tufting of distal phalanges referred to as "Spade phalanx sign". This is seen in Acromegaly. It results from: Chronic excess growth hormone (GH) GH → ↑ IGF-1 → periosteal bone formation This produces: Enlargement of terminal phalanges Characteristic spade-shaped appearance on X-ray It is a classic and high-yield radiologic feature of acromegaly Often associated with other imaging findings: Enlarged sella turcica Increased heel-pad thickness Rheumatoid arthritis (Option A): Causes marginal erosions and joint space narrowing. Hyperparathyroidism (Option C): Causes subperiosteal bone resorption, not widening. Osteoarthritis (Option D) : Shows osteophytes and cartilage loss, not tufting.



A
B

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2966.

↑ *Back to this question in Part A*

@Neet_pg_bot

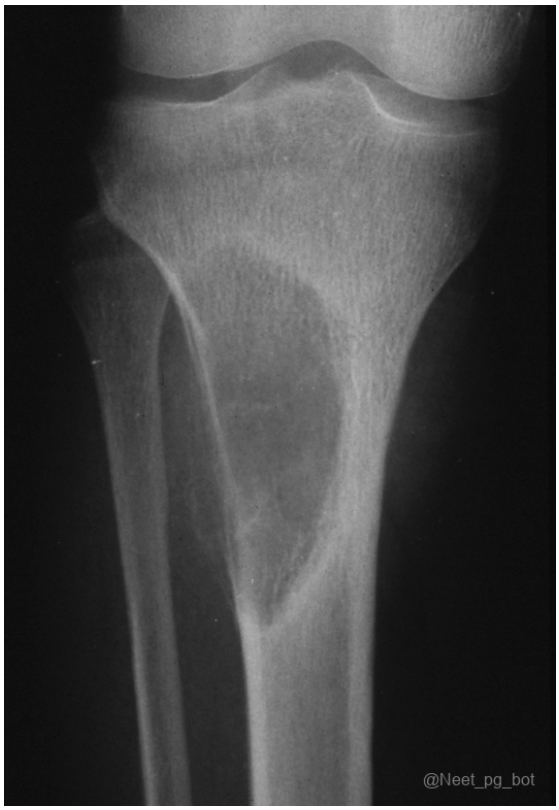
Q10: A 65 y/o man with untreated primary hyperparathyroidism presents with severe pain in his right thigh. An X-ray is as follows. Based on the described condition, which of the following histologic findings is most characteristic of this lesion? (Q890432)

A. Mosaic pattern of lamellar bone with cement lines

B. Replacement of marrow elements by fibrous tissue and giant multinucleated osteoclasts

C. Accumulation of unmineralized osteoid matrix

D. Malignant proliferation of plasma cells



Correct Answer: B. Replacement of marrow elements by fibrous tissue and giant multinucleated osteoclasts

Explanation: In severe, untreated primary hyperparathyroidism , patients can develop “brown tumours” of bone. These are focal lytic lesions caused by excessive osteoclastic activity and fibroblastic proliferation. Osteitis fibrosa cystica is the classic skeletal manifestation of chronic, severe hyperparathyroidism Radiological features: Well-defined lytic lesions (“brown tumours”) Subperiosteal bone resorption Salt-and-pepper skull (in advanced disease) Pathophysiology: Excess PTH → marked osteoclastic activation Bone resorption exceeds formation Histologic hallmark: Giant multinucleated osteoclasts in Howship’s lacunae Replacement of normal marrow by fibrovascular tissue Brown tumours are reactive, non-neoplastic lesions, despite their aggressive radiographic appearance Mosaic pattern of lamellar bone with cement lines (Option A): Mosaic cement lines are characteristic of Paget disease of bone. Accumulation of unmineralized osteoid matrix (Option C): Unmineralized osteoid defines osteomalacia. Malignant proliferation of plasma cells (Option D) : Plasma cell proliferation suggests multiple myeloma.

Harrison’s Principles of Internal Medicine, 22nd Edition, Pages 3277, 3278.

↑ *Back to this question in Part A*

@Neet_pg_bot

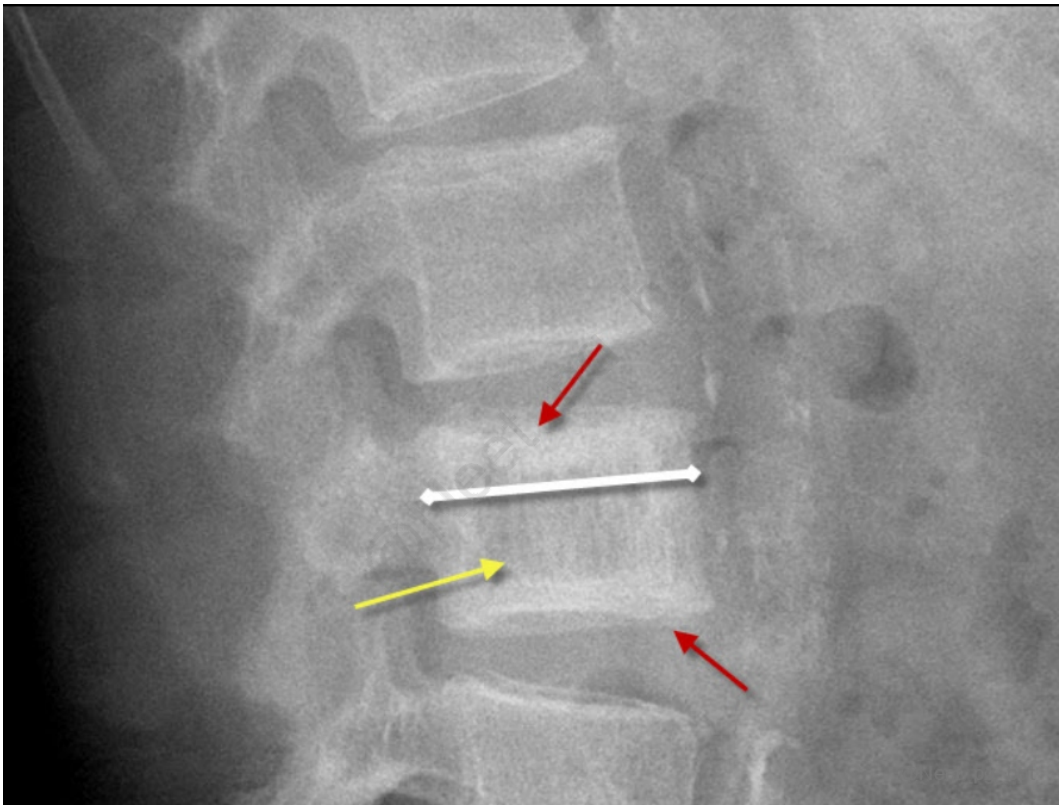
Q11: A patient presents with bone pain and an elevated alkaline phosphatase. A radiograph of the lumbar spine shows enlargement of a vertebral body with marked cortical thickening of the superior and inferior end plates, producing a "picture-frame" appearance. Which of the following is the most likely diagnosis? (Q890431)

A. Primary hyperparathyroidism

B. Paget's disease of bone

C. Fibrous dysplasia

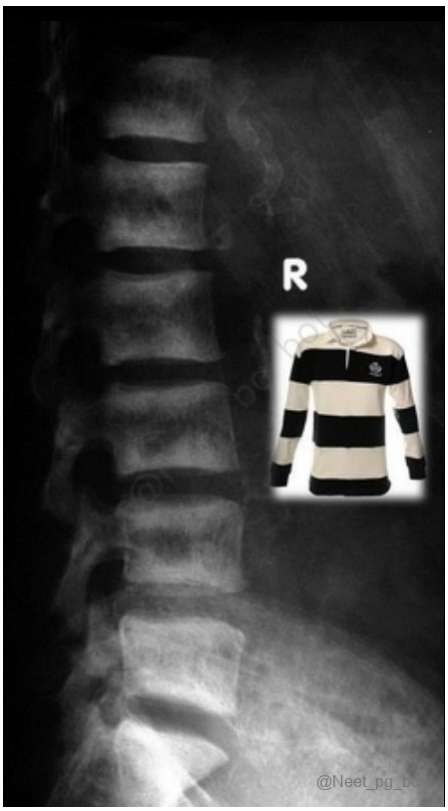
D. Osteomalacia



Correct Answer: B. Paget's disease of bone

Explanation: This patient presents with bone pain, elevated alkaline phosphatase , and radiographic changes of the spine showing an enlarged vertebral body with cortical thickening of the end plates , producing a "picture-frame" appearance . These findings are classic for Paget's disease of bone. Paget's disease of bone is characterised radiographically by: Cortical thickening and bony enlargement Sclerosis of vertebral margins Classic "picture-frame vertebra" This appearance must be distinguished from hyperparathyroidism-related spinal changes Rugger-jersey spine (hyperparathyroidism): Dense sclerosis of the superior and inferior vertebral endplates Relative central lucency Most commonly seen in secondary hyperparathyroidism due to chronic kidney disease Reflects high bone turnover from chronic PTH excess Key distinction: Paget's disease → enlarged vertebra +

picture-frame cortex Secondary HPT → band-like endplate sclerosis (rugger-jersey spine) Primary hyperparathyroidism (Option A): Causes osteopenia and subperiosteal bone resorption, not picture-frame sclerosis. Fibrous dysplasia (Option C): Produces expansile, radiolucent “ground-glass” lesions. Osteomalacia (Option D) : Shows osteopenia and Looser’s zones (pseudofractures).



References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Pages 3312-3314.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: In differentiating Familial Hypocalciuric Hypercalcemia (FHH) from primary hyperparathyroidism, which of the following urinary biochemical findings most strongly supports a diagnosis of FHH? (Q890430)

A. 24-hour urinary calcium >300 mg

B. Calcium-to-creatinine clearance ratio (CCCR) >0.02

C. Calcium-to-creatinine clearance ratio (CCCR) <0.01

D. Frank hematuria

Correct Answer: C. Calcium-to-creatinine clearance ratio (CCCR) <0.01

Explanation: The calcium-to-creatinine clearance ratio (CCCR) is the most useful test to differentiate FHH from primary hyperparathyroidism (PHPT). Primary hyperparathyroidism (PHPT) is most commonly caused by: Solitary parathyroid adenoma (~80-85%) Parathyroid hyperplasia (~10-15%) Parathyroid carcinoma (<1%) A critical cause mimicking PHPT is Familial Hypocalciuric Hypercalcemia (FHH), which must be excluded before surgery FHH pathophysiology: Inactivating mutation of the calcium-sensing receptor (CaSR) The kidney perceives serum calcium as low Results in increased renal calcium reabsorption Key distinguishing biochemical feature: Low urinary calcium excretion CCCR <0.01 → FHH CCCR >0.02 → Primary hyperparathyroidism This distinction is essential because, PHPT is surgical FHH is benign and managed conservatively 24-hour urinary calcium >300 mg (Option A): Hypercalciuria favours primary hyperparathyroidism, not FHH. Calcium-to-creatinine clearance ratio (CCCR) >0.02 (Option B): CCCR >0.02 is typical of PHPT Frank hematuria (Option D) : Hematuria is not a diagnostic biochemical discriminator.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Pages 3279, 3280.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following biochemical patterns is most characteristic of primary hyperparathyroidism? (Q890429)

A. Low calcium, high phosphate, high PTH

B. High calcium, low phosphate, high PTH

C. High calcium, high phosphate, low PTH

D. Low calcium, low phosphate, low PTH

Correct Answer: B. High calcium, low phosphate, high PTH

Explanation: Primary hyperparathyroidism results from autonomous secretion of parathyroid hormone (PTH), most commonly due to a parathyroid adenoma Key biochemical effects of excess PTH: ↑ Serum calcium (Option A and D ruled out) Increased bone resorption Increased renal tubular calcium reabsorption ↓ Serum phosphate: PTH inhibits proximal tubular phosphate reabsorption → phosphaturia. (Option C ruled out) ↑ PTH levels despite hypercalcemia: Loss of normal calcium-mediated negative feedback. This biochemical triad (high Ca, low phosphate, high PTH) is the hallmark of primary hyperparathyroidism and distinguishes it from secondary and PTH-independent causes of hypercalcemia.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Pages 3275, 3276.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: Which of the following findings represents the most common underlying cause of primary hyperparathyroidism? (Q890428)

A. Parathyroid carcinoma

B. Diffuse hyperplasia of all four parathyroid glands

C. Solitary parathyroid adenoma

D. Multiple parathyroid adenomas

Correct Answer: C. Solitary parathyroid adenoma

Explanation: The most common cause of primary hyperparathyroidism is a solitary parathyroid adenoma , which autonomously secretes parathyroid hormone (PTH) , leading to hypercalcemia. Primary hyperparathyroidism results from autonomous overproduction of parathyroid hormone (PTH), leading to hypercalcemia The distribution of causes is: Solitary parathyroid adenoma → ~80-85% (most common) Parathyroid hyperplasia (all four glands) → ~10-15% Parathyroid carcinoma → <1% Solitary adenoma: Usually, a benign neoplasm of chief cells Produces unregulated PTH secretion Leads to classic biochemical findings: hypercalcemia, hypophosphatemia, increased bone resorption Parathyroid carcinoma (Option A): Hypercalcemia due to excess calcium intake + absorbable alkali, not bone turnover. Diffuse hyperplasia of all four parathyroid glands (Option B): Less common; classically associated with MEN 1. Multiple parathyroid adenomas (Option D) : Occur, but are far less frequent than a single adenoma.

Harrison’s Principles of Internal Medicine, 22nd Edition, Pages 3275, 3276.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: Which of the following conditions causes hypercalcemia primarily due to increased bone turnover, in which bone resorption exceeds bone formation? (Q890426)

A. Milk-alkali syndrome

B. Vitamin D intoxication

C. Hyperthyroidism

D. Sarcoidosis

Correct Answer: C. Hyperthyroidism

Explanation: Hypercalcemia results from increased calcium entry into the extracellular fluid, which can occur via: Increased bone resorption Increased intestinal calcium absorption Increased renal calcium reabsorption Hyperthyroidism causes hypercalcemia through: Thyroid hormone-mediated high bone turnover Bone resorption exceeds bone formation Occurs in up to 20% of hyperthyroid patients Resulting hypercalcemia is usually mild to moderate but reflects a bone-driven mechanism Common features of hypercalcemia across causes include: Neurologic: fatigue, lethargy, confusion Renal: polyuria, nephrogenic diabetes insipidus GI: constipation, nausea Musculoskeletal: proximal muscle weakness Cardiac: shortened QT interval Milk-alkali syndrome (Option A): Hypercalcemia due to excess calcium intake + absorbable alkali, not bone turnover. Vitamin D intoxication (Option B): Predominantly causes hypercalcemia via increased intestinal calcium absorption. Sarcoidosis (Option D) : Caused by unregulated extrarenal 1,25-(OH)■D production, increasing gut absorption.

Harrison’s Principles of Internal Medicine, 22nd Edition, Pages 3274, 3275.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: Which of the following gastrointestinal symptoms is most commonly associated with hypercalcemia? (Q890424)

A. Diarrhoea

B. Hyperactive bowel sounds

C. Constipation

D. Hematochezia

Correct Answer: C. Constipation

Explanation: The gastrointestinal symptom most commonly associated with hypercalcemia is constipation. Hypercalcemia causes depression of neuromuscular excitability by increasing the threshold for action potentials. This results in smooth muscle relaxation, particularly affecting the gastrointestinal tract System-wise clinical manifestations of hypercalcemia: System Clinical manifestation Gastrointestinal Constipation (most common) Anorexia Nausea and vomiting Abdominal pain Ileus in severe hypercalcemia Renal Polyuria and polydipsia Nephrogenic diabetes insipidus Dehydration → prerenal azotemia Nephrolithiasis Nephrocalcinosis (chronic cases) Neurologic / Psychiatric Fatigue Impaired concentration Confusion and lethargy Stupor and coma in severe

hypercalcemia Depression, apathy (“psychiatric overtones ”) Musculoskeletal Proximal muscle weakness Bone pain (if due to malignancy or hyperparathyroidism) Cardiovascular Shortened QT interval Arrhythmias in severe cases These findings are classically remembered as “stones, bones, groans, thrones, and psychiatric overtones.” Diarrhoea (Option A) and Hyperactive bowel sounds (Option B): Hypercalcemia causes decreased GI motility, not diarrhoea or hyperactive bowel sounds Hematochezia (Option D) : Hematochezia is unrelated to calcium homeostasis

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Pages 3274, 3275.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 65-year-old patient presents with constipation, abdominal pain, nausea, vomiting, confusion, and bone pain. Laboratory tests reveal elevated calcium levels. Considering the role of the calcium-sensing receptor (CaSR) in calcium homeostasis, which of the following is regulated by CaSR? (Q850696)

A. PTH

B. FGF-23

C. Vitamin D3

D. Calcitonin

Correct Answer: A. PTH

Explanation: The parathyroid glands, located behind the thyroid, consist of four small glands that produce parathyroid hormone (PTH) , an 84-amino acid peptide. The calcium-sensing receptor (CaSR), a G-protein-coupled receptor (GPCR) regulates PTH secretion, which responds to changes in serum calcium levels. FGF-23 (Fibroblast growth factor 23) (Option B) is a phosphaturic hormone that suppresses parathyroid hormone (PTH). It regulates calcium and phosphate metabolism by reducing phosphate levels and increasing calcium levels in the blood, which can lead to nephrolithiasis. Vitamin D3 (Option C) promotes calcium absorption, bone mineralisation and tissue differentiation. Deficiency of this vitamin leads to hypocalcemia, rickets, and osteomalacia , while its excess can result in hypercalcemia. Calcitonin (Option D) is a peptide hormone secreted by the parafollicular C cells of the thyroid gland. It is a tumour marker in medullary thyroid carcinoma and can be used therapeutically for conditions such as osteoporosis and Paget’s disease of bone.

@Neet_pg_bot

Q18: A 28-year-old woman presents with complaints of irregular menstrual cycles and infertility & reports increased headaches and visual changes over the past few months. An MRI reveals a large pituitary tumor. Family history is significant for several relatives with breast and thyroid cancers. Which syndrome is most likely associated with her condition? (Q850741)

A. McCune-Albright Syndrome

B. Von Hippel-Lindau (VHL) Disease

C. Cowden Syndrome

D. Carney Complex

Correct Answer: C. Cowden Syndrome

Explanation: The most likely diagnosis is Cowden Syndrome, characterized by a family history of breast and thyroid cancers and pituitary tumors. The patient's symptoms of irregular menstrual cycles, infertility, and the pituitary tumor on MRI are consistent with this syndrome. Cowden Syndrome: Cause: PTEN mutation (chr 10q23.31) Features: Multiple hamartomas (skin, mucosa, organs), ↑ risk of thyroid, breast, pituitary tumors Endocrine: Prolactin-secreting pituitary adenomas → irregular menses, infertility; requires monitoring McCune-Albright Syndrome (MAS) (Option A): GNAS1 mutation; polyostotic fibrous dysplasia, café-au-lait spots, precocious puberty Von Hippel-Lindau (VHL) Disease (Option B): VHL mutation (chr 3); hemangioblastomas, organ cysts, RCC, pheochromocytoma, possible pituitary tumors Carney Complex (CNC) (Option D): PRKAR1A mutation (chr 17q); myxomas, spotty pigmentation, endocrine tumors including GH-secreting pituitary adenomas → acromegaly

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Page 2990, 2991, 2992

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: 40-year-old man presents with salt wasting, salt craving and postural hypotension. He has a family history of autoimmune disorders. Laboratory tests reveal elevated blood glucose levels and positive autoantibodies. Autoimmune

Polyendocrine Syndrome is suspected. Which of the following statements regarding the diagnosis is not true? (Q850736)

A. Associated with Addison disease

B. Associated with Autoimmune thyroiditis

C. Associated with Celiac disease

D. Associated with Hypoparathyroidism

Correct Answer: D. Associated with Hypoparathyroidism

Explanation: Presentation of diabetes mellitus and autoimmunity in a 40-year-old man is suggestive of Autoimmune polyendocrine syndrome type 2 . Hypoparathyroidism is a part of APS type 1. APS is a group of disorders characterized by the simultaneous occurrence of multiple autoimmune conditions affecting the endocrine system, which are also associated with non-endocrine conditions. Addison's disease (Option A), Autoimmune thyroiditis (Option B), and Celiac disease (Option C) are all associated with APS type 2

References:

Harrison’s principle of internal medicine, 22nd edition, Page 3089

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A 35-year-old man presents with recurrent kidney stones, abdominal pain, and peptic ulcers. His blood pressure is elevated, and he has a family history of thyroid carcinoma. Laboratory tests reveal high serum calcium and parathyroid hormone levels. What is the most likely diagnosis? (Q850735)

A. MEN Type 1

B. MEN Type 4

C. MEN Type 2B

D. MEN Type 2A

Correct Answer: D. MEN Type 2A

Explanation: This patient features points toward multiple endocrine neoplasia type 2A (MEN2A) . Primary hyperparathyroidism → causes kidney stones and elevated calcium. Pheochromocytoma → explains hypertension . Medullary thyroid carcinoma → suggested by family history of thyroid cancer . MEN Type 1 (Option A)

involves the “3 Ps”: parathyroid, pancreatic endocrine tumors, and pituitary tumors , typically not associated with medullary thyroid carcinoma. MEN Type 4 (Option B) is rare, caused by CDKN1B mutations , and resembles MEN1 but usually without thyroid carcinoma. MEN Type 2B (Option C) Features medullary thyroid carcinoma, pheochromocytoma, mucosal neuromas, and Marfanoid habitus . Kidney stones and parathyroid hyperplasia are uncommon.

References:

Harrison’s principle of internal medicine, 21st edition, Page 2983 - 2990 Davidson’s Principles and Practice of Medicine, 24th Edition, Page 868, 869

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 3-year-old boy with growth delays and leg bowing has not improved after six months of vitamin D treatment. Labs show low calcium, low phosphate, and elevated alkaline phosphatase. Genetic testing indicates a Vitamin D gene mutation. What is the best management option? (Q850733)

A. Increase in vitamin D dosage

B. Initiate phosphate supplementation

C. Administer Calcium

D. Administer Calcitriol

Correct Answer: D. Administer Calcitriol

Explanation: The gene mutation of 25-hydroxyvitamin D 1α-hydroxylase (CYP27B1) enzyme, which helps in the conversion of inactive metabolites of Vitamin D to the active form (1,25 (OH) Vit D3), is called Type 1 Vitamin D dependent Rickets , and it is treated with supplementing the active form, Calcitriol. If rickets is resistant to treatment with vitamin D supplementation, it is most likely due to either type 1 or type 2 vitamin D-dependent rickets or hypophosphatemic rickets. An increase in vitamin D dosage (Option A) wouldn't help due to a defect in the enzyme needed to convert vitamin D into its active form in this type of rickets; therefore, it is managed by administering the active form directly. Initiate phosphate supplementation (Option B) alone does not correct the underlying defect. Administer Calcium (Option C) may help transiently but will not address the vitamin D activation deficiency.

References:

Harrison’s principle of internal medicine, 21st edition, Page 3168 Davidson’s Principles and Practice of Medicine, 24th Edition, Page 1052, 1053

↑ *Back to this question in Part A*

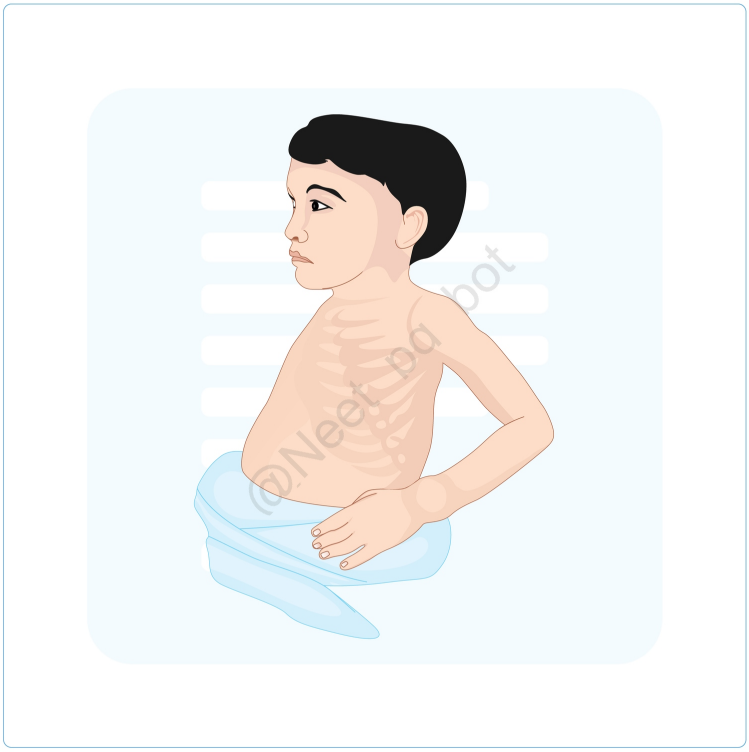
Q22: A 6-year-old boy presents with a history of recurrent fractures and pain in his lower limbs.He has a history of poor dietary intake, particularly low dairy consumption. Clinical examination leads to the findings similar to the images given below. Based on these observations, which of the following lab findings would be most consistent with his condition? (Q850731)

A. Low Parathyroid hormone, High Calcium

B. Low Calcium, High Phosphate

C. High Calcium, Low Phosphate

D. High Parathyroid hormone, Low Calcium



@Neet_pg_bot

Correct Answer: D. High Parathyroid hormone, Low Calcium

Explanation: The child appears to have nutritional rickets , which commonly results from vitamin D deficiency. This leads to secondary hyperparathyroidism (high PTH) . This condition is associated with low calcium and low phosphate levels (due to increased renal excretion), causing defective mineralisation of the bone matrix at the growth plate in children before the fusion of epiphysis. Low Parathyroid hormone, High Calcium (Option A) is not consistent, as PTH would rise in low calcium states. Low Calcium, High Phosphate (Option B) is seen in hypoparathyroidism, not nutritional rickets. High Calcium, Low Phosphate (Option C) occurs in primary hyperparathyroidism, not in dietary deficiency-induced rickets.

References:

Harrison’s principle of internal medicine, 21st edition, Page 3168 Davidson’s Principles and Practice of Medicine, 24th Edition, Page 1051, 1052

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A 65-year-old woman with a history of chronic kidney disease secondary to hypertension presents with symptoms of nausea, vomiting, and confusion. On Investigating her Lab values are Serum calcium: 12.0 mg/dL (normal range: 8.5-10.5 mg/dL) Serum phosphate: 4.9 mg/dL (normal range: 2.5-4.5 mg/dL) Serum PTH: 200

pg/mL (normal range: 10-65 pg/mL) Which of the following is the most likely diagnosis of this patient? (Q850729)

A. Primary Hyperparathyroidism

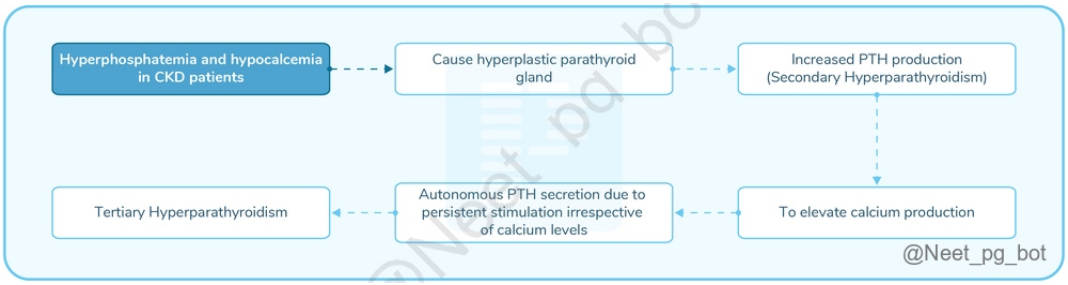
B. Secondary Hyperparathyroidism

C. Pseudohypoparathyroidism

D. Tertiary Hyperparathyroidism

Correct Answer: D. Tertiary Hyperparathyroidism

Explanation: Tertiary hyperparathyroidism occurs in chronic kidney disease after prolonged secondary hyperparathyroidism, leading to autonomous PTH secretion and hypercalcemia despite persistent kidney disease. {{caption_text}} Primary Hyperparathyroidism (Option A) usually presents with elevated calcium and PTH but without underlying CKD. Secondary Hyperparathyroidism (Option B) presents with low or normal calcium and high PTH due to CKD, not hypercalcemia. Pseudohypoparathyroidism (Option C) presents with hypocalcemia and elevated PTH due to target organ resistance, not hypercalcemia.



References:

Harrison’s principle of internal medicine, 21st edition, Page 3188. Davidson’s Principles and Practice of Medicine, 24th Edition, Page 663, 664.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: An 8-year-old boy presents with characteristic skeletal and developmental defects, such as short stature and shortened 4th and 5th metacarpals. Laboratory findings show elevated PTH levels, hypocalcemia, and hyperphosphatemia. Genetic testing reveals a deficiency in the Gsα subunit. Based on these findings, what is the most likely diagnosis? (Q850727)

A. Pseudopseudohypoparathyroidism (PPHP)

B. Pseudohypoparathyroidism type 1a (PHP1A)

C. Pseudohypoparathyroidism type 1b (PHP1B)

D. Hypoparathyroidism

Correct Answer: B. Pseudohypoparathyroidism type 1a (PHP1A)

Explanation: PHP1A : Albright hereditary osteodystrophy (AHO): short stature, shortened 4th/5th metacarpals Biochemistry: ↑ PTH, ↓ calcium, ↑ phosphate Mechanism: Renal resistance to PTH due to defective Gsα subunit This combination is classic for PHP1A . Pseudopseudohypoparathyroidism (PPHP) (Option A) shows skeletal features but normal calcium, phosphate, and PTH levels. Pseudohypoparathyroidism type 1b (PHP1B) (Option C) lacks skeletal deformities but has renal PTH resistance. Hypoparathyroidism (Option D) presents with low PTH, hypocalcemia, and hyperphosphatemia but no skeletal defects.

References:

Harrison’s principle of internal medicine, 21st edition, Page 3188

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: A 45-year-old adult patient presents with symptoms of chronic hypocalcemia. Which of the following features is associated with this condition? (Q850723)

A. Extrapyramidal symptoms like dystonia

B. Tissue deposition of calcium due to hyperphosphatemia

C. Skin infections such as candidiasis

D. All of the above

Correct Answer: D. All of the above

Explanation: Chronic hypocalcemia, especially due to hypoparathyroidism, leads to basal ganglia calcification causing extrapyramidal symptoms, soft tissue calcium deposition due to hyperphosphatemia, and chronic mucocutaneous candidiasis due to immune dysfunction. Chronic Hypocalcemia In chronic hypocalcemia, often associated with conditions like chronic kidney disease, hyperphosphatemia (Option B) can lead to ectopic calcifications in tissues. Extrapyramidal symptoms like dystonia (Option A) occurs due to basal ganglia calcifications Ocular cataract Abnormal dentition Autoimmune polyglandular syndrome Cutaneous candidiasis (Option C) Salt wasting Postural hypotension

References:

Harrison’s principle of internal medicine, 21st edition, Page 3186-3187

↑ *Back to this question in Part A*

@Neet_pg_bot

Q26: A 65-year-old woman with primary hyperparathyroidism presents with nausea, vomiting, confusion, and dehydration. She shows signs of hypovolemia and altered mental status. Labs reveal high serum calcium, low phosphate, and elevated PTH. What is the first line of treatment? (Q850720)

A. Intravenous Bisphosphonates

B. Aggressive hydration with normal saline

C. Peritoneal dialysis

D. Calcitonin nasal spray

Correct Answer: B. Aggressive hydration with normal saline

Explanation: The first-line treatment for severe hypercalcemia in primary hyperparathyroidism is aggressive intravenous hydration with normal saline to correct hypovolemia and promote renal calcium excretion. Intravenous bisphosphonates (Option A) are used after hydration to inhibit bone resorption. Peritoneal dialysis (Option C) is reserved for refractory hypercalcemia with renal failure. Calcitonin nasal spray (Option D) has a rapid but short-lived effect and is not first-line therapy.

References:

Harrison’s principle of internal medicine, 21st edition, Page 3182-3183

↑ *Back to this question in Part A*

@Neet_pg_bot

Q27: A 52-year-old man diagnosed with hypoparathyroidism six months ago after neck surgery presents with tingling in his hands and feet, muscle cramps, and fatigue. His lab results indicate low serum calcium, elevated phosphate, and severely low parathyroid hormone (PTH) levels. What is the most appropriate treatment for his condition? (Q850717)

A. Initiate intravenous calcium gluconate therapy

B. Administration of Alendronate

C. Administration of Teriparatide

D. Start oral calcium and Vitamin D supplement

Correct Answer: C. Administration of Teriparatide

Explanation: Teriparatide, a recombinant PTH analog, is the most appropriate treatment for chronic hypoparathyroidism when calcium and Vitamin D supplements fail to maintain normal calcium levels. It helps restore calcium-phosphate balance and mimics natural PTH action. Initiate intravenous calcium gluconate (Option A) is used for acute, symptomatic hypocalcemia. Administration of Alendronate (Option B) is used for osteoporosis, not hypoparathyroidism. Start oral calcium and Vitamin D supplement (Option D) is the initial therapy but may not suffice in refractory cases.

References:

Harrison’s principle of internal medicine, 21st edition, Page 3187

↑ *Back to this question in Part A*

@Neet_pg_bot

Q28: A 45-year-old woman undergoes total thyroidectomy for a large goiter. Two days post-surgery, investigations reveal low serum calcium and low parathyroid hormone (PTH) levels. During clinical examination, the following observation is made. What is this sign known as ? (Q850712)

A. Trousseau sign

B. Chvostek sign

C. Hoffman's sign

D. Brudzinski's sign

Correct Answer: B. Chvostek sign

Explanation: Chvostek's sign is a clinical sign of hypocalcemia, where tapping over the facial nerve (at the parotid gland) causes twitching of the facial muscles. This occurs due to the increased neuromuscular excitability caused by l ow calcium levels , commonly seen in hypoparathyroidism. Trousseau sign (Option A) is carpopedal spasm induced by inflating a BP cuff in hypocalcemia. Hoffman's sign (Option C) indicates corticospinal tract lesion, not hypocalcemia. Brudzinski's sign (Option D) is seen in meningitis, not in postoperative hypocalcemia.

References:

Harrison's principle of internal medicine, 21st edition, Page 358, 3185-3186

↑ *Back to this question in Part A*

@Neet_pg_bot

Q29: A 45-year-old woman presents to the emergency department with muscle cramps, tingling in her fingers, and a tight sensation around her mouth. She has a history of thyroid surgery for papillary carcinoma. Examination revealed increased neuromuscular excitability. Lab results show low PTH, low calcium, and elevated phosphate levels. Which syndrome is most likely associated with this presentation? (Q850707)

A. Cushing’s syndrome

B. McCune-Albright Syndrome

C. Turner syndrome

D. DiGeorge syndrome

Correct Answer: D. DiGeorge syndrome

Explanation: The condition described, characterized by neuromuscular excitability, low calcium, low PTH, and elevated phosphate levels, is diagnosed as Hypoparathyroidism , which can be associated with DiGeorge syndrome . DiGeorge Syndrome : Failure of development of the 3rd and 4th pharyngeal pouches Features - CATTCH-22 Deletion of chromosome 22q11 C ongenital heart disease A bnormal facial features - Low set ears and hypertelorism T hymus gland abnormalities or absence and T racheo-esopahgeal fistulas C left platelet/lip H ypoparathyroidism and H ypocalcemia Cushing’s syndrome (Option A) is characterised by excess cortisol, which leads to symptoms such as weight gain (moon facies), tiredness, muscle weakness, hypertension, mood swings, hirsutism, osteoporosis, and elevated blood sugar. It is not associated with hypocalcemia, low PTH, or neuromuscular excitability. McCune-Albright Syndrome (Option B) is a genetic disorder caused by an active mutation in a G protein (mosaic pattern). It involves bone abnormalities (fibrous dysplasia), skin pigmentation, and endocrine issues (e.g., precocious puberty). It does not typically affect the parathyroid glands or cause hypocalcemia. Turner syndrome (Option C) is a genetic disorder affecting females, characterised by a 45XO karyotype. It presents with short stature, a fish-like mouth, a high-arched palate, a webbed neck, a broad chest, and underdeveloped ovaries, leading to primary amenorrhea and infertility . It is not associated with parathyroid dysfunction or abnormal calcium and phosphate levels.

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Volume I, Page 358, 3187, Davidson’s Principles and Practice of Medicine, 24th Edition, Page 664.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q30: A 58-year-old man with chronic kidney disease (CKD) returns for a follow-up, reporting fatigue, bone pain, and muscle weakness. Examination reveals bone tenderness, and lab tests show elevated parathyroid hormone (PTH) levels. Which of the following findings is not typically associated with this condition? (Q850704)

A. Elevated serum calcium levels

B. Raised serum alkaline phosphatase levels

C. Elevated serum phosphate levels

D. Raised urinary albumin creatinine ratio

Correct Answer: A. Elevated serum calcium levels

Explanation: The patient has secondary hyperparathyroidism due to CKD . In CKD, the kidneys fail to excrete phosphate and cannot activate vitamin D adequately. This leads to: Hyperphosphatemia → phosphate binds calcium → ↓ serum calcium Reduced 1,25-(OH)■ vitamin D → ↓ intestinal calcium absorption Hypocalcemia → stimulates ↑ PTH (secondary hyperparathyroidism) High PTH → increased bone turnover → bone pain, tenderness, ↑ alkaline phosphatase Therefore, Serum calcium is low , not high. Raised serum alkaline phosphatase (Option B): Seen due to high bone turnover from elevated PTH → typical in secondary hyperparathyroidism. Elevated serum phosphate (Option C): CKD reduces phosphate excretion → hyperphosphatemia is expected. Raised urinary albumin creatinine ratio (Option D): Reflects ongoing kidney damage and is commonly elevated in CKD.

References:

Harrison's Principles of Internal Medicine, 21st Edition, Volume I, Page 2313, 2314,

Davidson's Principles and Practice of Medicine, 24th Edition, Page 663.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q31: A 39-year-old woman presents with persistent constipation, abdominal pain, and intermittent lower back pain. She has a history of recurrent kidney stones and reports fatigue. Lab tests reveal elevated calcium and decreased phosphate levels. She has been advised to undergo a sestamibi Tc-99 scan. Which of the following is not an indication for surgery in this condition? (Q850700)

A. Nephrolithiasis

B. Renal impairment

C. Age >50 years

D. Osteoporosis

Correct Answer: C. Age >50 years

Explanation: The given scenario indicates Primary Hyperparathyroidism , where the treatment of choice is surgical excision of the tumor . Age <50 years is an indication for surgery. The treatment of choice for parathyroid adenoma is surgical excision. Indications for surgery: Age <50 years Nephrolithiasis (Option A) confirmed by imaging Elevated serum calcium level (documented) Osteoporosis (Option D) confirmed by DEXA scan (T-score < -2.5 S.D.) Renal impairment (Option B) (creatinine clearance <60 ml/min) Elevated urinary calcium levels (24 hours) Vertebral fracture confirmed by imaging

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Volume I, Page 31776-3178. Davidson’s Principles and Practice of Medicine, 24th Edition, Page 663, 664.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q32: A 60-year-old female presents with complaints of abdominal pain, constipation, and recent episodes of confusion and depression. Laboratory tests reveal elevated serum calcium and alkaline phosphatase (SAP) levels and decreased phosphate levels. Which of the following clinical features is not typically associated with this condition? (Q850698)

A. Recurrent nephrolithiasis

B. Osteitis fibrosa cystica

C. Tetany

D. Urinary tract infection

Correct Answer: C. Tetany

Explanation: The scenario of constipation, abdominal pain, elevated calcium levels, increased bone turnover (indicated by elevated alkaline phosphatase), and decreased phosphate levels suggests Primary Hyperparathyroidism , where tetany is not observed; instead, it is typically seen in hypoparathyroidism. Tetany is characterized by muscle spasms resulting from increased excitability of peripheral nerves due to serum calcium levels falling below 7 mg/dl, as seen in hypoparathyroidism. Recurrent nephrolithiasis (Option A) is common due to hypercalciuria. Osteitis fibrosa cystica (Option B) is a classic skeletal manifestation of hyperparathyroidism. Urinary tract infection (Option D) can occur secondary to nephrolithiasis and urinary stasis.

Q1: Which of the following is the sequence of hormonal supplementation in a patient of Panhypopituitarism (Q850924)

A. Glucocorticoids → Thyroid hormones → Growth hormone → Sex hormones

B. Glucocorticoid → thyroid hormone → Sex hormones → Growth hormone

C. Thyroid hormones → Sex hormones → Glucocorticoids → Growth hormone

D. Sex hormones → Growth hormone → Glucocorticoids → Thyroid hormones

Correct Answer: B. Glucocorticoid → thyroid hormone → Sex hormones → Growth hormone

Explanation: For panhypopituitarism, the sequence of hormone replacement therapy is Glucocorticoid → thyroid hormone → Sex hormones → Growth hormone Hormonal therapy for Panhypopituitarism Hormone deficient Hormone replacement ACTH Corticosteroid replacement should be started first to reduce the risk of triggering an adrenal crisis. Hydrocortisone 10-20 mg/day in divided doses Cortisone acetate 15-25 mg/day in divided doses Prednisolone 5 mg/day TSH Thyroid hormone replacement is then added for hypothyroidism L-thyroxine 0.0075 - 0.15 mg/day FSH/LH After thyroid hormone replacement - sex hormone replacement is initiated Males - testosterone Females - estrogen / progesterone / gonadotropins GH Adults - Somatotropin (0.1 - 1.25 mg SC QID) Children - Somatotropin (0.02 - 0.05 mg/kg/day) Vasopressin Intranasal desmopressin (5–20 g BID/day) Oral 300–600 µg QID

@Neet_pg_bot

Q2: A 38-year-old woman with a known pituitary adenoma presents with a sudden onset of severe headache, vomiting and rapidly progressive visual loss. MRI brain suggests an acute haemorrhage within the pituitary gland. Which of the following conditions is not associated with increased risk of developing this emergency? (Q890236)

A. Acute hypovolemic shock

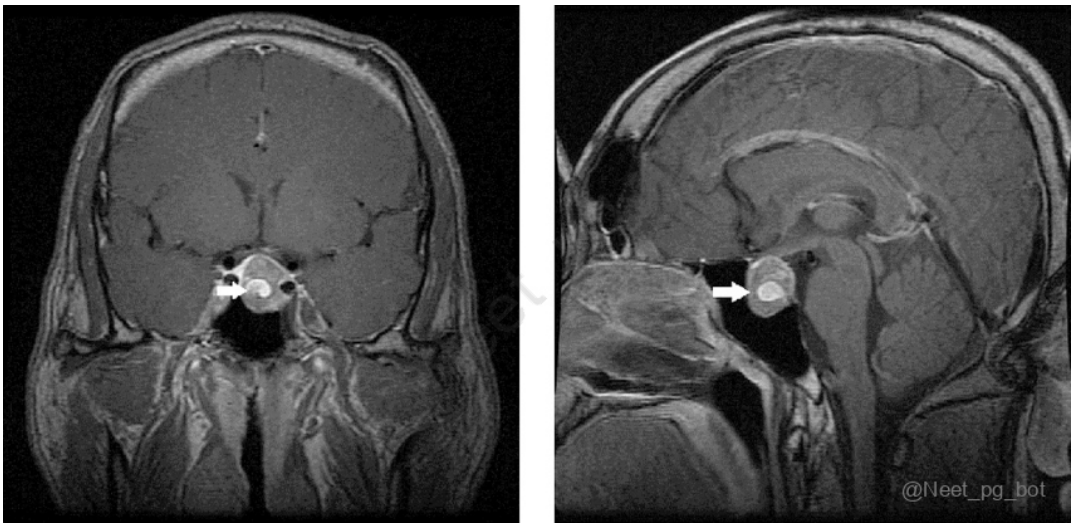
B. Sickle cell anaemia

C. Poorly controlled diabetes mellitus

D. Graves' disease

Correct Answer: D. Graves' disease

Explanation: The given clinical scenario of a middle-aged woman with an acute onset of symptoms, along with her imaging, points towards the diagnosis of pituitary apoplexy and Graves' disease (hyperthyroidism) is not associated with it. Pituitary apoplexy is a life-threatening endocrine emergency caused by acute haemorrhage or infarction of the pituitary gland, most commonly occurring in patients with pituitary adenomas. It is precipitated by conditions that cause vascular instability, infarction, or haemorrhage, including: Pituitary adenoma (spontaneous) Acute shock Diabetes mellitus Hypertension Sickle cell anaemia Sheehan syndrome



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2993.

↑ *Back to this question in Part A*

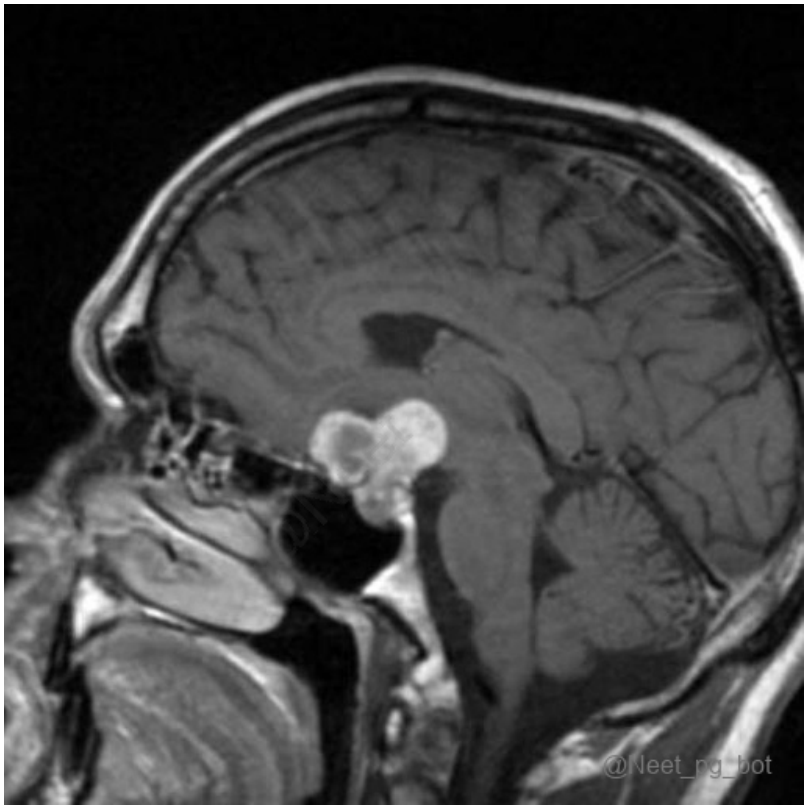
Q3: A 14-year-old boy presents with progressive headache, vomiting, declining school performance and polyuria. MRI brain reveals the following finding. Which of the following statements about this lesion is most accurate? (Q890235)

A. In the papillary variant, calcifications are commonly seen

B. In the adamantinomatous variant, calcifications are rare

C. Complete surgical excision is usually curative

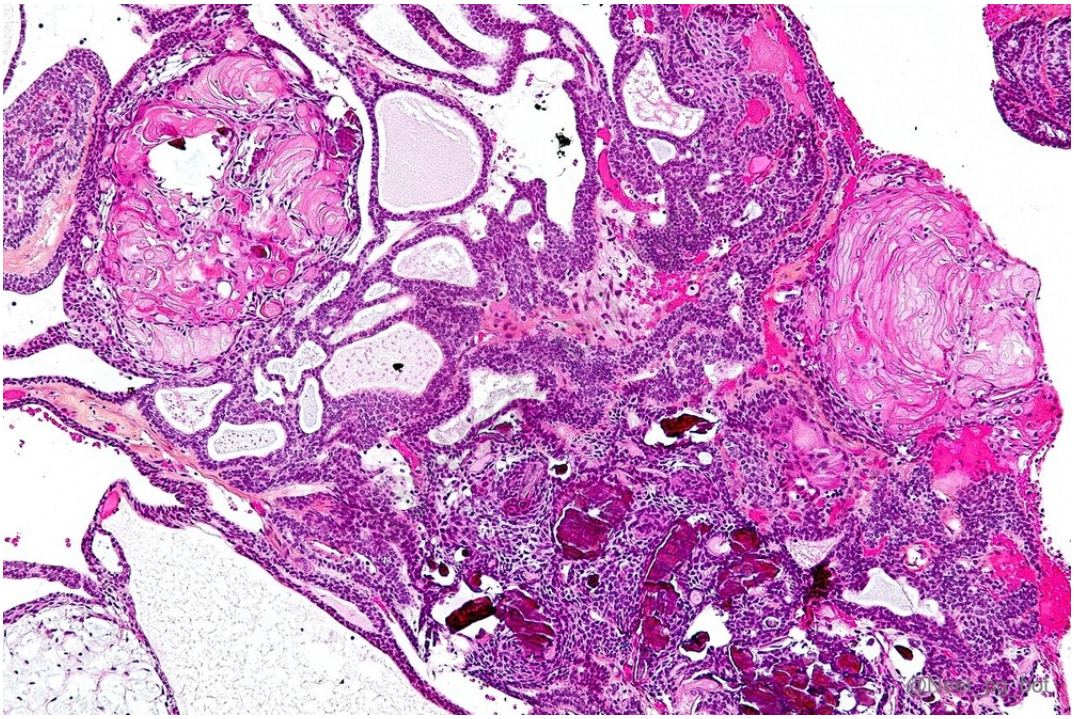
D. Biopsy shows cholesterol crystals within the cyst

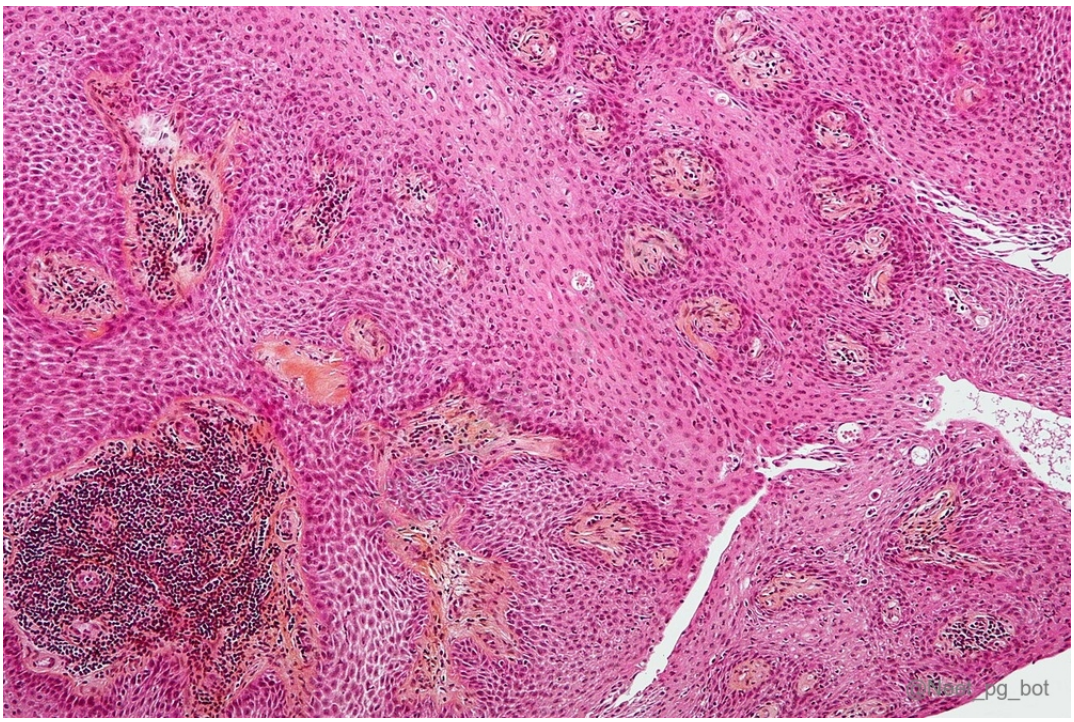


Correct Answer: D. Biopsy shows cholesterol crystals within the cyst

Explanation: Craniopharyngiomas are benign epithelial suprasellar tumors derived from Rathke's pouch remnants. They characteristically contain cholesterol-rich machine oil fluid, so a biopsy reveals cholesterol crystals within the cyst (Option D). Causes central diabetes insipidus, hypopituitarism, and bitemporal hemianopia. Bimodal age distribution (children & 50-65 yrs). They are locally adherent to surrounding hypothalamic and optic structures, so complete surgical excision is not curative in most patients and must be followed by post-operative radiotherapy to prevent recurrence. (Option C) Two pathological variants exist: Adamantinomatous (children) (Option B): cystic,

calcifications common , keratin nodules Papillary (adults) (Option A): solid, calcifications rare





References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3002.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 49-year-old man presents with gradually progressive lethargy, loss of appetite and intermittent vomiting for several months. He also reports excessive thirst and passing large volumes of urine. MRI brain shows a suprasellar mass with mixed cystic-solid components and areas of calcification. Which of the following is the most common initial clinical presentation of this condition? (Q890234)

A. Bitemporal hemianopia

B. Hypogonadotropic hypogonadism

C. Persistent headache

D. Central diabetes insipidus

Correct Answer: C. Persistent headache

Explanation: Craniopharyngiomas are benign suprasellar cystic tumors derived from Rathke's pouch remnants. They commonly cause early obstruction of CSF pathways and raised intracranial pressure, making headache the most common presenting symptom across both pediatric and adult age groups. Raised intracranial pressure also produces: Early-morning vomiting Papilledema Lethargy Hydrocephalus Craniopharyngiomas can present with: Headache - most common symptom Hypopituitarism - due to pituitary destruction Hypogonadotropic hypogonadism (Option B) - Results from pituitary stalk involvement and hypothalamic damage Central diabetes insipidus (Option D) - due to posterior pituitary involvement Bitemporal hemianopia (Option A) - due to optic chiasmal compression

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3002.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 28-year-old man is diagnosed with a hereditary endocrine tumour syndrome and is being planned for surveillance imaging. In which of the following conditions is routine pituitary tumour screening not required? (Q890233)

A. MEN 1

B. MEN 4

C. Carney complex

D. MEN 2

Correct Answer: D. MEN 2

Explanation: MEN 2 is characterised by medullary thyroid carcinoma, pheochromocytoma, and hyperparathyroidism , but does not involve pituitary adenomas. Therefore, routine pituitary imaging and hormonal screening are not indicated in MEN 2. MEN 2 includes MEN-2A, MEN-2B (MEN-3), and familial medullary thyroid carcinoma variants - none of which involve pituitary tumours. The genetic syndromes associated with pituitary tumours include: MEN 1 (Option A): Caused by menin gene mutation; classically causes pituitary adenomas, pancreatic NETs, and parathyroid hyperplasia ("3 Ps"). MEN 4 (Option B): CDKN1B mutation syndrome; MEN-1-like disorder that includes pituitary adenomas . Carney complex (Option C): Associated with GH-secreting pituitary adenomas , leading to acromegaly, along with cardiac myxomas and skin pigmentation. McCune-Albright syndrome is another important genetic disorder associated with GH-secreting pituitary adenomas.

Harrison's Principles of Internal Medicine, 22nd Edition, Pages 3004, 3080.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 34-year-old woman presents with secondary amenorrhea and spontaneous galactorrhea for 6 months. She also complains of gradually worsening peripheral vision. MRI brain reveals a 16-mm pituitary lesion. Which of the following visual field defects is most likely in this patient? (Q890232)

A. Bitemporal superior quadrantanopia

B. Homonymous superior quadrantanopia

C. Central scotoma

D. Monocular temporal hemianopia

Correct Answer: A. Bitemporal superior quadrantanopia

Explanation: This patient has a pituitary macroprolactinoma causing early optic chiasmal compression. Pituitary macroadenomas (>10 mm) initially compress the ventral portion of the optic chiasm, which contains the inferior nasal retinal fibres. These fibres carry information from the superior temporal visual fields. Therefore, the earliest visual field defect is bitemporal (heteronymous) superior quadrantanopia. With further tumour growth, complete bitemporal hemianopia develops. Homonymous superior quadrantanopia (Option B): Occurs due to temporal lobe optic radiation lesions ("pie in the sky") , not chiasmal compression. Central scotoma (Option C): Seen in optic neuritis and macular disease . Monocular temporal hemianopia (Option D): Indicates pre-chiasmal optic nerve

compression , not chiasmal involvement.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 222, 223.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 55-year-old man presents with progressive fatigue and recent visual field defects. MRI shows a large sellar mass compressing the pituitary gland. Which of the following findings would be least likely to be present in this patient? (Q890231)

A. Increased adiponectin levels

B. Hypogonadotropic hypogonadism

C. Secondary hypothyroidism

D. Diffuse mucocutaneous hyperpigmentation

Correct Answer: D. Diffuse mucocutaneous hyperpigmentation

Explanation: The patient has a pituitary macroadenoma causing panhypopituitarism. Large pituitary macroadenomas destroy normal pituitary tissue, leading to panhypopituitarism: ↓ ACTH → Secondary adrenal insufficiency ↓ TSH → Secondary hypothyroidism (Option C) ↓ LH/FSH → Hypogonadotropic hypogonadism (Option B) ↓ GH → Growth failure and adult hyposomatotropism ↓ PRL→ Lactation failure Because ACTH levels are low, melanocyte-stimulating activity is reduced; therefore, mucocutaneous hyperpigmentation does not occur. Hyperpigmentation is seen only when ACTH is in excess (primary adrenal failure, ectopic ACTH). Cortisol deficiency also causes increased adiponectin → increased insulin sensitivity . (Option A)

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3055.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 28-year-old woman presents with oligomenorrhea and spontaneous galactorrhea. Serum prolactin is 78 ng/mL. MRI of the sellar region is planned. Which of the following lesion sizes would classify the pituitary tumour as a microadenoma? (Q890230)

A. < 5 mm

B. < 8 mm

C. < 10 mm

D. < 15 mm

Correct Answer: C. < 10 mm

Explanation: The patient has a prolactin-secreting pituitary adenoma (prolactinoma) with biochemical hyperprolactinemia. Pituitary adenomas are classified based on size: Microadenoma: < 10 mm Macroadenoma: ≥ 10 mm Pituitary adenomas may be detected incidentally on imaging or suspected in patients with features of hormone hypersecretion (e.g., galactorrhea, amenorrhea) or mass effect. MRI with contrast is the best investigation to detect pituitary tumours and assess suprasellar extension and optic chiasm involvement. In all patients with suspected pituitary adenoma, measurement of pituitary hormone levels is mandatory to evaluate both hypersecretion and hyposecretion syndromes. Microadenomas commonly cause endocrine symptoms, while macroadenomas commonly present with visual field defects and hypopituitarism.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3003.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 46-year-old man presents with progressively worsening headache and difficulty seeing objects in the peripheral field of vision. MRI reveals a large sellar mass compressing the optic chiasm. Hormonal evaluation shows mildly elevated serum prolactin with low cortisol and low TSH levels. Which of the following cell types is the most likely origin of this tumour? (Q890229)

A. Lactotroph cells

B. Corticotroph cells

C. Gonadotroph cells

D. Thyrotroph cells

Correct Answer: C. Gonadotroph cells

Explanation: The patient has a non-functioning pituitary adenoma producing mass-effect manifestations and evolving hypopituitarism. Non-functioning pituitary adenomas do not produce clinically active hormone excess

and therefore typically present with mass-effect symptoms rather than endocrine syndromes. Nearly 80% of non-functioning pituitary adenomas arise from gonadotroph cells, making them the most common cell of origin. As these tumours enlarge, they produce: Headache and bitemporal hemianopia from optic chiasm compression Cranial nerve palsies causing diplopia and ptosis Mild hyperprolactinemia (stalk effect) due to loss of dopaminergic inhibition Progressive hypopituitarism in later stages from compression of normal pituitary tissue Lactotroph cells (Option A): Cause prolactinomas, which produce marked hyperprolactinemia with galactorrhea and amenorrhea. Corticotroph cells (Option B): Produce ACTH-secreting adenomas causing Cushing's disease. Thyrotroph cells (Option D): Produce TSH-secreting adenomas causing hyperthyroidism.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3013.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 27-year-old woman presents with 6 months of amenorrhea, spontaneous galactorrhea and infertility. Serum prolactin is 120 ng/mL. Which of the following is the most appropriate next step in evaluation? (Q884050)

A. MRI of pituitary fossa

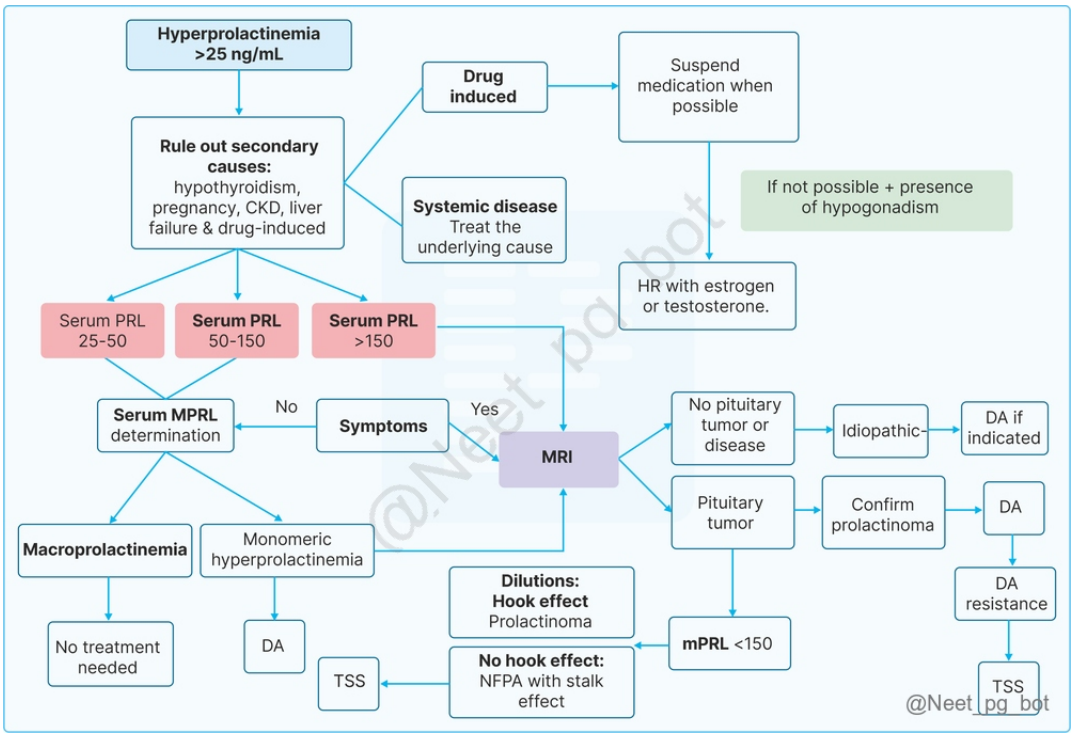
B. Serum free T4 and TSH levels

C. Serum LH and FSH levels

D. Start cabergoline therapy

Correct Answer: B. Serum free T4 and TSH levels

Explanation: The patient has hyperprolactinemia, causing hypogonadotropic hypogonadism. Primary hypothyroidism is a frequent, reversible cause of hyperprolactinemia. Primary hypothyroidism causes low circulating thyroid hormone, leading to elevated TRH. TRH directly stimulates pituitary lactotrophs, producing hyperprolactinemia, which suppresses GnRH → ↓ LH/FSH → amenorrhea, galactorrhea and infertility. Therefore, thyroid function testing must be done before pituitary imaging or dopamine-agonist therapy. Correction of hypothyroidism alone can normalise prolactin levels. Diagnostic algorithm of hyperprolactinemia. CKD = Chronic kidney disease; PRL = Prolactin; MPRL = Macroprolactin ; mPRL = Monomeric prolactin; HR: Hormonal replacement; DA = Dopamine agonists; RPCS = Progressive chiasmatic syndrome; PA = Pituitary apoplexy ; NFPA = Non-functioning pituitary adenoma; TSS = Transphenoidal surgery. MRI pituitary (Option A): Should be performed only after excluding reversible causes of hyperprolactinemia. LH & FSH (Option C): Will be suppressed, but do not identify the aetiology. Start cabergoline (Option D): May mask a reversible endocrine cause if started prematurely.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3005.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 29-year-old woman presents with secondary amenorrhea and milky nipple discharge for 6 months. She also reports an inability to conceive despite regular unprotected intercourse. Which of the following clinical features would be least likely to be part of her underlying disorder? (Q884049)

A. Galactorrhea

B. Infertility

C. Diminished libido

D. Visual field defect

Correct Answer: C. Diminished libido

Explanation: The patient is suffering from hyperprolactinemia, causing hypogonadotropic hypogonadism. Hyperprolactinemia suppresses pulsatile GnRH secretion, leading to decreased LH and FSH, producing:

Amenorrhea (secondary > primary) Galactorrhea (Option A): Due to prolactin-mediated milk secretion Infertility (Option B): Occurs due to suppression of gonadotropins and anovulation Visual field defects (Option D) due to optic chiasmal compression (in macroadenomas) Always rule out hypothyroidism (↑TRH → ↑PRL) and pregnancy before labelling idiopathic hyperprolactinemia. Diminished libido is not a typical presenting feature in women and is classically described in men with hyperprolactinemia.

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3004.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 40-year-old man presents with progressive increase in ring and shoe size, coarse facial features, excessive sweating, arthralgia and new-onset diabetes mellitus. Serum IGF-1 is elevated, and growth hormone fails to suppress following an oral glucose tolerance test. MRI sella reveals a pituitary mass. What is the most common underlying aetiology of his condition? (Q884048)

A. Ectopic GHRH secretion from bronchial carcinoid

B. Pure somatotroph pituitary adenoma

C. Lactotroph adenoma with stalk effect

D. Hypothalamic hamartoma

Correct Answer: B. Pure somatotroph pituitary adenoma

Explanation: Acromegaly is caused by chronic excess growth hormone secretion after epiphyseal fusion, leading to elevated IGF-1 levels and progressive acral enlargement, arthropathy, hyperhidrosis and metabolic complications. In more than 95% of cases, acromegaly is pituitary in origin, and the most common cause is a pure somatotroph pituitary adenoma, making it the predominant etiology. Oral glucose suppression failure is diagnostic of acromegaly. Most patients present with macroadenomas. First-line treatment is transsphenoidal surgery. Causes of acromegaly are classified as: 1. Pituitary causes (~98%) Pure somatotroph adenoma - ~60% (most common) Mixed somatotroph-lactotroph adenoma Other plurihormonal pituitary tumours These are responsible for autonomous GH secretion and account for the vast majority of cases. 2. Extrapituitary causes (Rare) A. Ectopic GH-GH-secreting tumours Very rare Can be seen in neuroendocrine tumours B. Excess GHRH secretion Central: Hypothalamic hamartoma Peripheral: Bronchial carcinoid Pancreatic neuroendocrine (islet cell) tumours These cause secondary pituitary somatotroph hyperplasia rather than a discrete adenoma. Ectopic GHRH secretion (Option A): Causes secondary pituitary somatotroph hyperplasia; rare compared to pituitary adenoma. Lactotroph adenoma with stalk effect (Option C): May cause hyperprolactinemia but does not produce GH excess. Hypothalamic hamartoma (Option D): Can secrete GHRH, but is a very uncommon cause of acromegaly.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3008.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 23-year-old woman undergoes dynamic pituitary testing. Following TRH administration, her serum growth hormone (GH) levels show a paradoxical rise. Which of the following clinical conditions is most likely to show this response? (Q884047)

A. Acromegaly

B. Simple protein-energy malnutrition

C. Cushing syndrome

D. Chronic kidney disease

Correct Answer: A. Acromegaly

Explanation: TRH physiologically stimulates TSH and prolactin secretion and does not stimulate GH. A rise in GH after TRH is abnormal and indicates pituitary or hypothalamic pathology with aberrant TRH receptor expression or dysregulated somatotroph control. In acromegaly, the somatotroph adenoma: Expresses ectopic TRH receptors Shows autonomous GH secretion Demonstrates abnormal pituitary receptor cross-reactivity This produces a classical paradoxical GH rise following TRH administration. Other conditions known to show paradoxical GH Rise after TRH: Prolactinoma/mixed GH-PRL adenoma: Aberrant lactotroph-somatotroph cross-talk Anorexia nervosa / chronic starvation: Central hypothalamic dysregulation Liver failure: ↓ IGF-1 feedback → ↑ GH with abnormal TRH sensitivity Simple protein-energy malnutrition (Option B): Peripheral nutritional deficiency without hypothalamic reprogramming does not cause paradoxical TRH-GH response. Cushing syndrome (Option C): Excess cortisol suppresses GH secretion. Chronic kidney disease (Option D): CKD produces GH resistance and altered clearance, but does not produce TRH-induced GH rise.

References:

https://pubmed.ncbi.nlm.nih.gov/2110409/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 15-year-old boy receiving recombinant growth hormone therapy for constitutional short stature presents with progressive weight gain, facial puffiness and

new-onset impaired fasting glucose. Which of the following adverse effects is he least likely to develop due to growth hormone therapy? (Q884046)

A. Slipped capital femoral epiphysis

B. Tinnitus

C. Pseudotumor cerebri

D. Hypotension

Correct Answer: D. Hypotension

Explanation: Growth hormone is a potent counter-regulatory hormone to insulin and antagonises insulin action, leading to impaired glucose tolerance and hyperglycemia; hence, it is contraindicated in uncontrolled diabetes mellitus. GH also causes dose-related sodium, potassium and water retention, producing weight gain, oedema and hypertension. It stimulates linear bone growth and epiphyseal cartilage widening, predisposing to slipped capital femoral epiphysis (Option A), and increases intracranial pressure, causing headache and pseudotumor cerebri (Option C) . Other recognised adverse effects include: Tinnitus (Option B) , Carpal tunnel syndrome, Joint pains, Gynecomastia, Pituitary tumour regrowth, Progression of skin lesions, Acromegaloid changes.

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 2997.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 4-year-old boy is brought in with proportionate short stature, frontal bossing and recurrent episodes of fasting hypoglycemia. His serum growth hormone levels are markedly elevated, but IGF-1 levels are very low. Which of the following is the most likely underlying abnormality? (Q884045)

A. Congenital GHRH deficiency

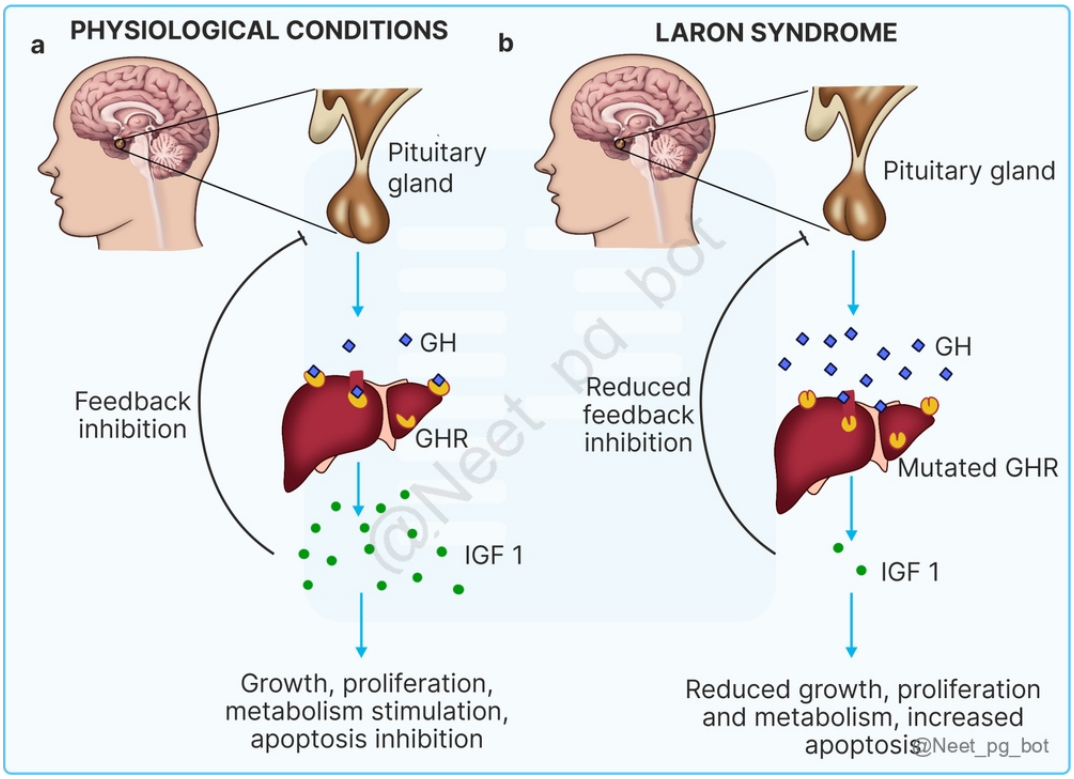
B. Inactivating mutation of the growth hormone receptor

C. Isolated pituitary somatotroph hypoplasia

D. Congenital absence of IGF-1 production

Correct Answer: B. Inactivating mutation of the growth hormone receptor

Explanation: Laron syndrome is an autosomal recessive disorder characterised by growth hormone receptor anomalies, resulting in failure of GH signalling despite elevated circulating GH levels. Because GH cannot act on its receptor, hepatic synthesis of IGF-1 is markedly reduced, leading to severe proportionate short stature, characteristic facies, and recurrent hypoglycemia (due to loss of GH's counter-regulatory effect on insulin). Treatment is by subcutaneous administration of recombinant IGF-1, not growth hormone, as GH therapy is ineffective in receptor-level resistance. GHRH deficiency (Option A): Causes secondary GH deficiency with low GH and low IGF-1, not elevated GH. Somatotroph hypoplasia (Option C): Produces primary pituitary GH deficiency , again associated with low GH levels , not GH resistance. Primary IGF-1 deficiency (Option D): Extremely rare; GH levels are not typically markedly elevated and the defect is post-receptor synthetic failure , not receptor insensitivity.



References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 2984, 2296.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A patient with acromegaly presents with large spade-like hands and impaired glucose tolerance. The pituitary MRI shows a somatotrope adenoma. Which of the following is the preferred medical therapy to shrink the tumor preoperatively? (Q850805)

A. Cabergoline

B. Lanreotide

C. Bromocriptine

D. Pegvisomant

Correct Answer: B. Lanreotide

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Lanreotide , a long-acting somatostatin analog , is the preferred preoperative medical therapy for GH-secreting pituitary adenomas . It effectively reduces tumor size and controls GH/IGF-1 levels , improving acromegaly symptoms and metabolic complications like impaired glucose tolerance . Cabergoline (Option A) and Bromocriptine (Option C) are dopamine agonists . They are less effective in shrinking GH-secreting tumors and are usually reserved for mild cases or patients intolerant to somatostatin analogs. Pegvisomant (Option D) is a GH receptor antagonist that normalizes IGF-1 and improves metabolic complications but does not reduce tumor size , so it is not preferred preoperatively .

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3009

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: Which of the following diseases is mismatched with its hormonal profile and management (Q850922)

A. Lymphocytic hypophysitis - variable deficiency in pituitary hormone Sheehan syndrome - treated with hormone replacement therapy Langerhans cell histiocytosis of pituitary - ADH deficiency present

B. Lymphocytic hypophysitis - Glucocorticoid to reduce inflammation Sheehan syndrome - Panhypopituitarism Langerhans cell histiocytosis of pituitary - surgical excision of the lesion

C. Lymphocytic hypophysitis - Glucocorticoid to reduce inflammation Sheehan syndrome - ADH deficiency present Langerhans cell histiocytosis of pituitary-thyroid hormone replacement is essential.

D. Lymphocytic hypophysitis - Surgical excision if vision is affected Sheehan syndrome - Thyroid hormone replacement after Corticosteroids are stabilized Langerhans cell histiocytosis of pituitary - Chemotherapy is systemic involvement present

Correct Answer: C. Lymphocytic hypophysitis - Glucocorticoid to reduce inflammation Sheehan syndrome - ADH deficiency present Langerhans cell histiocytosis of pituitary-thyroid hormone replacement is essential.

Explanation: Features Sheehan syndrome Lymphocytic hypophysitis LCH of pituitary Cause Occurs due to postpartum ischemic necrosis of the pituitary, commonly presenting with panhypopituitarism An autoimmune inflammation of the pituitary, causing variable hormone deficiencies Infiltration of the pituitary by Langerhans cells Hormone profile Panhypopituitarism, except for ADH Variable deficiencies : often low ACTH, TSH, LH, FSH, PRL, ADH deficiency presenting as central diabetes insipidus May have low or normal pituitary hormones depending on the degree of infiltration Treatment Hormone replacement Glucocorticoid replacement to manage adrenal insufficiency. Thyroid hormone replacement after corticosteroids are stabilized. Gonadal hormone replacement Corticosteroids to manage inflammation Hormone replacement as needed for any deficiencies. Surgery only if visual field compromise or other complications arise. Surgical resection of affected mass Chemotherapy may be needed if systemic involvement present Vinblastine Methotrexate-containing regimens Cytarabine

@Neet_pg_bot

Q18: A 60-year-old male with a history of pituitary adenoma presents with sudden-onset severe headache, palpitations, excessive sweating, and hypotension. Lab results show severe hypoglycemia, and imaging reveals hemorrhage within the pituitary and deviation of the pituitary stalk. What is the initial management for this patient? (Q850921)

A. Urgent surgical decompression

B. High dose IV glucocorticoid

C. IV dextrose administration

D. Oral hydrocortisone

Correct Answer: B. High dose IV glucocorticoid

Explanation: Considering this patient’s history of pituitary adenoma and his current clinical presentation, he has most likely developed pituitary apoplexy. High-dose IV glucocorticoids are the first-line treatment that addresses adrenal insufficiency, stabilizes blood pressure, and corrects hypoglycemia. Pituitary apoplexy Management High-dose glucocorticoids is the first line of treatment to correct adrenal insufficiency, stabilize blood pressure, and correct hypoglycemia. Patients without evident visual loss or impaired consciousness can be managed conservatively with high-dose glucocorticoids. Urgent surgical decompression (Option A): Required for patients with significant or progressive visual loss, cranial nerve palsy, or loss of consciousness. Monitoring: Visual recovery is inversely correlated with the duration of time after the acute event, so timely intervention is crucial. IV dextrose administration (Option C) can temporarily address hypoglycemia but it does not address the underlying adrenal insufficiency which is a medical emergency. Oral hydrocortisone (Option D) is not preferred as this is an acute endocrine emergency, and oral corticosteroids are not fast acting thus only IV forms of corticosteroid are preferred.

Harrison’s Principles of Internal Medicine, 21st Edition, Page 2897 and 2898

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: Match the following pituitary gland disorders with their respective serum hormone levels. Pituitary gland disorder Serum hormone levels 1. Hypopituitarism a) Severe ↓ ACTH and GH, other hormones maybe ↓ or normal 2. Sheehan syndrome b) GH, ACTH, TSH, LH, FSH, prolactin, ADH ↓ 3. Pituitary apoplexy c) GH, ACTH, TSH, LH, FSH normal or ↓; prolactin ↑ 4. Stalk effect d) GH, ACTH, TSH, LH, FSH, prolactin ↓ and ADH normal (Q850920)

A. 1-c, 2-b, 3-d, 4-a

B. 1-b, 2-d, 3-a , 4-c

C. 1-d, 2-a, 3-c, 4-b

D. 1-a, 2-c, 3-b, 4-d

Correct Answer: B. 1-b, 2-d, 3-a , 4-c

Explanation: Pituitary hormone levels in different pituitary gland disorders Hypopituitarism It occurs due to damage in the pituitary gland caused by tumors, surgery, trauma, or genetic conditions. GH, ACTH, TSH, LH, FSH, prolactin, ADH ↓ (deficiency varies based on which cells are affected). Sheehan syndrome Postpartum hypopituitarism caused by ischemic necrosis of the pituitary gland following severe blood loss during childbirth. GH, ACTH, TSH, LH, FSH, prolactin ↓ and ADH norma l Pituitary apoplexy A medical emergency involving sudden hemorrhage or infarction in the pituitary gland. Severe ↓ ACTH and GH, other hormones may be ↓ or normal Stalk effect Compression or disruption of the pituitary stalk causing a reduction in hypothalamic inhibition

of prolactin, resulting in elevated prolactin levels without other pituitary hormone abnormalities. GH, ACTH, TSH, LH, FSH normal or ↓, prolactin ↑

Harrison's Principles of Internal Medicine, 21st Edition, Page 2898, 2906

Factors Influencing Disconnection Hyperprolactinemia and Reversal of Serum Prolactin after Pituitary Surgery in a Non-Functioning Pituitary Macroadenoma - PMC.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: Which of the following is not true regarding the stalk effect of the pituitary? (Q850918)

A. Hyperprolactinemia occurs due to a hypersecreting macroadenoma

B. There is reduced secretion of dopamine in the pituitary stalk

C. Significant deficiencies in other pituitary hormones are not present

D. Prolactin level is usually less than 200 ng/ml

Correct Answer: A. Hyperprolactinemia occurs due to a hypersecreting macroadenoma

Explanation: Hyperprolactinemia in the stalk effect occurs due to compression of the pituitary stalk by a non-secreting pituitary macroadenoma and not due to a hypersecreting macroadenoma. Compression of the pituitary stalk results in reduced hypothalamic dopamine delivery to the pituitary due to stalk compression, which leads to unopposed prolactin secretion (Option B ruled out) A serum prolactin level below 200 ng/mL can be observed in cases with a "stalk effect". Serum prolactin level above 200 ng/mL typically indicates a prolactin-secreting macroadenoma. (Option D ruled out) Other pituitary hormones are usually normal initially , but large tumors may eventually cause hypopituitarism (Option C ruled out) Thus, the hormonal profile in the stalk effect GH, ACTH, TSH, LH, FSH normal or ↓ Prolactin ↑ but less than 200 ng/mL {{caption_text}}

Pituitary Adenoma - StatPearls - NCBI Bookshelf

Factors Influencing Disconnection Hyperprolactinemia and Reversal of Serum Prolactin after Pituitary Surgery in a Non-Functioning Pituitary Macroadenoma - PMC

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 32 year old nulliparous woman comes to the OB-GYN department for investigation of infertility. She also complains of occasional headaches and galactorrhoea. Lab tests and imaging lead to a diagnosis of prolactinoma. If we want to restore fertility in this patient, which of the following is the treatment of choice in this patient? (Q850917)

A. Cabergoline therapy till pregnancy is confirmed

B. Bromocriptine therapy till pregnancy is confirmed

C. Radiotherapy for mass reduction of tumor

D. Transsphenoidal resection of the mass

Correct Answer: B. Bromocriptine therapy till pregnancy is confirmed

Explanation: In order to restore fertility in this patient, Bromocriptine therapy can be used until pregnancy is confirmed Treatment of prolactinoma in pregnancy Desire for fertility DOC - Bromocriptine Bromocriptine therapy is initiated to restore fertility It is short-acting and has low teratogenic effects After pregnancy is confirmed - the drug is discontinued, and serial monitoring of prolactin levels Drug may be reintroduced if tumor growth is apparent Visual field defect If the tumor is very large and threatens the vision, surgical decompression may be done Cabergoline therapy (Option A), although it is the first line therapy for prolactinoma, is not preferred in those patients desiring fertility because it is long acting as it has a high affinity for D2-receptors. Radiotherapy for mass reduction of tumor (Option C) is reserved for aggressive tumors that do not respond to dopamine agonists or surgery; thus, it is not recommended for this patient.

References:

Harrison's Principles of Internal Medicine, 21st Edition, Pages 2911 and 2912

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: A 40-year-old man presents with erectile dysfunction and galactorrhea. Blood tests confirm elevated prolactin levels and an MRI reveals a macroadenoma. Which of the following management strategies is most appropriate for this patient? (Q850916)

A. Trans sphenoidal surgery

B. Start cabergoline

C. Observation & regular follow-up with MRI

D. Start Lanreotide

Correct Answer: B. Start cabergoline

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: For patients with macroadenomas and significant symptoms, initiation of dopamine agonist therapy (such as cabergoline or bromocriptine) is the first-line treatment to reduce prolactin levels and shrink the tumor. Lanreotide is used to shrink GH producing adenoma in case of acromegaly. Diagnosis of Prolactinoma: PRL levels > 200 µg/L most likely indicates prolactinoma PRL levels below 100 µg/L may indicate microadenomas MRI Head is recommended for all patients with hyperprolactinemia Shows suprasellar mass. Management: Asymptomatic microadenomas: No treatment if fertility is not desired. Regular monitoring and imaging are recommended. Symptomatic microadenomas: Use dopamine agonists, titrated for optimal PRL suppression. Normal PRL levels do not guarantee tumor shrinkage. Macroadenomas: Perform visual field testing before starting

dopamine agonists. Follow-up with MRI and visual field assessments every 6-12 months.

Page 3004, Harrison’s Principles of Internal Medicine, 22 nd Edition,

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A 28-year-old woman presents to her primary care physician with complaints of irregular menstrual cycles, galactorrhea, and difficulty conceiving. Laboratory tests reveal elevated serum prolactin levels. MRI of the patient is given below. Which of the following statements about the given condition is not true? (Q850915)

A. Female-to-Male ratio is approximately 20:1 for microadenomas

B. Men generally present with symptoms earlier than women

C. Macroadenoma may cause bitemporal hemianopia

D. Prolactin levels correlate with the size of the tumor

Correct Answer: B. Men generally present with symptoms earlier than women

Explanation: The given clinical scenario with elevated prolactin levels & MRI showing a mass in the sellar region suggests Prolactinoma , where men often present later with larger tumours due to less obvious signs of hormonal imbalance. Prolactin levels correlate with the size of the tumour (Option D ruled out) Classification of Tumors: Microadenomas : Tumors < 1 cm in diameter. Macroadenomas : Tumors greater than 1 cm in diameter & can be locally invasive and compress adjacent structures such as Optic Chaisma , resulting in Bitemporal Hemianopia) (Option C ruled out) Female-to-male ratio for micro prolactinomas is approximately 20:1 (Option A ruled out) For macroadenomas, the ratio is close to 1:1.

@Neet_pg_bot

Q24: Which of the following is the most appropriate initial management for a patient with Sheehan syndrome? (Q850914)

A. Immediate thyroid hormone replacement

B. Hydrocortisone administration

C. Fludrocortisone administration

D. GH administration

Correct Answer: B. Hydrocortisone administration

Explanation: The clinical presentation, along with a history of PPH during delivery & low cortisol & thyroid hormone levels, suggests Sheehan Syndrome . The initial management for a patient with suspected Sheehan syndrome, particularly with evidence of adrenal insufficiency, is to start hydrocortisone to replace cortisol. Sheehan syndrome Management Hormone Replacement Therapies: Cortisol Replacement: Administer hydrocortisone (Initial treatment) if there is ACTH deficiency. Mineralocorticoid is not typically recommended. (Option C) Thyroid Hormone Replacement: Indication : Levothyroxine (50–150 μg) should be given once daily. Aim to maintain serum T4 in the upper range of normal. Thyroid hormone (Option A) should not be administered without glucocorticoid therapy in cases of adrenal insufficiency, as this can lead to an adrenal crisis. Sex Hormone Replacement: Recommended for women under 50 years with gonadotropin deficiency and for men to restore sexual function and prevent osteoporosis. Growth Hormone Replacement: Growth hormone (GH) is given via daily subcutaneous injections for children and adolescents with GH deficiency (Option D) Side Effects : The primary side effect is sodium retention, which may present as peripheral oedema or carpal tunnel syndrome GH replacement should start at a low dose, with regular monitoring of serum IGF-1 to assess response.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: A 32-year-old woman experiences severe postpartum hemorrhage during delivery, requiring a blood transfusion. Two weeks later, she reports fatigue, weight loss and failure of lactation. Which of the following hormone replacement will not be required in this case? (Q850913)

A. Hydrocortisone

B. Melatonin

C. Thyroxine

D. Somatotropin

Correct Answer: B. Melatonin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation, along with a history of PPH during delivery, suggests sheehan syndrome. It refers to acute infarction and ischemic necrosis of the pituitary gland due to postpartum hemorrhage and subsequent hypovolemic hypotension. Melatonin is released from pineal gland and regulates circadian rhythm /sleep–wake cycle and does not need replacement in sheehan syndrome Lifelong hormone replacement is of 1. Glucocorticoids (Hydrocortisone / Prednisone) → always replace first to avoid adrenal crisis. 2. Levothyroxine (for secondary hypothyroidism) 3. Estrogen ± Progesterone (for women not desiring fertility) Or GnRH/gonadotropins if fertility desired. 4. Growth Hormone/ Somatotropin replacement may be considered in selected adults with hypopituitarism to improve metabolic function and quality of life, but is not required in all cases.

Page 2996: Harrison 22nd edition

↑ *Back to this question in Part A*

@Neet_pg_bot

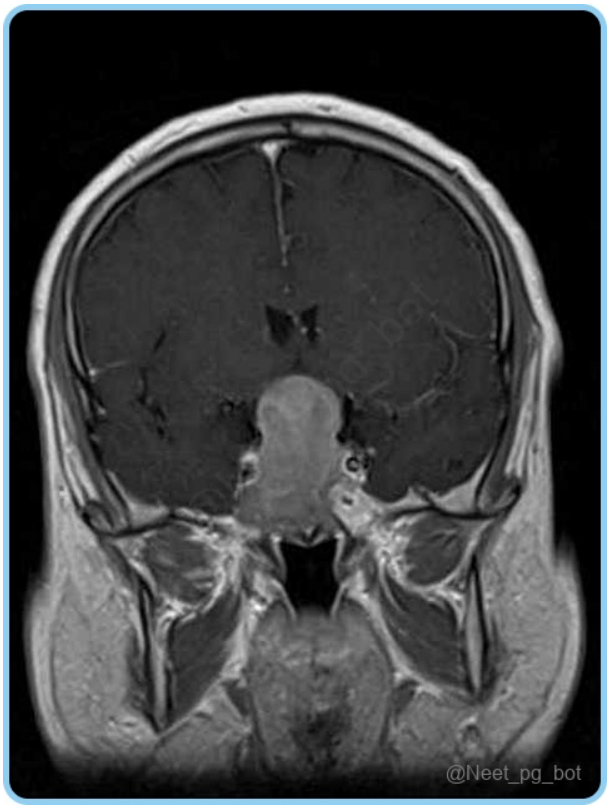
Q26: 45-year-old man presents with headaches, frequent change in shoe size and visual field defects. MRI head is shown below. IGF-1 is elevated and GH levels remain elevated on glucose challenge. Which of the following is the most appropriate management for this patient? (Q850912)

A. Initiate treatment with oral cabergoline

B. Start long-acting Octreotide

C. Perform transsphenoidal surgical resection

D. Initiate external beam radiation therapy



Correct Answer: C. Perform transsphenoidal surgical resection

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical signs of enlargement of feet, visual field defects likely from optic chiasma compression and biochemical evidence of excess of GH points to acromegaly. MRI head shows somatotroph pituitary macroadenoma with mass effect . Transsphenoidal surgical resection is the preferred treatment. Management of Acromegaly Surgical Treatment Transsphenoidal surgical resection is the preferred treatment, especially for those with GH-secreting adenomas. Post-Surgery: Improvement in soft tissue swelling and normalization of GH levels typically occur shortly after surgery IGF-1 levels normalize within 3-4 days. There is a 10% recurrence rate of acromegaly years later, and up to 15% of patients may develop hypopituitarism. Medical therapy Preferred in

medical therapy if curative surgery is not feasible or if GH fails to decrease post resection Somatostatin Receptor Ligands (SRLs): (Option B ruled out) Long-acting injectable forms (octreotide, lanreotide) . Normalizes GH and IGF-1 levels in about 50% of patients. Side Effects : GI disturbances, transient nausea, and gallbladder issues. GH receptor antagonist: Pegvisomant blocks peripheral GH receptors, normalizing IGF-1 levels in about 70% of patients, though GH levels remain elevated. It is administered through daily subcutaneous injections and is used for recurrences or poor responses to SRLs. Dopamine Agonists: (Option A ruled out) High doses of cabergoline can provide modest GH suppression. Radiation Therapy (Option D ruled out) External beam radiation therapy or stereotactic techniques are considered for patients not achieving biochemical control through surgery or medical therapy.

Harrison's Principles of Internal Medicine, 22nd edition, Page 3010

↑ *Back to this question in Part A*

@Neet_pg_bot

Q27: 50-year-old woman presents with increase in size of hand and feet with voice changes and carpal tunnel syndrome. IGF -1 levels are increased. Which of the following findings will likely not be seen in this case? (Q850911)

A. Hypoglycemic attacks

B. Galactorrhea

C. Bitemporal Hemianopia

D. Colonic polyps

Correct Answer: A. Hypoglycemic attacks

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypoglycemic attacks GH is counter regulatory hormone causing increase of blood glucose and impaired glucose tolerance in patients with acromegaly. Presence of Mammosomatotrope cell adenoma can explain galactorrhea Pituitary adenoma > 10 mm can press on optic chiasma leading to bitemporal hemianopia Acromegaly is associated with increased risk of colonic polyps and mortality from colonic malignancy

References:

Harrison's Principles of Internal Medicine, 22nd Edition, Page 3008

↑ *Back to this question in Part A*

@Neet_pg_bot

Q28: A 45-year-old man presents with spade like hands, coarse facies and increased spacing between his lower teeth. Which of the following is screening test for this case? (Q850910)

A. IGF-1 levels

B. IGF-2 levels

C. GH Levels

D. GH levels after 2 hour of glucose challenge test

Correct Answer: A. IGF-1 levels

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient has classic features of acromegaly (spade-like hands, coarse facial features, increased interdental spacing). IGF-1 is the best screening test because: It reflects integrated GH secretion over the day It is elevated consistently in acromegaly It is not affected by pulsatile GH release IGF-2 levels (Option B): IGF-2 is not used in acromegaly screening . GH levels (Option C): GH secretion is pulsatile , making random GH levels unreliable. GH levels after 2-hour OGTT (Option D): This is the confirmatory (diagnostic) test . Failure of GH suppression after glucose load confirms acromegaly.

References:

Harrison’s Principles of Internal Medicine, 21st Edition, Page 2912

↑ *Back to this question in Part A*

@Neet_pg_bot

Q29: Prolactin levels can be increased in all of the following conditions except? (Q850909)

A. Acromegaly

B. Primary hypothyroidism

C. Secondary hypothyroidism

D. Prolactinoma

Correct Answer: C. Secondary hypothyroidism

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Acromegaly can arise from Mammosomatotrope cell adenoma leading to excess GH as well as prolactin TRH stimulates the anterior pituitary to release TSH and prolactin. In primary hypothyroidism , T4 and T3 are low causing rise of TRH. (Option B) This increased TRH will cause both TSH and prolactin to rise contributing to galactorrhea. Secondary hypothyroidism has pituitary damage leading to low TSH and low or normal prolactin Prolactinoma will cause excess prolactin leading to galactorrhea and menstural abnormalities (Option D)

References:

Harrison’s Principles of Internal Medicine, 22nd Edition, Page 3008

↑ *Back to this question in Part A*

@Neet_pg_bot

Q30: Best test to confirm the diagnosis of acromegaly is? (Q850806)

A. IGF-1

B. IGF-2

C. Oral Glucose Tolerance Test

D. MRI pituitary

Correct Answer: C. Oral Glucose Tolerance Test

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Diagnosis of acromegaly is confirmed by an Oral Glucose Tolerance Test (OGTT) using 75 g glucose. Glucose should suppress GH, but in acromegaly it fails to suppress . In acromegaly, GH fails to suppress to <0.4 µg/L within 1–2 hours , confirming the diagnosis. IGF-1 level(Option A): IGF-1 is the best screening test , not confirmatory. It reflects integrated GH secretion but cannot alone confirm acromegaly. IGF-2 (Option B): IGF-2 is involved mainly in fetal (prenatal) growth , not postnatal growth, and has no role in diagnosing acromegaly. MRI pituitary (Option D): MRI helps identify the pituitary adenoma , but it cannot confirm hormonal excess .

Q1: A patient presents with weight gain, thinning of hair, and dry skin. Diagnosis is Hashimoto's thyroiditis. Which antibody is seen in this case? (Q866788)

A. Anti-TPO antibody

B. Anti TSH

C. Anti TBG

D. Long-acting thyroid-stimulating antibody

Correct Answer: A. Anti-TPO antibody

Explanation: Hashimoto's thyroiditis is the most common cause of hypothyroidism in iodine-sufficient areas, and it is strongly associated with anti-thyroid peroxidase (anti-TPO) antibodies. These antibodies cause autoimmune

destruction of the thyroid gland. Anti-TPO antibodies target the enzyme thyroid peroxidase, which is essential for thyroid hormone synthesis (oxidation and iodination of iodine, coupling of iodotyrosines). Their presence confirms autoimmune thyroid disease, especially Hashimoto's. Other antibodies, like anti-thyroglobulin, may also be present but anti-TPO has the highest diagnostic relevance. Hashimoto's thyroiditis: AKA Chronic autoimmune lymphocytic thyroiditis. Epidemiology: More common in women, especially middle-aged. Pathogenesis: Autoantibodies (anti-TPO, anti-thyroglobulin) → chronic inflammation → fibrosis → hypothyroidism. Clinical features: Weight gain, cold intolerance, dry skin, hair thinning, constipation, menstrual irregularities. Lab findings: High TSH, low free T4, positive anti-TPO antibodies. Histopathology : Diffuse lymphocytic infiltration Formation of germinal centers Hurthle cells (large oxyphilic epithelial cells with granular cytoplasm) replacing follicular epithelium Atrophic thyroid follicles with dense fibrosis in late stages Treatment: Lifelong levothyroxine replacement. Complications: Increased risk of thyroid lymphoma. Incorrect Options: Anti TSH (Option B) – Not seen in Hashimoto's; would interfere with TSH action, not a diagnostic marker. Anti TBG (Option C) – Antibodies against thyroxine-binding globulin are rare and not relevant for Hashimoto's diagnosis. Long-acting thyroid-stimulating antibody (Option D) – Seen in Graves' disease, causes hyperthyroidism, not hypothyroidism.

@Neet_pg_bot

Q2: A patient has developed a cough and weight loss for the last 3 months. Biopsy of lung mass shows expression of chromogranin and synaptophysin. Which paraneoplastic syndrome will most likely occur in this patient? (Q866793)

A. Hypercalcemia

B. Cushing syndrome

C. Gynaecomastia

D. SIADH

Correct Answer: D. SIADH

Explanation: Chromogranin and synaptophysin positivity suggests a neuroendocrine tumor , such as small cell carcinoma of the lung. These tumors often produce ectopic ADH, leading to syndrome of inappropriate antidiuretic hormone secretion (SIADH). In SIADH, excessive ADH secretion causes water retention without corresponding sodium retention, resulting in dilutional hyponatremia and low plasma osmolality. Small cell lung carcinoma is notorious for secreting ectopic hormones, particularly ADH and ACTH. The presence of neuroendocrine markers confirms the tumor's secretory nature. Small Cell Carcinoma: Origin: Neuroendocrine Kulchitsky cells in the lung. Markers: Chromogranin, synaptophysin, neuron-specific enolase (NSE). Paraneoplastic syndromes: SIADH (ADH), Cushing syndrome (ACTH), Lambert–Eaton myasthenic syndrome (autoantibodies against presynaptic calcium channels). Histology: Small cells with scant cytoplasm, nuclear molding, high mitotic count. Prognosis: Aggressive, early metastasis; often unresectable at diagnosis. Treatment: Combination chemotherapy ± radiotherapy; surgery rarely indicated. Salt and pepper chromatin (black arrows) Paraneoplastic Syndromes in Lung Cancers: Lung Cancer Type Paraneoplastic Syndromes Small cell carcinoma SIADH, Cushing syndrome, Lambert–Eaton Squamous cell carcinoma Hypercalcemia (PTHrP) Adenocarcinoma Hypertrophic osteoarthropathy Carcinoid tumor Carcinoid syndrome Paraneoplastic syndromes seen in other cancers: Cancer Type Paraneoplastic Syndrome Mechanism / Mediator Renal cell carcinoma Polycythemia Erythropoietin production Hepatocellular carcinoma Polycythemia Erythropoietin production Ovarian teratoma Anti–NMDA receptor encephalitis Autoantibodies to NMDA receptors Thymoma Myasthenia gravis Autoantibodies to postsynaptic AChRs Breast cancer Dermatomyositis / Polymyositis Immune-mediated Gastric carcinoma Acanthosis nigricans Growth factors stimulating melanocytes Pancreatic carcinoma Trousseau syndrome (migratory thrombophlebitis) Hypercoagulability (mucin) Lymphomas Hypercalcemia 1,25-(OH)■ vitamin D production Medullary thyroid carcinoma Diarrhea, flushing Calcitonin, VIP Incorrect Options: Hypercalcemia (Option A) – Classically associated with squamous cell carcinoma via PTHrP secretion. Cushing syndrome (Option B) – Possible in small cell carcinoma (ectopic ACTH), but SIADH is more common in this setting. Gynaecomastia (Option C) – Seen in some germ cell tumors or liver disease, not typical for small cell carcinoma.

@Neet_pg_bot

Q3: A patient presents with palpitations, headache, and sweating. His BP is 180/100 mmHg. 24-hour urinary metanephrine values are elevated. What is the diagnosis? (Q866794)

A. Carcinoid tumor

B. Pheochromocytoma

C. Carcinoid crisis

D. Neuroblastoma

Correct Answer: B. Pheochromocytoma

Explanation: Pheochromocytoma is a catecholamine-secreting tumor of the adrenal medulla. Classic symptoms are episodic headache, sweating, and palpitations with hypertension. Elevated 24-hour urinary metanephrines confirm catecholamine excess. Pheochromocytomas arise from chromaffin cells derived from neural crest tissue. Excess secretion of epinephrine and norepinephrine causes paroxysmal hypertension and sympathetic overactivity. Metanephrines are catecholamine metabolites, and their measurement in a 24-hour urine sample or plasma is the most sensitive test for diagnosis. Pheochromocytoma: Origin: Chromaffin cells (adrenal medulla). Rule of 10s: ~10% bilateral, 10% malignant, 10% extra-adrenal (paraganglioma), 10% in children. Associations: MEN 2A, MEN 2B, von Hippel–Lindau disease, NF1. Treatment: α-blockade (phenoxybenzamine) before β-blockade, then surgical resection. Histology: Zellballen pattern (nests of cells with rich vascular stroma). Incorrect Options: Carcinoid tumor (Option A): Presents with flushing, diarrhea, and bronchospasm; diagnosis by urinary 5-HIAA, not metanephrines. Carcinoid crisis (Option C): Severe complication of carcinoid tumor with profound hypotension and bronchospasm; unrelated to catecholamines. Neuroblastoma (Option D): Pediatric tumor of adrenal medulla or sympathetic chain; elevated HVA/VMA (dopamine metabolites), not metanephrines in adults.

@Neet_pg_bot

Q4: A known case of hyperthyroidism, who is not on medication, is scheduled for total thyroidectomy. The PAC check was not done properly. What is the leading complication that can occur during surgery? (Q866801)

A. Hyperthermia

B. Hypothermia

C. Arrhythmia

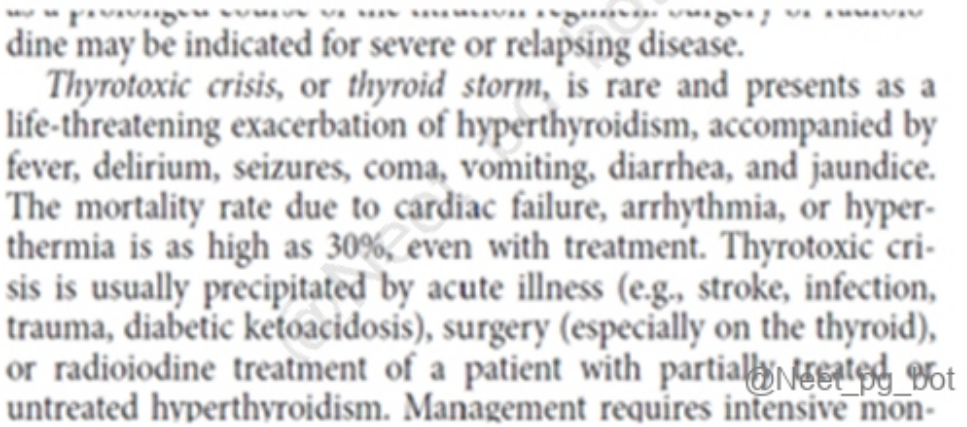
D. Hypothyroidism

Correct Answer: C. Arrhythmia

Explanation: In uncontrolled hyperthyroidism, catecholamine sensitivity is increased, predisposing the patient to severe intraoperative arrhythmias, especially during surgical manipulation of the thyroid gland. A patient with untreated hyperthyroidism undergoing thyroidectomy is at high risk of thyroid storm, precipitated by surgical stress . This can manifest with tachyarrhythmias, hyperthermia, and hypertension. Arrhythmia (especially atrial fibrillation or supraventricular tachycardia) is the most immediate and dangerous intraoperative complication.

Proper preoperative control with antithyroid drugs, β-blockers, and adequate preparation is essential. Incorrect Options: Hyperthermia (Option A): Can occur in thyroid storm but is not the leading intraoperative danger; arrhythmia is more acutely life-threatening. Hypothermia (Option B): Not typically associated with hyperthyroidism; more a concern in prolonged surgeries in cold OR environments. Hypothyroidism (Option D): Develops postoperatively, not during surgery.

Page 2942: Harrison 21st



dine may be indicated for severe or relapsing disease.

Thyrotoxic crisis, or *thyroid storm*, is rare and presents as a life-threatening exacerbation of hyperthyroidism, accompanied by fever, delirium, seizures, coma, vomiting, diarrhea, and jaundice. The mortality rate due to cardiac failure, arrhythmia, or hyperthermia is as high as 30%, even with treatment. Thyrotoxic crisis is usually precipitated by acute illness (e.g., stroke, infection, trauma, diabetic ketoacidosis), surgery (especially on the thyroid), or radioiodine treatment of a patient with partially treated or untreated hyperthyroidism. Management requires intensive mon-

@Neet_pg_bot

Q5: Patient presents with hypertension and hypokalemic metabolic alkalosis. CT scan shows a mass over the kidney with elevated ARR. What is the next best step for the management of this patient? (Q866803)

A. Spironolactone on a lifelong basis

B. Adrenalectomy

C. ACTH stimulation test

D. Dexamethasone suppression test

Correct Answer: B. Adrenalectomy

Explanation: This patient likely has primary hyperaldosteronism (Conn's syndrome) due to an adrenal adenoma. In unilateral disease confirmed by imaging and biochemistry (elevated Aldosterone–Renin Ratio), surgical adrenalectomy is the treatment of choice. Hypertension + hypokalemic metabolic alkalosis + high ARR + adrenal mass suggests unilateral aldosterone-producing adenoma. After confirming lateralization (often with adrenal venous sampling in some protocols), the definitive treatment is laparoscopic adrenalectomy. Medical management with mineralocorticoid receptor antagonists (spironolactone/eplerenone) is reserved for bilateral adrenal

hyperplasia or non-surgical candidates. Primary Hyperaldosteronism: Feature Primary Hyperaldosteronism Common causes Adrenal adenoma (Conn's), bilateral adrenal hyperplasia Key features Hypertension, hypokalemia, metabolic alkalosis Screening Elevated ARR (Aldosterone–Renin Ratio) Confirmatory tests Saline suppression test, fludrocortisone suppression test Treatment – unilateral Surgical adrenalectomy Treatment – bilateral Spironolactone/eplerenone Incorrect Options: Spironolactone (Option A): First-line for bilateral hyperplasia or non-surgical patients, not preferred for unilateral adenoma in a surgical candidate. ACTH stimulation test (Option C): Used for adrenal insufficiency diagnosis, not hyperaldosteronism. Dexamethasone suppression test (Option D): Used for diagnosing Cushing's syndrome.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A female presents with amenorrhea and galactorrhea. Serum prolactin is elevated. MRI shows pituitary adenoma. Best management for this patient? (Q866806)

A. Bromocriptine

B. Letrozole

C. Tamoxifen

D. Goserelin

Correct Answer: A. Bromocriptine

Explanation: The patient has hyperprolactinemia due to a pituitary adenoma (prolactinoma). Hyperprolactinemia → suppresses GnRH → ↓ LH/FSH → menstrual irregularities and infertility. First-line treatment for prolactinomas is dopamine agonists (Bromocriptine or Cabergoline) as they inhibit prolactin secretion and can shrink the tumor. Bromocriptine is safe in women desiring pregnancy. Surgery (trans-sphenoidal resection) is reserved for drug-resistant or compressive symptoms (e.g., visual loss). Prolactinoma: Causes: Pituitary adenoma (most common) Drugs: antipsychotics, metoclopramide Hypothyroidism (↑ TRH → ↑ prolactin) Symptoms: Women: amenorrhea, galactorrhea, infertility Men: decreased libido, erectile dysfunction, gynecomastia Mass effect: headaches, bitemporal hemianopia if the optic chiasm is compressed Diagnosis: serum prolactin, MRI brain with pituitary protocol Treatment: dopamine agonists (Bromocriptine, Cabergoline) → surgery if not responsive Incorrect Options: Letrozole (Option B) – Aromatase inhibitor for estrogen-dependent breast cancer and infertility, not first-line for prolactinoma. Tamoxifen (Option C) – Selective estrogen receptor modulator (SERM) used in breast cancer, unrelated to prolactinomas. Goserelin (Option D) – GnRH agonist used in prostate/breast cancer and endometriosis, not for prolactinoma.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: Hyperpigmentation in Addison’s disease is due to increased secretion of: (Q866480)

A. Cortisol

B. ACTH

C. Aldosterone

D. Renin

Correct Answer: B. ACTH

Explanation: ACTH In primary adrenal insufficiency (Addison’s disease) , destruction of the adrenal cortex leads to low cortisol and aldosterone . The pituitary compensates by secreting more ACTH from the precursor proopiomelanocortin (POMC) , which also produces melanocyte-stimulating hormone (MSH) . MSH stimulates melanin production, causing skin and mucosal hyperpigmentation . Addison's disease refers to primary adrenocortical failure : Etiology Autoimmune: M/C/C Worldwide Sporadic Polyglandular syndromes Tuberculosis: M/C/C in India Histoplasmosis HIV/AIDS Metastatic carcinoma Bilateral adrenalectomy Clinical features Glucocorticoid insufficiency Weight loss, anorexia, malaise, weakness, nausea, vomiting, diarrhea or constipation, postural hypotension, shock, hypoglycemia, hyponatremia (dilutional), hypercalcemia Mineralocorticoid insufficiency: Hypotension, shock, hyponatremia, hyperkalemia ACTH excess: Pigmentation Adrenal androgen insufficiency: Decreased body hair and loss of libido, especially in females Cortisol (Option A) : Deficient in Addison’s disease; low levels stimulate ACTH production but do not directly cause pigmentation. Aldosterone (Option C) : Deficient in Addison’s disease; loss leads to hyperkalemia and hypotension, not pigmentation. Renin (Option D) : Elevated due to hypovolemia, but has no role in pigmentation.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A patient presents with palpitations, headache and diaphoresis + elevated 24 hour urine metanephrine levels. Which of the following drugs can be used both preoperatively and intraoperatively for control of BP? (Q866494)

A. Phenoxybenzamine

B. Esmolol

C. Clonidine

D. Labetalol

Correct Answer: D. Labetalol

Explanation: Correct answer: D) Labetalol Labetalol is a combined α- and β-adrenergic blocker that can be used both preoperatively and intraoperatively in pheochromocytoma to control hypertension. While non-selective α-blockade (e.g., phenoxybenzamine) is preferred initially to prevent hypertensive crises, labetalol can be used when both α- and β-blockade are desired and during surgery to manage BP surges. Phenoxybenzamine (Option A): An irreversible α-blocker, used mainly preoperatively, but not ideal intraoperatively due to prolonged action and inability to titrate rapidly. Esmolol (Option B): A short-acting β1-blocker, used after adequate α-blockade if tachycardia persists; not used alone for BP control in pheochromocytoma. Clonidine (Option C): Central α2 agonist, not first-line for pheochromocytoma BP control; may reduce sympathetic outflow but less effective for catecholamine surges.

@Neet_pg_bot

Q9: A 56-year-old diabetic patient is currently on Metformin and Insulin Glargine. His HbA1c is 8.2%, indicating suboptimal glycemic control. Echocardiography reveals a reduced ejection fraction (EF) of 35%. Which of the following is the most appropriate agent to add to his current regimen? (Q866500)

A. Pioglitazone

B. Glimepiride

C. Sitagliptin

D. Empagliflozin

Correct Answer: D. Empagliflozin

Explanation: Empagliflozin is an SGLT2 inhibitor that not only lowers blood glucose but also has proven cardiovascular benefits , particularly in patients with heart failure with reduced ejection fraction (HFrEF) , irrespective of diabetes status. In this diabetic patient with suboptimal glycemic control and EF 35%, empagliflozin is the preferred add-on as it reduces hospitalizations for heart failure and improves survival. Pioglitazone (Option A): Causes fluid retention and can worsen heart failure — contraindicated in EF <40%. Glimepiride (Option B): A sulfonylurea that increases hypoglycemia risk and offers no cardiovascular benefit. Sitagliptin (Option C): A DPP-4 inhibitor with neutral cardiovascular effects; not first choice for HFrEF.

@Neet_pg_bot

Q10: A patient presents with salt wasting, craving, hyperkalemia, metabolic acidosis, and skin pigmentation. What is the most likely diagnosis? (Q866509)

A. Addison’s disease

B. Cushing’s syndrome

C. Conn’s syndrome

D. Pheochromocytoma

Correct Answer: A. Addison’s disease

Explanation: The most likely diagnosis is Addison’s disease, Addison’s disease (primary adrenal insufficiency) is characterized by: Mineralocorticoid deficiency → salt wasting, salt craving, hyperkalemia, metabolic acidosis. Glucocorticoid deficiency → weakness, fatigue, weight loss. Increased ACTH due to loss of cortisol negative feedback → skin hyperpigmentation from excess melanocyte-stimulating hormone (MSH). Investigations Random plasma cortisol measurement (values >500 nmol/L exclude adrenal insufficiency) Short ACTH stimulation test- if random cortisol levels are between 100-500, 1 microgram ACTH, serum cortisol levels of <500 is considered confirmatory for adrenal insufficiency. Plasma renin and aldosterone (high renin with low/lower part of the reference range aldosterone in mineralocorticoid deficiency) Dehydroepiandrosterone sulfate (DHEAS) and androstenedione in women Adrenal autoantibodies for autoimmune causes; imaging (CT/MRI) if antibodies are negative. Management 1. Glucocorticoid Replacement: Oral hydrocortisone is preferred, and Prednisolone and dexamethasone may also be used. 2. Mineralocorticoid Replacement: Fludrocortisone Addisonian crisis An Addisonian crisis is a life-threatening medical emergency that occurs when there is a severe deficiency of cortisol and aldosterone. It is most commonly seen in people with Addison's disease (primary adrenal insufficiency), especially when their hormone replacement therapy is inadequate or missed or during periods of extreme stress (e.g., illness, trauma, or surgery). Management: IV Hydrocortisone Cushing’s syndrome (Option B): Due to cortisol excess; presents with central obesity, moon face, hypertension, hyperglycemia—not salt wasting or hyperkalemia. Conn’s syndrome (Option C): Primary hyperaldosteronism; causes sodium retention, hypertension, hypokalemia, metabolic alkalosis—not hyperkalemia or pigmentation. Pheochromocytoma (Option D): Catecholamine-secreting tumor; presents with episodic headache, sweating, tachycardia, hypertension—not salt wasting or hyperpigmentation.

@Neet_pg_bot

Q11: A known type 1 diabetic presents with glucose 799 mg/dL, Na■ 128 mEq/L, Cl■ 88 mEq/L, and signs of dehydration. Which of the following is NOT used in the initial management? (Q866515)

A. 0.9% Normal saline

B. 3% Saline

C. IV infusion insulin

D. Potassium monitoring

Correct Answer: B. 3% Saline

Explanation: The clinical presentation points towards DKA In DKA, the initial management focuses on: Fluid resuscitation with isotonic saline (0.9% NaCl) to correct dehydration. Insulin infusion to correct hyperglycemia and ketosis. Potassium monitoring and replacement as insulin therapy and fluids can cause hypokalemia. Updated Management of Diabetic Ketoacidosis (ISPAD 2022): 3% hypertonic saline is not indicated unless there is severe symptomatic hyponatremia with neurological symptoms (usually Na■ < 120 mEq/L and acute onset). In this case, hyponatremia is dilutional and corrects with normal saline and DKA management.

@Neet_pg_bot

Q12: A female patient with type 1 DM and hypothyroidism presented with chronic oral mucocutaneous candidiasis for 5 years. She is diagnosed with autoimmune polyendocrinopathy syndrome type 1. Which of the following is incorrect about this condition? (Q853349)

A. DM type-1 association is high

B. Starts in infancy

C. Hypoparathyroidism

D. High association with candidiasis

Correct Answer: A. DM type-1 association is high

Explanation: Type 1 diabetes mellitus (DM) is commonly associated with APS Type 2, it is less frequently seen in APS Type 1. Autoimmune Polyendocrinopathy Syndrome (APS) Type 1 is also known as APECED (Autoimmune Polyendocrinopathy, Candidiasis, and Ectodermal Dystrophy). APS Type 1 is more associated with conditions like hypoparathyroidism, adrenal insufficiency, and chronic mucocutaneous candidiasis. Autoimmune Polyendocrinopathy Syndrome (APS) Autoimmune Polyendocrinopathy Syndrome iis a group of autoimmune disorders characterized by the immune system mistakenly attacking multiple endocrine glands, leading to hormonal imbalances. It is classified into two main types Feature APS-1 (APECED - Autoimmune Polyendocrinopathy-Candidiasis-Ectodermal Dystrophy) APS-2 (Schmidt syndrome) Gene AIRE mutation HLA-DR3, DR4 Inheritance Autosomal recessive Polygenic Age Childhood (Option B ruled out) Adulthood Classic triad Candidiasis + Hypoparathyroidism + Addison disease (Options C & D ruled out) Addison + Thyroid disease + Type 1 DM Candidiasis Very common Rare Hypoparathyroidism Common Rare Type 1 DM Rare Common

@Neet_pg_bot

Q13: A patient presents with hypotension, hyponatremia and blackening of the knuckles and perioral area. Which of the following conditions is most likely associated with these symptoms? (Q844204)

A. Conn syndrome

B. Cushing's syndrome

C. Primary ACTH deficiency

D. Addison’s disease

Correct Answer: D. Addison’s disease

Explanation: Correct Option D - Addison’s Disease: Addison’s Disease : Symptoms : Hypotension : Due to insufficient cortisol production affecting blood pressure. Hyponatremia : Caused by low aldosterone levels, leading to reduced sodium reabsorption. Hyperpigmentation : Characterized by darkening of the skin, including knuckles and perioral areas, due to increased ACTH levels stimulating melanocytes. Incorrect Options: Option A - Conn Syndrome: Characterized by primary hyperaldosteronism, which typically leads to hypertension, hypokalemia (low potassium), and metabolic alkalosis, but not usually associated with hyperpigmentation or hyponatremia. Option B - Cushing’s Syndrome: Results from excess cortisol production and can present with hypertension, hyperglycemia, and hypokalemia. Hyperpigmentation is not a common feature; instead, you might see features such as easy bruising and a “moon facies.” Option C - Primary ACTH Deficiency: Leads to low cortisol levels but not usually associated with hyperpigmentation. Patients may experience symptoms of adrenal insufficiency, but hyperpigmentation is more characteristic of primary adrenal insufficiency (Addison’s disease) rather than ACTH deficiency.

@Neet_pg_bot

Q14: A patient with a history of Wilson's disease presents with neurological manifestations. Which of the following is the best diagnostic modality? (Q844223)

A. Serum ceruloplasmin

B. Urinary copper excretion

C. Hepatic parenchymal demonstration of copper

D. Anti-tissue transglutaminase (Anti-tTG) antibody

Correct Answer: C. Hepatic parenchymal demonstration of copper

Explanation: Correct Option C - Hepatic parenchymal demonstration of copper: The gold standard for diagnosing Wilson’s disease—especially when neurological symptoms are present—is quantitative hepatic copper estimation via liver biopsy . A level >250 µg/g dry weight confirms the diagnosis with high specificity. Serum ceruloplasmin (Option A): While serum ceruloplasmin is often low in Wilson's disease, it is not the most reliable diagnostic tool, as ceruloplasmin levels can be low in other conditions and may be normal in some patients with Wilson's disease. Urinary copper excretion (Option B): This test measures 24-hour urinary copper excretion and is elevated in Wilson's disease, but it is not as definitive as hepatic copper measurement. It is useful as part of the diagnostic workup but not the best single test. Anti-tissue transglutaminase (Anti-tTG) antibody) (Option D): This antibody is associated with celiac disease and is not relevant to the diagnosis of Wilson's disease.

@Neet_pg_bot

Q15: A patient presents with large sweaty hands, macroglossia, and frontal bossing. Select the best test for confirmation of the diagnosis: (Q844227)

A. GHRH levels

B. IGF- 1

C. IGF- 2

D. GH levels after glucose suppression

Correct Answer: D. GH levels after glucose suppression

Explanation: Correct Option D - GH levels after glucose suppression: The best test for confirming a diagnosis of acromegaly (often caused by excess growth hormone) is GH suppression test. 75g of oral glucose is administered and blood GH levels are checked at 30, 60, 90, and 120 minutes. Normally, glucose suppressess GH, If GH > 1ng/ml, it is confirmatory of acromegaly. Incorrect Options: Option A - GHRH levels: Growth Hormone-Releasing Hormone (GHRH) levels are not typically used for the diagnosis of acromegaly. While GHRH can stimulate growth hormone release, its levels are not directly indicative of acromegaly. Option C - IGF-2: IGF-2 is not typically used for diagnosing acromegaly. It is more relevant in conditions like certain tumors and is not a primary diagnostic marker for acromegaly. Option B - Insulin-like Growth Factor 1 (IGF-1) . IGF-1 levels are elevated in acromegaly due to the increased secretion of growth hormone. IGF-1 is a stable marker that reflects chronic exposure to growth hormone and is therefore used as the screening test for acromegaly.

@Neet_pg_bot

Q16: In a patient with type 1 diabetes at the 3rd stage of beta cell damage, which of the following conditions is most likely to be observed? (Q844327)

A. Autoimmune positive + normoglycemia

B. Autoimmune negative + normoglycemia

C. Autoimmune positive + dysglycemia

D. Autoimmune negative + dysglycemia

Correct Answer: C. Autoimmune positive + dysglycemia

Explanation: Correct Option C - Autoimmune positive + dysglycemia: In Stage 3 of type 1 diabetes, there is significant beta cell damage due to an ongoing autoimmune process, leading to dysglycemia (impaired glucose levels). At this stage, there is insufficient insulin production to maintain normal glucose levels, causing hyperglycemia, which characterizes dysglycemia. Incorrect Options: Option A - Autoimmune positive + normoglycemia: This situation is typically seen in the early stages of type 1 diabetes (Stage 1), where there is an autoimmune response against beta cells, but blood glucose levels remain normal because there is still enough insulin production to maintain glucose homeostasis. Option B - Autoimmune negative + normoglycemia: This scenario is not associated with type 1 diabetes. In type 1 diabetes, the autoimmune process is the hallmark feature. If there are no autoimmune markers (autoantibodies), it suggests that type 1 diabetes is unlikely. Normoglycemia in such a context would also not indicate any beta cell damage typical of type 1 diabetes. Option D - Autoimmune negative + dysglycemia: This condition is more suggestive of type 2 diabetes or other forms of diabetes where autoimmune destruction of beta cells is not present. Dysglycemia without autoimmunity does not fit with the progression of type 1 diabetes, which is defined by the presence of autoimmune markers.

@Neet_pg_bot

Q17: A patient presents with features of hyperthyroidism, characterized by decreased TSH levels and elevated free T3 and T4. Which of the following statements about this condition is NOT true? (Q844328)

A. The condition will improve simultaneously with improvement in the thyrotoxic state.

B. In 10% of cases, the condition is present without hyperthyroidism.

C. Severe disease can cause vision loss.

D. No specs criteria is used for this condition.

Correct Answer: A. The condition will improve simultaneously with improvement in the thyrotoxic state.

Explanation: Correct Option A - The condition will improve simultaneously with improvement in the thyrotoxic state: This statement is not true because the condition being referred to is likely Graves' ophthalmopathy (thyroid eye disease), which does not always improve simultaneously with the resolution of the thyrotoxic state. The eye manifestations can persist or even worsen independently of the thyroid hormone levels. Incorrect Options: Options B, C and D are true statements regarding hyperthyroidism and Graves' ophthalmopathy.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A young woman presents with weight loss, tachycardia, heat intolerance, and tremors. On examination, she has exophthalmos. What is the most likely diagnosis? (Q844329)

A. Parkinson's disease

B. Graves' disease

C. Addison's disease

D. Alzheimer's disease

Correct Answer: B. Graves' disease

Explanation: Correct Option B - Graves' disease: Graves' disease is an autoimmune disorder that leads to hyperthyroidism. Symptoms such as weight loss, tachycardia, heat intolerance, and tremors are all characteristic of an overactive thyroid. Exophthalmos (protrusion of the eyes) is a hallmark feature of Graves' disease, distinguishing it from other thyroid conditions. This makes Graves' disease the most likely diagnosis given the patient's symptoms and findings. Incorrect Options: Option A - Parkinson's disease: Parkinson's disease is a neurodegenerative disorder characterized by tremors, bradykinesia (slowness of movement), rigidity, and postural instability. It does not typically present with weight loss, heat intolerance, or exophthalmos, which are more suggestive of a hyperthyroid state. Option C - Addison's disease: Addison's disease is a disorder of adrenal insufficiency characterized by symptoms such as fatigue, weight loss, hyperpigmentation, hypotension, and salt cravings. It does not typically present with tachycardia, heat intolerance, tremors, or exophthalmos, which are indicative of hyperthyroidism rather than adrenal insufficiency. Option D - Alzheimer's disease: Alzheimer's disease is a neurodegenerative condition that primarily affects memory and cognitive function. It does not cause weight loss, tachycardia, heat intolerance, tremors, or exophthalmos, which are not associated with its clinical presentation.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: In Type 1 Diabetes Mellitus, what characterizes stage 3 of beta-cell destruction? (Q844286)

A. Symptomatic hyperglycemia

B. Dysglycemic symptomatic

C. Normoglycemic symptomatic

D. Dysglycemic asymptomatic

Correct Answer: A. Symptomatic hyperglycemia

Explanation: Correct Option A - Symptomatic hyperglycemia : In Type 1 Diabetes Mellitus (DM), the progression of beta-cell destruction typically occurs in stages: Stage 1: Autoimmune destruction of beta cells, but no symptoms are present. Normal blood glucose levels. Stage 2: Progressive beta-cell destruction with dysglycemia (impaired glucose metabolism) but no symptoms of hyperglycemia yet. Stage 3: Significant beta-cell destruction leading to symptomatic hyperglycemia. Patients will present with symptoms such as polyuria, polydipsia, and weight loss due to elevated blood glucose levels. At Stage 3, the destruction is advanced enough that insulin production is insufficient to maintain normal glucose levels, resulting in symptomatic hyperglycemia. Incorrect Options: Option B - Dysglycemic symptomatic: Dysglycemia refers to abnormal glucose levels, which could be either high (hyperglycemia) or low (hypoglycemia). In Type 1 DM, Stage 3 is characterized specifically by symptomatic hyperglycemia, not just dysglycemia. Option C - Normoglycemic symptomatic: Normoglycemic means normal

blood glucose levels. In Stage 3 of Type 1 DM, the patient is not normoglycemic; instead, they are experiencing symptomatic hyperglycemia due to the loss of beta-cell function. Option D - Dysglycemic asymptomatic: Dysglycemia asymptomatic implies abnormal glucose levels without symptoms. In Stage 3 of Type 1 DM, patients are symptomatic due to hyperglycemia, so this option does not fit the stage described.

@Neet_pg_bot

Q20: Which of the following antidiabetic drugs can cause glucosuria? (Q860437)

A. Glimepiride

B. Exenatide

C. Acarbose

D. Empagliflozin

Correct Answer: D. Empagliflozin

Explanation: Empagliflozin belongs to the class of SGLT-2 inhibitors that work by blocking sodium-glucose cotransporter 2 in the proximal convoluted tubules of the nephron. This mechanism prevents the reabsorption of glucose and sodium back into the bloodstream, leading to glucosuria. The drug provides multiple benefits including reduced progression of chronic kidney disease, diuretic effects through sodium loss, and blood pressure reduction of 3-6 mmHg. However, these drugs are contraindicated in patients with eGFR <45 ml/min due to reduced efficacy and risk of urinary tract infections. Sodium-glucose co-transporter 2 (SGLT2) Inhibitors Examples Canagliflozin Dapagliflozin Empagliflozin Mechanism of Action Blocks reabsorption of glucose in the proximal convoluted tubule, promoting the excretion of sodium and glucose in urine Indications Reduce progression of chronic kidney disease (CKD) Diuretic effect, leading to sodium loss Reduces systolic blood pressure (SBP) by 3-6 mmHg Cardiorenal advantage CHF to decrease mortality with or without DM Side Effects Increased risk of urinary tract infections (UTIs) Glucosuria (leading to UTIs and vulvovaginal candidiasis) Dehydration (orthostatic hypotension) Weight loss Contraindications Not recommended if estimated glomerular filtration rate (eGFR) < 45 ml/min Use with caution in renal insufficiency (decreased efficacy with decreased GFR) Glimepiride (Option A) : This sulfonylurea medication works by stimulating insulin release from pancreatic beta cells, causing hypoglycemia and weight gain. It does not cause glucosuria as its mechanism of action is focused on increasing insulin secretion. Exenatide (Option B): This GLP-1 receptor agonist binds to GLP-1 receptor in pancreatic beta-cells in turn increasing insulin secretion and suppressing glucagon secretion. Its actions include delayed gastric emptying, induces early satiety (weight loss) & stabilizes atherosclerotic plaque (reduction in cardiovascular mortality). Its mechanism does not involve renal glucose reabsorption thus does not cause glucosuria. Acarbose (Option C) : This alpha-glucosidase inhibitor works by controlling post-prandial glucose spikes through reduced carbohydrate absorption in the intestine. It may cause abdominal bloating and diarrhea but

does not affect renal glucose handling or cause glucosuria.

@Neet_pg_bot

Q21: A diabetic patient came to the outpatient department with complaints of fatigue and frequent urination. On examination vitals are stable and an HbA1c is done. What is the cut-off percentage used for determining controlled diabetes? (Q860444)

A. 6.0

B. 6.5

C. 7.0

D. 7.5

Correct Answer: C. 7.0

Explanation: According to the American College of Physicians, the target HbA1c for determining controlled diabetes is <7.0% for adults with diabetes. This value represents optimal glycemic control, though it may be adjusted to <8.0% in elderly frail patients . Glycated Hemoglobin (HbA1c) effectively assesses overall glycemic control and is suitable for diagnosing diabetes in asymptomatic individuals. HbA1c prediction in undiagnosed individuals: < 5.7% : Normal 5.7% - 6.5% : Pre-diabetic > 6.5% : Diabetic For patients with existing diabetes, HbA1c is used to evaluate the degree of effective control on diabetes. The cutoffs recommended by ACP for monitoring effective control include: HbA1c < 7.0% Preprandial capillary plasma glucose between 80-130 mg/dL Postprandial capillary plasma glucose <180 mg/dL. 6.0 (Option A) , 6.5 (Option B) & 7.5 (Option D) are incorrect values according to ACP recommendation.

@Neet_pg_bot

Q22: Which of the following is associated with MEN-1 syndrome? (Q860448)

A. Parathyroid adenoma

B. Parotid tumor

C. Renal cell carcinoma

D. Pheochromocytoma

Correct Answer: A. Parathyroid adenoma

Explanation: MEN-1 syndrome, also known as Wermer syndrome , results from a mutation in the MEN-1 gene located on chromosome 11q13 . This gene mutation leads to uncontrolled mitosis in endocrine glands. The classic triad of MEN-1 includes parathyroid adenoma (the most common manifestation), pancreatic adenoma, and pituitary adenoma . Parathyroid involvement is typically the first and most frequent manifestation of this syndrome. Types of Multiple Endocrine Neoplasia MEN Type I MEN Type II MEN Type III MEN Type IV Cause Defect of chromosome 11q13 causing MEN 1 gene mutation Also called Wermer's syndrome Defect of chr.10 leading to mutation of RET gene Also called Sipple's syndrome Also called MEN II B , it is a variant of Type 2 MEN Defect of chr.12 causing CDKN1B gene Tumors Included Parathyroid adenoma (most common) It presents with primary hyperparathyroidism (↑ PTH and ↑ Ca) All the 4 glands can be included. Rx: Total/subtotal parathyroid resection Parathyroid adenoma (most common, and calcium can be normal) Medullary carcinoma thyroid (most common) Parathyroid adenoma (Presents as hypercalcemia) Pancreatic adenoma Presents as Gastrinoma or Zollinger-Ellison syndrome This leads to peptic ulcer disease in the duodenum, which is the leading cause of death in this type. Pheochromocytoma . Pheochromocytoma (Most important criterion for both MEN 2 and MEN 3): Presents with elevated blood pressure. Pituitary adenoma: Prolactinoma Pituitary adenoma: Prolactinoma, causing amenorrhea and Infertility Medullary thyroid carcinoma Calcitonin is the tumor marker present Cold nodules are seen on the thyroid scan Metastasis can be traced with PET scan Visible neck mass, causing dysphagia Rx - Prophylactic thyroidectomy Reproductive tract tumors Testicular tumors Neuroendocrine tumor (Cervix) Associated conditions Angio■broma Collagenoma Adrenocortical tumor Carcinoid tumors/Argenta■noma Pheochromocytoma (only in 1%) Congenital aganglionosis, Hirschsprung disease Marfanoid habitus Medullated corneal nerve ■bers Mucosal neuromas Megacolon and Multiple diverticulae Occasionally with Renal tumor Adrenal tumor Parotid tumor (Option B) : Parotid tumors are not part of the multiple endocrine neoplasia syndromes. These tumors affect the salivary glands and are not associated with endocrine disorders. Renal cell carcinoma (Option C) : While some renal manifestations may occur in MEN syndromes (such as in MEN IV), renal cell carcinoma is not a feature of MEN-1. It may be coincidentally present but is not a defining feature of the syndrome. Pheochromocytoma (Option D) : Pheochromocytoma is actually associated with MEN-II/Sipple syndrome & MEN-III, not MEN-1.
