Viewer Guide

Navigation Tips:

- Use the outline/bookmarks pane (left side in most PDF viewers) to jump between sections.
- Click links at the bottom of each question to switch between Part A (questions) and Part B (answers).
- Master Index links take you to topic parts.

Viewer Settings:

- Adobe Reader: View > Show/Hide > Navigation Panes > Bookmarks
- Chrome: Install PDF viewer extension if needed.
- Mobile: Use apps like Adobe Acrobat or Xodo for outline support.

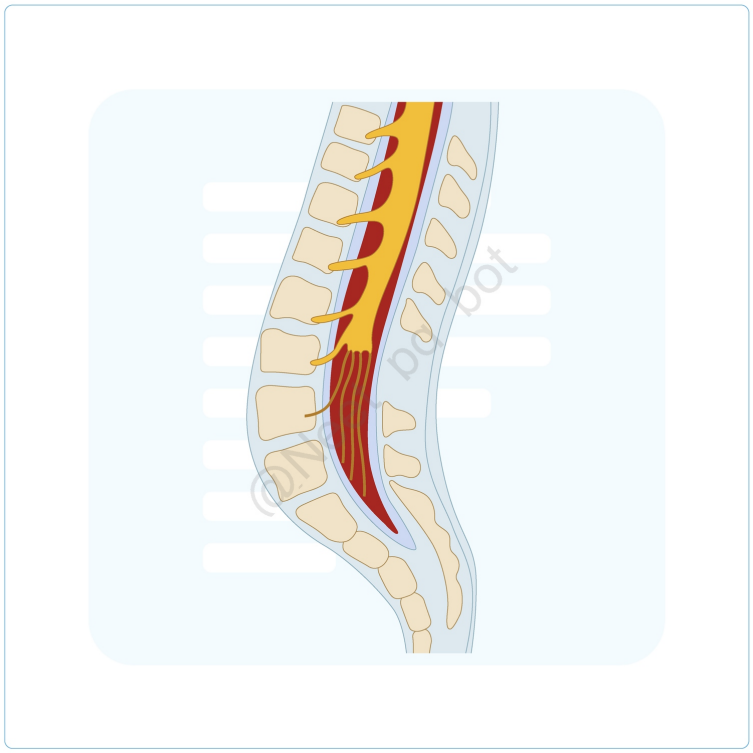
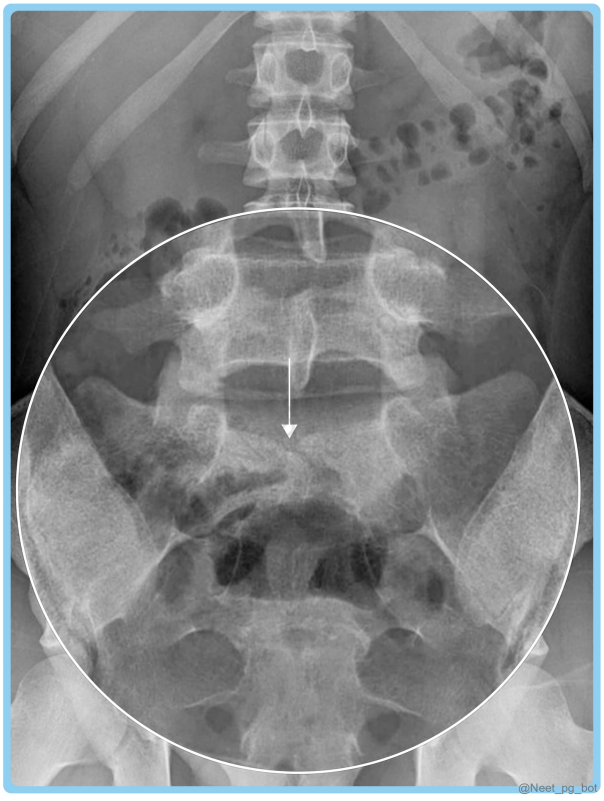
[01_Neurosurgery] 001 Cerebrovascular Diseases — Quick Jump

Q1 (p. 16) *Q2 (p. 18)* *Q3 (p. 18)* *Q4 (p. 18)* *Q5 (p. 19)* *Q6 (p. 19)*
Q7 (p. 20) *Q8 (p. 21)* *Q9 (p. 22)* *Q10 (p. 22)* *Q11 (p. 23)* *Q12 (p. 23)*



Q1: A 25-year-old asymptomatic patient undergoes a routine lumbar spine X-ray for an unrelated complaint. The radiologist notices an incidental finding on the image. Which of the following findings would be inconsistent with spina bifida occulta? (Q849163)

A. Tuft of hair or dimple over the affected area



B. Often asymptomatic and found incidentally on imaging

C. Failure of vertebral arches to fuse with intact spinal cord and meninges

D. Visible sac with cerebrospinal fluid and neural elements protruding through a defect

@Neet_pg_bot

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 28-year-old pregnant woman at 20 weeks of gestation undergoes a routine ultrasound, which reveals a fluid-filled sac at the lower back of the fetus. Which statement about myelomeningocele is most accurate? (Q849164)

A. Protrusion of meninges through a vertebral defect

B. Sac contains cerebrospinal fluid but no neural elements.

C. Better prognosis than other spina bifida types

D. Includes spinal cord tissue within the protruding sac.

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following medications, when taken during pregnancy, is most strongly associated with an increased risk of myelomeningocele in the developing fetus? (Q849165)

A. Metformin

B. Valproic acid

C. Amoxicillin

D. Levothyroxine

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following is most commonly associated with Arnold-Chiari malformation type II? (Q849166)

A. Syringomyelia

B. Myelomeningocele

C. Adult-onset headaches

D. Scoliosis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is NOT part of the classic triad of Dandy-Walker malformation? (Q849167)

A. Cystic dilatation of the fourth ventricle

B. Complete or partial agenesis of the cerebellar vermis

C. Enlarged posterior fossa

D. Hydrocephalus

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 42-year-old male is brought to the emergency department after collapsing at home. His family reports that he suddenly screamed in pain, clutching his head and describing it as the "worst headache of his life," followed by several episodes of vomiting. On examination, he is confused, has significant neck stiffness (nuchal rigidity), and shows marked photophobia. There is no history of recent head trauma. A non-contrast CT scan of the brain is shown below. Which of the following is the most common cause of this patient's condition? (Q849169)

A. Smoking

B. Rupture of a berry aneurysm

C. Severe hypertension

D. Arteriovenous malformation

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 55-year-old patient presents with a sudden severe headache, brief loss of consciousness, nausea, and vomiting. Neurological examination shows decreased consciousness and mild focal deficits. A non-contrast CT scan of the head is provided. What is the most probable diagnosis? (Q849170)

A. Subdural Hematoma (SDH)

B. Extradural Hematoma (EDH)

C. Subarachnoid Hemorrhage

D. Periventricular Hemorrhage

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 52-year-old male with a history of hypertension and smoking presents with sudden onset of nausea, vomiting, and confusion. On examination, he has a decreased level of consciousness and neck stiffness. A non-contrast CT scan reveals subarachnoid haemorrhage. Which of the following statements about Berry aneurysms is not true? (Q849173)

A. Associated with connective tissue disorders like Marfan's syndrome.

B. Absence of smooth muscle and intimal elastic lamina.

C. Most commonly seen at the bifurcation of the vertebrobasilar arteries.

D. Unruptured cases are asymptomatic

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old man with a recent dental infection presents with persistent headaches, fever, and confusion. He exhibits focal neurological deficits and seizures. The radiological findings are provided. Given his clinical presentation and imaging, what is the most appropriate next step in the management of this patient? (Q849174)

A. Initiate IV antibiotics and immediate surgical drainage

B. Start oral antibiotics and monitor with CT every 48 hours

C. Administer high-dose corticosteroids and supportive care

D. Begin antiepileptic medications and refer for op follow-up.

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 58-year-old patient presents with a significant right-sided brain tumour. During the neurological examination, the patient exhibits right-sided weakness. Which of the following best accounts for this presentation? (Q849175)

A. Kernohan notch phenomenon

B. Brown-Sequard syndrome

C. Tullio phenomenon

D. Uhthoff's phenomenon

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 62-year-old man is brought to the emergency department after a fall from a ladder. He has a GCS score of 9 (E2V3M4), and his right pupil is dilated and nonreactive. The CT scan shows a large right-sided subdural hematoma with a significant midline shift to the left. BP: 180/100 mmHg, HR: 52 beats/minute with irregular breathing patterns. Which type of brain herniation is most likely occurring in this patient? (Q849177)

A. Subfalcine herniation

B. Tonsillar herniation

C. Upward transtentorial herniation

D. Uncal herniation

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 62-year-old man undergoes emergent decompressive craniectomy for a large right hemispheric infarct with significant mass effect. Post-surgery, he remains comatose and, six hours later, develops pinpoint pupils and irregular breathing. A stat CT scan shows resolution of the midline shift but reveals new bilateral hyperdense lesions in the midbrain. What is the most likely explanation for these new CT findings? (Q849179)

A. Contrast extravasation

B. Hemorrhagic transformation of infarct

C. Duret haemorrhage

D. Hypertensive microbleeds

See Answer in Part B → Q12

@Neet_pg_bot

[01_Neurosurgery] 002 Cns Tumors — Quick Jump

Q1 (p. 25)	*Q2 (p. 25)*	*Q3 (p. 26)*	*Q4 (p. 26)*	*Q5 (p. 26)*	*Q6 (p. 27)*
Q7 (p. 28)	*Q8 (p. 28)*	*Q9 (p. 29)*	*Q10 (p. 30)*	*Q11 (p. 30)*	*Q12 (p. 31)*
Q13 (p. 32)	*Q14 (p. 32)*	*Q15 (p. 33)*	*Q16 (p. 33)*	*Q17 (p. 34)*	

Q1: A 7-year-old child presents with a headache which gets worse in the morning, associated with nausea, vomiting, and vertigo. The radiograph revealed a type of brain tumour in the 4th ventricle. Which of the following is the investigation of choice in this case? (Q849223)

A. MRI

B. Ultrasonography

C. X-ray

D. CT scan

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 40-year-old man presents with symptoms of spinal cord compression, including back pain and weakness in the legs. MRI reveals a spinal tumour. Which of the following statements about spinal tumours is NOT true? (Q849239)

A. Osteoblastic metastases are often associated with prostate cancer

B. Ependymomas are the most common intramedullary tumours in adults

C. The malignant primary tumour usually involves the vertebral body

D. Most common metastases to the spine are from the Lungs

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55-year-old man with a history of immunosuppression is suspected for Primary CNS lymphoma and evaluated. Which of the following is not accurate about this condition? (Q849238)

A. Often shows a dramatic but short-lived response to steroids.

B. Steroids should be withheld before biopsy.

C. Shows no response to steroids.

D. Diagnosis is confirmed with a stereotactic biopsy.

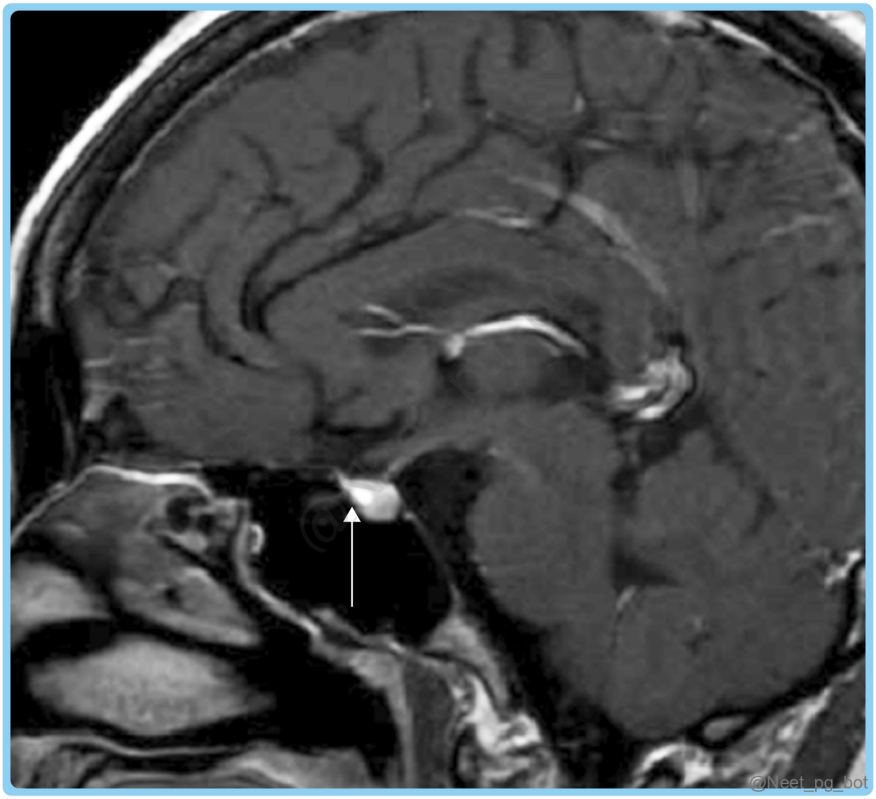
See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 65-year-old patient with a small brain metastasis is being considered for Stereotactic Radiosurgery (SRS). Which statement correctly describes Stereotactic Radiosurgery (SRS)? (Q849237)

A. Delivers broad radiation to treat the entire brain.

B. Delivers a focused dose of radiation to the tumour from multiple angles.



C. Requires prior surgical removal of the tumour.

D. Used for large, invasive tumours needing extensive surgery.

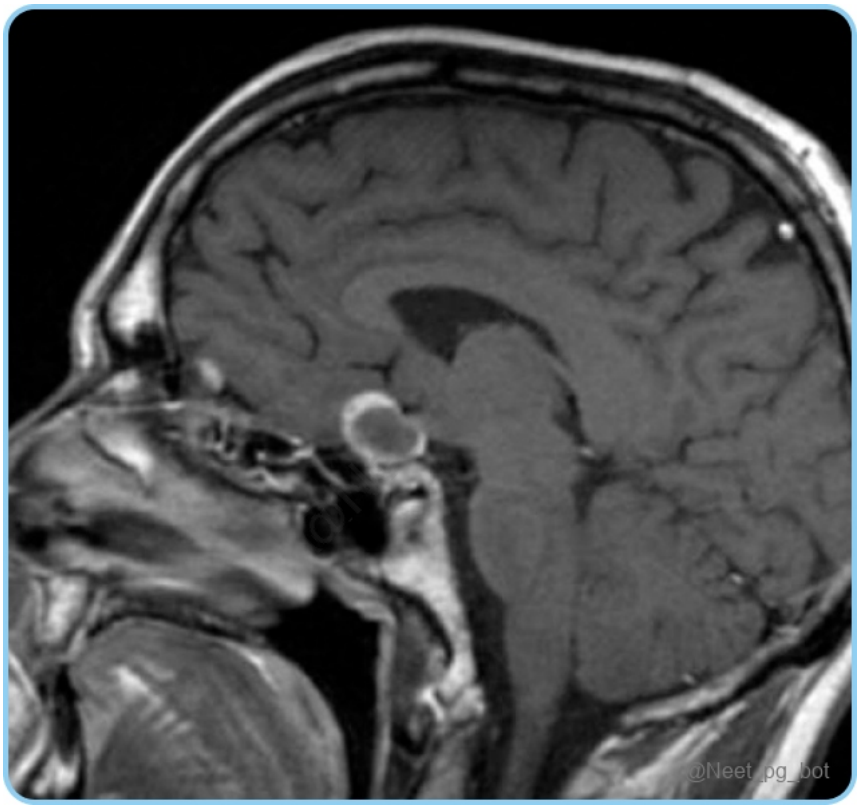
See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 32-year-old woman visits your clinic with complaints of missed periods and noticeable visual disturbances over the past few months. She also reports frequent headaches and mild galactorrhea. MRI shows the findings given in the image. What visual defect is most commonly associated with this condition? (Q849236)

See Answer in Part B → Q5

@Neet_pg_bot



Q6: A 6-year-old child presents with headache, vomiting, blurring of vision, weakness, recent aggression, and weight gain. Examination reveals growth retardation and signs of hypopituitarism. MRI findings are noted. Which of the following is not true regarding this condition? (Q849235)

A. Hypopituitarism is the characteristic feature

B. It is more common in children

C. It is derived from pituitary stalk

D. Growth retardation is also observed

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 52-year-old female patient presents with complaints of difficulty understanding speech and tinnitus. On examination, there is unilateral sensorineural hearing loss, reduced corneal sensitivity, and numbness of the face. Which of the following nerves is most commonly involved in this condition? (Q849234)

A. Inferior vestibular nerve

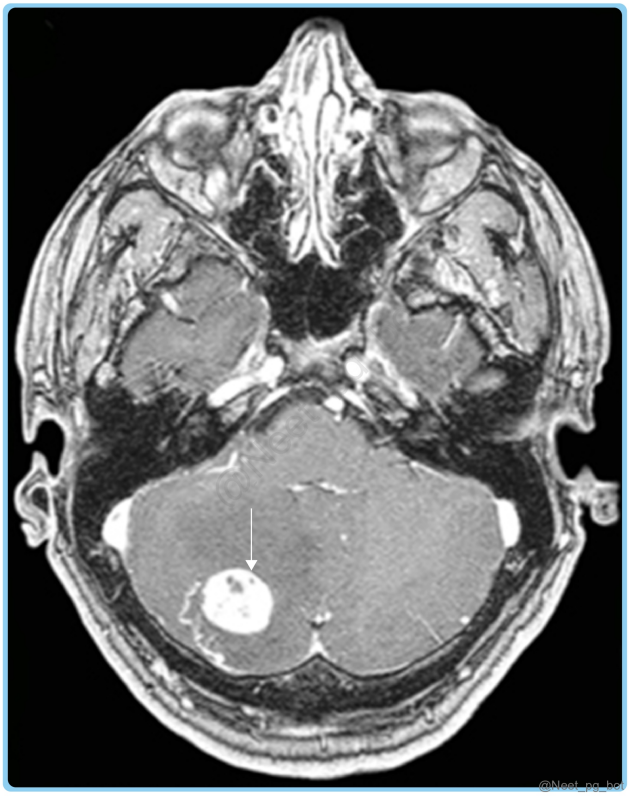
B. Superior vestibular nerve

C. Cochlear nerve

D. Facial nerve

See Answer in Part B → Q7

@Neet_pg_bot



Q8: A 48-year-old male presented with headache, blurring of vision, weakness and loss of balance. His radiological investigations suggested hydrocephalus and pheochromocytoma. A tumour is detected whose radiograph is given below. Which of the following genetic syndromes is most commonly associated with this condition? (Q849233)

A. MEN 1 syndrome

B. VHL syndrome

C. Lynch syndrome

D. Gardner's syndrome

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 3-year-old child presented with complaints of severe morning headache associated with nausea, vomiting and seizure. On examination, the doctor suspected a brain tumour and suggested an MRI, which revealed a tumour at the vermis region.

Which of the following syndromes is associated with this condition? (Q849224)

A. Gorlin syndrome

B. NF1 syndrome

C. VHL syndrome

D. Turcot’s syndrome

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45-year-old woman presents with worsening headaches, cognitive issues, and personality changes. MRI reveals a large mass in the left frontal lobe with surrounding oedema, likely a primary brain tumour. What is the overall most common type of primary brain tumour in adults? (Q849181)

A. Medulloblastoma

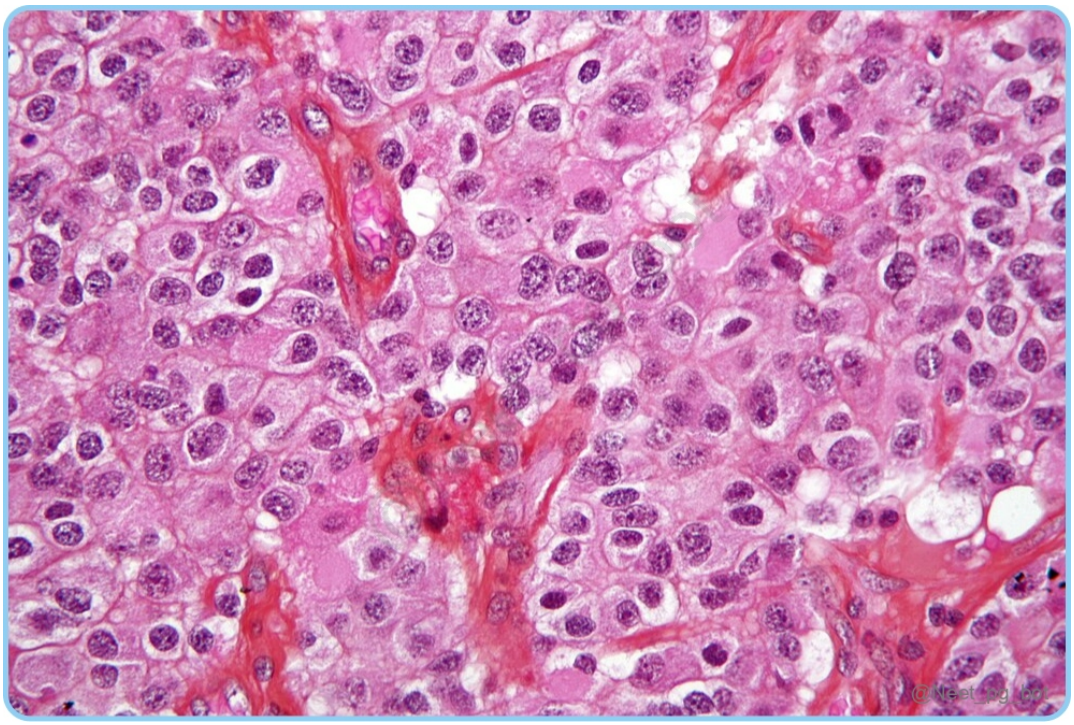
B. Glioblastoma

C. Meningioma

D. Oligodendroglioma

See Answer in Part B → Q10

@Neet_pg_bot



Q11: A 45-year-old male presents with recurrent seizures and headaches. MRI reveals a mass located in the cerebral hemisphere. Histopathological examination of the mass shows cells with a "fried egg" appearance and a chicken-wire capillary pattern. Which of the following is the most likely diagnosis? (Q849222)

A. Meningioma

B. Oligodendroglioma

C. Craniopharyngioma

D. Glioblastoma

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 55-year-old female presents with headaches and visual disturbances. Imaging studies reveal a well-circumscribed mass in the brain. On histopathological examination, the tumour shows calcifications and cells arranged in whorls. Which of the following radiological findings is most characteristic of this tumour type? (Q849221)

A. Calcified mass

B. Ring enhancement

C. Dural tail sign

D. Vasogenic oedema

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 60-year-old patient presents with worsening headaches, focal neurological deficits, and personality changes. MRI imaging reveals a ring-enhancing lesion surrounded by significant oedema. Based on these imaging characteristics, which of the following is the most likely diagnosis and management in recurrent cases? (Q849220)

A. Meningioma, Bevacizumab

B. Glioblastoma Multiforme, Temozolomide

C. Metastatic Brain Tumor, Evacizumab

D. Primary CNS Lymphoma, Doxorubicin

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 45-year-old patient presents with headaches and focal neurological deficits. Imaging reveals a tumour located in the cerebral hemispheres, characterised by

infiltrative growth and low cellularity. Which of the following options best describes the likely diagnosis for this tumour? (Q849195)

A. Pilocytic Astrocytoma

B. Diffuse Astrocytoma

C. Anaplastic Astrocytoma

D. Glioblastoma Multiforme

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 12-year-old child presents with headaches, vomiting, and unsteady gait. Imaging reveals a mass in the posterior fossa. The lesion is surgically resected, and histology reveals a tumour with a low mitotic index. Which of the following best describes the most common location and prognosis of this tumour? (Q849189)

A. Hypothalamus, Poor prognosis

B. Cerebellum, Good prognosis

C. Cerebellum, Poor prognosis

D. Hypothalamus, Good prognosis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which type of brain tumour is most likely to cause personality changes, impaired judgment, and difficulty with motor planning? (Q849183)

A. Frontal lobe tumors

B. Temporal lobe tumors

C. Occipital lobe tumors

D. Cerebellar tumors

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 62-year-old man with a 40-pack-year smoking history presents with worsening headaches, confusion, ataxia, and right-sided weakness. A CT scan reveals multiple ring-enhancing brain lesions and further imaging identifies a mass in the right upper lobe of the lung. What is the most likely primary source of brain metastases? (Q849182)

A. Colorectal cancer

B. Prostate cancer

C. Lung cancer

D. Melanoma

See Answer in Part B → Q17

@Neet_pg_bot

Q1: What is the classification of the head injury of a patient involved in a road traffic accident, based on a GCS score of 10? (Q793536)

A. Moderate traumatic brain injury

B. Severe traumatic brain injury

C. Minor traumatic brain injury

D. Mild traumatic brain injury

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is most likely to be seen due to the rupture of a saccular aneurysm? (Q855826)

A. Subdural hemorrhage

B. Subarachnoid hemorrhage

C. Intracerebral hemorrhage

D. Hydrocephalus

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A cricket player was initially hit on the head with a cricket ball, appearing fine but later collapsing, regaining consciousness to play well, and then found unconscious in the dressing room. What is the probable diagnosis based on the result of the CT scan provided? (Q859882)

A. Extradural hemorrhage

B. Artifact

C. Subdural hemorrhage

D. Subarachnoid hemorrhage

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 27-year-old man came to the clinic with a headache, palpitations, and sweating. As there is a history of renal problems in his brother and father, he requested an abdominal ultrasound, which revealed the presence of multiple renal and pancreatic

cysts. 24-hour urinary metanephrine was sent, which was elevated. What is the most likely diagnosis? (Q859827)

A. Multiple endocrine neoplasia type I

B. Von Hippel-Lindau disease

C. Birt-Hogg-Dube syndrome

D. Tuberous sclerosis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: What is the diagnosis for the unconscious patient brought to the casualty department following a road accident, as depicted in the provided CT scan image? (Q859631)

A. Extradural hematoma (EDH)

B. Subdural hematoma (SDH)

C. Intraparenchymal bleed

D. Subarachnoid hemorrhage (SAH)

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 15-year-old boy presents with a slow-growing, rubbery, non-tender swelling on the side of the neck, as shown in the image. Examination shows the presence of freckles and light skin patches over the face and trunk. What is the most likely diagnosis? (Q856736)

A. Cystic hygroma

B. Chemodectoma

C. Neural tumour

D. Lipoma

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Calculate the Glasgow Coma Scale (GCS) of a patient admitted after a road traffic accident and receiving mechanical ventilation. The patient demonstrates a response by opening their eyes upon verbal command and exhibits spontaneous movement in all four limbs. (Q856539)

A. Eyes-2, Verbal-1, Motor-5

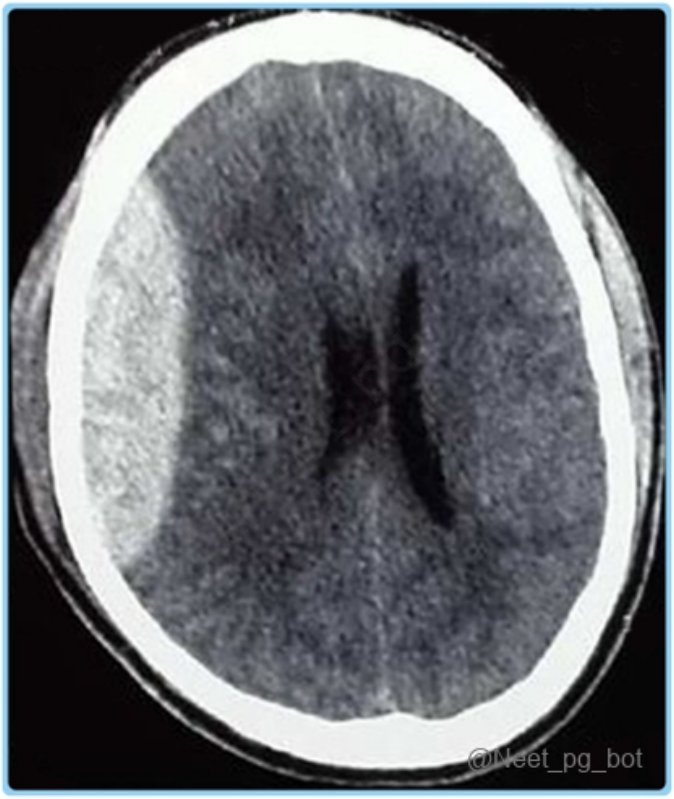
B. Eyes-2, Verbal-NT, Motor-5

C. Eyes-3, Verbal-1, Motor-6

D. Eyes-3, Verbal-NT, Motor-6

See Answer in Part B → Q7

@Neet_pg_bot



Q8: What potential diagnosis should be considered for a patient admitted to the Emergency department following a road traffic accident exhibiting an altered level of consciousness and a Glasgow Coma Scale (GCS) score of 10, as depicted in the provided CT scan? (Q857436)

A. Subdural hematoma

B. Intracerebral hemorrhage

C. Extradural hematoma

D. Hemorrhagic contusion

See Answer in Part B → Q8

@Neet_pg_bot

Q9: An old lady sustained a fall and developed a headache and neurological symptoms a few days later. What is your diagnosis? (Q855261)

A. Multi-infarct dementia

B. Frontal lobe meningioma

C. Korsakoff disease

D. Subdural hematoma

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 34-year-old woman was brought to the AIIMS emergency following a road traffic accident. She was hemodynamically stable, and her GCS score was 3. She was intubated and sent for non-contrast C,T which was found to be normal. What is the most likely diagnosis? (Q855175)

A. Subdural hemorrhage

B. Extradural hemorrhage

C. Diffuse axonal injury

D. Cerebral contusion

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 30 year male old patient presents to OPD with complaints of recurrent headache and nausea, MRI brain shown. What is the diagnosis? (Q866457)

A. Meningioma

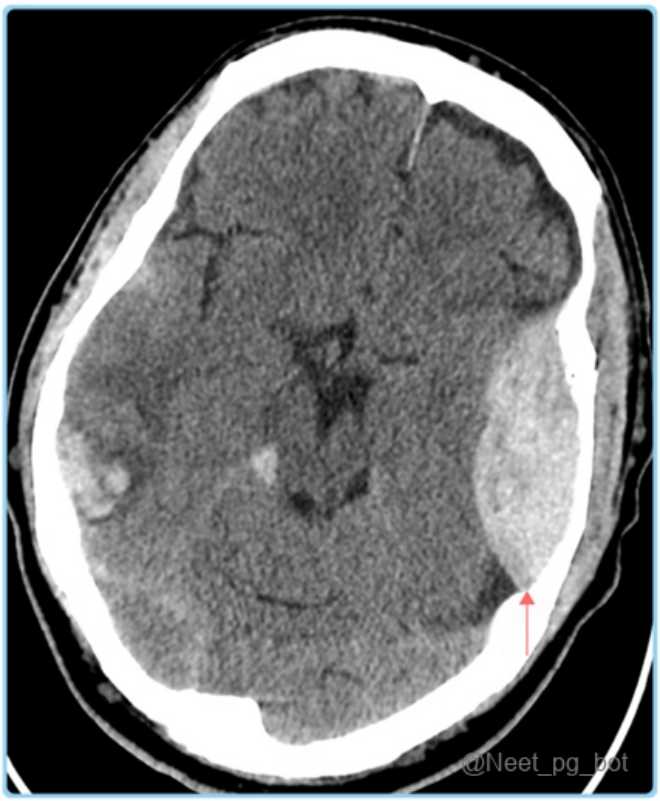
B. Glioma

C. Ependymoma

D. Pilocytic astrocytoma

See Answer in Part B → Q11

@Neet_pg_bot



Q12: What is the probable diagnosis for a 30-year-old woman who experienced nausea and vomiting after being involved in a road traffic accident, and was brought to the emergency room unconscious, based on the findings of the NCCT brain? (Q857856)

A. Extradural hemorrhage

B. Subdural hemorrhage

C. Intra-parenchymal hemorrhage

D. Subarachnoid hemorrhage

See Answer in Part B → Q12

@Neet_pg_bot

Q13: What is the most appropriate course of action for the management of a patient who presents to the emergency department with a severe headache and has a blood pressure reading of 160/100 mmHg, along with a CT scan showing evidence of a subarachnoid haemorrhage? (Q855267)

A. Nimodipine

B. Angiography

C. Surgery

D. Fibrinolytic therapy

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 50-year-old patient presents with confusion and ataxia following trauma one week ago. He has a history of alcohol dependence, with his last intake 2 weeks ago. A CT scan reveals the following findings. What is the most likely diagnosis? (Q855207)

A. Extradural hemorrhage

B. Subdural hemorrhage

C. Intra-parenchymal hemorrhage

D. Subarachnoid hemorrhage

See Answer in Part B → Q14

@Neet_pg_bot

Q15: What is the Glasgow Coma Scale (GCS) score of a patient who was admitted to the emergency room after being involved in a road traffic accident and, on examination, opens his eyes in response to a painful stimulus, speaks inappropriately, and withdraws his limbs in response to a painful stimulus? (Q855182)

A. E2V2M3

B. E3V3M3

C. E2V3M4

D. E3V2M2

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following conditions is associated with perineural invasion? (Q854781)

A. Adenoid cystic carcinoma

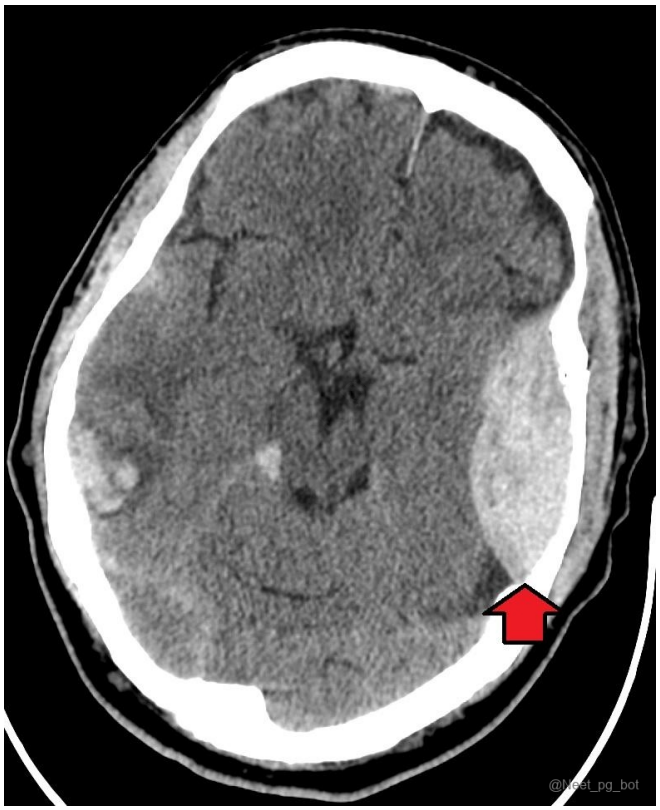
B. Pleomorphic adenoma

C. Mucoepidermoid tumour

D. Pancreatic cancer

See Answer in Part B → Q16

@Neet_pg_bot



Q17: A 32-year-old patient had a RTA and was brought to the ER. On examination, his GCS was E2M4V2 and his CT scan is given below. Which of the following is the preferred treatment in this condition? (Q820167)

A. Ventilation

B. Craniotomy with evacuation of hematoma

C. Anticoagulants

D. Steroids

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which type of intracranial hemorrhage is most likely depicted in the image given below? (Q860287)

A. Extradural hemorrhage

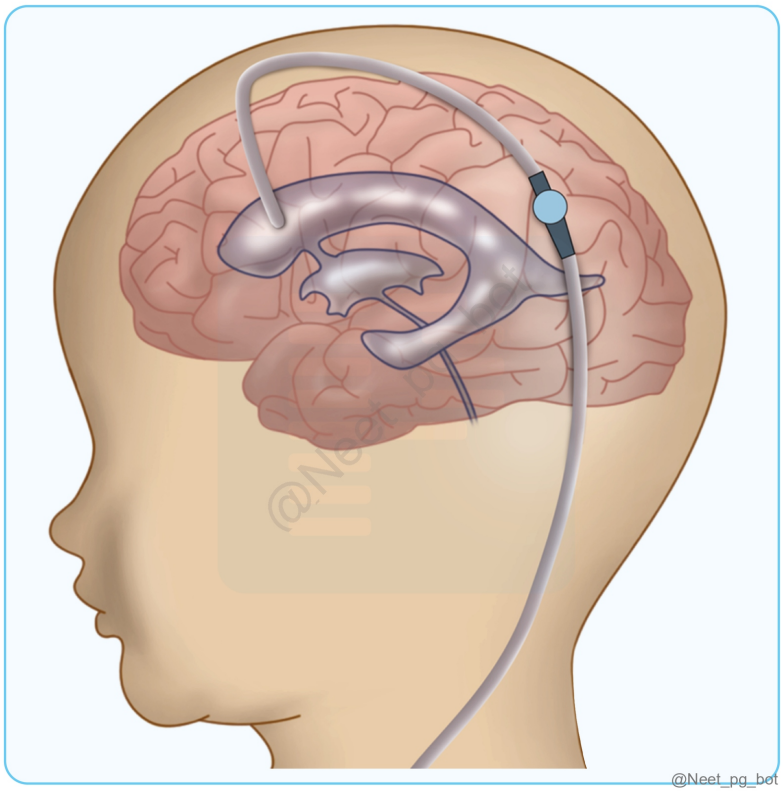
B. Subarachnoid hemorrhage

C. Subdural hematoma

D. Intraparenchymal hemorrhage

See Answer in Part B → Q18

@Neet_pg_bot



Q19: A 7-year-old boy is brought with complaints of headache, and vomiting for a few days. He had undergone a ventriculoperitoneal (VP) shunt placement for hydrocephalus a year ago. What is the most common cause of shunt malfunction in this patient? (Q860460)

A. Shunt infection

B. Shunt obstruction

C. Shunt tip migration

D. Shunt disconnection

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 65-year-old patient with a history of thromboembolic stroke, currently taking warfarin and aspirin, presents with a headache and confusion after a fall in the toilet. A non-contrast CT of the head is given in the image. What is the next best step in management? (Q860383)

A. Aspirin + Clopidogrel

B. Vitamin K + FFP + Neurosurgery consultation

C. IV Mannitol

D. Observation

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 25 year patient had a Road traffic accident was initially conscious but later became unconscious and subsequently died. On postmortem examination, multiple petechial haemorrhages are seen in the corpus callosum, what is the probable diagnosis (Q866463)

A. EDH

B. Diffuse axonal injury

C. Subdural hematoma

D. SAH

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following is the next step in the management of an old patient who has undergone complete excision of glioblastoma ? (Q793556)

A. Chemotherapy with Bevacizumab

B. No further management

C. Chemoradiation

D. Radiotherapy

See Answer in Part B → Q22

Q1: A 55-year-old male presents with a 2 cm ulcerative lesion located on the lateral border of the anterior portion of the tongue, closer to the tip. During surgical planning, which group of lymph nodes is the most likely initial site of lymphatic drainage for this lesion? (Q849605)

A. Level I

B. Level II

C. Level III

D. Level IV

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 65-year-old patient presents with metastatic adenocarcinoma, but the primary tumor site remains unidentified. Which of the following is the most appropriate next step in the workup to help locate the primary tumor? (Q849630)

A. Complete blood count

B. PET scan

C. Start chemotherapy

D. Exploratory surgery

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 58-year-old patient who recently had a neck dissection is experiencing swelling, pain, and fluid accumulation in the surgical area. Which of the following is NOT a typical complication associated with neck dissection? (Q849629)

A. Wound dehiscence

B. Chyle leak

C. Accessory nerve injury

D. Facial nerve paralysis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A patient undergoes a neck dissection that involves removing lymph nodes from levels I-V, while preserving the spinal accessory nerve, and internal jugular vein. What type of neck dissection was performed? (Q849628)

A. Radical neck dissection

B. Anterolateral Neck Dissection

C. Modified Radical Neck Dissection Type II

D. Modified Radical Neck Dissection Type III

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 58-year-old male is scheduled for a neck dissection due to metastatic squamous cell carcinoma of the oral cavity. Which incision will the surgeon choose to provide optimal access to all cervical lymph node levels? (Q849619)

A. Macfee incision

B. Modified Schobinger incision

C. Y-shaped incision

D. Modified Macfee incision

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 60-year-old female diagnosed with oral cavity cancer presents with a non-healing ulcer on her lower lip. Which of the following lymph node levels is most likely involved in this patient? (Q849618)

A. Levels IV and V

B. Levels II, III and IV

C. Levels I, II and III

D. Level VII

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 35-year-old male presents with a smooth, tender swelling in the right lower jaw in relation to tooth caries. A panoramic radiograph shows a well-defined radiolucency around the roots of the lower right first molar. What is the most likely diagnosis? (Q849612)

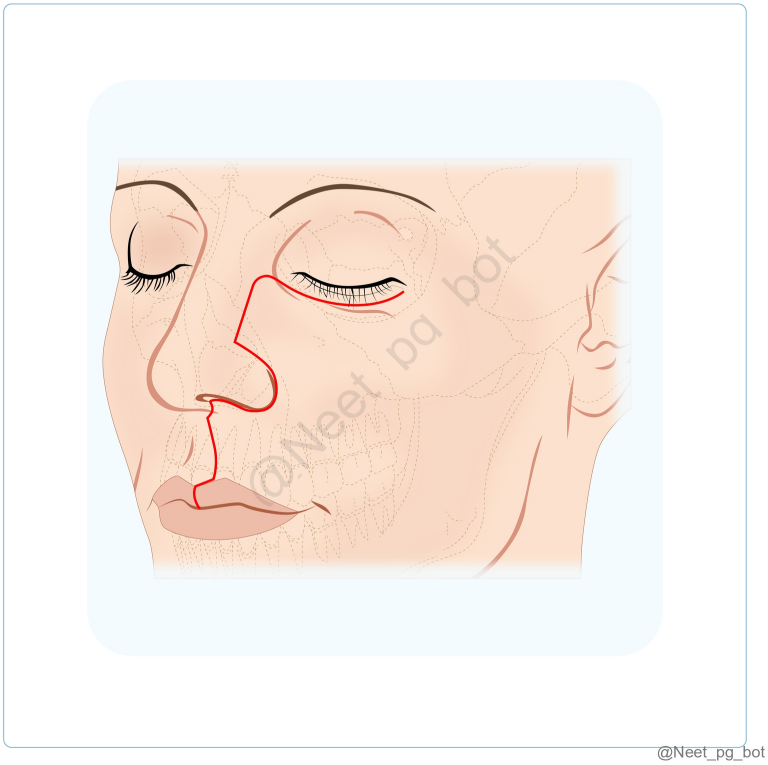
A. Dentigerous cyst

B. Dental cyst

C. Ameloblastoma

D. Epulis

See Answer in Part B → Q7



Q8: A 55-year-old male presents with a large tumor involving the floor of the maxillary sinus, causing facial swelling and nasal obstruction. During surgery, the surgical team uses the approach shown in the image. Identify the type of incision used in this procedure. (Q849611)

A. Caldwell-Luc Incision

B. Weber-Fergusson Incision

C. Modified Blair Incision

D. Lateral Rhinotomy Incision

See Answer in Part B → Q8

Q9: A 55-year-old male patient requires mandibular reconstruction following the resection of a tumor. The surgeon is considering different bone graft options. Which of the following bone grafts is not likely to be chosen for bony reconstruction of the mandible? (Q849610)

A. Fibula bone graft

B. Iliac crest bone graft

C. Tibia bone graft

D. Scapula bone graft

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A patient is scheduled for segmental mandibulectomy due to a lower alveolar tumor invading the mandible. Which statement accurately describes this procedure? (Q849609)

A. Preserves mandible continuity.

B. Suitable for tumors not invading the mandible.

C. Removes the entire height of the mandible.

D. Resection of partial thickness of the mandible.

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 65-year-old male with lower alveolar squamous cell carcinoma presents with an ulcerated mass, extensive cortical bone erosion, invasion beyond the inferior alveolar canal. What is the most appropriate treatment? (Q849608)

A. Radiotherapy

B. Local excision with marginal resection

C. Segmental mandibulectomy

D. Marginal resection, along with block dissection

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A patient presents with 2.5 cm ulceroproliferative adenoid cystic carcinoma on the left side of the hard palate. Imaging shows no evidence of bone invasion or lymph node involvement. Which of the following is the most appropriate management strategy? (Q849607)

A. Wide local excision with frozen section control

B. Partial maxillectomy with ipsilateral neck dissection

C. Partial maxillectomy without neck dissection

D. Radiotherapy alone

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A female who chews betel quid has pale, fibrous oral mucosa and a 2 cm interincisal opening. Biopsy revealed increased collagen deposition in the lamina propria. Which of the following is the most likely complication of this condition if left untreated? (Q849606)

A. Candidiasis

B. Malignant transformation

C. Bilateral submandibular gland hypertrophy

D. Spontaneous remission of fibrosis

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following statements about the extent of the oral cavity is false? (Q849562)

A. The anterior border of the oral cavity begins at the vermillion border.

B. Superiorly, the oral cavity includes the soft palate up to the uvula.

C. The posterior extent of the oral cavity ends at the circumvallate papillae of the tongue.

D. The tonsils are not a part of the oral cavity.

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 65-year-old patient presents with a 2.5 cm ulcerative lesion on the right side of his lower lip confirmed as squamous cell carcinoma. Which of the following statements is correct regarding the primary lymphatic drainage and surgical management of this lesion? (Q849594)

A. Drains to submental nodes; level I neck dissection is sufficient.

B. Drains to ipsilateral submandibular nodes; levels I-III neck dissection is recommended.

C. High risk of contralateral metastasis; bilateral neck dissection is needed.

D. Drains to preauricular and parotid nodes; requires superficial parotidectomy.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 72-year-old farmer presents with a 3.5 cm exophytic lesion on his lower lip. Biopsy confirms well-differentiated squamous cell carcinoma with 8 mm depth of invasion. There are no palpable lymph nodes. Which of the following is the correct management strategy? (Q849593)

A. Wide local excision with 5 mm margins and neck observation.

B. Wide local excision with 1 cm margins and ipsilateral neck dissection.

C. Wide local excision with 1 cm margins and bilateral neck dissection.

D. Radiotherapy alone.

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 62-year-old male with recurrent squamous cell carcinoma of the oral cavity is being considered for immunotherapy using pembrolizumab. Which of the following correctly describes the mechanism of action of the drug? (Q849592)

A. Inhibits VEGF to prevent tumor angiogenesis

B. Blocks PD-1 receptor, enhancing T-cell anti-tumor activity

C. Targets EGFR to inhibit tumor cell proliferation

D. Activates NK cells to induce antibody-dependent cellular cytotoxicity

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 59-year-old male with T2N2bM0 squamous cell carcinoma of the buccal mucosa underwent surgery. The postoperative histopathology report reveals close surgical margin (< 5 mm) and extracapsular extension in two lymph nodes. What is the most appropriate adjuvant treatment for this patient? (Q849591)

A. Radiotherapy alone

B. Chemotherapy alone

C. Concurrent chemoradiotherapy

D. Observation and close follow-up

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 58-year-old male with a 6 cm x 4 cm defect involving more than 50% of the tongue after excision for a T3N1M0 squamous cell carcinoma needs reconstruction. Which of the following flaps would be most appropriate for reconstruction for this patient? (Q849590)

A. Radial forearm free flap

B. Anterolateral thigh free flap

C. Pectoralis major myocutaneous flap

D. Supraclavicular artery island flap

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 62-year-old male presents with a T2N1M0 squamous cell carcinoma of the lateral border of the tongue. According to the latest National Comprehensive Cancer Network (NCCN) guidelines, what is the most appropriate initial management for this patient? (Q849589)

A. Wide local excision of the primary tumor only.

B. Definitive radiotherapy with concurrent chemotherapy.

C. Surgery followed by adjuvant radiotherapy.

D. Neoadjuvant chemotherapy followed by surgery.

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A male presents with a painful 2.5 cm ulceroproliferative growth on the right lateral border of the tongue with induration extending to the floor of the mouth and a single, firm, mobile 1.5 cm lymph node palpable in the right submandibular region. The CT scan shows no mandible or extrinsic muscle involvement. What is the correct TNM staging for this patient? (Q849570)

A. T2N1M0

B. T3N1M0

C. T4aN1M0

D. T2N2aM0

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 55-year-old patient presents with a non-healing ulcer in the oral cavity and is diagnosed with carcinoma oral cavity. Which of the following statements regarding carcinoma oral cavity is most accurate? (Q849569)

A. Distant metastasis is common.

B. Ulcer lasting over 3 weeks is significant.

C. Adenocarcinoma is the most common oral cancer.

D. Oral carcinoma is the least common among head and neck tumors.

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A patient who had developed a buccal squamous cell carcinoma was treated by complete resection and radiation therapy. After his treatment was completed and he had clear margins after the resection, he developed a new tumor in his oral cavity on his tongue. What is the basis of this development of a second primary tumor? (Q849568)

A. Field defect

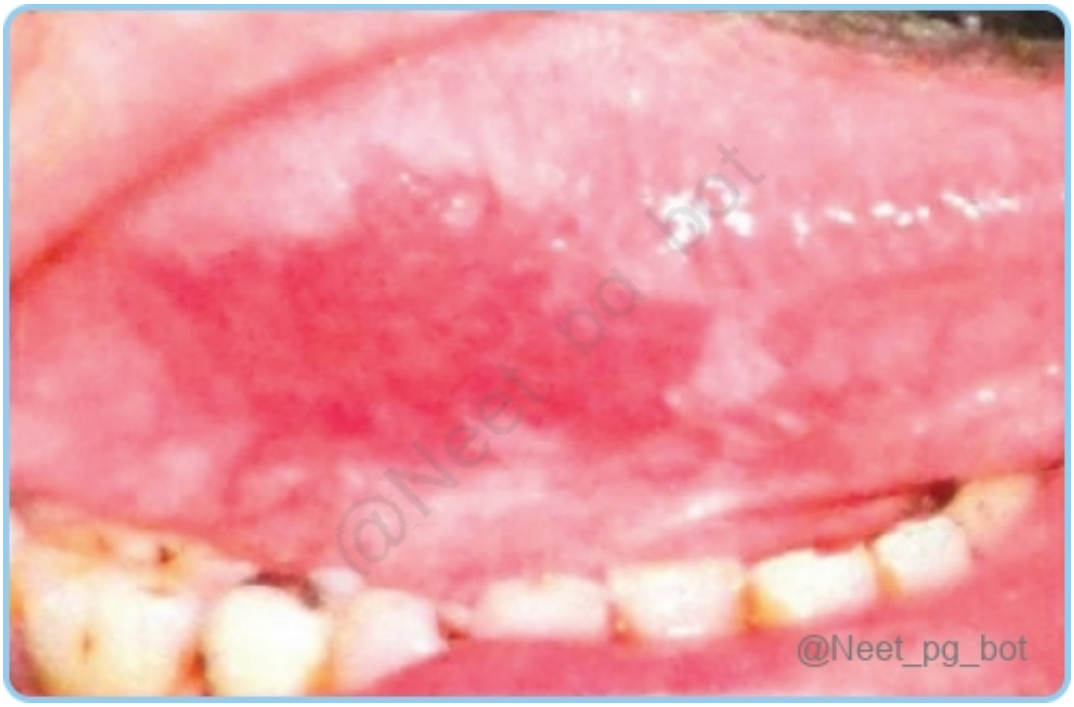
B. Field effect

C. Field cancerization

D. All of the above

See Answer in Part B → Q23

@Neet_pg_bot



Q24: A 45-year-old female comes to the clinic with a reddish patch on her tongue, as shown in the figure. She gives a history of chewing pan masala for more than 15 years. She has no difficulty in opening her mouth and has no other comorbidities. What is the most probable diagnosis? (Q849565)

A. Oral submucosal fibrosis

B. Erythroplakia

C. Plummer-Vinson syndrome

D. Leukoerythroplakia

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 50-year-old patient comes to the OPD concerned about a newly developed whitish discolouration in his mouth. On examination, a white plaque-like lesion was

found in his buccal mucosa, which could not be rubbed off. What is the most likely diagnosis? (Q849564)

A. Leukoplakia

B. Erythroplakia

C. Speckled leukoplakia

D. Chronic hyperplastic Candidiasis

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 45-year-old male comes to the hospital after noticing abnormal growth on the right side of his mouth. He has had a habit of smoking and chewing betel quid for more than 20 years. On further evaluation, he also gives a history of a red lesion present in the same location before the current state. Which of the following, in this case, is not a risk factor for oral carcinoma? (Q849563)

A. Age above 40 years

B. Erythroplakia

C. Smoking

D. Betel quid

See Answer in Part B → Q26

@Neet_pg_bot

Q19 (p. 72)

Q1: A 45 y/o woman undergoes a superficial parotidectomy for a pleomorphic adenoma. Which of the following is a known complication associated with this condition or its treatment? (Q849649)

A. Permanent facial nerve paralysis is common after parotidectomy.

B. Pleomorphic adenomas rarely recur after surgical excision.

C. Radiotherapy for pleomorphic adenoma is risk-free and only used as a primary treatment.

D. Frey’s syndrome is characterized by sweating and flushing in the preauricular area during meals.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 28-y/o male presents with a painless, soft swelling in the submandibular region that has been gradually enlarging over the past 2 months. On examination, the swelling is dumbbell-shaped, fluctuant, and bidigitally palpable. The overlying mucosa appears thick with a bluish hue. Fine needle aspiration yields a viscous, "egg white-like" fluid with high amylase content, confirming the diagnosis. What is the most appropriate treatment for this patient? (Q849658)

A. Incision and drainage of the cyst

B. Marsupialization (unroofing) of the ranula

C. Surgical excision of the ranula and involved sublingual gland

D. Observation and follow-up

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 16 y/o female has a painless, soft, fluctuant swelling in the anterior floor of her mouth that has increased in size over a few weeks. There is no history of trauma or infection. What is the most appropriate next step in confirming the diagnosis? (Q849657)

A. Magnetic Resonance Imaging

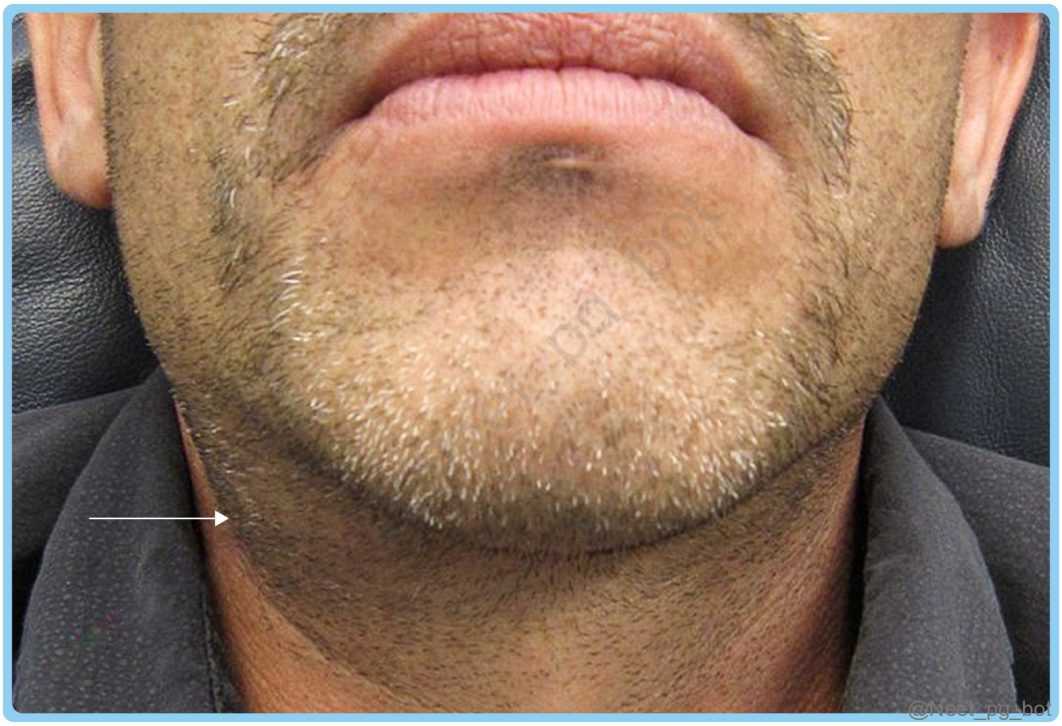
B. Computed Tomography

C. Incisional biopsy

D. Aspiration of the lesion

See Answer in Part B → Q3

@Neet_pg_bot



Q4: A 52 y/o male has recurrent pain and swelling in the left lower jaw, worsening over several months. On examination, there is a significant swelling of the right submandibular gland, but no palpable stone. A CT scan shows an 8 mm stone deep within the submandibular gland, inaccessible by sialendoscopy. What is the best next step in management? (Q849656)

A. Endoscopic removal of the stone

B. Ductal slitting for stone extraction

C. External shock wave lithotripsy (ESWL)

D. Gland excision

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45 y/o woman is undergoing surgery for the removal of a submandibular gland mass. Postoperatively, she complains of numbness and a burning sensation of her tongue. Which nerve is most likely to have been injured during the procedure?

(Q849655)

A. Facial Nerve

B. Lingual Nerve

C. Hypoglossal Nerve

D. Glossopharyngeal Nerve

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 60 y/o man with a diagnosis of adenoid cystic carcinoma has undergone surgical resection of a tumour located in the palate. Postoperative imaging reveals no residual tumour but shows the involvement of regional lymph nodes. What is the most appropriate additional treatment for this patient? (Q849654)

A. Additional surgical resection

B. External beam radiotherapy

C. Preoperative chemotherapy

D. Observation and regular follow-up

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 60 y/o man presents with a slow-growing, painless mass in the submandibular region. O/E, the mass is firm and non-tender and biopsy reveals a tumor with a combination of tubular and solid histological patterns. Imaging shows perineural invasion extending towards the base of the skull. Which histopathological type in this carcinoma is associated with the worst prognosis? (Q849653)

A. Cribriform

B. Tubular

C. Solid

D. Papillary

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which immunohistochemical marker helps to distinguish acinic cell carcinoma from secretory carcinoma? (Q849652)

A. p53

B. Mammaglobin

C. S100

D. Ki-67

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45 y/o female has a firm, enlarging swelling below her left ear for 6 months. O/E, the swelling is hard and nodular, with no signs of facial nerve involvement. FNAC shows malignant cells, and imaging reveals a tumour in both lobes of the parotid gland with no distant metastases. What is the most likely diagnosis? (Q849651)

A. Pleomorphic adenoma

B. Mucoepidermoid carcinoma

C. Adenoid cystic carcinoma

D. Warthin’s tumor

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following statements about Warthin's tumour and its diagnostic features is correct? (Q849650)

A. It is best identified on imaging by its hypoechoic appearance and confirmed with FNAC.

B. A Tc99 pertechnetate scan showing a "hotspot" is indicative of Warthin's tumour.

C. HPE shows mucin-secreting cells

D. Warthin's tumour generally exhibits low uptake on Tc99 pertechnetate scans

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following salivary glands secretes saliva through Stensen’s duct? (Q849640)

A. Parotid gland

B. Submandibular gland

C. Sublingual gland

D. Minor salivary glands

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 35 y/o female has a slowly enlarging, painless, well-defined mass in the left parotid gland, present for two years. O/E there is no facial nerve involvement. Ultrasound shows a well-lobulated, hypoechoic lesion, and FNAC suggests a benign neoplasm. What is the most appropriate next step in management? (Q849648)

A. Observation and follow-up

B. Radiotherapy

C. Surgical excision with a margin of normal tissue

D. Enucleation of the tumour

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 50 y/o female with swelling and pus discharge from the left cheek for two weeks, worsening with eating, recently had a superficial parotidectomy. Examination reveals a small external opening at the parotid region with saliva-like discharge. What is the best initial management? (Q849647)

A. Antibiotics and observation

B. Sialography to evaluate the fistula

C. Surgical exploration and repair

D. Anticholinergic therapy with hyoscine bromide

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 60 y/o male undergoes a parotidectomy for a benign tumour located in the superficial lobe of the parotid gland. On the second postoperative day, he notices sweating and flushing in the area just in front of his ear when he eats. The patient also reports mild numbness of the earlobe. Which of the following nerves is most commonly affected? (Q849646)

A. Facial nerve

B. Auriculotemporal nerve

C. Great auricular nerve

D. Hypoglossal nerve

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 45 y/o patient presents with a parotid gland tumour located deep to the facial nerve. The tumour has been identified as malignant and has extended beyond the parotid gland. Given these findings, which surgical approach is most appropriate for this patient? (Q849645)

A. Radical parotidectomy

B. Total conservative parotidectomy

C. Superficial parotidectomy

D. Adequate parotidectomy

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 62 y/o woman presents with a recurrent adenoid cystic carcinoma of the submandibular gland. The tumour has been surgically resected twice before, and each time, the pathology report showed perineural invasion. What is the most appropriate next step in managing her condition? (Q849644)

A. Repeat surgical excision

B. Radiation therapy

C. Chemotherapy

D. Targeted therapy

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 45 y/o woman presents with a progressively enlarging mass in her right parotid gland. The mass is non-tender and has been present for 6 months. An ultrasound revealed a well-defined hypoechoic lesion with no evidence of calcification or increased vascularity. Which of the following is the most appropriate next step for this patient? (Q849643)

A. Sialography

B. Positron Emission Tomography (PET-CT)

C. Core Needle Biopsy

D. Fine-needle aspiration Cytology (FNAC)

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which is the most common salivary gland tumour found in infants and young children? (Q849642)

A. Pleomorphic adenoma

B. Mucoepidermoid carcinoma

C. Hemangioma

D. Adenoid cystic carcinoma

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 50 y/o male presents with a swelling in his parotid gland, and a biopsy reveals a Warthin's tumour. Which of the following is most likely a contributing risk factor for this patient's condition? (Q849641)

A. Radiation exposure in childhood

B. Chronic inflammation of the salivary glands

C. Smoking history

D. Immunocompromised state

See Answer in Part B → Q19

@Neet_pg_bot

Q25 (p. 84)					

Q1: A patient is brought to the trauma unit after being assaulted. He presents with severe pain, swelling, and deformity in the lower jaw. Imaging confirms a "bucket handle" fracture of the mandible. What is the most likely nerve to be injured in this type of fracture? (Q849719)

A. Lingual nerve

B. Inferior alveolar nerve

C. Hypoglossal nerve

D. Facial nerve

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Match the following LeFort's fracture types: LeFort's types Features 1. LeFort's I a- Craniofacial dislocation 2. LeFort's II b- Horizontal fracture 3. LeFort's III c- Pyramidal fracture d- Tripod fracture (Q849716)

A. 1-b, 2-c, 3-a

B. 1-d, 2-b, 3-a

C. 1-c, 2-d, 3-b

D. 1-a, 2-c, 3-b

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 30-year-old male presents to the emergency department after a motor vehicle accident. On assessment, there is bruising around the left eye, and tenderness over the zygomatic arch. Which of the following imaging views is most appropriate for assessing a suspected zygomatic bone fracture? (Q849715)

A. Caldwell's view

B. Water's view

C. Lateral skull view

D. Towne's view

See Answer in Part B → Q3

@Neet_pg_bot

Q4: All of the following are true regarding the clinical presentation of zygomatic bone fracture except? (Q849714)

A. Epistaxis

B. Anesthesia in infra-orbital nerve distribution

C. Flattening of malar prominence

D. Deranged dental occlusion

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 22-year-old male presents with pain in the jaw and difficulty opening his mouth after a fall from a bicycle, landing directly on his chin. On examination, there is tenderness at the left preauricular region with limited mouth opening. CT scan

confirms an undisplaced fracture of the left mandibular condyle. The patient has no other injuries and is otherwise stable. What is the most appropriate management? (Q849708)

A. Open reduction with internal fixation (ORIF)

B. Observation with a soft diet

C. Intermaxillary fixation (IMF)

D. Surgical excision of the condylar head

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 24-year-old male presents to the emergency department after a motorcycle accident. He complains of severe pain in his lower jaw, difficulty closing his mouth properly, and numbness in his lower lip on the right side. Physical examination reveals swelling and tenderness over the right jaw, malocclusion, and a palpable step-off in the premolar region. The paresthesia in the patient's lower lip is most likely due to the involvement of which nerve? (Q849707)

A. Facial nerve

B. Inferior alveolar nerve

C. Mental nerve

D. Lingual nerve

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 3-month-old female infant presents with feeding difficulties and a noticeable facial deformity. On examination, the infant has a unilateral complete cleft involving the left lip, extending through the alveolus and hard palate, with an intact soft palate on the left side. The right side of the lip and palate are completely intact. What is the LAHSHAL classification for this patient's cleft abnormality? (Q849706)

A. 0000HAL

B. LAH0000

C. LAHS000

D. LAHSAL

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A mother brings her apparently normal 20-day-old newborn to the pediatric clinic with a complaint of milk coming through the nasal passages of the baby during feeding. Upon examination, you find the following: This condition is due to the failure of which of the following processes during embryonic development? (Q849702)

A. Fusion of the maxillary and medial nasal processes

B. Formation of the lateral palatine processes

C. Fusion of the palatal shelves

D. Formation of the primary palate

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old male is diagnosed with a mandibular condyle fracture following an assault. The fracture is associated with malocclusion and facial asymmetry. Which of the following is a common post-surgical complication after open reduction and internal fixation (ORIF) of this fracture? (Q849718)

A. Temporomandibular joint ankylosis

B. Persistent pain and facial contour deformities

C. Complete loss of mandibular function

D. Intraoral hemorrhage

See Answer in Part B → Q9

@Neet_pg_bot

Q10: All of the following statements are true regarding the management of midface fractures, except? (Q849717)

A. Interdental or intermaxillary fixation is not mandatory

B. Reestablish the proper dentoskeletal relationship

C. Immobilize the fractured bone

D. Ensure normal postoperative occlusion

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 3-month-old infant presents to the pediatric clinic with feeding difficulties and nasal regurgitation. On examination, the infant has a cleft involving only the soft palate. There are no other abnormalities or syndromic features observed. When should surgery be planned for this infant with a cleft of only the soft palate? (Q849705)

A. At birth

B. At 6 months

C. After 1 year

D. After 5 years

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 2-day-old male infant is born with a unilateral cleft lip and palate. He is the first child of healthy, non-consanguineous parents with no significant family history. On physical examination, the infant has a noticeable cleft lip and palate. No other obvious abnormalities are noted. You suspect a syndromic association. Which of the following is the most common syndrome associated with cleft lip? (Q849704)

A. Van der Woude syndrome

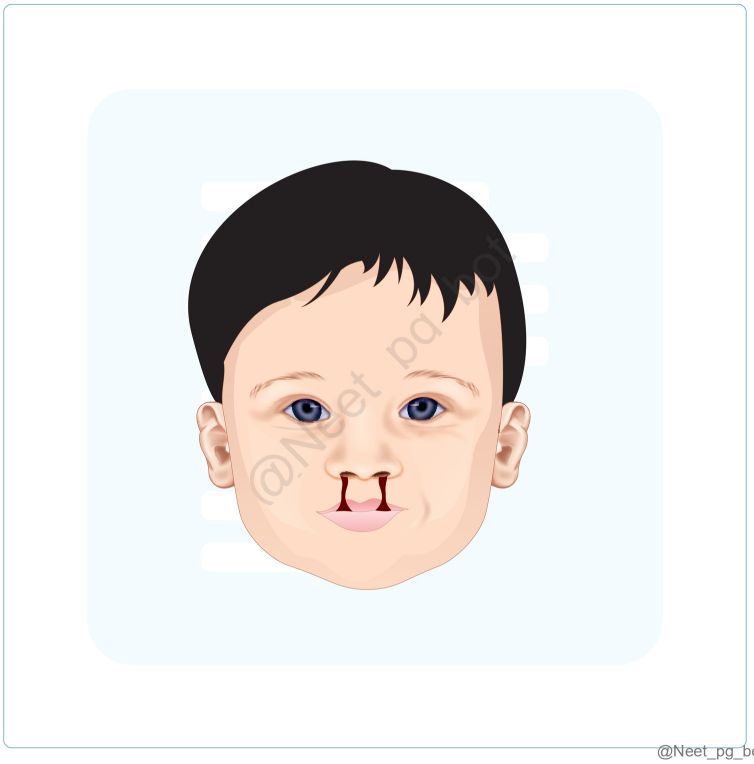
B. Pierre Robin sequence

C. Treacher Collins syndrome

D. DiGeorge syndrome

See Answer in Part B → Q12

@Neet_pg_bot



Q13: A 3-day-old male neonate is brought to you by his parents, concerned about the appearance of his face. On examination, the neonate has the appearance as shown in the image. Which of the following embryological events is most likely responsible for this defect? (Q849703)

A. Failure of fusion between the lateral palatine processes and nasal septum.

B. Non-fusion of the maxillary prominences and medial nasal prominences.

C. Incomplete fusion of the mandibular prominences.

D. Non-fusion of the lateral nasal prominences and the medial nasal prominences.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 60-year-old patient is found to have a carotid body tumor that completely encases the carotid vessels, posing significant surgical challenges. According to the Shamblin classification system, what type of tumor does this describe? (Q849620)

A. Type I

B. Type II

C. Type III

D. Cannot be determined.

See Answer in Part B → Q14

@Neet_pg_bot

Q15: The intermaxillary segment gives rise to all of the following structures EXCEPT: (Q849701)

A. Philtrum of the lip

B. Primary palate

C. Secondary palate

D. Four incisor teeth

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Match the structures formed in Column II with the corresponding prominence in Column I: Column I Column II A. Lateral Nasal Prominence 1. Lower lip B. Maxillary Prominence 2. Philtrum of upper lip, crest, and tip of nose C. Medial Nasal Prominence 3. Cheeks, lateral portion of upper lip D. Mandibular Prominence 4. Alae

of nose (Q849700)

A. A-2, B-1, C-3, D-2

B. A-4, B-1, C-3, D-2

C. A-2, B-3, C-4, D-1

D. A-4, B-3, C-2, D-1

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 55-year-old male patient with squamous cell carcinoma of the oral cavity undergoes a right radical neck dissection. Three days postoperatively, the patient complains of shoulder weakness and difficulty in lifting his right arm above his shoulder. On physical examination, he has a limited range of motion in the right shoulder and exhibits winging of the scapula on the right side. What is the most likely nerve injured during the neck dissection that could explain this patient's symptoms? (Q849699)

A. Accessory nerve (CN XI)

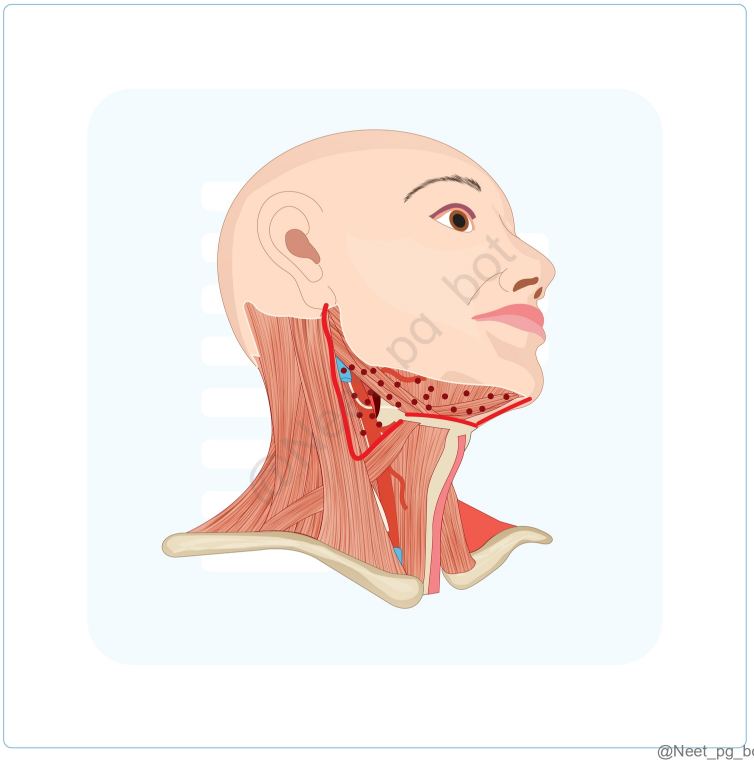
B. Phrenic nerve

C. Cervical sympathetic chain

D. Hypoglossal nerve (CN XII)

See Answer in Part B → Q17

@Neet_pg_bot



Q18: A 60-year-old male patient presents to the clinic with a non-healing ulcer on the left lateral border of the tongue. Upon examination, the lesion measures 2 cm and has been present for 6 weeks and there is a palpable lymph node in the left submandibular region. After evaluation, the surgeon decides to perform a neck dissection. The image below depicts the lymph nodes to be removed during the procedure. What type of neck dissection is planned for this patient? (Q849698)

A. Radical neck dissection

B. Modified radical neck dissection

C. Supraomohyoid neck dissection

D. Extended supraomohyoid neck dissection

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which lymph node level in the neck is primarily responsible for draining the thyroid gland? (Q849627)

A. Level Ib

B. Level IIa

C. Level VI

D. Level III

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following nerves is most likely to be injured during surgery in the posterior triangle of the neck, potentially leading to weakness in shoulder elevation? (Q849626)

A. Hypoglossal Nerve (CN XII)

B. Vagus Nerve (CN X)

C. Phrenic Nerve

D. Spinal Accessory Nerve (CN XI)

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following conditions is most commonly associated with a cervical rib? (Q849625)

A. Rotator Cuff Tear

B. Cervical Spondylosis

C. Thoracic Outlet Syndrome

D. Pancoast’s syndrome

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which branchial cleft remnant typically passes behind the carotid artery? (Q849624)

A. First branchial cleft remnant

B. Second branchial cleft remnant

C. Third branchial cleft remnant

D. Fourth branchial cleft remnant

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A branchial fistula typically presents with which of the following characteristics? (Q849623)

A. A midline neck mass that moves with swallowing

B. A lateral neck opening that drains mucus or saliva

C. A neck swelling that enlarges after a respiratory infection

D. A solid mass in the posterior triangle of the neck

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 38-year-old patient presents with a soft, translucent swelling on the front edge of the sternocleidomastoid muscle. The swelling is non-tender and has not been associated with any infection. It is diagnosed as a branchial cyst. Which of the following is false regarding the given diagnosis? (Q849622)

A. Typical location is the meeting of upper and middle thirds of sternocleidomastoid.

B. It has an onset in late adulthood.

C. Cancerous lymph nodes may have to be ruled out.

D. Complete removal is done, ideally when not infected.

See Answer in Part B → Q24

@Neet_pg_bot

Q25: An infant presents with a translucent swelling in the neck that has been expanding over time as shown in the image below The swelling is filled with clear lymph and increases in size when the infant coughs.. Which of the following is false regarding the given condition? (Q849621)

A. Common locations include the cheek, axilla, groin, and mediastinum.

B. It has an unpredictable growth pattern.

C. It is incompressible and cystic in nature.

D. Injection of sclerosing agents can be given to reduce size.

See Answer in Part B → Q25

Q1: What is the definition of the Miami criteria regarding intraoperative parathyroid hormone (PTH) measurement among the options listed below? (Q854934)

A. Quarter fall in 5 min

B. Quarter fall in 10 min

C. Half fall in 5 min

D. Half fall in 10 min

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 28-year-old female presents with a bluish translucent extravasation cystic sublingual swelling . The swelling is accompanied by visible veins over the swelling and is transilluminant . What is the most likely diagnosis? (Q820193)

A. Thyroglossal cyst

B. Dermoid cyst

C. Ranula

D. Sublingual tumour

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 6-year-old child presents with a swelling in the subhyoid region of the neck that moves with deglutition and protrusion of the tongue. What is the recommended treatment for this patient? (Q820236)

A. Total thyroidectomy

B. Ramstedt's operation

C. Hemi-thyroidectomy

D. Sistrunk's operation

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old female patient undergoes a routine thyroid examination, during which a palpable thyroid nodule is discovered. Fine-needle aspiration cytology confirms the presence of papillary thyroid cancer. All of the following statements are true regarding papillary thyroid cancer Except: (Q820244)

A. It often presents with cervical lymph node metastases.

B. It is the most common type of thyroid cancer.

C. It arises from parafollicular C-cells

D. It is TSH dependent

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A patient presents with swelling in the floor of the mouth. Upon examination, the swelling appears as shown in the image. What is the most likely diagnosis? (Q854776)

A. Cystic hygroma

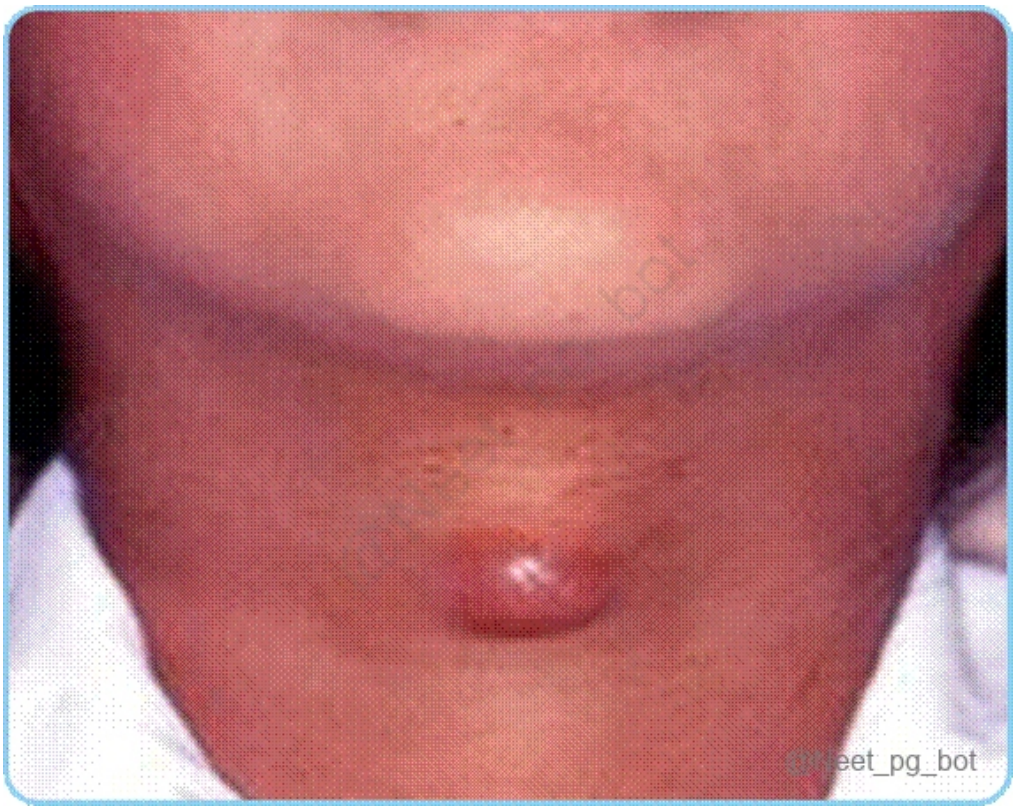
B. Ranula

C. Dermoid

D. Branchial cyst

See Answer in Part B → Q5

@Neet_pg_bot



Q6: A 23-year-old male patient presents with a swelling in the midline of his neck that shifts when he swallows or sticks out his tongue. What is the probable diagnosis? (Q855273)

A. Brachial cyst

B. Thyroglossal cyst

C. Plunging ranula

D. Dermoid cyst

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 32-year-old man with a history of chronic tobacco chewing presents with a painless white patch in the gingivobuccal sulcus that has persisted for the past 7 months. The lesion is non-scrapable and there is no restriction of mouth opening. What is the most appropriate next step in management? (Q857858)

A. Local excision and biopsy

B. Advise cessation of tobacco and observe

C. Intralesional steroid injections

D. Sclerotherapy

See Answer in Part B → Q7

@Neet_pg_bot

Q8: The false statement about cystic masses of the neck is: (Q857144)

A. Type 3 branchial fistula has its internal orifice on cricopharynxgeus

B. Cystic hygroma is filled with clear lymph

C. Thyroglossal cyst moves upwards on swallowing, and tongue protrusion

D. Fluctuation is positive in branchial cyst

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following structures is most likely to be injured, leading to lower lip paralysis in a 30-year-old teacher who underwent parotidectomy? (Q856747)

A. Temporal branch of the facial nerve

B. Cervical branch of facial nerve

C. Parotid duct

D. Mandibular branch of facial nerve

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which part of cranial fossa is injured in Raccoon eyes? (Q820177)

A. Anterior cranial fossa

B. Middle cranial fossa

C. Posterior cranial fossa

D. Bone aponeurotic layer

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which statement regarding retrosternal goitre is accurate? (Q855029)

A. Operated in all patients regardless of symptoms

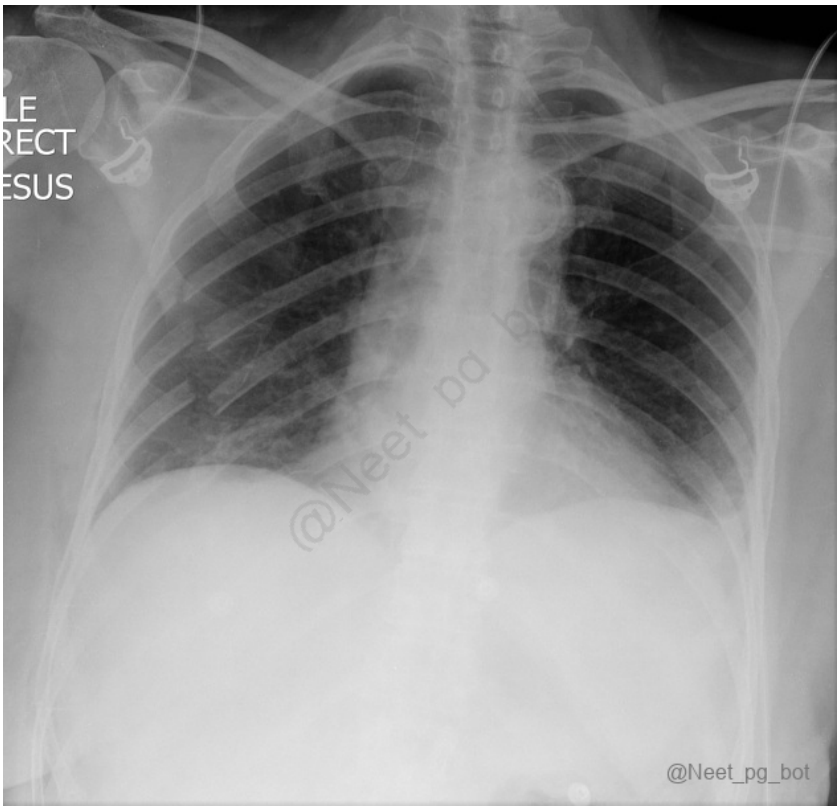
B. Sternal incision is always required to operate

C. It receives blood supply from the thoracodorsal artery

D. Most of the retrosternal goitres can be removed by a neck incision

See Answer in Part B → Q11

@Neet_pg_bot



Q12: A car driver was brought into the A & E following a RTA with complaints of breathlessness. On examination, his vitals are PR-112/min, BP-100/70, SpO2-90 %, and there is extensive bruising on his chest. What is the management of this patient? (Q859614)

A. Chest tube drainage

B. 24% oxygen

C. IPPV

D. Internal operative fixation of the fracture’s segments

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following tests would a surgeon advise first in a patient with a large thyroid swelling? (Q859615)

A. Ultrasound of the neck

B. FNAC

C. Biopsy

D. Radioiodine uptake

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 32-year-old patient who is a chronic alcoholic presents with oral ulcers and a burning sensation. A picture of the oral cavity is given below. What is the most likely diagnosis? (Q855770)

A. Leukoplakia

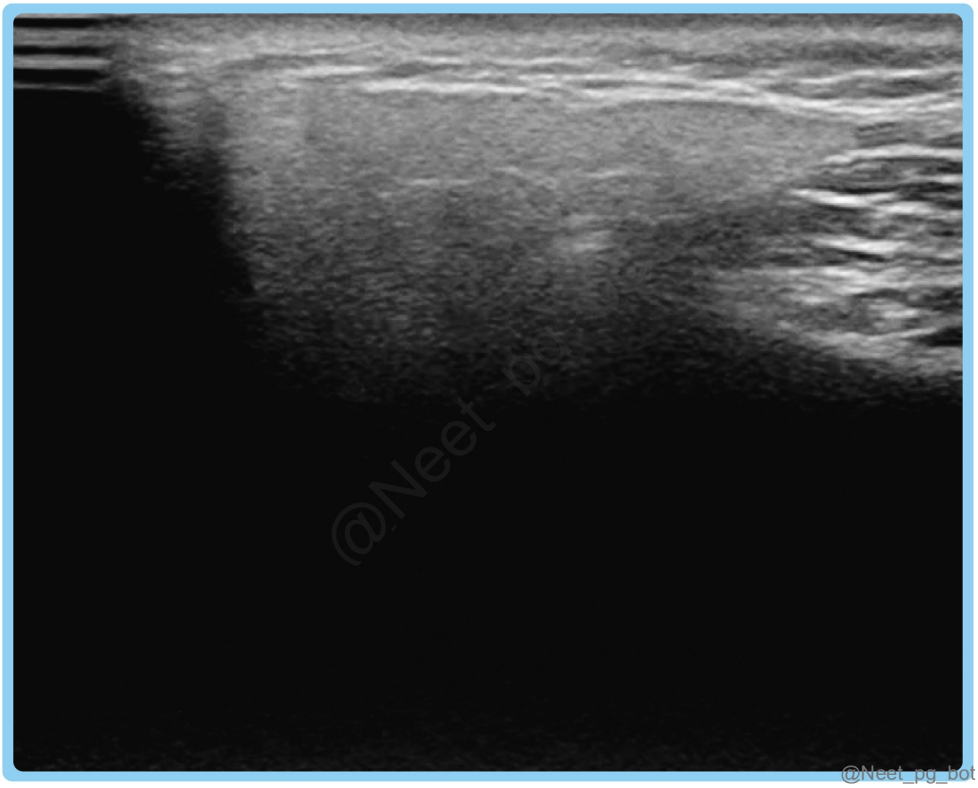
B. Erythroplakia

C. Submucosal fibrosis

D. Malakoplakia

See Answer in Part B → Q14

@Neet_pg_bot



Q15: A 45-year-old patient complained of pain in one side of the neck. She is afraid of eating food as it worsens the pain. Ultrasound imaging of the salivary glands is done and shown below. What is the most likely diagnosis? (Q855805)

A. Sialolithiasis

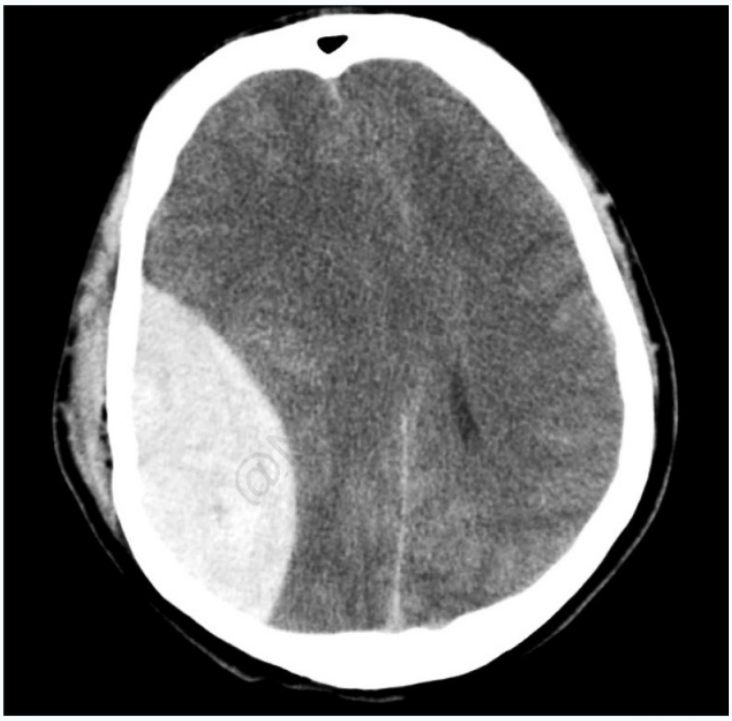
B. Foreign body

C. Osteoma of the floor of the mouth

D. Cervical lymphadenopathy

See Answer in Part B → Q15

@Neet_pg_bot



Q16: A 30-year-old patient of RTA was brought to the emergency department. There was a history of vomiting. The patient was initially conscious and oriented, but after a few hours, he became drowsy and then progressed to stupor and coma. This sequence of lucid interval was followed by neurological deterioration. What is the preferred treatment option? (Q879144)

A. Wait for spontaneous resolution

B. Burr hole and evacuation

C. Craniotomy

D. Conservative management with IV mannitol

See Answer in Part B → Q16

@Neet_pg_bot

Q17: What is the most common site of a Berry aneurysm in the circle of Willis? (Q879234)

A. Anterior cerebral artery

B. Middle cerebral artery

C. Basilar artery

D. Vertebral artery

See Answer in Part B → Q17

@Neet_pg_bot

Q18: In modified radical neck dissection, which of the following structures is NOT preserved? (Q860278)

A. Sternocleidomastoid muscle

B. Internal jugular vein

C. Spinal accessory nerve

D. Submandibular gland

See Answer in Part B → Q18

@Neet_pg_bot

Q19: History of pulsatile mass in the neck. Digital angiography image shown. Not filling on carotid compression. But refilling on releasing pressure. What is the diagnosis? (Q866454)

A. Carotid Aneurysm

B. Carotid Body tumour

C. AV fistula

D. Haemangioma

See Answer in Part B → Q19

@Neet_pg_bot

Q20: An elderly male presents with foul-smelling breath and dysphagia. A barium swallow X-ray is provided. What is the most likely diagnosis? (Q853043)

A. ■■■Tracheoesophageal fistula

B. Achalasia cardia

C. Carcinoma esophagus

D. Zenker's diverticulum

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 60 y/o male suddenly experiences an intense headache, described as the worst headache of his life, followed by vomiting and photophobia. O/E he has neck stiffness and a dilated pupil on the right side. A CT scan reveals bleeding in the subarachnoid space. Which of the following is the most common cause of this condition? (Q852704)

A. Hypertension

B. Intracranial aneurysm

C. Arteriovenous malformation (AVM)

D. Brain tumour

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Identify the level of lymph nodes indicated in the marked region of the neck in the given anatomical image. (Q852717)

A. Level II

B. Level Ia

C. Level Ib

D. Level IV

@Neet_pg_bot

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following is an indication for adjuvant radiotherapy in oral malignancy after resection and modified radical neck dissection (MRND)? (Q844310)

A. Extranodal extension

B. Multiple lymph node metastasis

C. T3 tumor

D. Close margin

See Answer in Part B → Q23

@Neet_pg_bot

Q24: In the evaluation of squamous cell carcinoma (SCC) of the lip, which biopsy technique is considered most appropriate for obtaining a representative tissue sample for histopathological diagnosis? (Q844291)

A. Superficial shave biopsy of the tumor surface

B. Complete excision of the lesion

C. Incisional biopsy including both tumor and adjacent normal tissue

D. Punch biopsy limited to the ulcerated surface

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 65-year-old smoker presents with ulcerative lesions on his lower lip for the past year. On examination, there is a palpable ipsilateral submental lymph node approximately 5x5 cm. A biopsy from the lesion is suggestive of squamous cell carcinoma. What is the next step in management? (Q860454)

A. Radiotherapy

B. Combined chemoradiotherapy

C. Resection with primary closure alone

D. Resection of primary lesion with lip reconstruction and MRND

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A patient arrives at the emergency department following severe maxillofacial trauma sustained in a road traffic accident. The airway is compromised, and immediate intervention is required. What is the most appropriate immediate management? (Q860234)

A. Tracheostomy

B. Orotracheal intubation

C. Cricothyroidotomy

D. Bag mask with jaw thrust

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A child presented with the following findings and is planned to undergo surgery, which muscle will be repaired during surgery? (Q865320)

A. Orbicularis oris

B. Orbicularis oculi

C. Zygomaticus major

D. Levator alae nasi

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which among the following is the most common parotid gland tumour? (Q860295)

A. Pleomorphic adenoma

B. Warthin’s tumor

C. Adenoid cystic carcinoma

D. Mucoepidermoid carcinoma

See Answer in Part B → Q28

@Neet_pg_bot

Q29: What is the most likely diagnosis for a young patient under 5 years of age presenting with a painless, soft, fluctuating mass on the lateral side of the neck? (Q860298)

A. Thyroglossal cyst

B. Cystic hygroma

C. Cervical lymphadenopathy

D. Ranula

See Answer in Part B → Q29

@Neet_pg_bot

Q30: What is the condition depicted in the given image, and what is the next investigation required for management? (Q860313)

A. Erythroplakia and biopsy

B. Erythroplakia and observation

C. Leukoplakia and biopsy

D. Leukoplakia and observation

See Answer in Part B → Q30

@Neet_pg_bot

Q31: Match the following features seen due to compression of the following structures in the case of thyroid swelling: Structure Features 1. Trachea a. Hoarseness 2. Esophagus b. Horner syndrome 3. Sympathetic chain c. Dyspnea 4. Recurrent laryngeal nerve d. Dysphagia (Q857298)

A. 1-c, 2-d, 3-b, 4-a

B. 1-d, 2-c, 3-a, 4-b

C. 1-a, 2-d, 3-b, 4-c

D. 1-c, 2-a, 3-d, 4-b

See Answer in Part B → Q31

@Neet_pg_bot

Q32: ABCD 2 scoring includes all the following parameters except? (Q820103)

A. Age

B. Hypertension

C. History of stroke

D. Diabetes Mellitus

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A 25-year-old patient had a RTA and was brought to the emergency room with bradycardia and a high BP. The GCS of this patient is < 8. What should be the immediate management in this patient? (Q820119)

A. Urgent CT head

B. Intubate and IPPV

C. Thrombolysis

D. Normal saline infusion

See Answer in Part B → Q33

@Neet_pg_bot

Q34: What is the Intubation of choice in a Maxillofacial trauma patient? (Q820169)

A. Tracheostomy

B. Laryngeal mask airway

C. Orotracheal intubation

D. Mask ventilation

See Answer in Part B → Q34

@Neet_pg_bot

Q35: A 50-year-old male chronic smoker came to OPD with cough, dyspnea, and difficulty swallowing . A palpable lump was present in the neck. Which of the following are smokers most likely to develop? (Q793891)

A. Adenocarcinoma

B. Squamous cell carcinoma

C. Large cell carcinoma

D. Adenoid cystic carcinoma

See Answer in Part B → Q35

Q25 (p. 118)					

Q1: A 62-year-old male patient is having complaints of loss of vision in the form of a curtain coming down in front of the right eye. He has a history of 2 episodes of strokes, after which he has left-sided sensory and motor loss limited to the face and neck. Which of the following blood vessels might be stenosed in this case? (Q849435)

A. Left vertebral artery

B. Carotid artery

C. First part of the left subclavian artery

D. Superior mesenteric vein

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 67-year-old male was having complaints of sudden onset of severe chest pain, which was radiating to his back, and suddenly, he went unconscious. He was chronically hypertensive, a drug defaulter, and was having weakness, dizziness and dyspnea for 1 day. His current BP is 90/50 mm Hg, and his Heart Rate is 140 bpm. What is the best investigation of choice in this condition? (Q849415)

A. CT Angiography

B. Aortography

C. Trans Esophageal Echocardiography

D. Chest x-ray

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following signs is seen in Arteriovenous fistula? (Q849404)

A. Murphy’s sign

B. Brudzinski’s sign

C. Hegar’s sign

D. Nicoladoni’s sign

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 35-year-old female experiences numbness and tingling in her right arm, worsened by arm elevation. During examination, she abducts her arms to 90° with external rotation, flexes her elbows to 90°, and opens and closes her hands for 3 minutes, which reproduces her symptoms. Which test was most likely performed? (Q849407)

A. Adson's Test

B. Roos Test

C. Wright's Test

D. Elvey Test

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 23-year-old competitive swimmer presents with progressive weakness and tingling in his right hand. On examination, there is wasting of the small muscles of the

hand and sensory loss in the medial side of the hand and forearm. Which of the following nerves is most likely compressed in this patient? (Q849406)

A. Median nerve (C5-T1

B. Ulnar nerve (C8-T1)

C. Radial nerve (C5-T1)

D. Axillary nerve (C5-C6)

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is the most preferred vascular graft for CABG? (Q849434)

A. Long saphenous vein

B. Dacron

C. Polyurethane

D. Left Internal Mammary Artery

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 48-year-old male presents with retrosternal chest pain, which was radiation to the left arm and shoulder. He has a previous history of acute myocardial infarction. CABG was advised, but the patient is insisting on using synthetic graft and wants to know more about it. Which of the following is the most preferred synthetic vascular graft for CABG? (Q849433)

A. Polyurethane

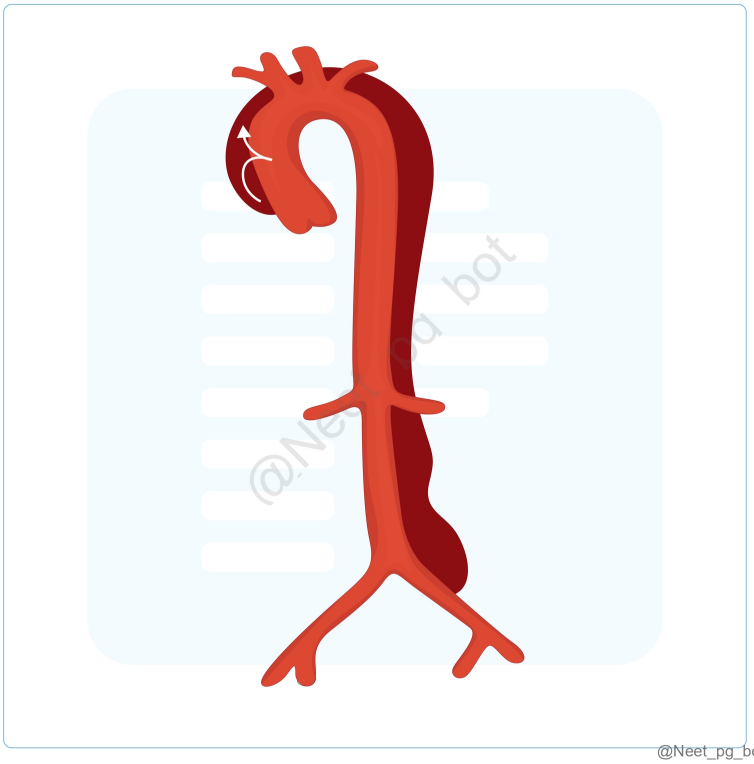
B. ePTFE

C. Dacron

D. Long saphenous vein

See Answer in Part B → Q7

@Neet_pg_bot



Q8: Based on the Stanford classification, which type of aortic dissection is shown below? (Q849418)

A. Type A

B. Type B

C. Type C

D. Type D

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 72-year-old male with a history of hypertension and smoking presents with back pain, and imaging shows a thoracoabdominal aortic aneurysm starting at the sixth intercostal space and extending to just above the renal arteries. According to the Crawford classification, which type does this aneurysm correspond to? (Q849413)

A. Type I

B. Type II

C. Type III

D. Type V

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 65-year-old male with a history of hypertension and smoking presents with an abdominal aortic aneurysm measuring 6.0 cm in diameter, detected during routine surveillance. Which of the following is the most appropriate next step in the management of this patient? (Q849412)

A. Regular ultrasound surveillance every 6 months

B. Begin beta-blocker therapy

C. Endovascular aneurysm repair

D. Lifestyle modifications and smoking cessation

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 45-year-old male with a history of bacterial endocarditis presents with sudden onset of severe headache, nausea, and vomiting. A CT scan of the head is shown below. Which of the following is the most likely cause of the haemorrhage in this patient? (Q849411)

A. Ruptured berry aneurysm

B. Traumatic brain injury

C. Hypertensive intracerebral haemorrhage

D. Ruptured mycotic aneurysm

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 58-year-old male presents with a pulsatile mass in the right groin following recent arterial catheterisation. Doppler ultrasound reveals an aneurysm. Which characteristic best describes this type of aneurysm? (Q849410)

A. Involves all three arterial wall layers

B. Fusiform dilation of the artery.

C. Wall composed of fibrous tissue only

D. Commonly caused by atherosclerosis

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 65-year-old male with a history of atrial fibrillation presents to the emergency department with sudden, severe abdominal pain that is disproportionate to physical examination findings. He also reports vomiting and the passage of blood in his stool. Given his history and clinical presentation, which artery is most likely involved in this patient's condition? (Q849409)

A. Superior Mesenteric Vein

B. Superior Mesenteric Artery

C. Inferior Mesenteric Artery

D. Inferior Mesenteric Vein

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 24-year-old woman presents with episodic colour changes in her fingers triggered by cold temperatures and stress. The episodes follow a characteristic sequence. What is the correct sequence of events in the skin colour changes seen in the Raynaud phenomenon? (Q849408)

A. Rubor → Cyanosis → Pallor

B. Cyanosis → Pallor → Rubor

C. Pallor → Cyanosis → Rubor

D. Rubor → Pallor → Cyanosis

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 58-year-old male presents to the emergency department with a sudden onset of severe pain in his left leg. The leg appears pale and feels cold to the touch, and the

patient is unable to move or feel his toes. On examination, no pulses are detectable below the knee. What is the most likely diagnosis? (Q849347)

A. Deep vein thrombosis

B. Acute limb ischemia

C. Chronic venous insufficiency

D. Cellulitis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 65-year-old male presents with a sudden onset of severe pain in his left leg, which has become cold and pale. On examination, there is an absence of distal pulses. Imaging reveals a large saddle embolus at the aortic bifurcation. What is the most appropriate catheter to use for embolectomy in this case? (Q849405)

A. Seldinger catheter

B. Swan-Ganz catheter

C. Fogarty catheter

D. Tenckhoff catheter

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 60-year-old male with end-stage renal disease is scheduled for the creation of a surgically created arteriovenous (AV) fistula to facilitate long-term hemodialysis. Which of the following is the most commonly used type of AV fistula for this purpose? (Q849401)

A. Cimino-Brescia fistula

B. Blalock-Taussig shunt

C. Snuff box fistula

D. Axillary-axillary loop graf

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 46-year-old male presents with intense pain in his left leg along with the following lesion. Which of the following is the most probable diagnosis? (Q849399)

A. Neuropathic ulcer

B. Venous ulcer

C. Arterial ulcer

D. Pressure ulcer

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 35-year-old male with a 12-year history of smoking presents with severe rest pain and discoloration of the left lower limb's digits as shown below. He has experienced worsening pain in this limb for the past 2 days, following 3 months of discomfort. What is the appropriate management for this condition? (Q849394)

A. Lumbar sympathectomy

B. Abstinence from smoking

C. Amputation

D. Vasodilators

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 56-year-old male presents with sudden pain and numbness in his right lower limb for 1 day. On examination, the limb is cold and pale and exhibits loss of sensory and mild motor functions. Doppler studies reveal only venous signals. What grade of Rutherford's classification is this case? (Q849393)

A. Grade I

B. Grade IIA

C. Grade IIB

D. Grade III

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 38-year-old chronic smoker presents with lower limb pain during walking for 2 weeks. Examination reveals an ankle-to-brachial systolic pressure ratio of 0.7. What is the correct interpretation of this finding? (Q849392)

A. Critical limb ischemia

B. Intermittent claudication

C. Normal index

D. Calcified vessels

See Answer in Part B → Q21

@Neet_pg_bot

Q22: What is the most specific investigation of choice for peripheral arterial disease? (Q849391)

A. Ankle-Brachial Index

B. Duplex ultrasonography

C. CT angiography

D. Magnetic Resonance Angiography

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 65-year-old man presents with pain in his right calf that occurs after walking 200 meters and is relieved by rest. The pain does not occur when he is at rest or when he walks shorter distances. Based on Boyd's classification of intermittent claudication,

which grade best describes this patient's condition? (Q849390)

A. Grade 0

B. Grade I

C. Grade II

D. Grade III

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 40-year-old male presents with pain in his hands and feet, which worsens with cold exposure. He has a history of heavy smoking. On examination, he has ulcers on his fingers and toes. Angiography reveals "corkscrew" collaterals and segmental occlusions. Which of the following conditions is most likely in this patient? (Q849389)

A. Systemic sclerosis

B. Thromboangiitis obliterans

C. Atherosclerosis

D. Frostbite

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 72-year-old man presents with a sudden onset of severe pain, numbness, and coldness in his left leg. On examination, the left leg appears pale, and no pulse is palpable below the femoral artery. What is the most probable cause of this acute peripheral arterial occlusion? (Q849388)

A. Atherosclerosis

B. Buerger's disease

C. Fibromuscular dysplasia

D. Arterial dissection

See Answer in Part B → Q25

Q25 (p. 130)	*Q26 (p. 131)*				

Q1: A 62-year-old male presents with left leg swelling and pain for 5 days and has a positive D-dimer test. Duplex ultrasonography confirms an extensive DVT involving the left popliteal and femoral veins. Which of the following is the most appropriate initial management strategy? (Q849439)

A. Unfractionated heparin followed by warfarin

B. LMWH followed by oral anticoagulant

C. Catheter-directed thrombolysis

D. IVC filter placement

See Answer in Part B → Q1

@Neet_pg_bot

Q2: An infant presents with a large, rapidly growing vascular malformation, along with severe thrombocytopenia and microangiopathic hemolytic anemia. What is the most likely diagnosis? (Q849459)

A. Klippel-Trénaunay Syndrome

B. Kasabach-Merritt Syndrome

C. Sturge-Weber Syndrome

D. Capillary Hemangioma

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 50-year-old man presents with prominent varicose veins on his medial thigh and calf. Upon examination, incompetence of the great saphenous vein (GSV) is identified. The surgeon is considering the appropriate surgical intervention. What is the primary indication for performing Saphenofemoral Junction Ligation and GSV Stripping? (Q849455)

A. Varicose veins on the posterolateral calf due to small saphenous vein incompetence

B. Incompetence of the great saphenous vein with varicose veins on the medial thigh and calf

C. Varicose veins on the anterior thigh due to incompetent perforator veins

D. Small varicose veins unsuitable for endovenous ablation

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old male with chronic venous insufficiency presents with a venous ulcer on his lower leg. He has a history of prolonged standing at work and reports aching and heaviness in his legs. What is correct regarding compression therapy in this patient? (Q849453)

A. Class 1 compression hosiery exerts 18-24 mmHg of pressure

B. Compression bandaging typically exerts less pressure than compression hosiery

C. Compression bandaging should be avoided in patients with a history of venous ulcers

D. Compression therapy is most effective when it exerts a graduated pressure to promote venous return

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following statements about the pathophysiology of varicose veins is incorrect? (Q849447)

A. Defects in the walls or valves of the veins lead to retrograde blood flow.

B. Inflammatory changes in walls lead to dilatation, elongation and valvular dysfunction.

C. The veins have a low end-diastolic volume.

D. Chronic ambulatory venous hypertension develops.

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A patient comes to the surgery OPD complaining of small swellings and a wound on his right lower leg. On clinical evaluation, he is found to have hyperpigmentation in his right leg around the ankle and lower third of the leg. He also has a healed venous ulcer and is symptomatic. According to the CEAP classification, what is the clinical stage of the disease in this case? (Q849449)

A. C5a

B. C5s

C. C3r

D. C6

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 50-year-old woman with inflammatory bowel disease presents with a painful ulcer on her leg. The ulcer has a necrotic edge and a purulent base, with significant surrounding erythema. What type of ulcer is most consistent with this presentation? (Q849461)

A. Neurotrophic ulcer

B. Pyoderma gangrenosum

C. Venous ulcer

D. Arterial ulcer

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 62-year-old man has a chronic ulcer on his leg from a burn injury sustained 12 years ago. Recently, the ulcer has developed indurated, painless, raised edges and surrounding fibrosis. What is the most likely diagnosis? (Q849460)

A. Venous ulcer

B. Pressure ulcer

C. Marjolin’s ulcer

D. Actinic keratosis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 64-year-old woman is scheduled for the great saphenous vein (GSV) stripping to treat her varicose veins. What is the most likely nerve injury she might experience post-operatively? (Q849458)

A. Sural nerve

B. Common peroneal nerve

C. Saphenous nerve

D. Tibial nerve

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A patient with chronic venous insufficiency presents with symptomatic varicose veins. The physician decides to use foam sclerotherapy, specifically the Tessari technique, to treat the affected veins. What is the typical ratio of sclerosant to air used in the Tessari technique for creating the foam? (Q849457)

A. 1:1

B. 1:2

C. 1:3

D. 1:6

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following statements best describes the difference between Dodd and Cockett surgeries? (Q849456)

A. Dodd: ligation in the thigh; Cockett: ligation in the lower leg

B. Dodd: open surgery; Cockett: endoscopic

C. Dodd: targets superficial veins; Cockett: targets deep veins

D. Dodd: higher risk of nerve injury; Cockett: lower risk

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old woman presents with symptomatic varicose veins. She is interested in learning about the available treatment options and their benefits. Her primary concern is to minimize recovery time and reduce post-operative pain. Which of the following surgical approaches is most appropriate for this patient? (Q849454)

A. Saphenofemoral ligation and great saphenous stripping

B. Saphenopopliteal junction ligation and small saphenous stripping

C. Endovenous laser ablation (EVLA)

D. Phlebectomy as a standalone procedure

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 45-year-old male presents with chronic leg pain, swelling, and visible varicose veins. A duplex ultrasound is performed to assess venous function. Which of the following statements is TRUE regarding interpreting the duplex scan in this patient? (Q849452)

A. The duplex scan should be performed with the patient in a supine position

B. A reflux time of less than 500 milliseconds is clinically significant

C. Presence of perforator vein with a diameter >3.5 mm is significant

D. The duplex scan is primarily used to locate perforating veins

See Answer in Part B → Q13

@Neet_pg_bot

Q14: The following test was conducted in the clinic for a patient suffering from varicose veins. On releasing only tourniquet 3, the filling of blood was observed. What does this signify? (Q849451)

A. Hunterian’s perforator incompetence

B. Boyd’s perforator incompetence

C. Dodd’s perforator incompetence

D. Cockett’s perforator incompetence

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A patient with varicose veins is being examined in the surgical OPD. The Brodie-Trendelenburg I test is done for the patient, and the surgeon notices that blood is filling from above. What does this signify? (Q849450)

A. Valvular incompetence

B. Perforator incompetence

C. Sapheno-femoral incompetence

D. Presence of DVT

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 45-year-old man presents with left leg swelling and pain for 3 days. Duplex ultrasonography reveals a thrombus in the popliteal vein. Which of the following veins is most likely to be involved next in the progression of this DVT? (Q849436)

A. Great saphenous vein

B. Common femoral vein

C. Posterior tibial vein

D. External iliac vein

See Answer in Part B → Q16

@Neet_pg_bot

Q17: After noticing small swellings over his legs, a 60-year-old man comes to the surgical OPD. He is a tailor by occupation and works long hours. He explains that he experiences a heaviness and aching in the legs after a long day of work but is relieved once he elevates his legs and rests. Which of the following is not a more severe sign of this disease? (Q849448)

A. Thrombophlebitis

B. Lipodermatosclerosis

C. Ulceration

D. Pedal edema

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 50-year-old woman presents with visible, dilated veins on both legs. She has a history of two pregnancies and works as a retail clerk. On examination, the dilated veins are most prominent along the posterior aspect of her calves. Which of the following describes the classification of her varicose veins based on the involved venous system? (Q849446)

A. Great Saphenous Vein System

B. Small Saphenous Vein System

C. Non-saphenous veins

D. Perforator veins

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 55-year-old woman presents with varicose veins in her left leg. On examination, you notice dilated, tortuous veins along the posterior aspect of her calf and lateral thigh. To accurately map the incompetent veins for potential treatment, which of the following describes the most likely location of the Boyd perforator vein? (Q849445)

A. Medial ankle, posterior to the medial malleolus

B. Medial calf, approximately 10 cm above the medial malleolus

C. Lateral calf, at the junction of the middle and lower thirds

D. Medial knee, approximately 10 cm below the knee joint line

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 55-year-old woman presents with recurrent episodes of tender, erythematous cord-like swellings along different superficial veins of her lower extremities over the past 3 months. Which of the following is most likely to be associated with this presentation? (Q849444)

A. Recent childbirth

B. Thromboangiitis obliterans

C. Pancreatic malignancy

D. Polycythemia vera

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 20-year-old competitive swimmer presents with a 2-day history of left arm pain, swelling, and mild discoloration after intense training. Duplex ultrasound shows a thrombus in the left subclavian vein. What is the most likely diagnosis? (Q849443)

A. Thoracic outlet syndrome

B. Paget-Schrotter syndrome

C. Raynaud's phenomenon

D. Lymphedema

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 30-year-old woman is in the post-operative ward after a cesarean section. She had no complications and gave birth to a healthy baby. Which of the following is a prophylactic step she needs to be advised to prevent deep vein thrombosis? (Q849442)

A. Early mobilization along with compression stockings

B. Low molecular weight heparin

C. Low-dose unfractionated heparin

D. Fondaparinux

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A patient came with complaints of discoloration of his left leg as shown in the image. He has a history of deep vein thrombosis and has been inconsistent on medication. What is the possible diagnosis here? (Q849441)

A. Venous gangrene

B. Venous ulcer

C. Atrophic blanche

D. Post-thrombotic leg

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 45-year-old man with metastatic colorectal cancer is diagnosed with an acute DVT of the left leg. He had an episode of upper GI bleed 2 days ago. His lab results show a platelet count of 40,000/μL and an INR of 1.8. Which of the following is the most appropriate management strategy for preventing pulmonary embolism in this patient? (Q849440)

A. Start anticoagulation with LMWH

B. Place a permanent IVC filter

C. Place a retrievable IVC filter

D. Start anticoagulation with UFH

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 45-year-old man with a history of colorectal cancer underwent surgery 3 weeks ago and is now presenting with complaints of left leg swelling and pain for 3

days. His left calf is 4 cm larger than the right. Using Wells' criteria for DVT, what is his pre-test probability score and risk category? (Q849438)

A. 2 points; Moderate risk

B. 5 points; High risk

C. 3 points; Moderate risk

D. 4 points; High risk

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 52-year-old male presents with a swollen, painful left calf that developed over the past two days. He reports no history of trauma, surgery, or prolonged immobility. Physical examination reveals a warm, erythematous, and tender left calf. Which of the following clinical features is most specific for diagnosing deep vein thrombosis? (Q849437)

A. Calf pain on dorsiflexion of the foot

B. Asymmetrical calf swelling

C. Pain that worsens with leg elevation

D. Localized tenderness along the course of the deep veins

See Answer in Part B → Q26

@Neet_pg_bot

Q1: A 40-year-old female presents with persistent swelling in her lower legs. Upon physical examination, the swelling is noted to be non-pitting, and the patient has no signs of irreversible skin changes. What is the most appropriate Brunner's classification grade for her condition? (Q849351)

A. Subclinical/latent

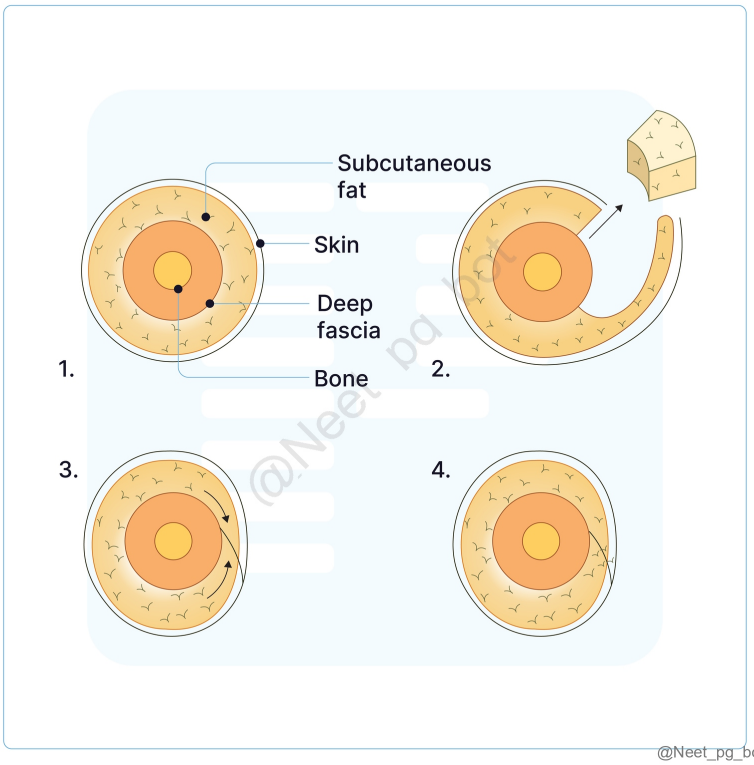
B. Grade I

C. Grade II

D. Grade III

See Answer in Part B → Q1

@Neet_pg_bot



Q2: A 60-year-old female with severe lymphedema of the lower limb, not responding to conservative therapies. Due to persistent swelling and functional impairment, she undergoes surgical intervention. An image of the surgical procedure is shown below. What is the procedure known as? (Q849354)

A. Thompson Procedure

B. Charles Procedure

C. Nielubowicz Operation

D. Kinmonth procedure

@Neet_pg_bot

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A patient with breast carcinoma after 11 years of Modified radical mastectomy and radiotherapy, now presents with pain, skin nodules and worsening of swelling of left arm as shown in the image below. What is the most probable diagnosis? (Q849356)

A. Lymphangiosarcoma

B. Venous thrombosis

C. Cellulitis

D. Lymphedema

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A patient with chronic lymphedema is being evaluated for surgical management. Which of the following is not a reduction procedure for lymphedema? (Q889676)

A. Liposuction

B. Charles' procedure

C. Homans' procedure

D. Lymphatic–venous shunt

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 35-year-old man presents to the emergency department with a rapidly spreading reddish streak on his left arm, accompanied by fever and swollen axillary lymph nodes. He reports sustaining a small cut on his hand two days ago while gardening. Physical examination reveals a tender, warm, erythematous streak extending from the hand to the upper arm, with blanching on pressure. What is the next best step in the management of this patient? (Q849348)

A. Immediate surgical incision and drainage of the affected area

B. Oral antihistamines and topical corticosteroids

C. Limb elevation and initiation of intravenous antibiotics like penicillin or cloxacillin

D. Watchful waiting for 48 hours before initiating any treatment

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A patient with chronic lymphedema is advised decongestive lymphatic therapy (DLT). Which of the following is not a component of decongestive lymphatic therapy? (Q889675)

A. Manual lymphatic drainage

B. Compression therapy

C. Regular diuretic therapy

D. Limb elevation

See Answer in Part B → Q6

@Neet_pg_bot

Q7: What is the most common site of mediastinal lymphoma? (Q889673)

A. Anterior mediastinum

B. Middle mediastinum

C. Posterior mediastinum

D. Superior mediastinum

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 60-year-old woman has had chronic lower-limb lymphedema for 15 years following cancer surgery. She presents for routine follow-up. Which of the following is not a complication of chronic lymphedema? (Q889672)

A. Recurrent cellulitis

B. Stewart-Treves Syndrome

C. Fibrosis

D. Venous ulcer

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Direct contrast lymphangiography is planned in a patient with a suspected lymphatic abnormality. Which of the following statements regarding this procedure is true? (Q889670)

A. It is a noninvasive imaging technique requiring no anaesthesia

B. Contrast is injected rapidly into a peripheral vein

C. Cannulation is usually performed on lymphatic vessels at the dorsum of the foot

D. It is commonly used as a routine diagnostic test for lymphedema

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A newborn is noted to have bilateral, non-pitting swelling of the feet and lower legs present since birth, as shown in the image. Examination shows thickened skin and prominent veins over the dorsum of the feet. The child's father has similar leg swelling. There is no history of surgery, infection, or trauma. Which of the following statements regarding this condition is true? (Q889667)

A. It is most commonly caused by filarial infection

B. It is inherited in an autosomal recessive pattern

C. It is associated with mutations in the FLT4 (VEGFR-3) gene

D. The lymphedema typically resolves spontaneously with age

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 52-year-old woman with a history of pelvic surgery and radiotherapy presents with long-standing swelling of the left leg.The clinical appearance is shown. Which grade of lymphedema does this most likely represent? (Q889664)

A. Grade 0

B. Grade I

C. Grade II

D. Grade III

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Identify the given condition and choose among the following: {{caption_text}} (Q849357)

A. Stewart - Treves syndrome

B. Lymphedema

C. Cystic hygroma

D. Marjolin’s ulcer

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 4-month-old baby is brought to the hospital with complaints of swelling in the neck as given in the image and diagnosed as cystic hygroma. Which of the following is true regarding the condition? {{caption_text}} (Q849355)

A. Swelling presents after the age of 1 year

B. It is a benign tumor

C. Laser excision is the treatment of choice

D. The size remains constant throughout the life

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following is the least preferred treatment option for early management of lymphedema? (Q849353)

A. Use of compression stockings

B. Limb elevation, regular check-up

C. Specialized complex physical therapy

D. Nielubowicz procedure

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 55-year-old male with chronic leg swelling presents with difficulty pinching the skin over the dorsum of his foot. What is this sign known as? {{caption_text}} (Q849352)

A. Buffalo hump

B. Square toes

C. Stemmer's sign

D. Merkel's sign

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 25-year-old female presents with swelling in her right calf and foot, which has gradually worsened over the past few years. She reports that the swelling started in her teenage years and has become more pronounced with time. What is the diagnosis in this patient? (Q849350)

A. Congenital lymphedema

B. Lymphedema praecox

C. Lymphedema tarda

D. None of the above

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 55-year-old woman presents with chronic swelling of her left arm. She has a history of breast cancer treatment 2 years ago. Which of the following is the most common iatrogenic cause of lymphedema in this patient's scenario? (Q849349)

A. Radiotherapy

B. Lymph node dissection

C. Chemotherapy

D. Biologic Targeted Therapy

See Answer in Part B → Q17

Q1: Which of the following paraneoplastic syndromes is NOT commonly associated with small cell lung carcinoma (SCLC)? (Q849541)

A. Syndrome of Inappropriate Antidiuretic Hormone (SIADH)

B. Eaton-Lambert Syndrome

C. Hypercalcemia

D. Cushing's Syndrome

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 3-year-old child presents with a history of choking followed by intermittent coughing and wheezing. The X-ray is as follows. What is the most appropriate investigation for diagnosis and intervention? (Q849521)

A. Chest X-ray

B. CT Scan

C. Rigid Bronchoscopy

D. Flexible Bronchoscopy

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55 y/o male with a persistent cough and occasional chest discomfort has a chest X-ray showing a 2.5 cm peripheral, sharply demarcated, lobulated mass with a "popcorn" appearance. No smoking history. What is the most likely diagnosis? (Q849522)

A. Pancoast Tumor

B. Pulmonary Hamartoma

C. Lung Abscess

D. Cystic Adenomatoid Malformation

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45 y/o male with a 3-month history of cough, hemoptysis, and wheezing has a CXR showing a central mass obstructing the right bronchus. Biopsy reveals a low-grade malignant tumour diagnosed as bronchial adenoma. Which of the following is NOT a type of bronchial adenoma? (Q849528)

A. Adenoid Cystic Carcinoma

B. Carcinoid

C. Small Cell Carcinoma

D. Mucoepidermoid Carcinoma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 65-y/o male, who worked for 30 years in shipbuilding, presents with a 6-month h/o progressive shortness of breath, chest pain, and significant weight loss. A CXR reveals a pleural effusion and a subsequent pleural biopsy confirms the diagnosis of malignant mesothelioma. Which subtype of malignant mesothelioma is most likely to be associated with a better prognosis in this patient? (Q849529)

A. Sarcomatoid subtype

B. Epithelial subtype

C. Mixed (biphasic) subtype

D. Both B and C

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 65 y/o male with a 30-year history in brake pad manufacturing presents with dyspnea, chest discomfort, and cough. Imaging shows pleural thickening and nodules. Biopsy confirms early-stage malignant mesothelioma. Which IHC markers and treatments are most consistent with this diagnosis? (Q849534)

A. Positive CEA, negative vimentin, treated with radiation therapy alone

B. Negative CEA, positive vimentin, treated with Extended Pleurectomy and Decortication (EPD) combined with chemotherapy

C. Positive CEA, negative cytokeratins, treated with chemotherapy only

D. Negative vimentin, positive cytokeratins, treated with Extrapleural Pneumonectomy (EPP) alone

See Answer in Part B → Q6

@Neet_pg_bot

Q7: What is the most common type of lung carcinoma? (Q849535)

A. Small cell lung carcinoma

B. Bronchogenic carcinoma

C. Adenocarcinoma

D. Squamous cell carcinoma

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 60-year-old male, with a 40-year history of smoking, presents with a persistent cough, hoarseness, and recent onset of facial swelling and distended neck veins. Imaging reveals a mass in the central region of the right lung. Based on the location and clinical features, what is the most likely diagnosis? (Q849538)

A. Adenocarcinoma

B. Squamous Cell Carcinoma (SCC)

C. Large Cell Carcinoma

D. Apical (Pancoast's) Tumor

See Answer in Part B → Q8

@Neet_pg_bot

Q9: What is the most common site of metastasis for lung cancer? (Q849539)

A. Liver

B. Brain

C. Adrenal Glands

D. Bone

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 65 y/o woman presents to the emergency with a sudden onset of shortness of breath, chest pain, and hypotension. She is diagnosed with a massive pulmonary embolism. Which of the following is the most appropriate initial treatment for this patient? (Q849520)

A. Inferior Vena Cava (IVC) Filter

B. Thrombolytic Therapy

C. Ventilator Support

D. Vitamin K Antagonists

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 65 y/o male with a 35-pack-year smoking history presents with worsening dyspnea, cough, and weight loss. A CT shows a 6.5 cm right upper lobe mass invading the chest wall, with ipsilateral mediastinal lymph node involvement and liver metastasis as seen on the PET scan. What is the TNM stage of his lung cancer? (Q849543)

A. T2b, N1, M0

B. T3, N2, M1b

C. T4, N2, M1a

D. T3, N3, M1c

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 65 y/o male with a confirmed diagnosis of stage IIIB non-small cell lung cancer (NSCLC) is being evaluated for treatment options. His disease is localized with significant mediastinal lymph node involvement, and he has a good performance status. Which of the following is the most appropriate initial treatment for this patient? (Q849544)

A. Surgical resection followed by adjuvant chemotherapy

B. Chemoradiation followed by maintenance immunotherapy

C. Systemic therapy with palliative radiation

D. Adjuvant chemotherapy alone

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 63-year-old man with a history of smoking presents with a central lung mass, weight loss, and a new diagnosis of squamous cell carcinoma (SCC). Which of the following is a common clinical presentation associated with squamous cell carcinoma of the lung due to its typical location? (Q849545)

A. Pleural effusion causing dyspnea

B. Hypercalcemia with renal stones

C. Superior vena cava syndrome

D. Horner's syndrome

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 62- y/o man with a history of heavy smoking is diagnosed with a central lung mass. He is also noted to have severe hypercalcemia and is receiving chemotherapy and radiation therapy. Which of the following statements is true? (Q849546)

A. SCLC is less aggressive than large cell carcinoma

B. Oat cells are seen in Large cell carcinoma

C. SCLC is strongly linked to smoking and can cause SIADH

D. Large cell carcinoma usually presents in central lung areas

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 72 y/o woman presents with severe shoulder pain and noticeable ptosis. Imaging reveals a mass at the apex of the lung, involving the upper ribs and vertebrae. Horner's syndrome is observed. Which imaging modalities are most suitable for the evaluation of this condition? (Q849547)

A. Chest X-ray

B. Ultrasound

C. CT scan

D. MRI

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following statements regarding cardiac tumours is true? (Q849548)

A. Angiosarcomas are the most common benign primary cardiac tumours.

B. Nearly 90% of primary cardiac tumours are malignant.

C. Myxomas are the most common primary cardiac tumours in adults.

D. Cardiac myocytes have high proliferative activity, contributing to the formation of cardiac tumours.

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 55 y/o female presents with symptoms of shortness of breath, occasional dizziness, and a recent episode of fever and weight loss. Imaging studies reveal a mass in the left atrium and is diagnosed with atrial myxoma. Which of the following is true? (Q849549)

A. The majority of atrial myxomas arise from the right atrium.

B. Atrial myxomas are more common in males, around 3rd decade of life.

C. Atrial myxomas can cause systemic emboli and obstruction of blood flow.

D. The genetic cause of atrial myxomas is always linked to an autosomal recessive pattern.

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 14 y/o boy presents with a chest wall deformity characterized by a protruding sternum, resulting in a convex appearance of the chest. The patient is otherwise asymptomatic, and his chest wall growth is nearing completion. Which of the following statements about the management of this condition is true? (Q849550)

A. The Nuss procedure is the preferred surgical approach.

B. Non-surgical bracing is effective in correcting pectus carinatum

C. The modified Ravitch procedure is exclusively used for treating the Pigeon chest.

D. Surgical intervention for pectus carinatum is typically recommended for cosmetic reasons.

See Answer in Part B → Q18

@Neet_pg_bot

Q19: The thoracic duct, the largest lymphatic vessel in the body, passes through the posterior mediastinum. Which of the following anatomical triangles is the key area used for locating and managing the thoracic duct? (Q849492)

A. Simon's triangle

B. Lesgaft's triangle

C. The triangle of Petit

D. Poirier’s Triangle

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 48 y/o female presents with fluctuating muscle weakness, difficulty speaking, and drooping eyelids that worsen with physical activity. Imaging reveals a mass in the anterior mediastinum. Which of the following is the most likely paraneoplastic syndrome associated with her condition? (Q849463)

A. Lambert-Eaton myasthenic syndrome

B. Myasthenia gravis

C. Cushing syndrome

D. Syndrome of inappropriate antidiuretic hormone (SIADH)

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 55 y/o male presents with a persistent cough and dyspnea on exertion. A chest x-ray reveals an anterior mediastinal mass with tracheal deviation. What is the next best step in evaluating this patient for a potential thymoma? (Q849464)

A. Serum markers

B. Chest X-ray with lateral view

C. Contrast-enhanced CT scan

D. Pulmonary function tests (PFTs)

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 63 y/o female is diagnosed with a Stage III thymoma and presents with symptoms of myasthenia gravis. The tumour appears to have invaded the superior vena cava and pericardium. What is the most appropriate treatment plan for this patient? (Q849465)

A. Complete surgical resection

B. Radiation therapy alone

C. Observation and periodic follow-up imaging

D. Chemotherapy as a primary treatment without surgery

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 48 y/o man with a history of pulmonary TB presents with progressive shortness of breath, facial swelling, and difficulty swallowing. His chest X-ray shows an abnormal shadow in the mediastinum. A CT scan reveals extensive fibrotic tissue compressing the SVC and oesophagus. What is the most likely diagnosis? (Q849466)

A. Superior vena cava syndrome

B. Pulmonary embolism

C. Chronic fibrous mediastinitis

D. Thymoma

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 72-year-old male with COPD presents with sudden severe shortness of breath and right-sided chest pain. On examination, he is cyanotic, in respiratory distress, and has diminished breath sounds on the right side. A CXR shows a large air collection in the right pleural space. What is the most likely diagnosis? (Q849474)

A. Primary Spontaneous Pneumothorax (PSP)

B. Secondary Spontaneous Pneumothorax (SSP)

C. Chylothorax

D. Hemothorax

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 30-year-old male presents to the emergency department after a stabbing injury to the chest, having respiratory distress, 4 cm wound on the right side. On examination, his breath sounds are decreased on the right side, and he shows signs of hypoxia. His vital signs are stable. What is the most appropriate first step in managing this patient? (Q849479)

A. Perform needle thoracocentesis in the 2nd intercostal space, midclavicular line

B. Insert a chest tube immediately at the site of the injury

C. Apply a sterile occlusive dressing over the wound, taped on three sides

D. Obtain a chest X-ray to assess the injury and confirm the diagnosis

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 25-year-old male, after a motor vehicle accident, presents with severe respiratory distress, decreased breath sounds on the right, hyper-resonance, and tracheal deviation to the left. His BP is 85/55 mmHg, and jugular veins are distended. What is the most appropriate next step in management? (Q849480)

A. Order an urgent chest X-ray to confirm the diagnosis

B. Perform an immediate needle thoracocentesis in the 5th intercostal space, in anterior axillary line

C. Insert a chest tube into the 5th intercostal space in the anterior axillary line

D. Perform a finger thoracostomy in the safe triangle

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 70 y/o woman with lung cancer presents with sudden severe chest pain and shortness of breath, 3 weeks post-lobectomy. She is pale, tachypneic, with BP 85/50 mmHg and HR 120 bpm. Examination reveals right-sided dullness and diminished breath sounds. A CXR shows a large pleural effusion, and thoracentesis drains 1000ml of blood. What is the most appropriate next step in management? (Q849481)

A. Observation and follow-up with chest X-ray

B. Administration of antibiotics and bronchodilators only

C. Thoracotomy with evacuation and lung decortication

D. Intercostal chest tube (ICT) placement

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which of the following is least likely to be found in the posterior mediastinum? (Q849462)

A. Neurofibroma

B. Thymoma

C. Ganglioneuroma

D. Aneurysm of descending aorta

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 45 y/o male presents with chest pain and dyspnea one week after undergoing oesophagal surgery. A pleural tap reveals milky white fluid with high triglyceride levels. Which of the following is the most appropriate next step in the management of this patient? (Q849493)

A. Oral antibiotics

B. Thoracic duct ligation via thoracoscopy

C. Oral diet with medium-chain triglycerides

D. Immediate pleurodesis with talc

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 35 y/o male presents with milky urine and abdominal pain after a fatty meal. He reports weight loss and frequent urinary infections. Urinalysis shows chyluria. What is the most likely underlying cause of chyluria in this patient? (Q849494)

A. Renal stone disease

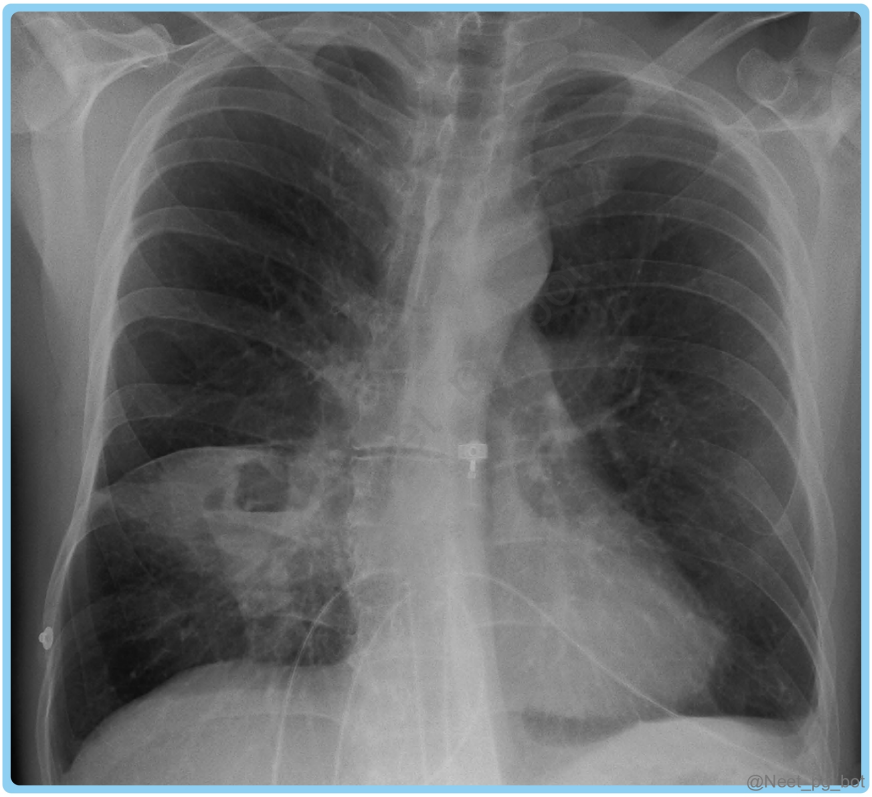
B. Filarial infection

C. Tuberculosis

D. Diabetes mellitus

See Answer in Part B → Q30

@Neet_pg_bot



Q31: A 60 y/o male presents with fever, cough, and foul-smelling sputum. A chest X-ray reveals a localized opacity in the apical lower lobe. Sputum culture shows the presence of anaerobic bacteria. Which of the following is the most likely cause? (Q849495)

A. Aspiration of oropharyngeal secretions

B. Hematogenous spread from endocarditis

C. Direct extension from pneumonia

D. Bronchial obstruction due to lung cancer

See Answer in Part B → Q31

@Neet_pg_bot

Q32: A 58 y/o male with a history of chronic kidney disease presents to the clinic with shortness of breath and chest discomfort. A chest X-ray shows a pleural effusion on the right side. Analysis of the pleural fluid reveals the following: Pleural fluid protein

to serum protein ratio: 0.7 Pleural fluid lactate dehydrogenase (LDH) to serum LDH ratio: 0.65 Pleural fluid LDH level: 300 U/L (serum LDH upper limit of normal is 200 U/L) Based on these findings and Light's criteria, which of the following is the most likely cause of this patient's pleural effusion? (Q849496)

A. Congestive heart failure

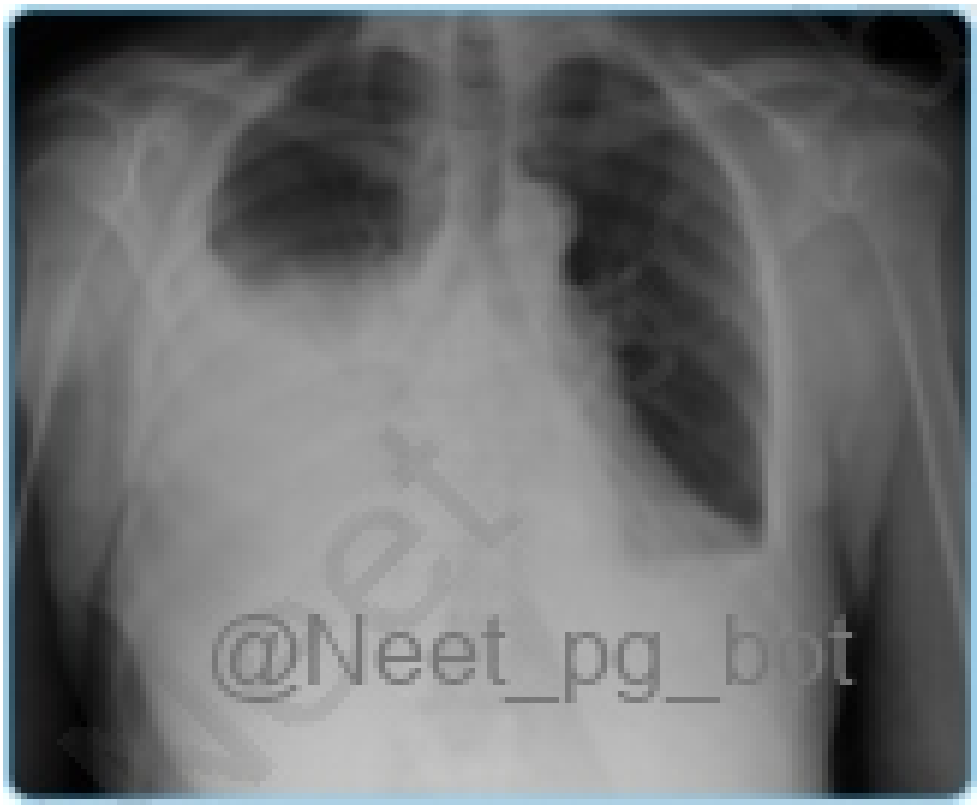
B. Lung cancer

C. Nephrotic syndrome

D. Cirrhosis

See Answer in Part B → Q32

@Neet_pg_bot



Q33: A 72 y/o male with h/o COPD presents with progressive shortness of breath and chest pain. The chest X-ray findings are shown below. Thoracentesis is performed, and analysis of the pleural fluid reveals high protein & LDH levels. Which of the following is the next best step in managing this patient? (Q849497)

A. Initiate diuretic therapy

B. Perform a pleural biopsy

C. Insert a chest tube for drainage

D. Administer antibiotics

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A 50 y/o male patient has been hospitalized following a hip replacement surgery for the past 6 days. He has a history of obesity and smoking. On the sixth day, he suddenly develops shortness of breath, and chest pain, and coughs up blood. Which of the following is the most likely contributing factor to his current condition? (Q849518)

A. Prolonged immobility

B. Dehydration

C. High blood pressure

D. Recent blood transfusion

See Answer in Part B → Q34

@Neet_pg_bot

Q35: Which of the following is the most commonly used gold standard investigation for diagnosing pulmonary embolism in a clinical setting? (Q849519)

A. Doppler Ultrasound

B. Chest X-ray

C. Ventilation-Perfusion (V/Q) Lung Scan

D. CT Pulmonary Angiography (CTPA)

See Answer in Part B → Q35

Q1: In a 35-year-old individual with a history of chronic smoking who is experiencing bluish discoloration of the toes and intermittent claudication, what would be the most suitable investigation to conduct next? (Q856763)

A. CT Angiography

B. MR Angiography

C. Digital subtraction angiography

D. Duplex scan

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Identify the type of ulcer? (Q866906)

A. Arterial Ulcer

B. Venous ulcer

C. Diabetic ulcer

D. Neuropathic

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 50-year-old diabetic man presents with a progressive increase in pain in his calf. He now prefers to sleep in a seated position by hanging his leg to alleviate pain.Pain is more in the distal part like toes and feet. It gets aggravated with movements and pressure. The pain is increased in lying down and elevation of foot; it may be reduced on hanging the foot down. Which of the following is the most likely cause? (Q793482)

A. Rest pain

B. Sciatica

C. Neurological claudication

D. Venous claudication

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following findings is likely to be seen in this patient? (Q855695)

A. Decreased posterior tibial & dorasalis pedis pulsations

B. Loss of sensation over the foot

C. Positive tredelenberg sign

D. Pain on compression of the calf

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 32-year-old male chronic smoker presents with pain in the fingers for a few months. On examination, gangrenous ulcers were present in the fingers, as shown below. Investigation showed blood glucose and lipid profile within normal limits.

Which of the following is the most likely diagnosis? (Q857126)

A. Buerger’s disease

B. Diabetic ulcers

C. Acute paronychia

D. Raynaud’s phenomenon

See Answer in Part B → Q5

@Neet_pg_bot

Q6: What is the probable medical condition for an 80-year-old male who experienced pain and swelling in the calf muscle on the right side after being immobilized due to a fracture in the right inter-trochanteric region? (Q857130)

A. Chronic osteomyelitis

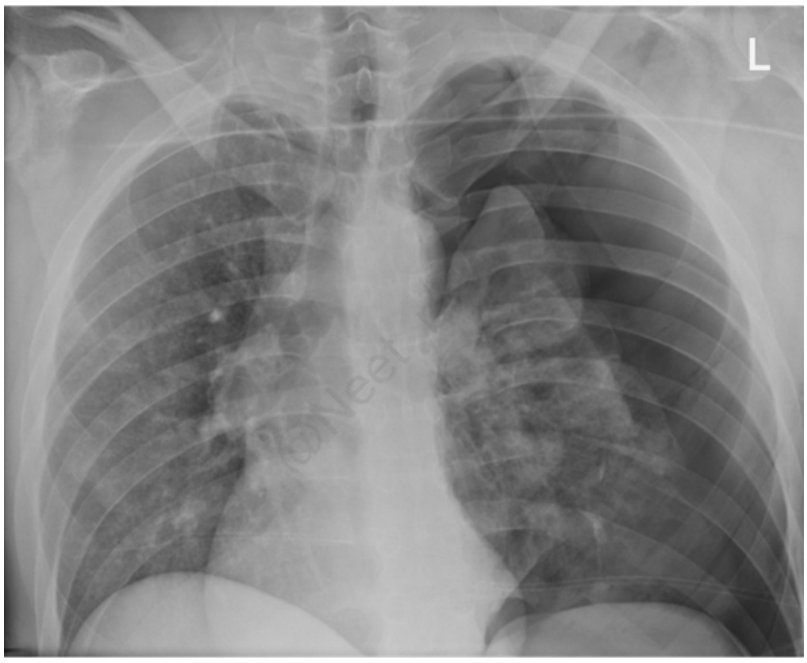
B. Deep vein thrombosis

C. Compartment syndrome

D. Arterial claudication

See Answer in Part B → Q6

@Neet_pg_bot



Q7: A 25-year-old male patient involved in a road traffic accident was managed upon arrival at the emergency room, with a respiratory rate of 25 breaths per minute and a blood pressure of 80/45mmHg, and exhibiting hyper-resonance on the left side of the chest, what is the appropriate action based on the findings from the chest x-ray? (Q857456)

A. Wide bore needle insertion in the 2nd ICS

B. Wide bore needle insertion in the 5th ICS followed by an intercostal drain in the 5th ICS

C. Aspiration of the pleural fluid

D. No intervention needed

@Neet_pg_bot

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A patient underwent surgery, for which she was immobilised. Patient started complaining of leg pain on the 5th postoperative day. On examination , Homan's sign is positive. What is the most probable diagnosis? (Q857539)

A. Deep Venous thrombosis

B. Urinary sepsis

C. Peripheral vascular disease

D. Lymphangitis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: How is empyema thoracis treated? (Q857541)

A. Antibiotics alone

B. Chest tube drainage and antibiotics

C. ICD alone

D. Wait and watch

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A man presented with a history of stab injury to the arm. On examination, there was a hematoma, and radial and ulnar pulses were not felt. A 3.5cm longitudinal tear is noted in the brachial artery. Which among the following is the best treatment option? (Q858346)

A. Primary repair with end-to-end anastomosis

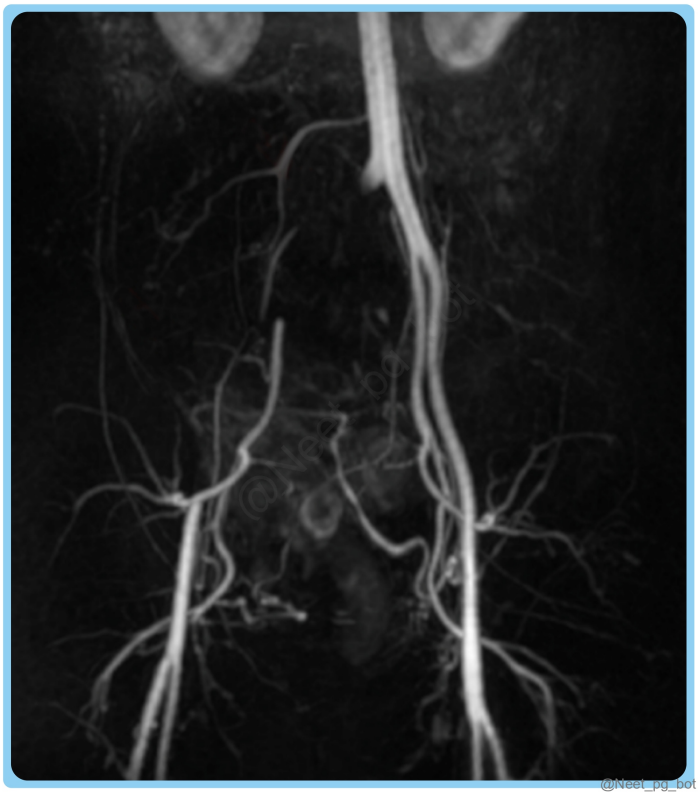
B. Repair with great saphenous vein graft

C. Repair with prosthetic graft

D. Repair with saphenous vein patch

See Answer in Part B → Q10

@Neet_pg_bot



Q11: A 70-year-old female patient presents with pain in the thigh during walking. MRA shows complete long-segment occlusion of the right common iliac artery extending into the proximal external iliac artery, with distal reconstitution through internal iliac collaterals. What is the best surgical management? (Q856200)

A. PTA with stenting

B. Femoroiliac bypass

C. Aortofemoral bypass

D. Aorto-iliac bypass

See Answer in Part B → Q11

@Neet_pg_bot

Q12: According to the CEAP classification, What will be the stage in this patient as the patient presents with the same problem again and again? (Q856207)

A. C2

B. C1

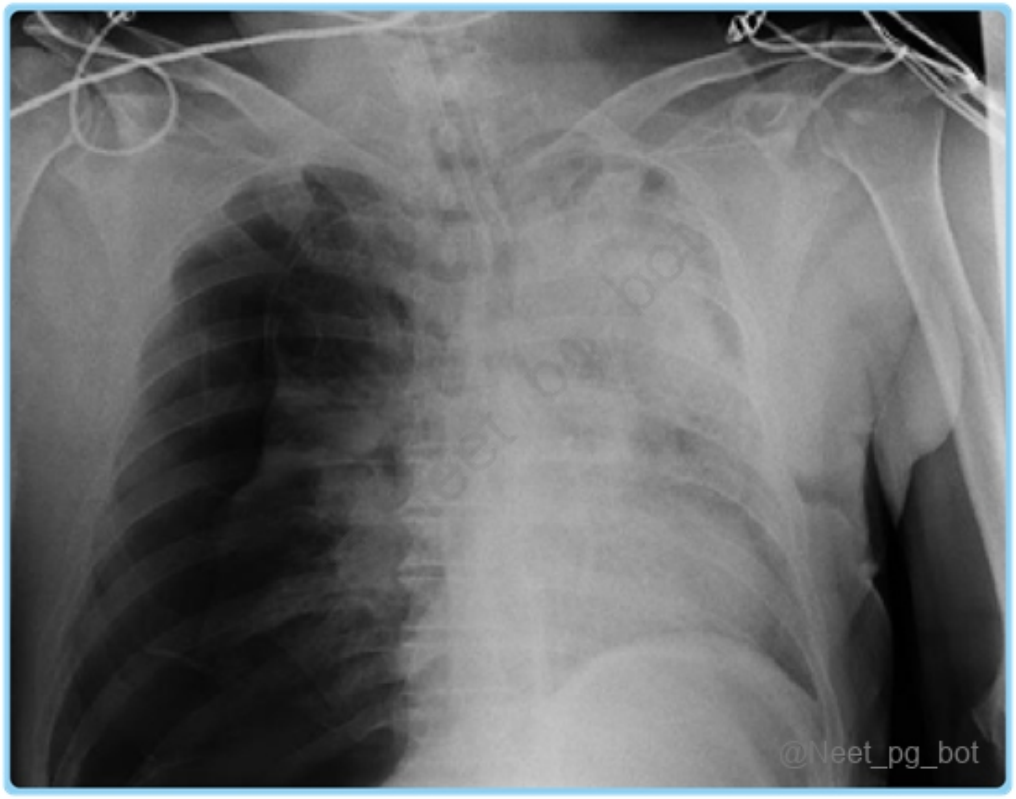
C. C4a

D. C5

See Answer in Part B → Q12

@Neet_pg_bot

Q13: What is the appropriate course of action for managing a 25-year-old male patient who was brought to the emergency room following a road traffic accident? The patient has a respiratory rate of 25 breaths per minute and a blood pressure of 80/45 mmHg. During examination, hyper-resonance is detected on the right side of the



chest. Please refer to the provided chest X-ray for further evaluation. (Q856746)

A. Wide bore needle insertion in the 5th intercostal space (ICS)

B. Wide bore needle insertion in the 5th ICS followed by an intercostal drain in the 5th ICS

C. Aspiration of the pleural fluid

D. No intervention is needed

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A bus conductor was diagnosed with varicose veins. On examination, skin eczema and lipodermatosclerosis were noted. According to the CEAP classification system, he would be classified as: (Q856753)

A. C1

B. C2

C. C3

D. C4

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 40-year-old smoker presents with sudden, severe, tearing chest pain radiating to his back, shortness of breath, and mild nausea. His BP is 190/110 mmHg, and heart rate is 105 bpm. What is the initial management? (Q857860)

A. Control blood pressure

B. Urgent surgery

C. Wait and watch

D. Blood transfusion

See Answer in Part B → Q15

@Neet_pg_bot

Q16: What is the most likely diagnosis of the lesion shown in the image below? (Q856766)

A. Arterial insufficiency

B. Neuropathic ulcer

C. Venous ulcer

D. Tuberculous ulcer

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following adverse effects is not observed following a massive blood transfusion? (Q856773)

A. Hypocalcemia

B. Hypercalcemia

C. Hypokalemia

D. Hyperkalemia

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 55-year-old man with IHD presents with sudden, severe, generalised abdominal pain and multiple episodes of vomiting. On examination, the pulse rate is 118 bpm, rhythm is irregularly irregular, and BP is 90/60 mmHg. The abdomen appears soft and non-distended, and bowel sounds are absent. Which of the following could be a likely diagnosis in this case? (Q856298)

A. Acute severe pancreatitis

B. Ruptured aortic aneurysm

C. Acute mesenteric ischemia

D. Peptic ulcer perforation

See Answer in Part B → Q18

@Neet_pg_bot

Q19: What is the management approach for a 50-year-old male patient who has a 40 mm abdominal aortic aneurysm detected during his routine annual checkup? (Q854937)

A. Urgent endovascular aneurysm repair

B. Surgery is indicated if the aneurysmal diameter is > 55mm

C. Urgently wheel the patient to OT for surgery

D. Surgery is indicated only if the aneurysm is > 77mm

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following statements regarding intermittent claudication is accurate? (Q854944)

A. Felt at rest

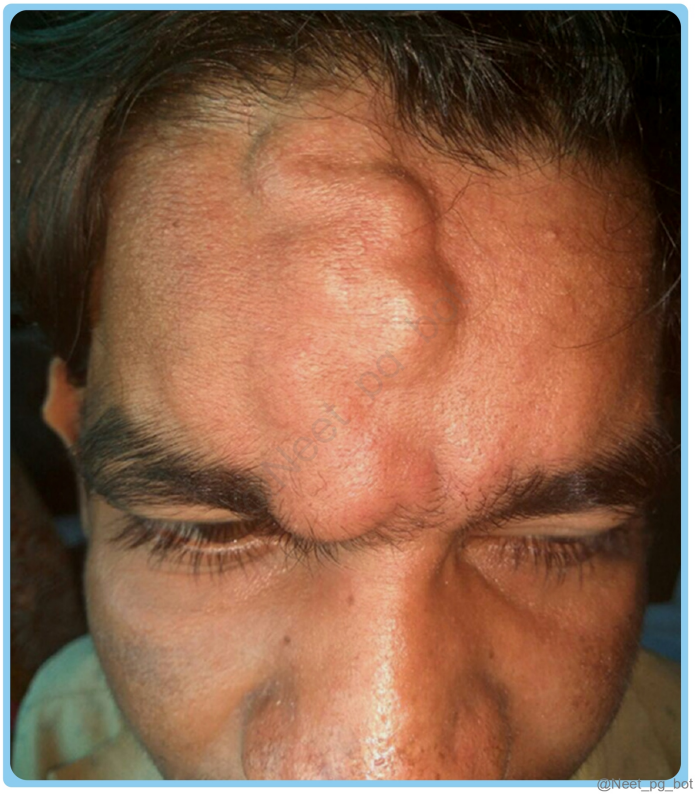
B. Most commonly felt in the calf muscles

C. Day-to-day distance is variable

D. Relieved after getting out of bed

See Answer in Part B → Q20

@Neet_pg_bot



Q21: What is the most probable diagnosis for a 41-year-old female patient who presented with a twisted swelling on the scalp and face, accompanied by a pulsating sensation and a bruit heard during auscultation? (Q854947)

A. Neurofibromatosis

B. Liposarcoma

C. Cirsoid Aneurysm

D. Varicocele

See Answer in Part B → Q21

@Neet_pg_bot

Q22: According to the TNM staging, a patient with lung cancer of size 2.5 cm is staged as: (Q854986)

A. T1b

B. T1c

C. T2a

D. T1a

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following is not a component of Thoracoscore? (Q855018)

A. Performance status

B. Complication of surgery

C. ASA grading

D. Priority of surgery

See Answer in Part B → Q23

@Neet_pg_bot

Q24: What is the probable diagnosis for a 50-year-old male who is a long-term smoker and experiences pain in both thighs and buttocks while walking approximately 500 meters? (Q858494)

A. Arterial disease involving the superficial femoral artery

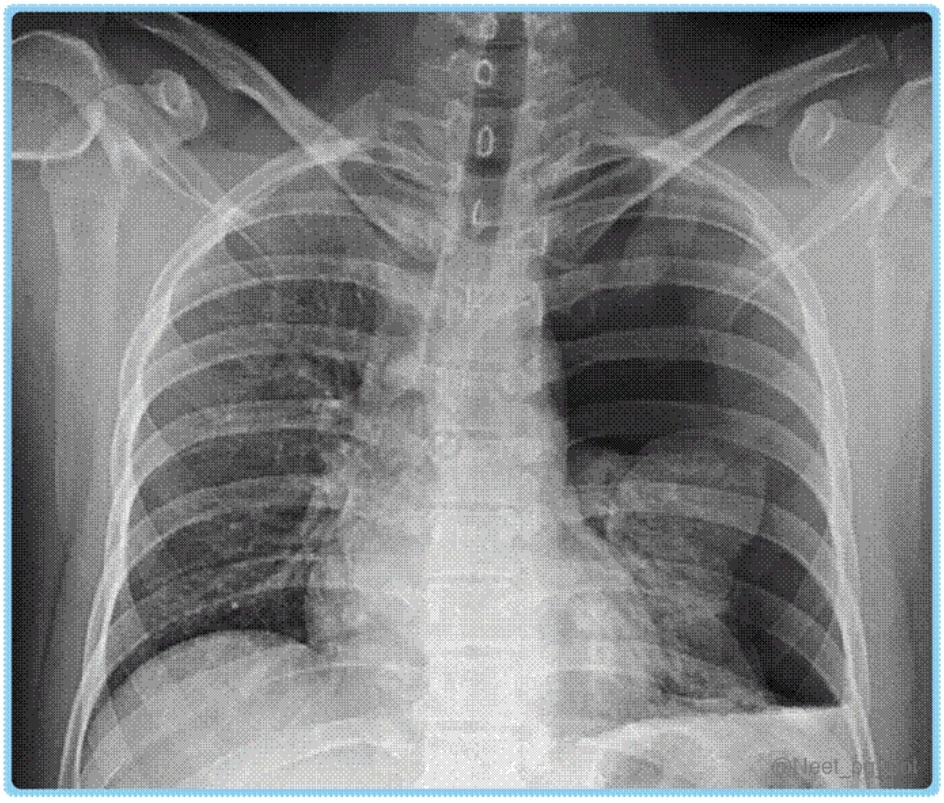
B. Arterial disease with aortoiliac involvement

C. Femoral venous insufficiency

D. Arterial disease involving the profunda femoris artery

See Answer in Part B → Q24

@Neet_pg_bot



Q25: What would be the appropriate course of action for managing a 25-year-old male patient who was brought to the emergency department after a road traffic accident (RTA)? The patient has a respiratory rate of 25 breaths per minute and a blood pressure of 80/45 mmHg. During examination, hyper-resonance is detected over the left side of the chest. The provided chest x-ray is shown below. (Q859600)

A. Wide bore needle insertion in the right 5th ICS

B. Wide bore needle insertion in the left 5th ICS followed by an intercostal drain

C. Aspiration of the pleural fluid

D. No intervention is needed

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A male patient presents with impotence and absent femoral pulse. The pain in the gluteal region is observed. At which level has the pathology occurred? (Q855764)

A. Bilateral popliteal arteries

B. Bilateral internal iliac arteries

C. Aortoiliac bifurcation

D. Bilateral femoral arteries

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A patient presents with a tender pulsatile mass, as shown in the image below. What will be done next for this patient? (Q855769)

A. Ultrasound Doppler

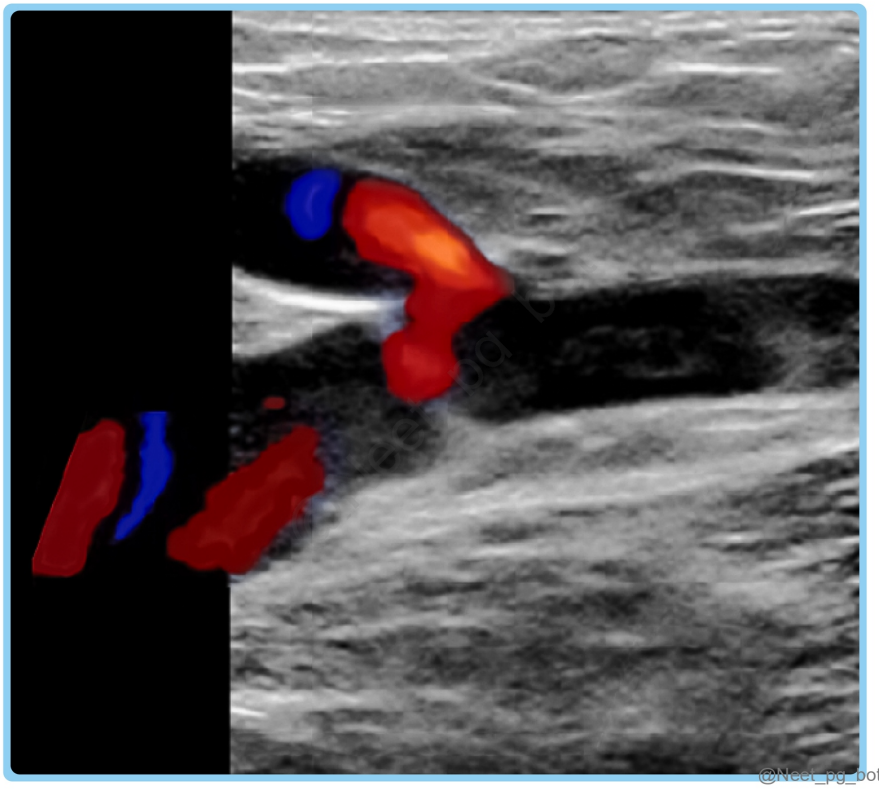
B. Needle aspiration

C. CT angiogram with percutaneous management

D. Intravenous antibiotics for 7 days

See Answer in Part B → Q27

@Neet_pg_bot



Q28: A patient presents with sudden onset right leg pain. An investigation was done, and the obtained image is shown below. What is the investigation? (Q855821)

A. Digital subtraction angiography

B. Ultrasound Doppler

C. MR angiography

D. Plethysmography

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 39-year-old male who had a road traffic accident and suffered from chest trauma was admitted to the ER. About 1800 ml of blood loss from the chest tube in an hour. What is the next step in management for this condition? (Q820129)

A. Emergency Thoracotomy

B. Conservative for next 6-hours

C. Continue resuscitation

D. Wait & watch

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 30-year-old male presented to EMT with H/o Penetrating chest trauma. On examination, severe tracheal deviation was present. What is the immediate step of management? (Q866927)

A. Needle decompression

B. Chest X-ray

C. E-FAST

D. O2 support at 100%

See Answer in Part B → Q30

@Neet_pg_bot

Q31: In a chronic limb ischemia patient, what is the ABI below which gangrene is imminent: (Q865388)

A. 0.5

B. 0.3

C. 0.9

D. 1

See Answer in Part B → Q31

@Neet_pg_bot

Q32: A 56 years old man presents with the following pathology, which of the following is correct? (Q866445)

A. Sclerotherapy is the best treatment

B. Lipodermatosclerosis/eczema can occurs

C. Telangiectasia is rare

D. No possibility of venous ulcer

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A chronic smoker presents with leg pain after walking 100 meters. On examination, there is an absent pulse in the bilateral dorsalis pedis, anterior tibial, and posterior tibial arteries, but no gangrene is noted. Intermittent claudication is suspected. Which of the following statements about this condition is correct? (Q853070)

A. Pain is more at night and sleep

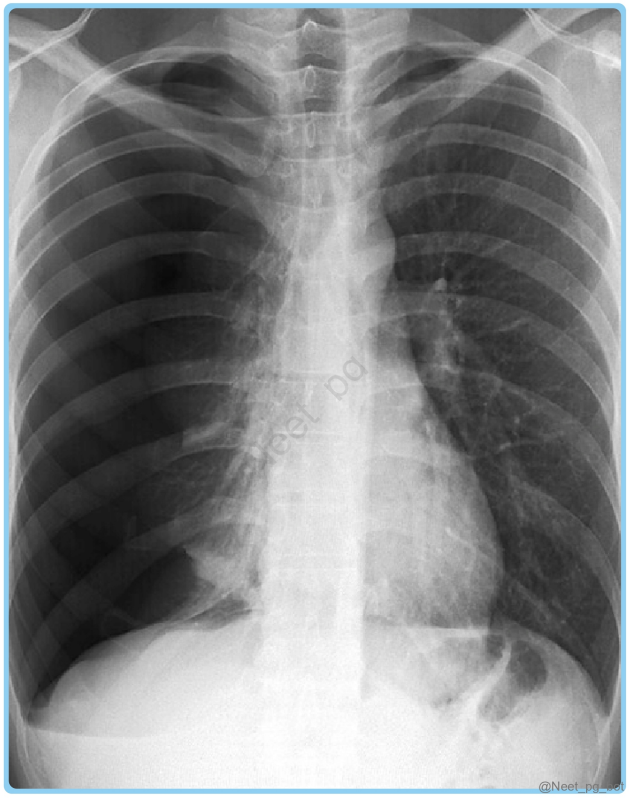
B. Pain aggravated by standing and relieved by bending forward

C. Development of pain on the 1st step of walking

D. Pain develops after walking some distance and is relieved by rest

See Answer in Part B → Q33

@Neet_pg_bot



Q34: Following a fight between 2 groups, a boy was brought with severe pain in the chest, distended neck veins, dyspnea, and a BP of 80/50 mmHg. X-ray shows the following findings: What is the diagnosis? (Q852683)

A. Tension pneumothorax

B. Primary Spontaneous Pneumothorax

C. Traumatic Pneumothorax

D. Bilateral Pneumothorax

See Answer in Part B → Q34

@Neet_pg_bot

Q35: A 62-year-old male presents with left leg swelling and pain for 5 days and has a positive D-dimer test. Duplex ultrasonography confirms an extensive DVT involving the left popliteal and femoral veins. Which of the following is the most appropriate initial management strategy? (Q852702)

A. Unfractionated heparin followed by warfarin

B. LMWH followed by oral anticoagulant

C. Catheter-directed thrombolysis

D. IVC filter placement

See Answer in Part B → Q35

@Neet_pg_bot

Q36: Which type of ulcer is given below? (Q844296)

A. Venous ulcer

B. Arterial ulcer

C. Trophic ulcer

D. Diabetic foot

See Answer in Part B → Q36

@Neet_pg_bot

Q37: What is the appropriate management for a patient presenting with constant chest pain and radiological findings of stanford type A aortic dissection? (Q844300)

A. Surgical management

B. Vasodilator

C. Beta blocker

D. Beta blocker plus vasodilator

See Answer in Part B → Q37

@Neet_pg_bot

Q38: A patient presented to the outpatient department with a dilated, tortuous vein in the leg. The patient reported a history of trauma to the same area 10 years prior. Upon examination, a pulsatile vein was also noted. What is the most likely diagnosis? (Q860393)

A. Varicose vein

B. Angiofibroma

C. Hemangioma

D. A-V Fistula

See Answer in Part B → Q38

@Neet_pg_bot

Q39: An elderly man with a chronic history of IV drug use presents with progressively increasing swelling in the groin on the right side. The swelling is non-fluctuant but pulsatile on examination. He has diminished pulses distal to the swelling on the same side. What is the next step in the management of this patient? (Q860455)

A. CT angiography followed by surgery

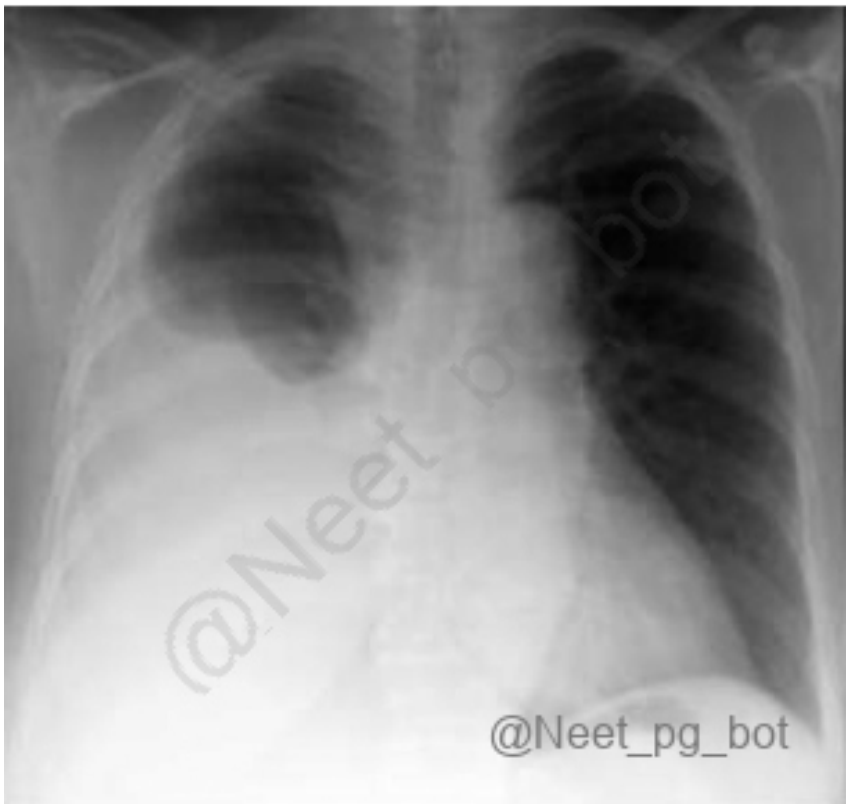
B. Oral antibiotics and observation

C. Compression stocking

D. Incision and drainage

See Answer in Part B → Q39

@Neet_pg_bot



Q40: A 32-year-old male presents to the emergency department after sustaining a stab wound to the right side of his chest. He is in acute distress, with a heart rate of 120 beats per minute, blood pressure of 90/60 mmHg, and respiratory rate of 28 breaths per minute. On physical examination, there are decreased breath sounds on the right side. A chest X-ray is shown below. What is the diagnosis? (Q840044)

A. Pneumothorax

B. Hemothorax

C. Tension Pneumothorax

D. Hydrothorax

See Answer in Part B → Q40

@Neet_pg_bot

Q41: A patient presents with calf pain while walking a certain distance. The pain is severe enough that he must stop and rest before continuing. According to Boyd's grading, which of the following grades best describes this condition? (Q860217)

A. Grade 1

B. Grade 2

C. Grade 3

D. Grade 4

See Answer in Part B → Q41

@Neet_pg_bot

Q42: A man presented with a history of stab injury over the arm. On examination, there was the presence of hematoma, and radial and ulnar pulses were not felt. A 3.5 cm longitudinal tear is noted in the brachial artery. Which of the following is the best treatment option? (Q857300)

A. Primary repair with end-to-end anastomosis

B. Repair with great saphenous vein graft

C. Repair with prosthetic graft

D. Repair with saphenous vein patch

See Answer in Part B → Q42

@Neet_pg_bot

Q43: After undergoing surgery to correct a left-sided varicocele, a 30-year-old male patient inquires about the primary route through which venous drainage occurs following the surgery. How should the surgeon correctly respond to the patient's question? (Q857310)

A. Cremasteric veins

B. Penile veins

C. Ectopic drainage in the iliac fossa

D. Testicular veins

See Answer in Part B → Q43

@Neet_pg_bot

Q44: Which is the least commonly used graft for coronary artery bypass graft (CABG)? (Q857806)

A. Long saphenous vein

B. Internal mammary artery

C. Intercostal artery

D. Radial artery

See Answer in Part B → Q44

@Neet_pg_bot

Q45: In a patient with aortic dissection, injury to which of the following structure will cause hiccups? (Q820139)

A. Phrenic nerve

B. Abdominal aorta

C. Thoracic aorta

D. Spinal accesory nerve

See Answer in Part B → Q45

@Neet_pg_bot

Q46: A 56-year-old patient presented with varicose veins. What is the investigation of choice for varicose veins? (Q820163)

A. Duplex scan

B. Plethysmography

C. MRI

D. CT

See Answer in Part B → Q46

@Neet_pg_bot

Q47: What is the most preferred site for the insertion of the intercostal tube drain? (Q820173)

A. Upper border of lower rib

B. Lower border of upper rib

C. Lower border of lower rib

D. Middle of intercostal space

See Answer in Part B → Q47

@Neet_pg_bot

Q48: A patient presents with dull, aching pain and tortuous veins in both lower limbs. Which test would be appropriate for evaluating superficial femoral vein (SFJ) competence? (Q854740)

A. Fegan's test

B. Homan’s test

C. Modified Perthes test

D. Brodie Trendelenburg test

See Answer in Part B → Q48

@Neet_pg_bot

Q49: A 62-year-old patient presents with pain in the calf muscles while walking. The pain subsides with rest. Which of the following is not typically seen in intermittent claudication? (Q854759)

A. Cramping in the muscles during exercise

B. Pain starting on taking the first step

C. The most common cause is atheroma

D. The level of occlusion cannot be decided based on symptoms

See Answer in Part B → Q49

@Neet_pg_bot

Q50: A patient presents with a sudden onset of chest pain shooting to the neck and interscapular region. X-ray shows a widened mediastinum. Blood pressure is 110/90 mmHg in the right upper limb and 160/100 mmHg in the left upper limb. What is the most likely diagnosis? (Q855199)

A. Acute coronary syndrome

B. Acute pulmonary embolism

C. Acute aortic dissection

D. Esophageal rupture

See Answer in Part B → Q50

@Neet_pg_bot

Q51: A construction worker presents to the OPD with complaints of white fingers. He has been working in the cement and concrete industry and has spent 20 years using

heavy machinery drills and polishing wood and furniture. What is the most likely etiology for this condition? (Q855246)

A. Candidal infection of the fingers due to continuous exposure to water

B. Exposure to thinners and paints

C. Continuous exposure to cement and concrete

D. Continuous exposure to drills and machines

See Answer in Part B → Q51

@Neet_pg_bot

Q52: Identify the given condition: (Q855253)

A. Venous ulcer

B. Malignant ulcer

C. Arterial ulcer

D. Trophic ulcer

See Answer in Part B → Q52

@Neet_pg_bot

Q53: A patient with varicose veins complains of eczema in the same region. According to the CEAP guidelines, what is the stage of the clinical classification? (Q855257)

A. C2

B. C3

C. C4a

D. C4b

See Answer in Part B → Q53

@Neet_pg_bot

Q54: A 17-year-old woman with no comorbidities presents with numbness and paraesthesia of the fingers along with the characteristic finding as shown in the image below. She has no history of smoking or history of other illnesses. She mentions the episodes occur when she is under excess stress or during cold temperatures. What is the most likely diagnosis? (Q857783)

A. Buerger’s disease

B. Atherosclerosis

C. Raynaud’s phenomenon

D. Giant cell arteritis

See Answer in Part B → Q54

@Neet_pg_bot

Q55: All of the following are classic anterior mediastinal masses EXCEPT: (Q857785)

A. Parathyroid adenoma

B. Lymphoma

C. Teratoma

D. Thymoma

See Answer in Part B → Q55

@Neet_pg_bot

Q56: While washing clothes in cold water, a female patient exhibits color changes in her hands from white to red . Which of the following drugs is best suited for this

patient? (Q793884)

A. ACE inhibitors

B. Calcium channel blockers

C. Thiazides

D. Alpha-blockers

See Answer in Part B → Q56

@Neet_pg_bot

Q57: Which of the following provides long-lasting results in a coronary artery bypass graft (CABG) ? (Q793485)

A. Long saphenous vein

B. Internal mammary artery

C. Poly tetra fluoro eythlene (PTFE)

D. Gastroepiploic artery

See Answer in Part B → Q57

Q13 (p. 197) *Q14 (p. 198)*

Q1: Which of the following is the most common type of primary liver tumor? (Q848891)

A. Metastasis

B. Hepatocellular carcinoma

C. Hepatoblastoma

D. Hemangioma

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 55-year-old male patient with a history of chronic hepatitis B presents with abdominal discomfort and weight loss. Imaging studies reveal a primary liver tumor with multiple metastatic lesions. Considering the typical metastatic pattern of liver tumors, what is the most likely site of these metastases? (Q848892)

A. Bones

B. Brain

C. Lungs

D. Kidneys

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old woman is incidentally found to have a 5 cm hepatic lesion on an ultrasound performed for evaluation of vague abdominal discomfort. A contrast-enhanced MRI shows a lesion with peripheral nodular enhancement and centripetal filling in the delayed phase. What is the most appropriate management for this patient? (Q848893)

A. Immediate surgical resection

B. Percutaneous biopsy

C. Observation with periodic imaging

D. Radiofrequency ablation

See Answer in Part B → Q3

@Neet_pg_bot

Q4: During a routine abdominal ultrasound of a 35-year-old female, a liver lesion was noted. imaging with a CECT scan shows a central stellate scar within the lesion. What is the most likely diagnosis? (Q848894)

A. Hepatocellular carcinoma

B. Focal nodular hyperplasia

C. Hepatic adenoma

D. Hemangioma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 24-year-old woman presents with complaints of right upper quadrant abdominal pain for the past few weeks. She has a history of using oral contraceptive pills for the past 5 years. On examination, the physician palpates a slightly tender, smooth, and well-defined mass in the right upper quadrant. Which of the following is the most likely diagnosis? (Q848895)

A. Hepatocellular carcinoma

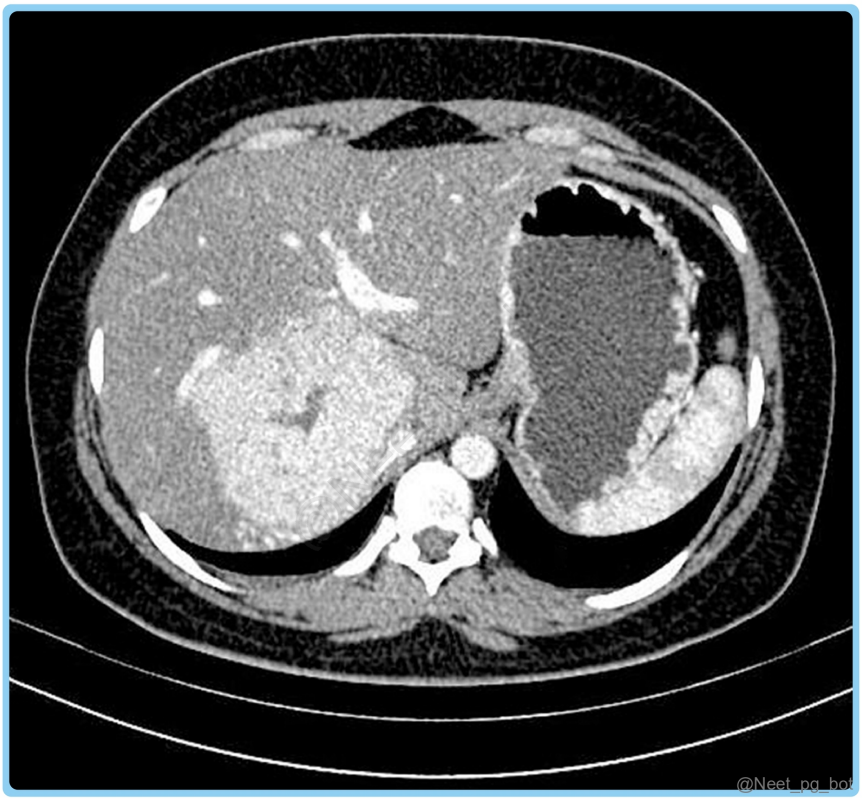
B. Hepatic hemangioma

C. Hepatic adenoma

D. Focal nodular hyperplasia

See Answer in Part B → Q5

@Neet_pg_bot



Q6: In which of the following conditions are these CECT findings seen? (Q848896)

A. Focal nodular hyperplasia

B. Serous cystadenoma of the pancreas

C. Renal oncocytoma

D. All of the above

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 55-year-old male patient presents with persistent abdominal pain and unexplained weight loss He has a history of chronic hepatitis B infection and moderate alcohol consumption. Physical examination reveals mild jaundice and hepatomegaly. Which of the following risk factors is most strongly associated with developing hepatocellular carcinoma (HCC) in this patient? (Q848901)

A. Age

B. Alcohol consumption

C. Hepatitis B infection

D. Male gender

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old man with a history of chronic hepatitis C and cirrhosis presents to the clinic with complaints of fatigue, unintentional weight loss, and abdominal discomfort. On physical examination, you note mild ascites and hepatomegaly. The serum alpha-fetoprotein level is elevated. What is the investigation of choice in this patient? (Q848902)

A. MRI with MRCP

B. CECT

C. Triple phase CT

D. Liver biopsy

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 12-year-old boy presents with a history of fatigue, abdominal distension, and jaundice. He has a known diagnosis of liver cirrhosis secondary to chronic hepatitis B infection. Recently, he has developed a palpable liver mass, and imaging studies confirm the presence of hepatocellular carcinoma. Which of the following parameters is not typically used in the prognosis of his condition? (Q848903)

A. Serum bilirubin

B. Serum ammonia

C. Serum albumin

D. Prothrombin time/INR

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 65-year-old male with a history of chronic hepatitis B presents with increasing fatigue, weight loss, and right upper quadrant pain. Physical examination reveals jaundice and hepatomegaly. Imaging shows multiple lesions with a 4 cm mass in the right lobe and satellite nodules in the left lobe, along with portal vein thrombosis. His LFT shows elevated bilirubin and low albumin levels. The patient is diagnosed with HCC. According to standard protocol, what is the most appropriate treatment option for this patient? (Q848905)

A. Surgical Resection

B. Liver Transplantation

C. Transarterial Chemoembolization (TACE)

D. Sorafenib

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 24-year-old female from Southeast Asia presents with abdominal pain and a palpable liver mass. She has no history of hepatitis B or C infection, and no signs of

cirrhosis. Imaging studies show a well-circumscribed, non-encapsulated tumor in the liver with a central stellate scar. Laboratory tests reveal normal alpha-fetoprotein levels but elevated neurotensin and B12 binding globulin. What is the most likely diagnosis? (Q848906)

A. Scirrhous Variant of Hepatocellular Carcinoma

B. Fibrolamellar Variant of Hepatocellular Carcinoma

C. Cholangiocarcinoma

D. Metastatic Liver Cancer

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 2-year-old male presents with an asymptomatic palpable abdominal mass detected during a routine physical examination. The child has a history of low birth weight and no history of hepatitis B or C infection. Laboratory tests reveal elevated alpha-fetoprotein levels. Imaging studies show a large intra-abdominal mass. Biopsy confirms hepatoblastoma. Which of the following statements about hepatoblastoma is incorrect? (Q848907)

A. Hepatoblastoma is the most common primary malignancy of the liver in children.

B. The most common route of spread for hepatoblastoma is lymphatic.

C. Hepatoblastoma is not associated with Hepatitis B or C infection.

D. The most characteristic laboratory abnormality is thrombocytosis.

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 55-year-old male with a history of chronic liver disease secondary to hepatitis C presents for evaluation due to worsening ascites, jaundice, and weight loss. He has been diagnosed with hepatocellular carcinoma (HCC). Imaging reveals a single liver lesion measuring 4 cm in diameter with no evidence of vascular invasion or

extrahepatic spread. Laboratory studies show stable liver function tests and AFP levels below 100 ng/mL. Which of the following criteria is the most critical in determining his eligibility for liver transplantation? (Q848908)

A. Tumor size less than or equal to 5 cm

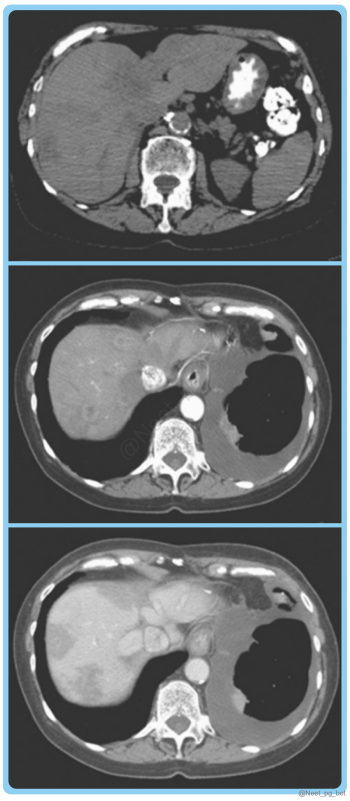
B. Absence of portal vein thrombosis

C. AFP (Alpha-fetoprotein) levels below 400 ng/mL

D. Platelet count greater than 100,000/µL

See Answer in Part B → Q13

@Neet_pg_bot



Q14: From the below given triple phase CT scan, which of the following statements is true regarding Liver cancer? (Q848909)

A. Hypodense in arterial phase in HCC

B. Hyperdense in arterial phase in Metastasis liver disease

C. Hyperdense in non-contrast CT in HCC

D. Hypodense in venous phase in Metastasis liver disease

See Answer in Part B → Q14

Q1: A 45-year-old female who recently underwent bone marrow transplantation presents with abdominal pain and swelling. The clinical features resonate with hepatic veno-occlusive disease and a transvenous hepatic biopsy confirms the diagnosis. Which of the following symptoms is NOT a part of the clinical triad of hepatic veno-occlusive disease? (Q849016)

A. Tender hepatomegaly

B. Hyperbilirubinemia (jaundice)

C. Retention of fluid (ascites)

D. Portal hypertension

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is a pre-sinusoidal cause of portal hypertension? (Q849006)

A. Cirrhosis

B. Budd-Chiari syndrome

C. Congestive cardiac failure

D. Schistosomiasis

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 52-year-old man presents to the emergency department with worsening abdominal distension and visible abdominal veins. He has a history of chronic alcohol abuse and has been experiencing increasing fatigue and jaundice. Collaterals are between the paraumbilical vein &.....: Which of the following vessels is involved in this condition? (Q849007)

A. Left gastric vein

B. Superior and inferior epigastric vein

C. Superior mesenteric vein

D. Inferior vena cava

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old man with a history of cirrhosis presents to the emergency department with hematemesis and melena. He is hypotensive and tachycardic. Which of the following is the most appropriate initial step in management? (Q849008)

A. Order an urgent upper endoscopy

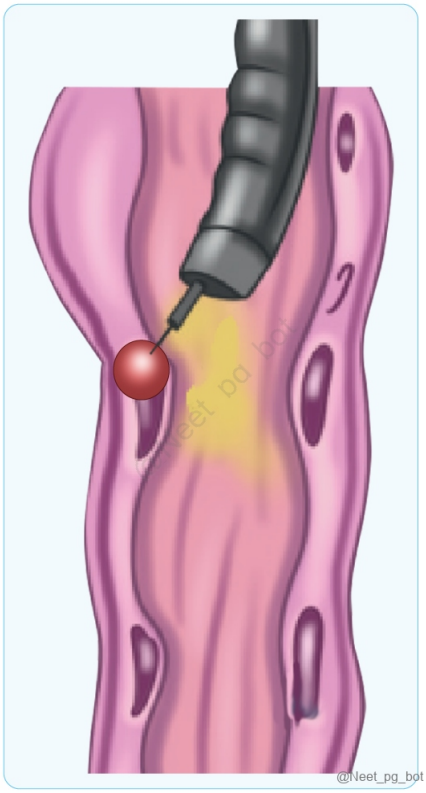
B. Administer a proton pump inhibitor

C. Request a CT scan of the abdomen

D. Initiate fluid resuscitation

See Answer in Part B → Q4

@Neet_pg_bot



Q5: Which of the following statements is true about the image below? (Q849009)

A. Technically difficult to perform

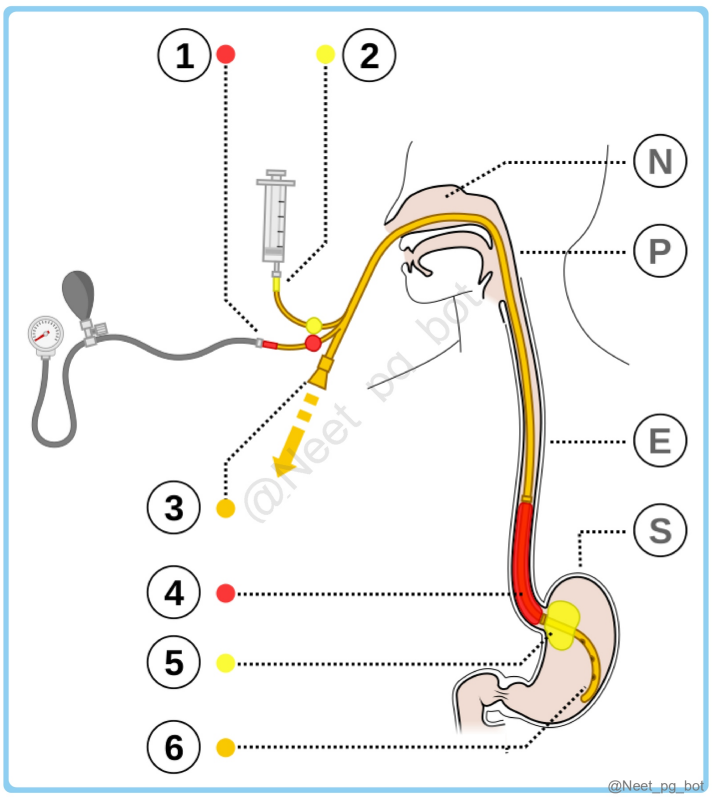
B. Decreased chances of perforation

C. Always preferred over ligation

D. Lack of depth perception is present

See Answer in Part B → Q5

@Neet_pg_bot



Q6: Identify the tube shown in the following image used in the management of portal hypertension. (Q849010)

A. Sengstaken-Blakemore tube

B. Minnesota tube

C. Linton-Nachlas tube

D. Nasogastric (Ryle's) tube

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 60-year-old patient with refractory ascites secondary to cirrhosis undergoes Transjugular intrahepatic portosystemic shunt placement. Two days post-procedure, the patient develops severe dyspnea, peripheral edema, jugular venous distension, and hypotension. A Doppler ultrasound reveals a patent shunt. Which of the following is the most likely cause of the patient's symptoms? (Q849011)

A. Right heart failure

B. Hepatorenal syndrome

C. Pulmonary hypertension

D. Porto-pulmonary hypertension

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following complications is most likely to occur after the creation of a side-to-side portocaval shunt (SSPCS)? (Q849012)

A. Encephalopathy

B. Renal failure

C. Recurrent variceal bleeding

D. Portal vein thrombosis

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which selective shunt procedure is associated with the preservation of portal perfusion to the liver while effectively decompressing varices? (Q849013)

A. Distal splenorenal shunt (DSRS)

B. Proximal splenorenal shunt (PSRS)

C. Side-to-side portocaval shunt (SSPCS)

D. Interposition grafts

See Answer in Part B → Q9

@Neet_pg_bot

Q10: In a patient with Budd Chiari Syndrome, which of the following imaging findings is most indicative of chronic disease? (Q849014)

A. Enlarged caudate lobe

B. Ascites

C. Hepatic vein thrombosis

D. Splenomegaly

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 12-year-old boy presents with a history of recurrent episodes of gastrointestinal bleeding. He has no history of liver disease, jaundice, or ascites. Physical examination reveals moderate splenomegaly but no hepatomegaly. Doppler ultrasound of the abdomen shows obstruction at the confluence of the splenic vein and the superior mesenteric vein. What is the most likely diagnosis? (Q849015)

A. Cirrhosis

B. Non-Cirrhotic Portal Fibrosis (NCPF)

C. Extrahepatic Portal Vein Obstruction (EHPVO)

D. Budd-Chiari Syndrome

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old man presents to the emergency department with a 3-day history of left upper quadrant abdominal pain and nausea. He has a history of chronic pancreatitis due to alcohol abuse. Physical examination reveals tenderness in the left upper quadrant and splenomegaly. Abdominal CT scan without contrast shows a thrombus in the splenic vein. What type of varices are likely to be seen on endoscopic examination? (Q849017)

A. Esophageal varices

B. Gastric varices

C. Esophageal and gastric varices, with esophageal predominant

D. Duodenal varices

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 60-year-old male with a history of cirrhosis presents with recurrent esophageal variceal bleeding that has not responded to endoscopic treatments. The patient is scheduled for a Sugiura procedure. Which of the following components is NOT part of the Sugiura procedure? (Q849018)

A. Splenectomy

B. Esophagogastric devascularization

C. Intraesophageal portacaval shunt

D. Esophageal transection

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 48-year-old male is diagnosed with portal hypertension. Hepatic venous pressure gradient (HVPG) measurements are taken to assess the severity of his portal hypertension. Based on the prognostic values of HVPG, what are the cut-off HVPG values for clinically significant portal hypertension and increased risk of acute variceal bleeding respectively? (Q849019)

A. ≥6 mm Hg, ≥10mm Hg

B. ≥8 mm Hg, ≥12 mm Hg

C. ≥10 mm Hg, ≥12 mm Hg

D. ≥16 mm Hg, ≥18 mm Hg

Q1: Which of the following is not a risk factor for gallbladder carcinoma? (Q849000)

A. Smoking

B. Gallstones

C. Porcelain gallbladder

D. Hepatitis B

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 65-year-old female presents with severe right upper quadrant pain, jaundice, and a history of recurrent cholangitis. Imaging reveals a cholecystocholedochal fistula involving up to two-thirds of the circumference of the common bile duct. Which type of Mirizzi syndrome is seen in this patient? (Q848994)

A. Type I

B. Type II

C. Type III

D. Type IV

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 75-year-old male in the ICU with sepsis and multiple organ failure develops sudden right upper quadrant pain and fever. Ultrasound reveals a distended gallbladder with thickened walls and no gallstones. Which of the following is not a predisposing factor for acalculous cholecystitis? (Q848992)

A. Parenteral nutrition

B. Extensive burns

C. Hypertension

D. Diabetes

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 75-year-old female with a history of cholelithiasis presents with acute abdominal pain, vomiting, and signs of bowel obstruction. O/E, she has abdominal distension and high-pitched bowel sounds. A radiograph shows pneumobilia and a calcified gallstone in the right lower quadrant. CT confirms an abnormal gallbladder with air and fluid accumulation. What is the most appropriate management for this patient? (Q848991)

A. Cholecystectomy and fistula repair

B. Endoscopic removal of the gallstone

C. Enterolithotomy

D. Conservative management with IV fluids and antibiotics

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 65-year-old male with a history of diabetes presents with severe right upper quadrant pain, fever, and jaundice. Imaging reveals gas within the gallbladder wall. Which of the following organisms is most likely to be the causative agent in this patient's condition? (Q848990)

A. Clostridium perfringens

B. Staphylococcus aureus

C. Streptococcus pyogenes

D. Pseudomonas aeruginosa

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 65-year-old female presents with right upper quadrant pain and nausea. An ultrasound reveals a 1.5 cm gallbladder polyp, and a follow-up scan shows an increase in size from the previous scan six months ago. She also has a history of gallstones. Which of the following factors increases the risk of invasive cancer in gallbladder polyps? (Q848996)

A. Age less than 60 years

B. Presence of gallstones

C. Polyp size more than 0.5 cm

D. The same polyp size on repeated scans

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 70-year-old female presents with vague right upper quadrant discomfort, but she is mostly asymptomatic. An abdominal X-ray reveals extensive calcification of the gallbladder wall. There is bluish appearance and brittle consistency of the gallbladder. What is the most likely diagnosis? (Q848999)

A. Gallbladder carcinoma

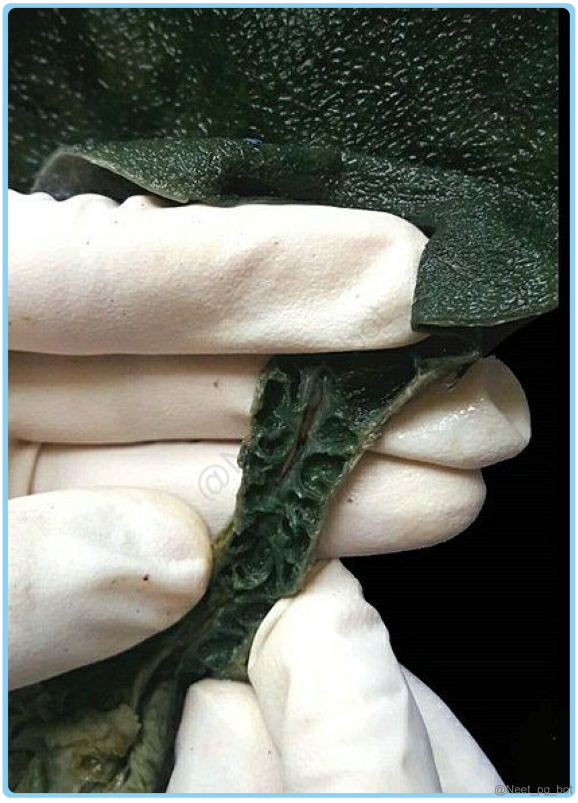
B. Cholesterolosis

C. Porcelain gallbladder

D. Acute cholecystitis

See Answer in Part B → Q7

@Neet_pg_bot



Q8: A 50 y/o woman undergoing laparoscopic cholecystectomy is found to have a structure that appears to have a spiral configuration. What is the most likely anatomical feature being observed? (Q843481)

A. Vasa vasorum

B. Sphincter of Oddi

C. Accessory Pancreatic Duct

D. Valves of Heister

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following risk factors is associated with both gallbladder cancer and cholangiocarcinoma? (Q849001)

A. Gallstones

B. Porcelain gallbladder

C. Primary sclerosing cholangitis (PSC)

D. Hepatitis C virus infection

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 45 y/o patient presents with recurrent right upper quadrant pain and nausea. Imaging reveals a pathological outpouching in the infundibular region of the gallbladder containing multiple gallstones. What is this feature known as? (Q843479)

A. Phrygian cap

B. Floating gallbladder

C. Hartmann's pouch

D. Gallbladder carcinoma

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which layer of the gastric wall is considered the strongest? (Q843478)

A. Mucosa

B. Submucosa

C. Muscularis Externa

D. Serosa

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 65 y/o female presents with a 3-month history of intermittent upper right quadrant pain, weight loss, and loss of appetite. She has jaundice and a palpable mass in the right upper quadrant. Laboratory tests reveal mild anaemia, leukocytosis, and elevated CA19-9 and carcinoembryonic antigen. USG suggests a gallbladder mass and a CT scan confirms the mass without distant metastases. What is the most appropriate next step in management? (Q849002)

A. Immediate laparoscopic cholecystectomy

B. Percutaneous biopsy of the gallbladder mass

C. Referral for palliative chemotherapy

D. Laparoscopic examination for staging

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following surgeons is correctly matched with their pioneering laparoscopic procedure and year of achievement? (Q849005)

A. Professor Erich Mühe - First video-assisted laparoscopic cholecystectomy in 1987

B. Dr. Philippe Mouret - First laparoscopic cholecystectomy in 1985

C. Dr. Kurt Semm - First laparoscopic appendicectomy in 1983

D. Professor Erich Mühe - First laparoscopic appendicectomy in 1983

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 62-year-old male presents with intermittent right upper quadrant pain and nausea. An ultrasound shows significant thickening of the gallbladder wall and hyperproliferation of the mucosa. Which of the following is NOT a USG finding in Adenomyomatosis? (Q848998)

A. Diamond ring sign

B. Comet tail artefacts

C. V-shaped artefacts

D. Porcelain appearance

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 58-year-old male, with past h/o cholesterol stones, presents with intermittent right upper quadrant pain and occasional nausea.USG reveals the gallbladder mucosa has a coarse, granular appearance with small nodules and some larger polypoid formations. On performing laparoscopic cholecystectomy of this patient, the following appearance of the gall bladder was observed. What is the most likely diagnosis? (Q848997)

A. Acute cholecystitis

B. Porcelain gallbladder

C. Cholesterolosis

D. Gallbladder carcinoma

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 65 y/o presents with jaundice, weight loss, and abdominal pain. O/E a palpable mass is noted in the right upper quadrant. Imaging studies reveal a mass involving the gallbladder, with signs of local invasion but no distant or lymph node metastasis. A biopsy confirms gallbladder carcinoma. Based on the TNM classification, which stage is most likely for this patient's tumour? (Q849003)

A. T1a N0 M0

B. T2b N1 M0

C. T3 N0 M0

D. T4 N2 M1

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 58 y/o presents with jaundice, weight loss, and upper right abdominal pain. Imaging studies including CT and MRI reveal a mass in the gallbladder with local invasion into the liver but no distant metastasis. The patient undergoes a laparoscopic examination confirming the staging. What is the most appropriate treatment approach for this patient? (Q849004)

A. Endoscopic stenting to relieve jaundice

B. Radical en bloc resection of the gallbladder, liver wedge, and regional lymph nodes

C. Palliative chemotherapy

D. No further treatment if the tumor is confined to the mucosa

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 58-year-old male presents with right upper quadrant pain, jaundice, and fever. Imaging reveals a gallstone eroding less than one-third of the circumference of the common bile duct. What is the management? (Q848995)

A. Bilio-enteric anastomosis

B. Percutaneous cholecystostomy

C. Subtotal/Partial cholecystectomy + ERCP stenting

D. Partial cholecystectomy with choledochoplasty

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 45-y/o female presents with symptomatic gallstones and is scheduled for laparoscopic cholecystectomy. During the procedure, the surgeon encounters difficulty due to unexpected anatomical variations. The right hepatic artery appears very tortuous and is located close to the cystic duct. What is the most likely anatomical anomaly encountered in this case? (Q843338)

A. Phrygian cap

B. Moynihan Hump

C. Floating Gallbladder

D. Mirizzi Syndrome

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 70-year-old critically ill male in the ICU with sepsis and multiple organ failure presents with sudden onset of right upper quadrant pain, fever, and jaundice. Bedside ultrasonography shows a distended gallbladder with thickened walls and pericholecystic fluid but no gallstones. What is the treatment of choice for this patient? (Q848993)

A. Laparoscopic cholecystectomy

B. Oral antibiotics and observation

C. Endoscopic retrograde cholangiopancreatography (ERCP)

D. Percutaneous cholecystostomy

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 45-year-old woman with asymptomatic gallstones is being evaluated for prophylactic cholecystectomy. Which of the following is NOT typically considered an indication for prophylactic cholecystectomy? (Q848989)

A. Gallstones larger than 3 cm

B. Presence of gallstones in the common bile duct

C. Asymptomatic small gallbladder polyps

D. Undergoing bariatric surgery

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following is an indication for dissolution therapy in gallstone management? (Q848988)

A. Non-functioning gallbladder

B. Stone larger than 1.5 cm

C. Cholesterol stones which are typically radiolucent

D. Multiple stones

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 60-year-old patient with a history of diabetes and hypertension presents with right upper quadrant pain, fever, and elevated white blood cell count. According to the Tokyo Guidelines (2013/2018), what is the recommended treatment approach if the patient is diagnosed with Grade II acute cholecystitis and does not respond to antibiotic treatment and supportive care? (Q848987)

A. Early laparoscopic cholecystectomy within 5-7 days.

B. Immediate discharge with oral antibiotics.

C. Early gallbladder drainage followed by delayed/elective cholecystectomy.

D. Delayed cholecystectomy after 6 weeks.

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 45-year-old patient presents with right upper quadrant (RUQ) pain and fever. On examination, the clinician notes localized tenderness over the right

hypochondrium. USG of the abdomen reveals gallbladder wall thickness of about 5mm along with the presence of pericholecystic fluid. According to the Tokyo Guidelines, which combination of findings would confirm a diagnosis of acute cholecystitis? (Q848986)

A. RUQ tenderness, elevated C-reactive protein, gallbladder wall thickening on USG.

B. Murphy's sign, fever, normal gallbladder wall on USG.

C. Palpable RUQ mass, normal white blood cell count, pericholecystic fluid on USG.

D. RUQ pain, elevated C-reactive protein, no imaging finding

See Answer in Part B → Q24

@Neet_pg_bot

Q25: An ultrasound image of the gallbladder is consistent with a congenital anatomical variant. What is the most likely diagnosis? (Q843484)

A. Floating gallbladder

B. Accessory gallbladder

C. Phrygian cap

D. Gallbladder septum

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 45 y/o woman presents to the ER with severe right upper quadrant abdominal pain, nausea, and vomiting. She has a history of gallstones and is diagnosed with acute cholecystitis. During laparoscopic cholecystectomy, the surgeon encounters difficulty identifying the cystic artery due to inflammation. Which anatomical landmarks within Calot's triangle would be most helpful in locating the cystic artery? (Q843480)

A. Gallbladder fundus

B. Cystic lymph node

C. Common bile duct

D. Portal vein

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 45 y/o woman presents with severe right upper quadrant pain, fever, and nausea. She has a history of pain after fatty meals. O/E, she has right upper quadrant tenderness and a positive Murphy's sign. Lab tests show elevated alkaline phosphatase, bilirubin, transaminases, and leukocytosis. Which investigation is best to confirm this patient’s diagnosis? (Q843342)

A. USG- Sonographic Murphy's sign positive.

B. Plain X-Ray- Identifies radio-opaque gallstones

C. CT Scan- Pericholecystic fluid, Impacted stones, gallbladder wall thickness

D. HIDA Scan- Non-visualization of the gallbladder

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 45 y/o woman presents to the ER with severe right upper quadrant pain radiating to her back. She has a h/o gallstones. O/E, she exhibits tenderness in the right upper quadrant. An abdominal CT scan shows a characteristic triradiate pattern of gas within a gallstone. Based on the CT findings, which of the following signs is most likely being described? (Q843341)

A. Murphy sign

B. Mermaid sign

C. Stellate scar sign

D. Mercedes-Benz sign

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Which of the following statements accurately describes a characteristic of pigment stones? (Q843340)

A. Black pigment stones are associated with bacterial β-glucuronidase activity in the bile duct.

B. Black pigment stones are associated with hemolysis.

C. Brown pigment stones are associated with excess bilirubin from hemolysis.

D. Black pigment stones are primarily composed of calcium bilirubinate and cholesterol.

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 49-y/o woman presents with intermittent right upper quadrant pain that worsens after fatty meals. She has a history of Sickle cell disease and has been on total parenteral nutrition (TPN) for the past six months due to severe Crohn's disease post-ileal resection. She also gives a h/o OCP usage for 5 years. The patient underwent cholecystectomy which showed the following finding. Which of the following factors is least likely to contribute to the formation of this patient's condition? (Q843339)

A. Total parenteral nutrition

B. Sickle cell disease

C. Ileal resection due to Crohn's disease

D. OCP usage

See Answer in Part B → Q30

Q1: A 50 year old woman presents with complaints of persistent fatigue, itching, and mild right upper quadrant abdominal pain. On examination, she has jaundice and hepatomegaly. Laboratory tests reveal elevated alkaline phosphatase and positive anti-mitochondrial antibodies. What is the most likely diagnosis? (Q843496)

A. Primary biliary cirrhosis

B. Primary sclerosing cholangitis

C. Autoimmune hepatitis

D. Drug-induced liver disease

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 70 year old male presents with painless obstructive jaundice, significant weight loss, and a palpable, non-tender mass in the right hypochondrium. Imaging reveals a mass at the liver hilum with no evidence of distant metastasis. What is the correct management of this patient? (Q848917)

A. Stenting through PTC or ERCP

B. Portal region clearance with hemihepatectomy

C. Extensive bile duct resection, nodal clearance, caudate lobe removal, and cholecystectomy

D. Chemotherapy with 5-FU and cisplatin

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55 year old woman undergoes a cholecystectomy, after which she develops jaundice and abdominal pain. Imaging reveals a bile duct stricture at the confluence of the right and left hepatic ducts, but the ducts themselves are intact. According to the Bismuth classification, what type of stricture does she have? (Q843542)

A. Type I

B. Type II

C. Type III

D. Type IV

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 25-year-old woman presents with persistent right upper quadrant pain for several days, fever, and jaundice. On examination, right upper quadrant tenderness is present. On USG, cystic dilation of the common bile duct is seen. Which of the following malignancies is not associated with this condition? (Q848898)

A. Cholangiocarcinoma

B. Squamous Cell carcinoma

C. Pancreatic Carcinoma

D. Renal cell carcinoma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45-year-old woman presents with worsening abdominal pain, jaundice, and fever. Ultrasound shows a choledochal cyst and bile duct obstruction. What imaging study is most appropriate for the next step in management? (Q848899)

A. CT Scan

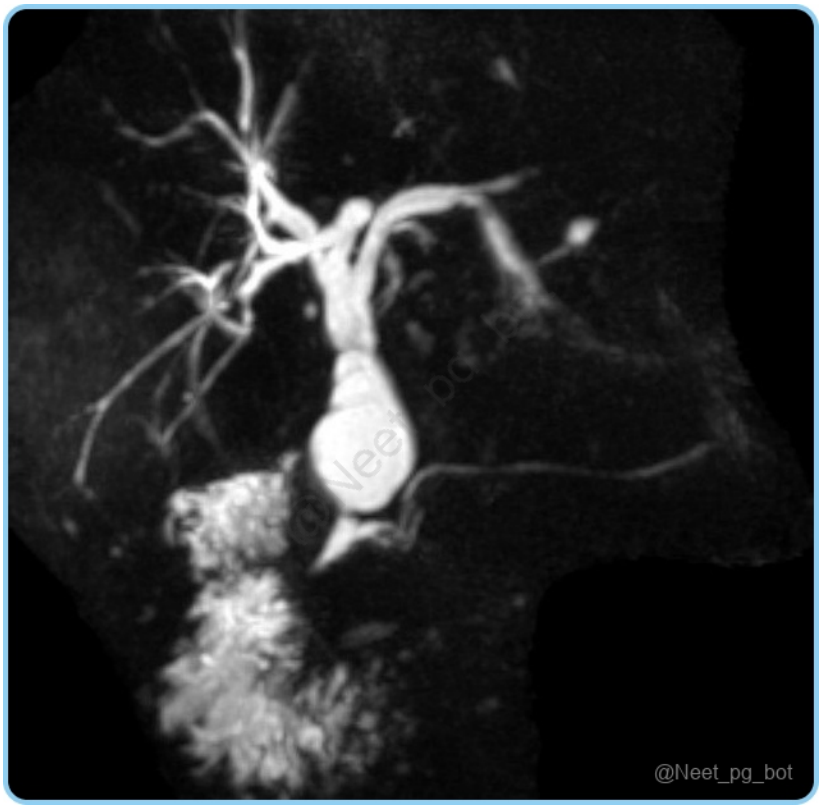
B. Magnetic Resonance Cholangiopancreatography

C. Endoscopic Retrograde Cholangiopancreatography

D. Percutaneous Transhepatic Cholangiography

See Answer in Part B → Q5

@Neet_pg_bot



Q6: MRCP imaging studies done for a 35 year old woman who presented with a history of recurrent cholangitis, jaundice, and right upper quadrant pain reveal the following. Based on the Todani classification, what is the most appropriate surgical treatment for this patient? (Q848897)

A. Liver transplantation

B. Transduodenal sphincteroplasty

C. Roux-en-Y hepaticojejunostomy

D. Partial hepatectomy

See Answer in Part B → Q6

@Neet_pg_bot

Q7: During a laparoscopic cholecystectomy, a lateral injury to the Common Bile Duct is identified. What is the most appropriate next step in management? (Q882176)

A. Continue the laparoscopic procedure and place a drain

B. Convert to open procedure with T-tube drainage

C. Ligate the duct proximal to the injury

D. Close the abdomen and refer for ERCP

See Answer in Part B → Q7

@Neet_pg_bot

Q8: According to the Strasberg classification, what type of bile duct injury does this image show? (Q848919)

A. Class A

B. Class B

C. Class C

D. Class D

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old male presents with severe colicky pain in the upper right quadrant, jaundice, and episodes of haematemesis and melaena. He had a history of blunt abdominal trauma a few weeks ago. Which is the investigation of choice for detecting the bleeding site in this patient? (Q848918)

A. Liver Function Tests

B. Ultrasound of the abdomen

C. Selective arteriography

D. Upper GI endoscopy

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 65 year old female presents with painless jaundice and a palpable, non-tender, globular mass in the right hypochondrium. Imaging suggests an obstructed biliary system. The patient has no history of gallstones. Based on Courvoisier's law, which of the following conditions is not an exception to the rule? (Q848916)

A. Double impacted stone

B. A large stone in Hartmann's pouch

C. Empyema of the gallbladder with a CBD stone

D. Chronic cholecystitis with multiple gallstones

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 58 year old female presents with painless obstructive jaundice, significant weight loss, and anorexia. Imaging reveals a tumour involving the confluence of the right hepatic duct and left hepatic duct, extending into both ducts. Based on the Bismuth-Corlette classification, which type of perihilar cholangiocarcinoma is most consistent with these findings? (Q848915)

A. Type 1

B. Type 2

C. Type 3A

D. Type 4

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is not a risk factor for cholangiocarcinoma? (Q848914)

A. Primary sclerosing cholangitis

B. Hepatitis C

C. Clonorchis sinensis infestation

D. Alcohol consumption

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is the classical triad of acute cholangitis? (Q848911)

A. Pain, jaundice, fever

B. Pain, jaundice, shock

C. Fever, jaundice, ↑WBC

D. Pain, ↑WBC, ↑Bilirubin

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 40 year old patient is experiencing persistent abdominal pain and elevated serum amylase after undergoing ERCP. The pain began shortly after the procedure. Which of the following is the most likely cause of the patient's symptoms? (Q848910)

A. Post-ERCP pancreatitis

B. Post-ERCP duodenal perforation

C. Post-ERCP cholangitis

D. Post-ERCP sphincter stenosis

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 55 year old male with history of obesity and a low-protein diet presents with intermittent abdominal pain, jaundice, and recurrent episodes of dark urine and light-colored stools. Recently, he developed a fever with chills. Blood tests show elevated WBC count and abnormal liver function tests. MRCP reveals multiple pigmented stones in the common bile duct and intrahepatic ducts. What is the most likely cause of his condition? (Q843489)

A. Primary Choledocholithiasis

B. Secondary Choledocholithiasis

C. Gallstone ileus

D. Chronic Pancreatitis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: How many sphincters make up the Sphincter of Oddi Complex? (Q848889)

A. 12

B. 9

C. 6

D. 4

See Answer in Part B → Q16

@Neet_pg_bot

Q17: During a gallbladder surgery, the surgeon identifies the hepatic artery running medially and carefully avoids injuring a structure located laterally to it. Which of the following is the most likely structure located lateral to the hepatic artery? (Q848888)

A. Common hepatic duct

B. Portal vein

C. Cystic artery

D. Common bile duct

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which artery primarily supplies the common hepatic duct and the common bile duct? (Q848887)

A. Gastroduodenal artery

B. Pancreaticoduodenal artery

C. Right hepatic artery

D. Left hepatic artery

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 50 year old man presents with jaundice and abdominal pain one week after a cholecystectomy. Imaging confirms a bile duct injury with a complete transection of the common bile duct. What is the recommended management for this injury at this stage? (Q843544)

A. Immediate surgical repair

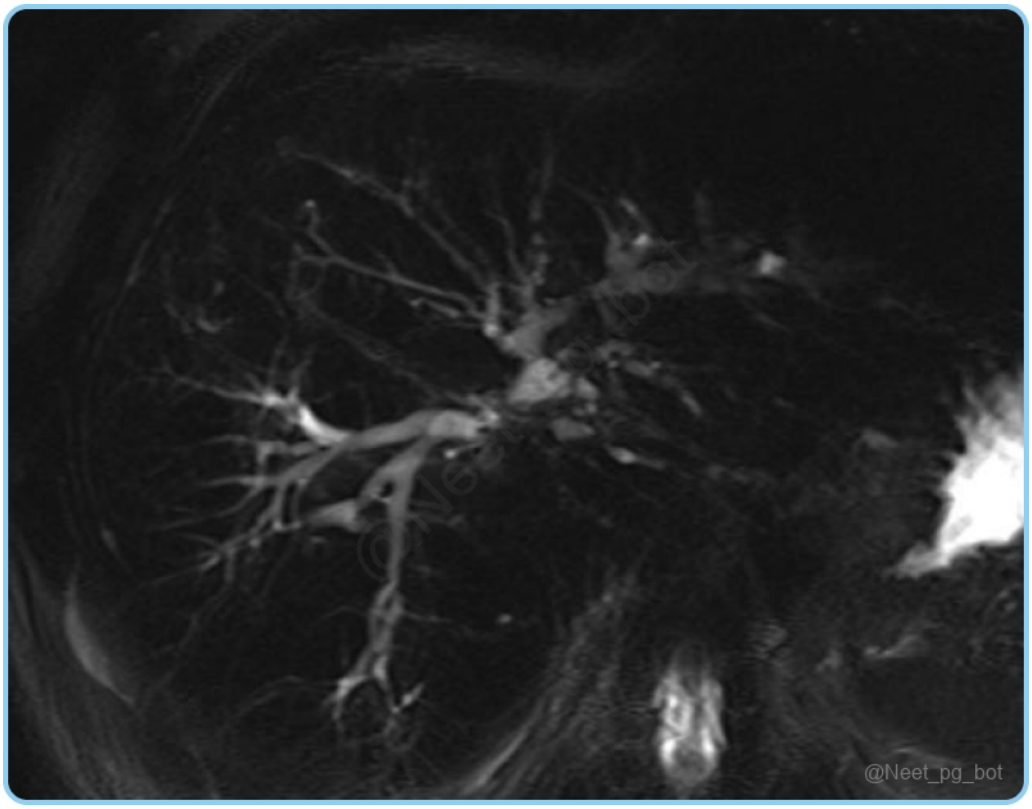
B. Conservative management with antibiotics and observation

C. Delay repair for 4-6 weeks and then perform Roux-en-Y choledochojejunostomy

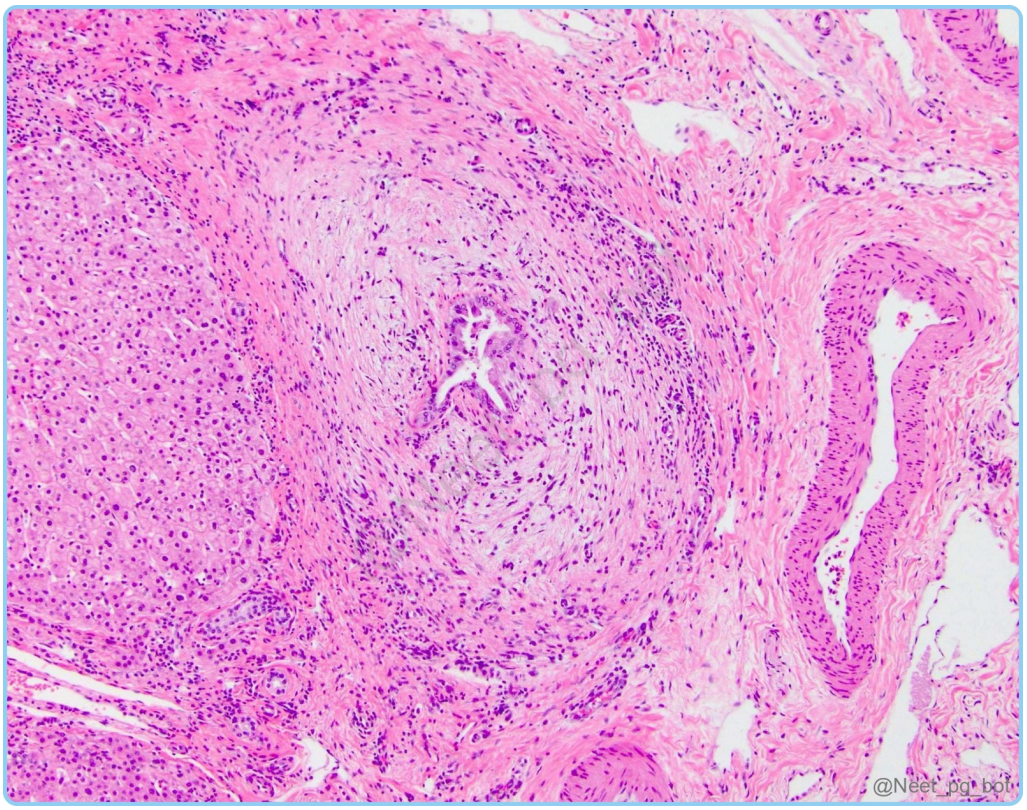
D. Endoscopic stenting and balloon dilation

See Answer in Part B → Q19

@Neet_pg_bot



Q20: A 40 year old male with a history of ulcerative colitis presents with fatigue, pruritus, jaundice, elevated ALP, and GGTP. The MRCP and Liver biopsy show the following findings. Despite endoscopic stenting, his symptoms persist, and liver function continues to decline. What is the most definitive treatment option for this patient? (Q843541)



A. Antibiotics and cholestyramine

B. Endoscopic retrograde cholangiopancreatography

C. Liver transplantation

D. Operative resection

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 45 year old male with a history of ulcerative colitis presents with jaundice, right upper quadrant pain, and intermittent fever. Laboratory tests reveal elevated serum ALP and gamma-glutamyl transpeptidase (GGTP). MRCP shows stricturing and beading of the bile ducts. What is the most likely diagnosis? (Q843540)

A. Primary sclerosing cholangitis

B. Acute cholangitis

C. Choledocholithiasis

D. Hepatocellular carcinoma

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 70 year old female presents with signs of severe cholangitis. Despite initial treatment with broad-spectrum antibiotics and an unsuccessful ERCP attempt, her condition continues to worsen. An ultrasound shows multiple stones and a severely dilated common bile duct. What is the next best step in management? (Q843495)

A. Repeat ERCP

B. Percutaneous transhepatic cholangiography (PTC)

C. Open biliary decompression

D. Continued observation and supportive care

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 62 year old male presents with jaundice and severe abdominal pain in the right upper quadrant that started abruptly after a heavy meal. He also reports dark urine, pale stools, and intermittent fever with chills. An ultrasound shows a dilated common bile duct. ERCP is planned for stone removal. What is the maximum size of the stone that can typically be removed by ERCP without additional procedures? (Q843491)

A. 17 mm

B. 15 mm

C. 20 mm

D. 25 mm

See Answer in Part B → Q23

Q1: Which type of pancreatic neoplasm most commonly arises in the tail of the pancreas? (Q848982)

A. Serous cystadenoma.

B. Mucinous cystadenoma

C. VIPOMA

D. Adenocarcinoma pancreas

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 60-year-old male presents with recurrent episodes of abdominal pain and is found to have jaundice. An ERCP is performed, revealing thick mucus extruding through the ampulla of Vater. Which of the following is the most likely diagnosis? (Q848974)

A. Pseudocyst

B. Main duct IPMN

C. Chronic pancreatitis

D. Pancreatic adenocarcinoma

See Answer in Part B → Q2

@Neet_pg_bot

Q3: What is the most common complication and common cause of death in a patient post pancreaticoduodenectomy? (Q848927)

A. Delayed gastric emptying, Pulmonary complication

B. Anastomosis leak, Pulmonary complication

C. Delayed gastric emptying, Perforated bowel obstruction

D. Anastomosis leak, Perforated bowel obstruction

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 48-year-old perimenopausal woman presents with abdominal discomfort. Imaging reveals a multilocular cyst with thick walls located in the pancreatic tail. Fine-needle aspiration of the cyst fluid shows high carcinoembryonic antigen levels exceeding 400 ng/mL, with normal amylase levels. What is the most likely diagnosis? (Q848965)

A. Pancreatic pseudocyst

B. Serous cystadenoma

C. Mucinous cystic neoplasm

D. Adenoma of the Ampulla of Vater

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45-year-old male has a history of recurrent peptic ulcers and severe abdominal pain. Despite the use of proton pump inhibitors, his symptoms persist. Endoscopic examination reveals small nodules in the medial wall of the duodenum. His family history is significant for multiple endocrine neoplasia type I. Which of the following

statements is most likely true regarding his condition? (Q848952)

A. The tumors are most commonly found in the tail of the pancreas.

B. The condition is curable with surgical removal of the primary tumor.

C. The patient's gastrinoma is likely located within the gastrinoma triangle.

D. The use of proton pump inhibitors has made diagnosis of this condition easier

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 70-year-old female patient is evaluated for a pancreatic cystic mass. The CT scan shows a lobular, hypodense lesion with multiple small cysts, a central hyperdense scar, and scattered "sunburst" calcifications. Based on these findings, what is the most likely diagnosis? (Q848962)

A. Mucinous cystic neoplasm

B. Pancreatic pseudocyst

C. Serous cystadenoma

D. Intraductal papillary mucinous neoplasm

See Answer in Part B → Q6

@Neet_pg_bot

Q7: What is the most common site of gastrinoma in patients with Zollinger–Ellison syndrome (Q848953)

A. Stomach

B. Pancreas

C. Duodenum

D. Liver

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Among the following, which option correctly describes the most common location of origin of insulinoma in the pancreas? (Q848984)

A. Head > Body > Tail

B. Body = Tail > Head

C. Tail > Body > Head

D. Head = Body = Tail

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which type of pancreatic neoplasm most commonly arises in the body and tail of the pancreas? (Q848978)

A. Serous cystadenom

B. Mucinous cystadenoma

C. Intraductal papillary mucinous neoplasm

D. Adenocarcinoma pancreas

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 55-year-old male presents with jaundice, weight loss, and epigastric pain. Imaging reveals a mass in the head of the pancreas. Which of the following conditions is most likely responsible for these symptoms? (Q848976)

A. Chronic Pancreatitis

B. Ductal Adenocarcinoma

C. Solid Pseudopapillary Neoplasm

D. Intraductal Papillary Mucinous Neoplasm

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A patient with a suspected intraductal papillary mucinous neoplasm (IPMN) has elevated serum CA 19-9 levels. What does this finding most likely suggest? (Q848971)

A. The IPMN is benign and does not require surgical intervention

B. The IPMN is likely malignant or has high-grade dysplasia

C. The IPMN is a branch duct type and requires conservative management

D. The IPMN is likely malignant and surgery is contraindicated

See Answer in Part B → Q11

@Neet_pg_bot

Q12: In a patient with a pancreatic cyst, peripheral eggshell calcification on CT is: (Q848967)

A. Common in benign cysts and easily detected.

B. Easily detected and a definitive marker of malignancy.

C. Difficult to detect but highly indicative of malignancy in mucinous cystic neoplasms.

D. Exclusively associated with pancreatic pseudocysts, not with malignancy.

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 45-year-old patient presents with chronic watery diarrhea. Laboratory tests reveal elevated levels of vasoactive intestinal peptide (VIP) > 150 pg/ml, achlorhydria, and hypokalemia. Imaging studies show a solitary mass in the body of the pancreas. What is the treatment of choice in this condition? (Q848960)

A. Initiate high-dose corticosteroid therapy with Prednisolone

B. Start treatment with Octreotide

C. Perform a distal pancreatectomy

D. Begin broad-spectrum antibiotic therapy

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 58-year-old female presents with diarrhea, weight loss, and itchy lesions around the mouth and vagina. Physical examination reveals a rash as shown in the image below. On evaluation, she has diabetes, and imaging studies indicate a large pancreatic mass. Which of the following is the most likely diagnosis? (Q848956)

A. Gastrinoma

B. Insulinoma

C. Glucagonoma

D. VIPoma

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 45-year-old woman with a family history of cancer presents for a routine check-up. Her mother and maternal aunt both had pancreatic cancer. Genetic testing reveals a gain-of-function mutation in the PRSS1 gene. Which of the following factors contributes the most to her increased risk of developing pancreatic cancer? (Q848920)

A. Chronic pancreatitis

B. Germline BRCA2 mutation

C. Lynch syndrome

D. Hereditary pancreatitis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which diagnostic finding is most indicative of an insulinoma? (Q848951)

A. Elevated serum glucose levels

B. Low C-peptide levels

C. Elevated serum insulin levels during hypoglycemia

D. Hyperinsulinemic response to oral glucose tolerance test

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following statements is true regarding neuroendocrine tumors of the pancreas? (Q848928)

A. The most common non-functional neuroendocrine tumor of the pancreas is insulinoma

B. Somatostatin receptor scintigraphy is used for the localization of NETs

C. The most common site of metastasis is the lungs

D. Functional NETs are diagnosed at a later stage and have poor prognosis

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which surgical procedure is characterized by the resection of the pancreatic head while preserving the stomach and pylorus? (Q848926)

A. Whipple procedure

B. Distal pancreatectomy

C. Longmire Traverso procedure

D. Total pancreatectomy

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A patient is scheduled to undergo a Whipple procedure for the treatment of pancreatic cancer. The surgeon needs to perform anastomosis to reconstruct the digestive tract after removing the affected tissues. In which sequence are the anastomoses typically performed during a Whipple procedure? (Q848925)

A. Hepaticojejunostomy → Pancreaticojejunostomy → Gastrojejunostomy

B. Pancreaticojejunostomy → Hepaticojejunostomy → Gastrojejunostomy

C. Gastrojejunostomy → Pancreaticojejunostomy → Hepaticojejunostomy

D. Pancreaticojejunostomy → Gastrojejunostomy → Hepaticojejunostomy

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 65-year-old male presents with jaundice, dark urine, and weight loss over the past two months. Courvoisier's Sign is positive on physical examination. What is the

next best step in the management of this patient to both visualize pancreatic and biliary ducts, and tissue sampling? (Q848924)

A. Computed Tomography

B. Endoscopic Ultrasonography

C. Endoscopic Retrograde Cholangiopancreatography

D. Diagnostic Laparoscopy

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 55-year-old man with no history of obesity or a family history of diabetes is recently diagnosed with diabetes mellitus. He also reports vague upper abdominal discomfort, significant weight loss, and mild jaundice. Which of the following findings on physical examination would most likely suggest a diagnosis of pancreatic cancer? (Q848923)

A. Tender and enlarged gallbladder

B. Hepatomegaly with jaundice

C. Courvoisier's sign

D. Murphy’s sign

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 56-year-old patient with pancreatic cancer has completed initial treatment. To monitor for potential recurrence, the oncologist decides to check a tumor marker. Which of the following tumor markers is commonly used for establishing a baseline and monitoring for recurrence in pancreatic cancer? (Q848922)

A. Alpha-fetoprotein

B. Carbohydrate Antigen 19-9

C. Carcinoembryonic Antigen

D. Human Chorionic Gonadotropin

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 65-year-old man presents with symptoms of jaundice and abdominal pain. Imaging studies reveal a solid mass in the pancreatic head. Histological examination shows a dense fibrous stroma with neoplastic tubular glands. The tumor is characterized by local spread along nerves, lymphatics, and blood vessels, and has metastasized to the liver. What is the most likely diagnosis? (Q848921)

A. Serous cystadenoma

B. Mucinous cystic neoplasm

C. Ductal adenocarcinoma

D. Solid pseudopapillary neoplasm

See Answer in Part B → Q23

Q73 (p. 287)					

Q1: What is the most probable diagnosis for a 42-year-old woman who came with symptoms of fever, vomiting, and right hypochondriac pain, which radiates to the neck? She has experienced similar episodes in the past, and a positive Murphy's sign was observed during the examination. (Q857521)

A. Acute cholecystitis

B. Carcinoma gallbladder

C. Peptic ulcer

D. Acute appendicitis

See Answer in Part B → Q1

@Neet_pg_bot

Q2: ERCP is least useful in the diagnosis of: (Q856781)

A. Recurrent pancreatitis

B. Unexplained jaundice

C. Periampullary mass

D. Acute Pancreatitis without choledocholithiasis

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 54-year-old female patient presents with abdominal pain and bilious vomiting. She had a history of abdominal hysterectomy 2 years back. On examination, abdomen auscultation revealed high-pitched bowel sounds. Investigations showed air within the biliary tree. What is the most likely diagnosis? (Q856242)

A. Gallstone ileus

B. Adhesive intestinal obstruction

C. Ischemic enterocolitis

D. Diverticulitis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: An alcoholic patient presented with severe abdominal pain. Pancreatitis was suspected, and a CT scan revealed lesions with fluid collected near the body of the pancreas. Which of the following enzymes is most likely to be elevated? (Q856230)

A. Serum GGT

B. CEA

C. Serum lipase

D. Serum bilirubin

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A patient underwent cholecystectomy for gallstones 2.5 years ago. She now presents with symptoms of obstructive jaundice. Investigation reveals a stone in the common bile duct. What is the stone most likely to be? (Q856204)

A. Primary

B. Secondary

C. Tertiary

D. Recurrent

See Answer in Part B → Q5

@Neet_pg_bot

Q6: What should be the subsequent course of action in the management of a female patient who experienced abdominal pain and increased heart rate three days after cholecystectomy? Her white blood cell count is 11000 cells / mm^3, and an ultrasound examination revealed a 5x5 cm accumulation of fluid in the sub-hepatic space on the right side. (Q856532)

A. Antibiotics and send home

B. USG-guided pigtail catheter drainage

C. Laparoscopy and re-exploration

D. ERCP and T-tube placement

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 16-year-old female with recurrent jaundice and abdominal pain is found to have a fusiform cystic dilatation of the common bile duct on ultrasound. Which investigation is best to fully delineate the biliary anatomy and confirm the diagnosis before surgery? (Q858369)

A. Magnetic Resonance Cholangiopancreatography

B. Endoscopic ultrasound

C. Percutaneous transhepatic cholangiography

D. Endoscopic retrograde cholangiopancreatography

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements about hepatocellular carcinoma (HCC) is/are correct? 1. TACE(Transarterial chemoembolization) is used for multinodular lesions 2. Lenvatinib is used for lesions less than 3 cm 3. The incidence of HCC is increasing 4. NASH and NAFLD are risk factors for HCC (Q858368)

A. 1, 2, 3

B. 2, 3, 4

C. 1, 3, 4

D. 1 and 2

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 40 year old woman presented with jaundice, fever, and abdominal pain. She is suspected to have cholangitis. Which of the following apart from abdominal pain makes up Reynold pentad? 1. Fever 2. Jaundice 3. Hypotension 4. Altered sensorium 5. Hematemesis 6. Melena (Q858359)

A. 1, 2, 3, 4

B. 2, 3, 4, 5

C. 1, 3, 4, 5

D. 1, 2, 4, 5

See Answer in Part B → Q9

@Neet_pg_bot

Q10: What is the most appropriate next step in the management of a female patient who has abdominal pain, multiple gallstones with no thickening of the gallbladder wall as seen on ultrasound, a common bile duct diameter of 12mm, serum bilirubin level of 0.8, alkaline phosphatase level of 380, and a 5-fold increase in GGT? (Q858345)

A. MRCP

B. ERCP

C. Endoscopic ultrasound

D. Laparoscopic cholecystectomy

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A patient presents with pain in the right upper quadrant on the second postoperative day following a cholecystectomy. Evaluation reveals a collection in the subhepatic space. A bile leak is suspected. What is the best next step in management? (Q856233)

A. MRCP

B. ERCP

C. HIDA

D. CECT

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 36-year-old man presents with dull aching epigastric pain. He gives a history of acute abdominal pain following a binge of alcohol 5 weeks back, which was managed conservatively. On examination, he appeared icteric, and a firm mass was palpable in the epigastrium. His CT scan is given below. Which of the following is the most likely diagnosis? (Q857497)

A. Pancreatic pseudocyst

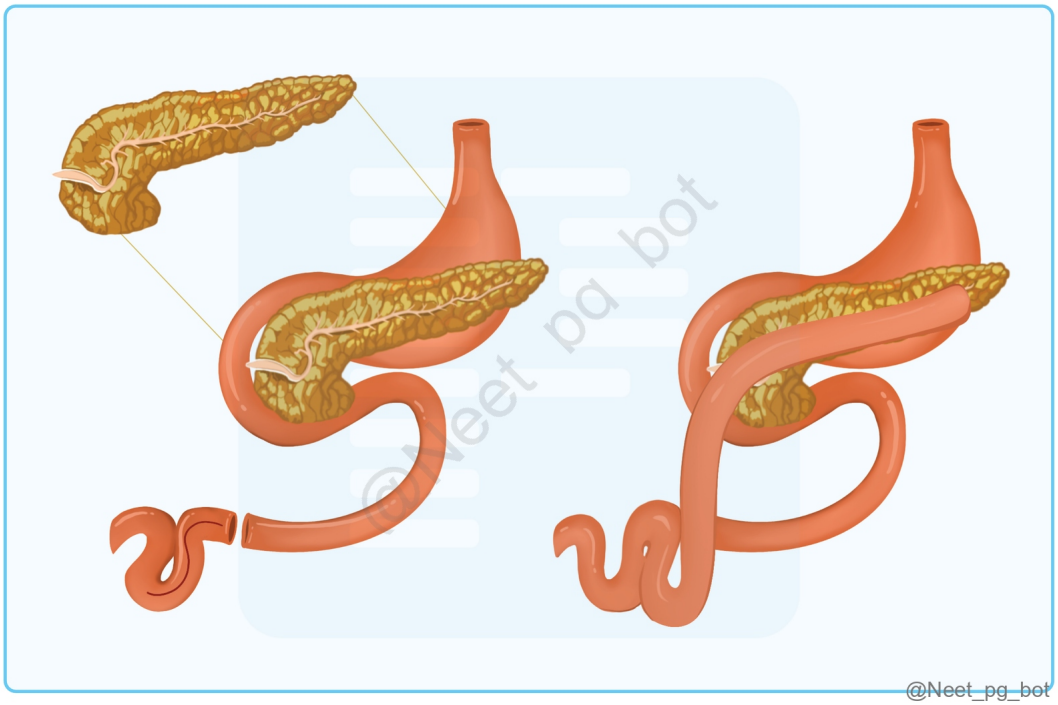
B. Large choledochal cyst

C. Gastric duplication cyst

D. Mesenteric cyst

See Answer in Part B → Q12

@Neet_pg_bot



Q13: Identify the procedure shown in the image below. (Q857478)

A. Gastrojejunostomy

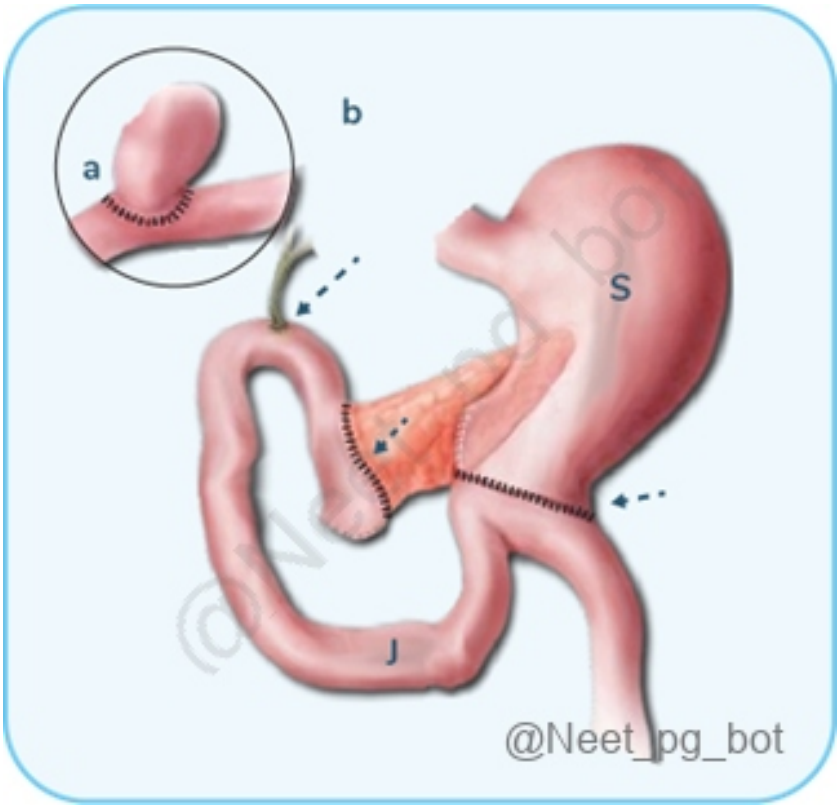
B. Pancreaticojejunostomy

C. Pancreatic Ileostomy

D. Duodenojejunostomy

See Answer in Part B → Q13

@Neet_pg_bot



Q14: Identify the procedure shown in the image: (Q857473)

A. Beger’s procedure

B. Whipple’s procedure

C. Frey’s procedure

D. Pancreatic redivision

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 40-year-old man is brought to the casualty with severe abdominal pain radiating to the back for the past 1 day and has had 3 episodes of vomiting. The pain radiates to the back and is slightly relieved in the sitting forward position. The following signs are seen on examination and lab investigations reveal elevated lipase and amylase. Which of the following is the most likely diagnosis? (Q857470)

A. Acute appendicitis

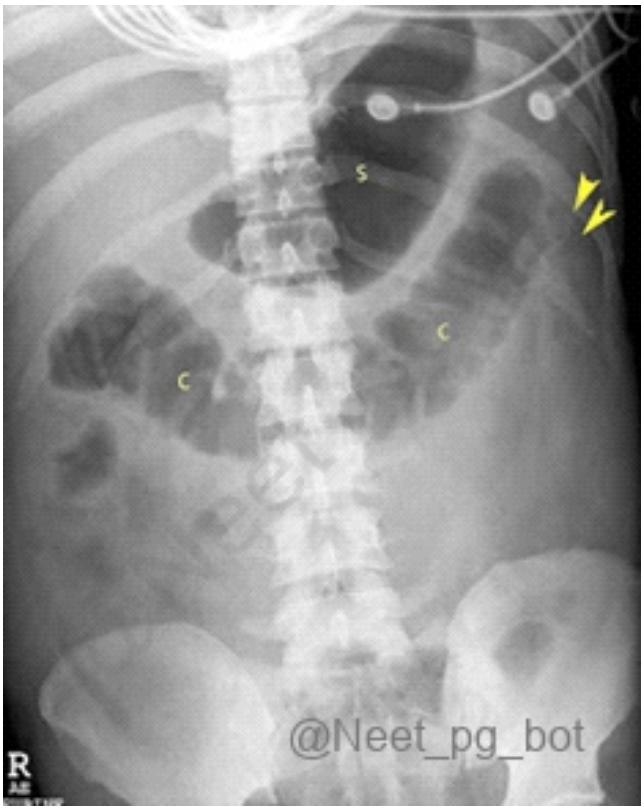
B. Acute cholecystitis

C. Acute pancreatitis

D. Acute ischemic colitis

See Answer in Part B → Q15

@Neet_pg_bot



Q16: A young man presents to the emergency department with complaints of severe abdominal pain and 3 episodes of vomiting in the past 9 hours. He says that the pain radiates to the back and is partially relieved by bending forwards. The abdominal radiograph of the patient is given below which shows a 'colon cut-off sign '. What is the most likely diagnosis? (Q857194)

A. Acute hepatitis

B. Acute pancreatitis

C. Acute colitis

D. Intestinal obstruction

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following is the most common side effect of cholecystectomy? (Q857190)

A. Acute kidney injury

B. Osteoporosis

C. Steatorrhea

D. Colorectal cancer

See Answer in Part B → Q17

@Neet_pg_bot

Q18: What would be your approach in managing a patient who is a 40-year-old woman with a 5 mm gallbladder polyp detected on abdominal ultrasound, but no gallbladder stones? The patient is overall healthy and shows no symptoms. (Q857186)

A. Regular follow-up every 2 months

B. Polypectomy

C. Laparoscopic cholecystectomy

D. Open cholecystectomy

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A patient underwent laparoscopic cholecystectomy and was discharged after removing the drain tube on the first postoperative day. On day two, the patient came back to the hospital with complaints of increasing abdominal pain with tachycardia and was febrile on examination. On ultrasound examination, there was a 5 x 5 cm collection in the subhepatic space. What is the most likely cause of this condition? (Q857185)

A. Infection

B. Surgical site pain

C. Bile leak

D. Retained gallstones

See Answer in Part B → Q19

@Neet_pg_bot

Q20: What is the term for a stone obstructing the cystic duct, causing dilation of the common hepatic duct, resulting in CBD obstruction and jaundice? (Q859850)

A. Acute cholecystitis

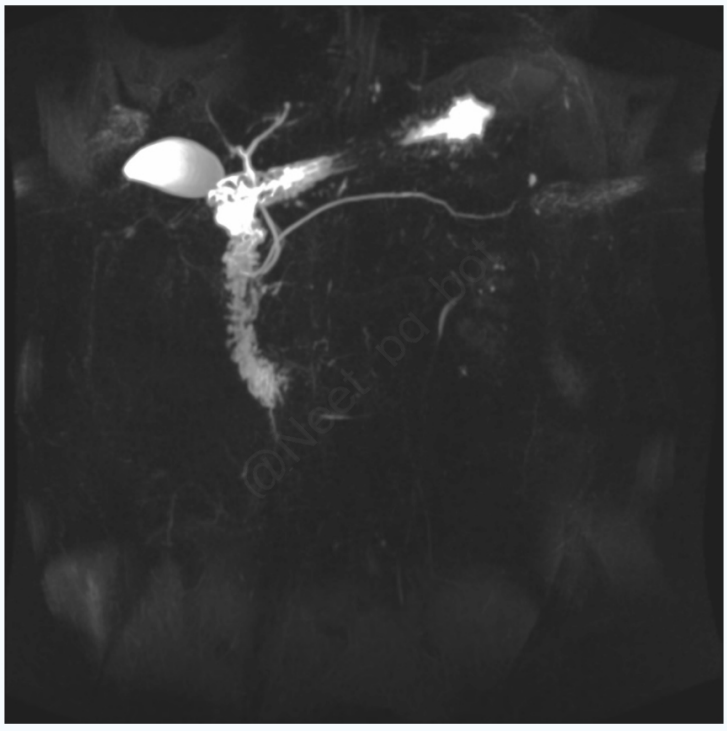
B. Porcelain gallbladder

C. Cholesterolosis

D. Mirizzi’s syndrome

See Answer in Part B → Q20

@Neet_pg_bot



Q21: A 17-year-old boy presents with recurrent episodes of abdominal pain. Serum amylase and lipase are elevated on two occasions, but exocrine pancreatic function is normal. An MRCP image is shown below. Which of the following is the most likely diagnosis? (Q879143)

A. Annular pancreas

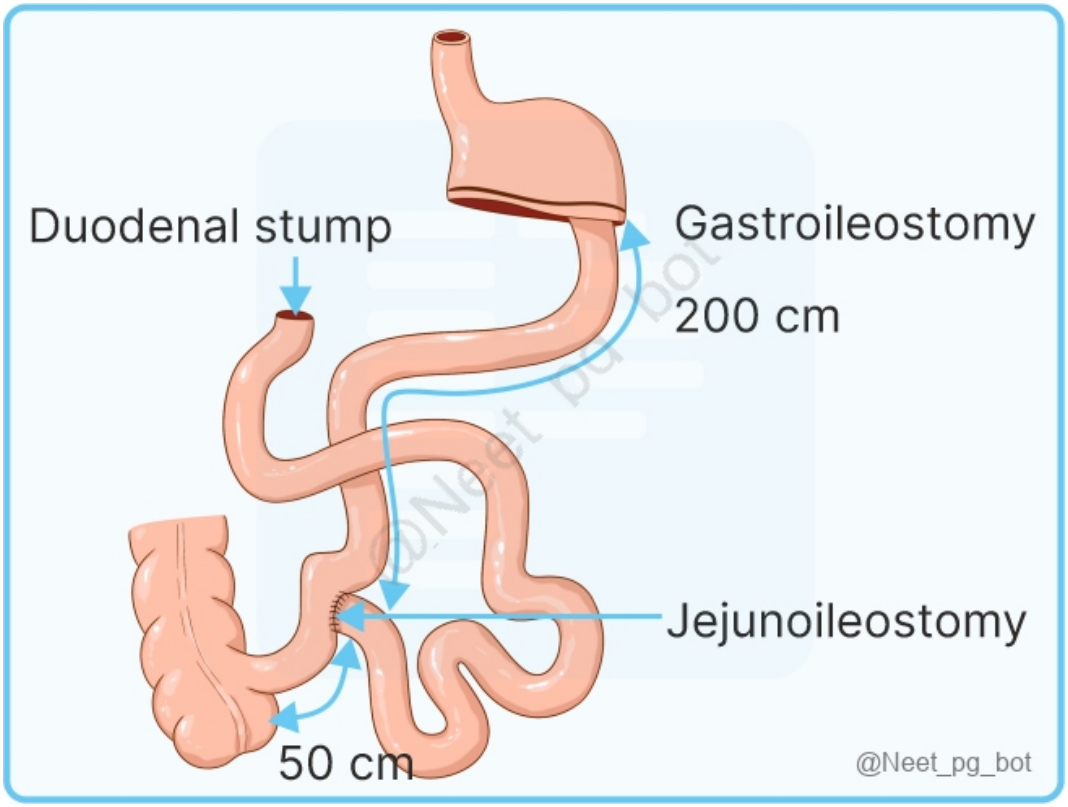
B. Chronic pancreatitis

C. Pancreas divisum

D. Choledochal cyst

See Answer in Part B → Q21

@Neet_pg_bot



Q22: Identify the procedure: (Q879138)

A. Biliopancreatic diversion

B. Roux -en Y procedure

C. Sleeve gastrectomy

D. Duodenal switch

See Answer in Part B → Q22

@Neet_pg_bot

Q23: TIGARO classification is used for? (Q879133)

A. Acute pancreatitis

B. Chronic pancreatitis

C. Acute cholecystitis

D. Pancreatic cancer

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A patient has undergone a laparoscopic cholecystectomy. A drain was inserted because of a difficult gallbladder dissection. Day 7 drain output is 300 ml. The patient is afebrile, and MRCP shows cystic duct stump leak. What is the next best management? (Q879124)

A. ERCP with or without a stent

B. USG-guided pigtail catheter insertion

C. Re – do laparoscopic ligation of the bile stump

D. Follow up as it will heal on its own

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Arrange the following steps of surgery in order: A. Creating pneumoperitoneum B. Dissection of hepatocystic triangle C. Ligation of cystic duct and artery D. Separation of the gallbladder from the liver bed (Q879106)

A. A-B-C-D

B. A-C-B-D

C. B-A-C-D

D. D-A-B-C

See Answer in Part B → Q25

@Neet_pg_bot

Q26: On day 3 after laparoscopic cholecystectomy, a stable patient develops worsening RUQ pain and low-grade fever. Imaging shows a 6-cm biloma and a small cystic duct stump leak. Symptoms persist despite antibiotics and observation. What is the next best step in management? (Q879097)

A. Observation

B. IV antibiotics

C. Image-guided pigtail drainage

D. ERCP with stenting

See Answer in Part B → Q26

@Neet_pg_bot

Q27: What is the most frequently occurring location for an intraperitoneal abscess to develop? (Q855584)

A. Suprahepatic

B. Subhepatic

C. Left lobe of the liver

D. Left side below diaphragm

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 70-year-old woman had her routine follow-up, and her USG is shown below. She is asymptomatic at present but has a history of mild right hypochondriac pain, which is relieved by taking analgesics. What is the most likely diagnosis? (Q859867)

A. Gallstones

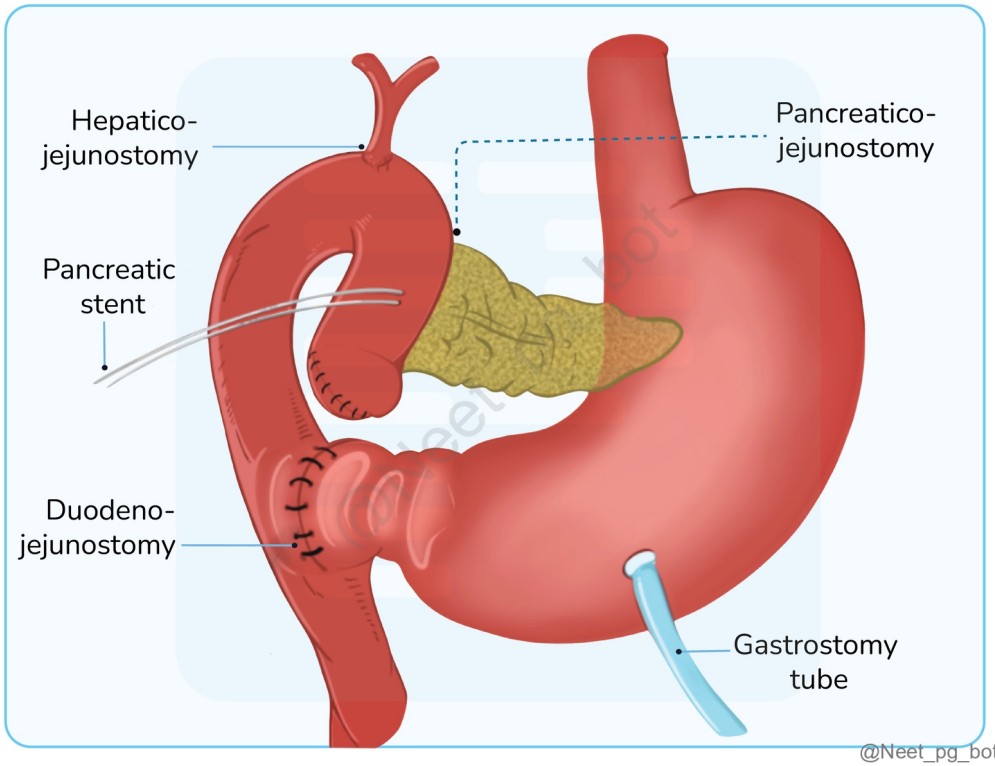
B. Amoebic liver abscess

C. Hydatid cyst

D. Acute cholecystitis

See Answer in Part B → Q28

@Neet_pg_bot



Q29: The following procedure is performed for the management of? (Q855692)

A. Advanced gastric carcinoma

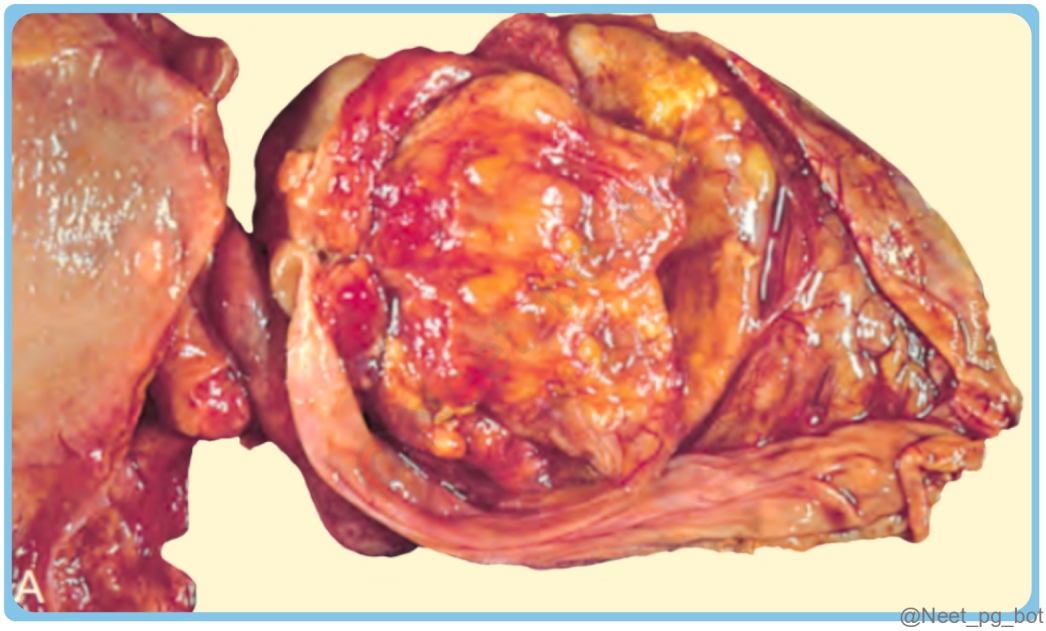
B. Gallbladder carcinoma

C. Distal cholangiocarinoma

D. Chronic calcific pancreatitis

See Answer in Part B → Q29

@Neet_pg_bot



Q30: A patient underwent a laparoscopic cholecystectomy for cholelithiasis. A picture of the resected gall bladder is shown below. What is the diagnosis? (Q859620)

A. Gall bladder carcinoma

B. Mixed stone in gallbladder

C. Cholecystitis

D. Choledocholithiasis

See Answer in Part B → Q30

@Neet_pg_bot

Q31: Which of the following is a tumour marker of pancreatic cancer? (Q859616)

A. NSE

B. Alpha-Fetoprotein

C. Ca 15-3

D. CA 19-9

See Answer in Part B → Q31

@Neet_pg_bot

Q32: A young sheep farmer presents to the OPD with pain in the right upper part of the abdomen. Upon examination, there was tenderness and enlargement of the liver. Blood investigations show eosinophilia, elevated liver enzymes, and abdominal ultrasound, as shown below. Which of the following is the most likely diagnosis? (Q859613)

A. Amoebic liver abscess

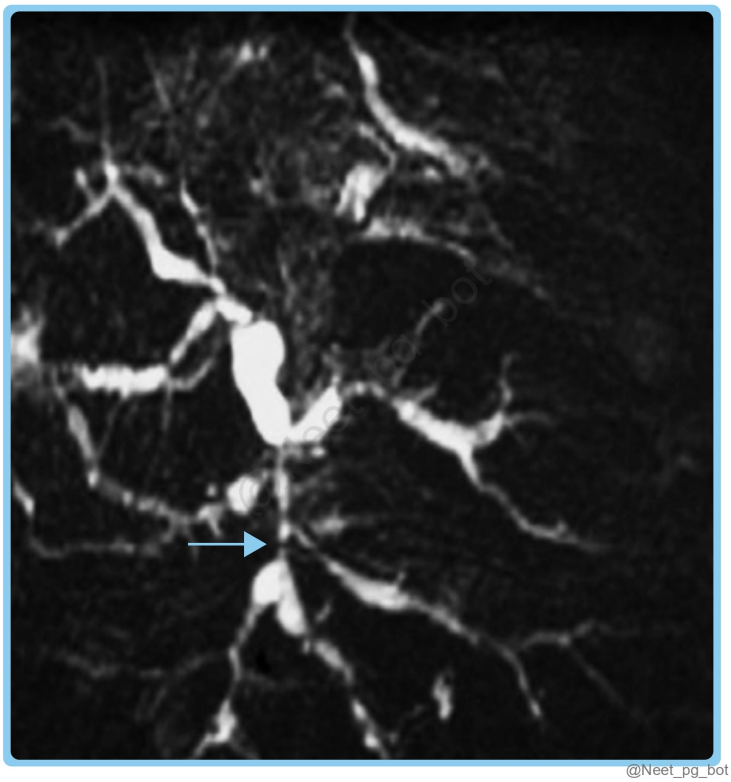
B. Hydatid cyst

C. Pyogenic liver abscess

D. Hepatocellular carcinoma

See Answer in Part B → Q32

@Neet_pg_bot



Q33: A 35-year-old man presented with recurrent episodes of fever with chills. The MRCP image is shown below. What is the most likely diagnosis? (Q858489)

A. Primary sclerosing cholangitis

B. Caroli disease

C. Oriental cholangitis

D. Primary biliary carcinoma

See Answer in Part B → Q33

@Neet_pg_bot

Q34: An 80-year-old woman presented with fatigue. Imaging revealed a scleroatrophic gallbladder with impacted stones and a large stone in the common bile duct, causing dilation of the biliary tree. What is the next step in management? (Q855020)

A. Immediately take up the patient for cholecystectomy

B. Endoscopic retrograde cholangiopancreatography

C. Wait and watch

D. CT scan

See Answer in Part B → Q34

@Neet_pg_bot

Q35: A 5-year-old child with Wilson's disease is being considered for liver transplantation. Which of the following is not a parameter in the selection criteria for transplantation? (Q855014)

A. Age < 10 years

B. Bilirubin > 300µmol/L

C. AST > 300 IU/L

D. PT > 100 s

See Answer in Part B → Q35

@Neet_pg_bot

Q36: A patient with recurrent pain in the right hypochondrium, nausea, and vomiting is diagnosed with biliary dyskinesia. Which of the following is least useful in the diagnosis of this condition? (Q856301)

A. CT scan

B. HIDA scan

C. ERCP

D. Endoscopy

See Answer in Part B → Q36

@Neet_pg_bot

Q37: According to Strasberg's classification of bile duct injuries, a bile leak from the cystic duct stump or a minor duct in the gallbladder fossa with continuity to the common bile duct is classified as: (Q856250)

A. Type A

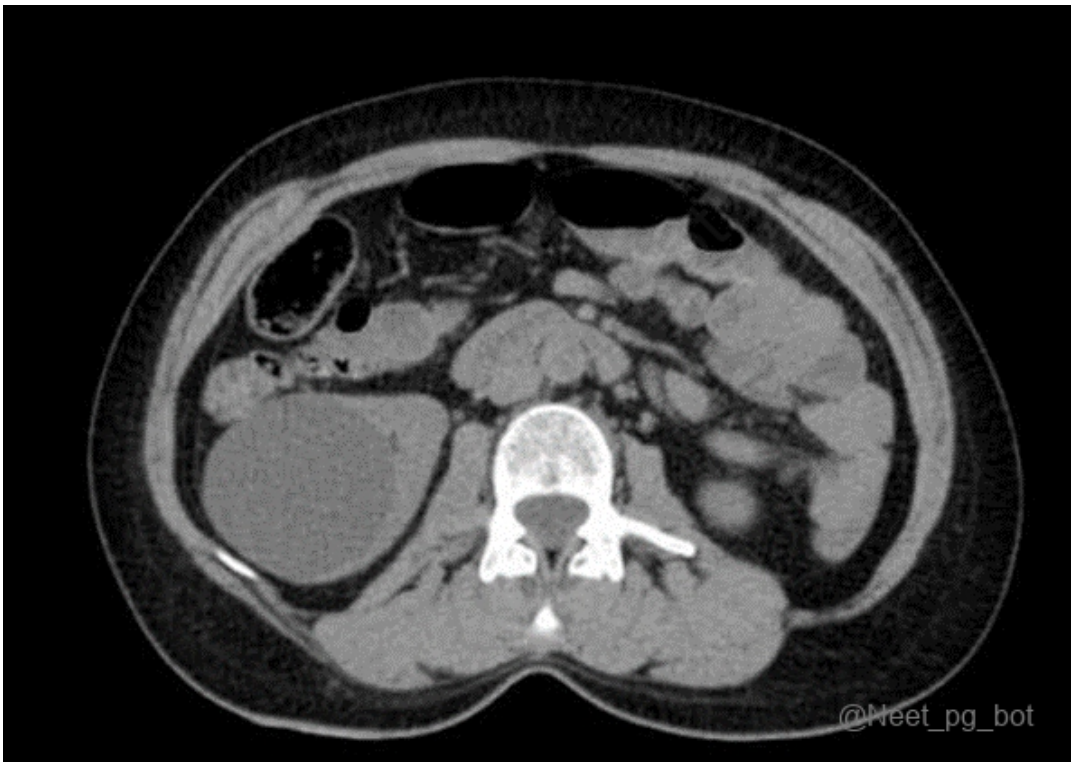
B. Type B

C. Type C

D. Type D

See Answer in Part B → Q37

@Neet_pg_bot



Q38: A 62-year-old female undergoes a contrast-enhanced abdominal CT scan for unrelated mild abdominal discomfort. The scan reveals a solitary, 4 cm, round, dark, fluid-filled lesion in the right kidney as shown in the image. The lesion does not change in appearance or become brighter after the administration of intravenous contrast. Based on these findings, what is the most likely diagnosis? (Q844294)

A. Renal cyst

B. Renal tumor

C. ADPKD

D. Hydatid cyst

See Answer in Part B → Q38

@Neet_pg_bot

Q39: A patient underwent cholecystectomy, and the histopathology reveals carcinoma with invasion into the muscular layer. What is the next best step? (Q857249)

A. Radiotherapy

B. Chemotherapy

C. Excision of the stump

D. Extended Cholecystectomy

See Answer in Part B → Q39

@Neet_pg_bot

Q40: Which classification system is used for bile duct injury, taking location, injury to the duct, and vessel involvement into account? (Q857247)

A. Bismuth

B. Strasberg

C. Stewart Way

D. Hannover

See Answer in Part B → Q40

@Neet_pg_bot

Q41: Which of the following is not a risk factor for gallbladder cancer? (Q857241)

A. Porcelain Gall Bladder

B. Primary Sclerosing Cholangitis

C. Polyp <10 mm

D. Gallstone >3 cm

See Answer in Part B → Q41

@Neet_pg_bot

Q42: A 45-year-old male presents to the emergency department with severe abdominal pain radiating to the back. Laboratory investigations reveal elevated serum amylase and lipase levels. Which of the following should be avoided in the management of the given condition? (Q860175)

A. Nil per oral

B. Administration of 5% dextrose

C. Parenteral nutrition

D. Early initiation of oral feedings

See Answer in Part B → Q42

@Neet_pg_bot

Q43: What is the most common complication of ERCP? (Q860172)

A. Duodenal perforation

B. Cholangitis

C. Hemorrhage

D. Pancreatitis

See Answer in Part B → Q43

@Neet_pg_bot

Q44: A newborn presents with jaundice. Biliary atresia is suspected when jaundice is persistent and exceeds? (Q860450)

A. 2 days

B. 2 weeks

C. 2 months

D. 2 years

See Answer in Part B → Q44

@Neet_pg_bot

Q45: A 45-year-old alcoholic patient presents to the ER with severe abdominal pain radiating to the back. Blood investigations reveal increased serum amylase and lipase levels. What is the most likely diagnosis? (Q860443)

A. Peptic ulcer disease

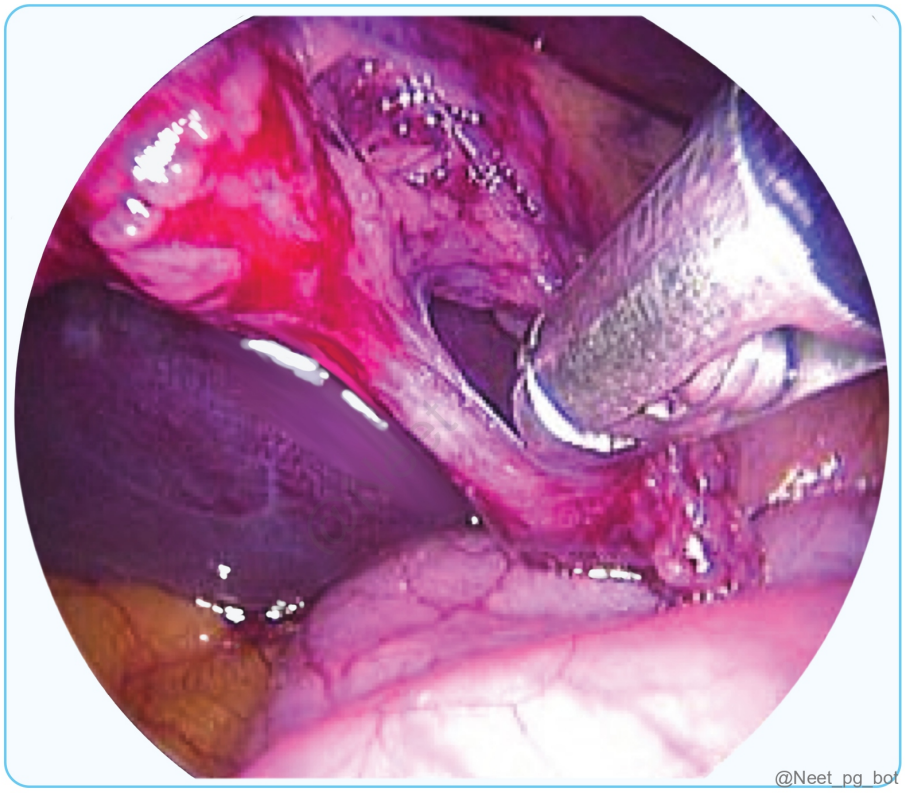
B. Acute pancreatitis

C. Acute cholecystitis

D. Pyogenic liver abscess

See Answer in Part B → Q45

@Neet_pg_bot



Q46: A patient underwent laparoscopic cholecystectomy. Identify the marked structure in the image. (Q860420)

A. Cystic artery

B. Cystic duct

C. Right hepatic artery

D. Hepatic duct

See Answer in Part B → Q46

@Neet_pg_bot

Q47: Which of the following statements about Choledochal Cyst is incorrect? (Q857250)

A. Increased risk of cholangiocarcinoma

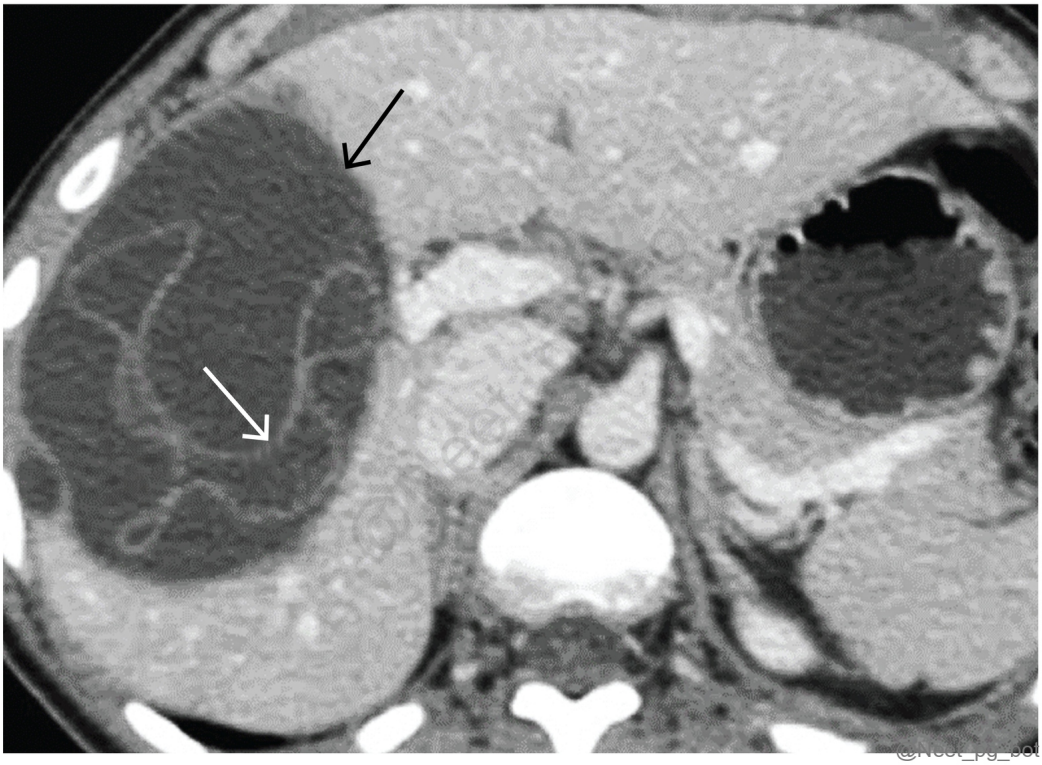
B. The cyst can be opened directly and drained

C. Todani classification is used for grading

D. Associated with abnormal Bilio-Pancreatic Junction

See Answer in Part B → Q47

@Neet_pg_bot



Q48: Identify the stage of disease given in the image. (Q844272)

A. Type 1

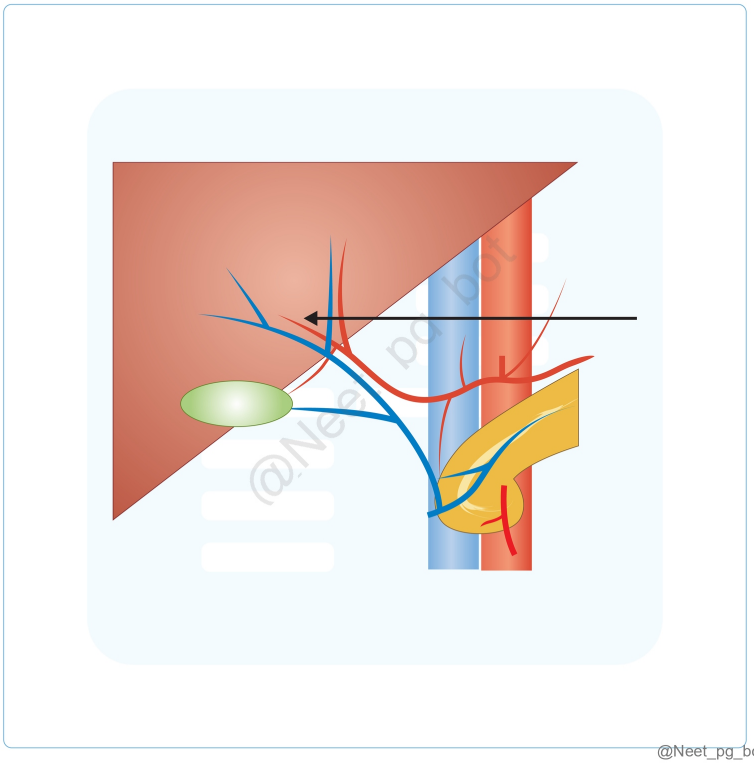
B. Type 2

C. Type 3

D. Type 4

See Answer in Part B → Q48

@Neet_pg_bot



Q49: Identify the marked structure? (Q852723)

A. Cystic artery

B. Right Hepatic artery

C. Hepatic duct

D. Cystic duct

@Neet_pg_bot

See Answer in Part B → Q49

@Neet_pg_bot

Q50: Which of the following is the classical triad of acute cholangitis? (Q852707)

A. Pain, jaundice, fever

B. Pain, jaundice, shock

C. Fever, jaundice, ↑WBC

D. Pain, ↑WBC, ↑Bilirubin

See Answer in Part B → Q50

@Neet_pg_bot

Q51: A 20-year-old male presents with acute epigastric pain and fever. He has a history of cholelithiasis. On examination, abdominal guarding and rigidity are noted. Laboratory results show elevated serum amylase and lipase levels, along with leukocytosis. What is the most likely diagnosis for his condition? (Q853061)

A. Serum amylase remains elevated even after 30 days of resolution of acute pancreatitis

B. ■■■> 75 per cent of patients present with hypercalcemia

C. Serum lipase is more specific than serum amylase

D. Increase in the level of serum lipase is directly proportional to the severity

See Answer in Part B → Q51

@Neet_pg_bot

Q52: A patient presents with a 2-year history of anorexia, epigastric pain, jaundice, and itching (pruritis). On examination, the gallbladder is palpable. What is the most likely diagnosis? (Q866482)

A. Gallbladder carcinoma

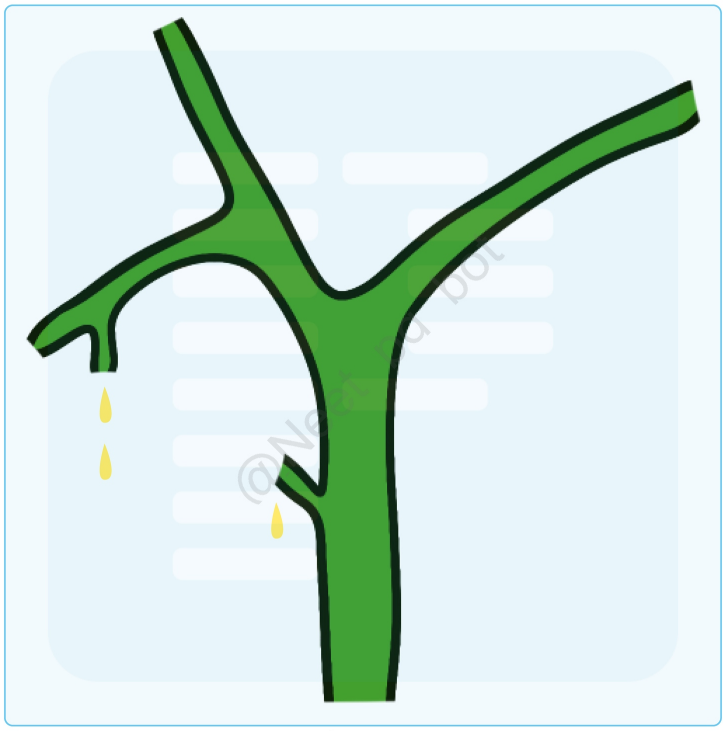
B. Hepatocellular carcinoma (HCC)

C. Cholelithiasis (gallstones)

D. Ca of the head of the pancreas

See Answer in Part B → Q52

@Neet_pg_bot



Q53: Based on the given image, which type of injury is shown according to the Bismuth-Strasberg classification: (Q866466)

A. Type A

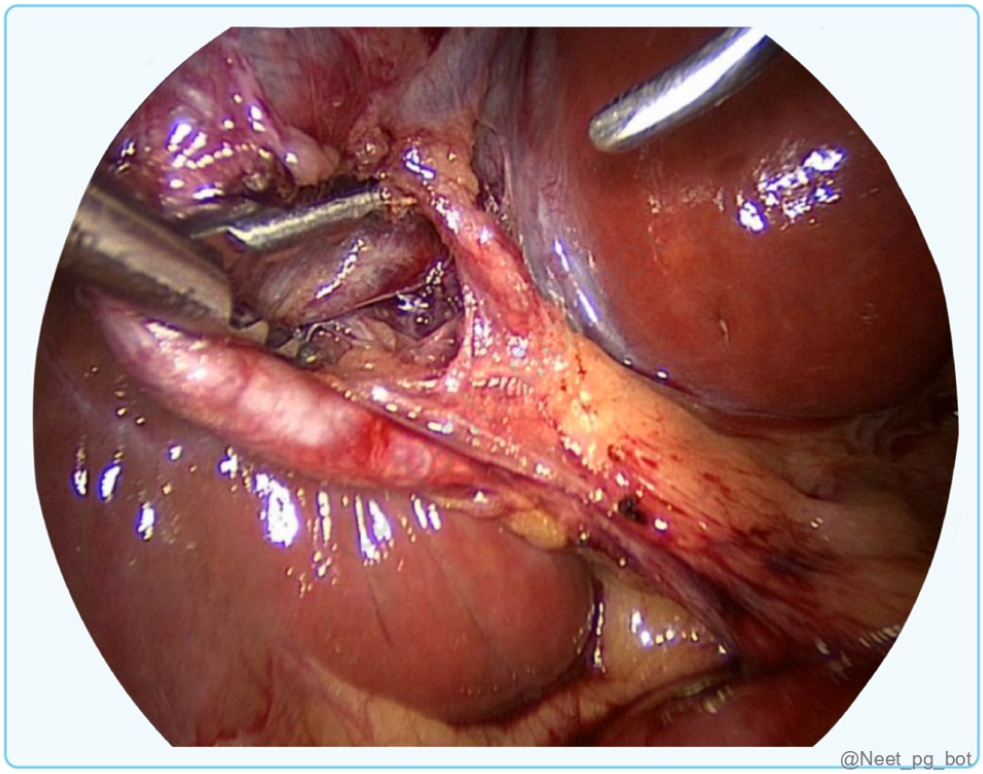
B. Type B

C. Type C

D. Type D

See Answer in Part B → Q53

@Neet_pg_bot



Q54: During a laparoscopic cholecystectomy, the surgeon carefully identifies the boundaries of the hepatocystic triangle to avoid injury to important structures. Which of the following is not a boundary of the hepatocystic triangle? (Q865336)

A. Cystic duct

B. Common hepatic duct

C. Inferior border of the liver

D. Cystic artery

See Answer in Part B → Q54

@Neet_pg_bot

Q55: A 30-year-old female presented with pain in the right upper quadrant of the abdomen after 4 days of cholecystectomy. On USG, it showed a significant collection in RUQ. What will you do further? (Q866916)

A. Re-explore laparoscopically

B. Higher antibiotics

C. MRCP

D. USG guided aspiration of content

See Answer in Part B → Q55

@Neet_pg_bot

Q56: A 55-year-old alcoholic patient presents with sudden and unintentional weight loss. Lab investigations revealed serum alkaline phosphatase (ALP) of 240 IU/L, alpha-fetoprotein (AFP) of 600 ng/ml, and normal serum AST and ALT levels. What is the most likely diagnosis? (Q855185)

A. Hepatic adenoma

B. Cholangiocarcinoma

C. Hepatocellular carcinoma

D. Alcoholic hepatitis

See Answer in Part B → Q56

@Neet_pg_bot

Q57: A 50-year-old alcoholic patient presents with a history of waxing and waning jaundice for the past 2 months. His CT examination reveals dilatation of the common bile duct and pancreatic duct. What is the most probable diagnosis in the patient? (Q855691)

A. Cholangiocarcinoma

B. Periampullary carcinoma

C. Common bile duct stone

D. Head of the pancreas carcinoma

See Answer in Part B → Q57

@Neet_pg_bot

Q58: A chronic-alcoholic presents to the emergency room with acute pain in the abdomen in the epigastric region radiating to the back with nausea, anorexia, and occasional vomiting. Investigations showed elevated amylase levels (3 times) and total

count. Likely diagnosis is: (Q857788)

A. Acute hepatitis

B. Acute pancreatitis

C. Acute cholecystitis

D. Acute appendicitis

See Answer in Part B → Q58

@Neet_pg_bot

Q59: Which of the following is the best preferred investigation for Neuroendocrine Tumors (NETs)? (Q857777)

A. USG

B. SRS

C. MRI

D. PET

See Answer in Part B → Q59

@Neet_pg_bot

Q60: A patient arrives with pain in the right upper abdomen. One week ago, the patient experienced a bout of diarrhoea. Abdominal CT scan results indicate the presence of a liver abscess measuring approximately 25 cubic centimetres. What should be the subsequent course of action in treating this patient? (Q855205)

A. PAIR

B. Surgery

C. Medical therapy

D. Percutaneous drainage

See Answer in Part B → Q60

@Neet_pg_bot

Q61: A patient presents with features of chronic pancreatitis, including recurrent attacks, and has a 10 mm dilatation of the pancreatic duct with intraductal calculi present. Which of the following is the surgery of choice? (Q855189)

A. Pancreaticoduodenectomy

B. Longitudinal pancreaticojejunostomy

C. ERCP and sphincterotomy

D. Coring of the pancreas head

See Answer in Part B → Q61

@Neet_pg_bot

Q62: A 46 year male had a tumor in his left lobe of liver, so left sided hemi hepatectomy was planned, which of the following lobes of liver will be resected in this procedure? (Q866907)

A. 2,3 and 4

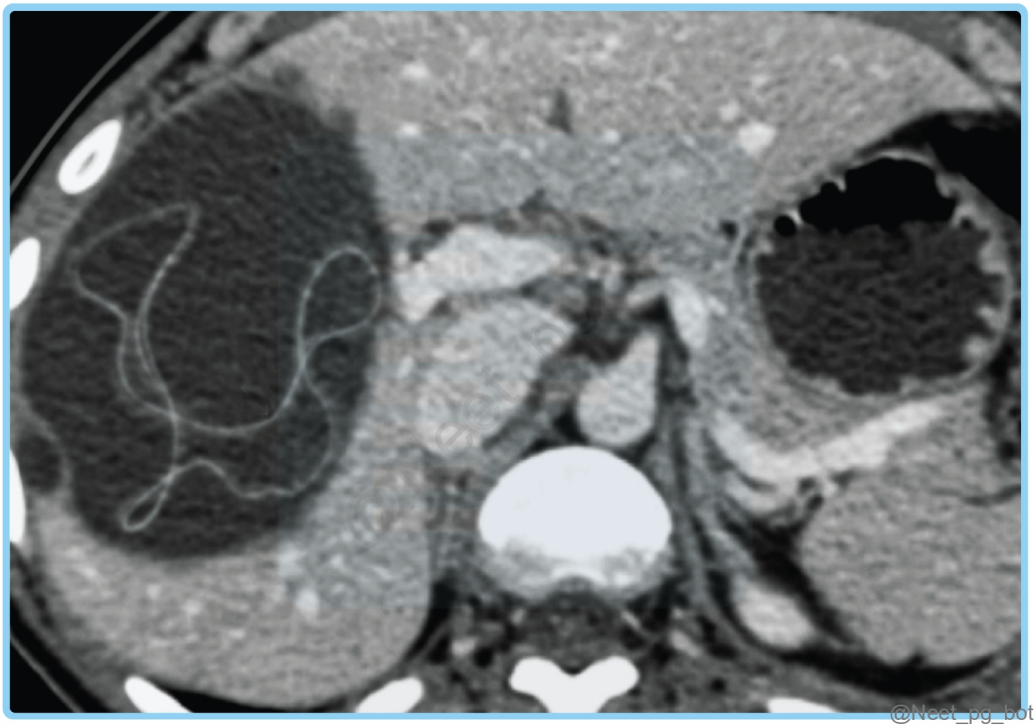
B. 1,2 & 3

C. 5, 6, 7 & 8

D. 2, 3, 4 & 5

See Answer in Part B → Q62

@Neet_pg_bot



Q63: A patient presents with fever, abdominal pain, and jaundice. Investigations show the given findings. Which of the following statements is true regarding this condition? (Q855184)

A. Surgery is mandatory

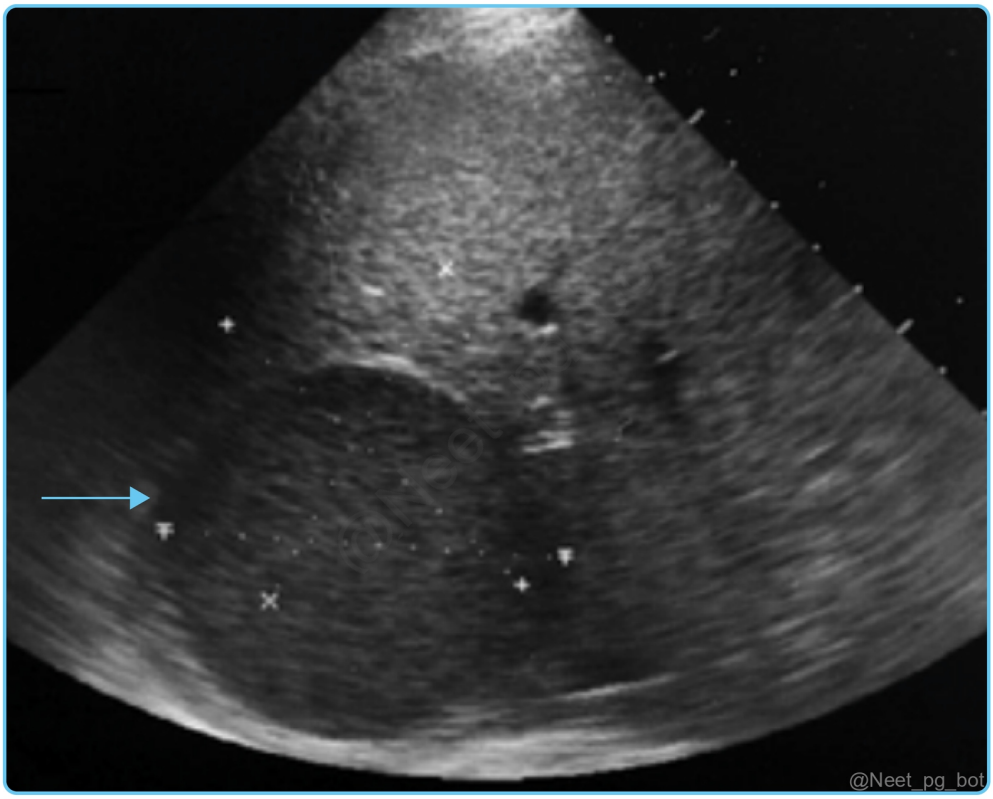
B. Fine-needle aspiration cytology is diagnostic

C. Angioembolization is the treatment of choice

D. Echinococcus species is involved in etiology

See Answer in Part B → Q63

@Neet_pg_bot



Q64: A 35-year-old patient with a history of dysentery for 6 weeks complains of pain in the right upper abdomen. On ultrasound, a hypoechoic hyperdense lesion is seen in the liver. Based on the given image, identify the condition. (Q854784)

A. Amoebic liver abscess

B. Pyogenic liver abscess

C. Hydatid cyst

D. Hemangioma

See Answer in Part B → Q64

@Neet_pg_bot

Q65: After laparoscopic cholecystectomy, what should the expected urine output be in a patient with normal renal function? (Q854780)

A. 500 ml/day

B. 0.5 ml/min

C. 0.5-1.5 ml/kg/hour

D. 1 ml/kg/min

See Answer in Part B → Q65

@Neet_pg_bot

Q66: What is the sign of the gallbladder seen in this USG? (Q854768)

A. Phrygian cap sign

B. Murphy sign

C. Claw sign

D. Omega sign

See Answer in Part B → Q66

@Neet_pg_bot

Q67: Which condition is most likely based on the image findings? {{caption_text}} (Q854742)

A. Stricture

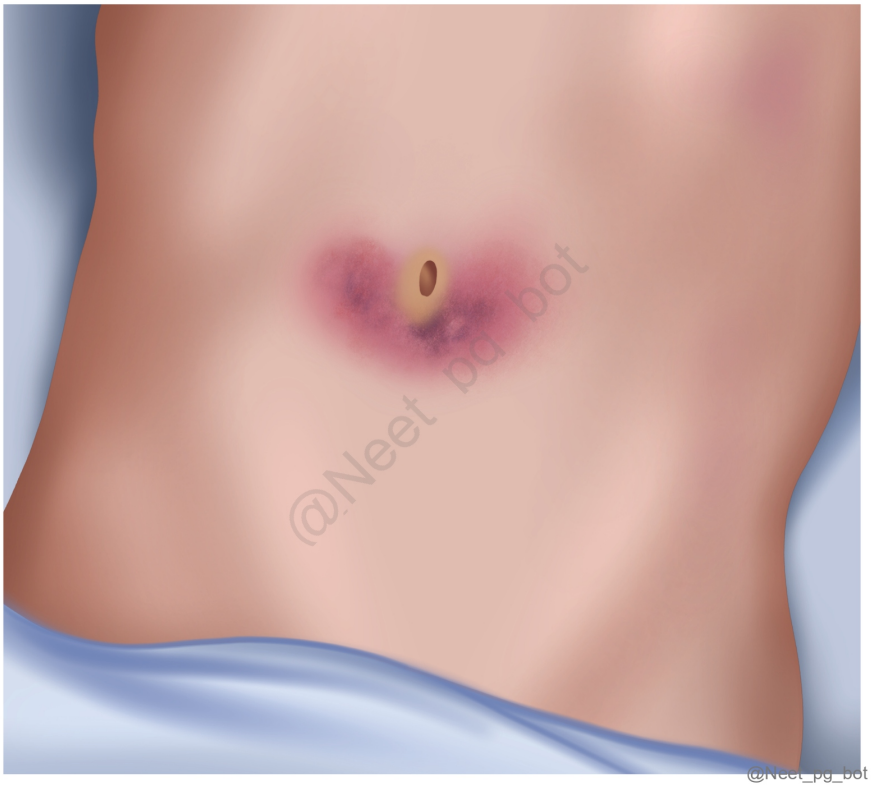
B. Choledocholithiasis

C. Cholecystitis

D. Cholangiocarcinoma

See Answer in Part B → Q67

@Neet_pg_bot



Q68: A 45-year-old male presents with abdominal pain in the emergency room. . On examination, there is blackish discoloration involving the periumbilical skin . What is the most likely diagnosis for this presentation? (Q820153)

A. Acute pancreatitis

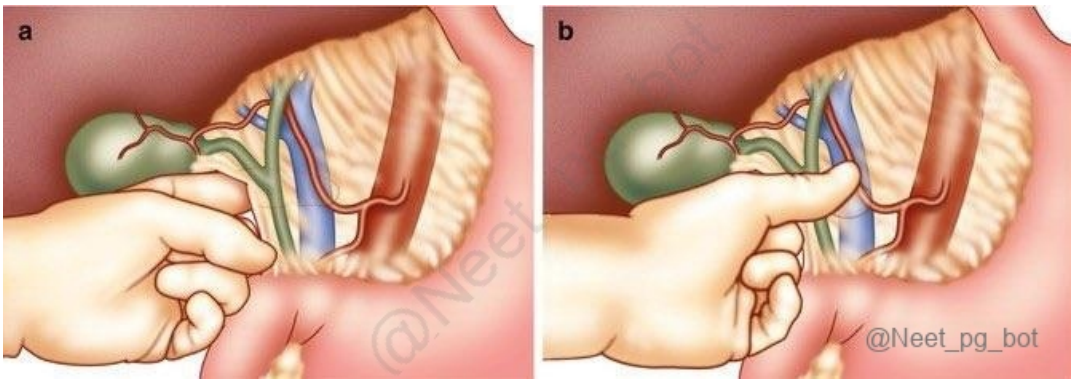
B. Necrotizing fasciitis

C. Chronic pancreatitis

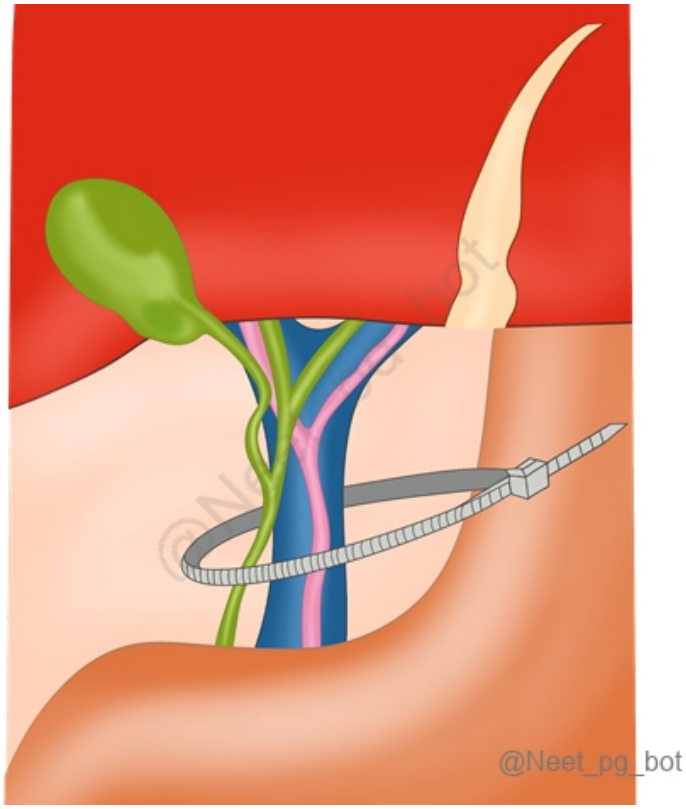
D. Traumatic fat necrosis

See Answer in Part B → Q68

@Neet_pg_bot



Q69: A 39-year-old patient presented with RTA and is brought to ER with a pulse rate of 120/min, and SBP of <80mmHg. Despite intravenous fluid resuscitation and BT, the patient's condition deteriorates with ongoing profuse bleeding from the liver . Identify the procedure shown in the image done to control massive liver bleed. (Q820112)



A. Kocher maneuver

B. Pringle’s maneuver

C. Cattell-Braasch maneuver

D. Mattox maneuver

See Answer in Part B → Q69

@Neet_pg_bot

Q70: What is the optimal management approach for a patient presenting with fever and abdominal pain five days after experiencing a common bile duct injury resulting in a leak ? (Q793377)

A. Ultrasound–guided aspiration

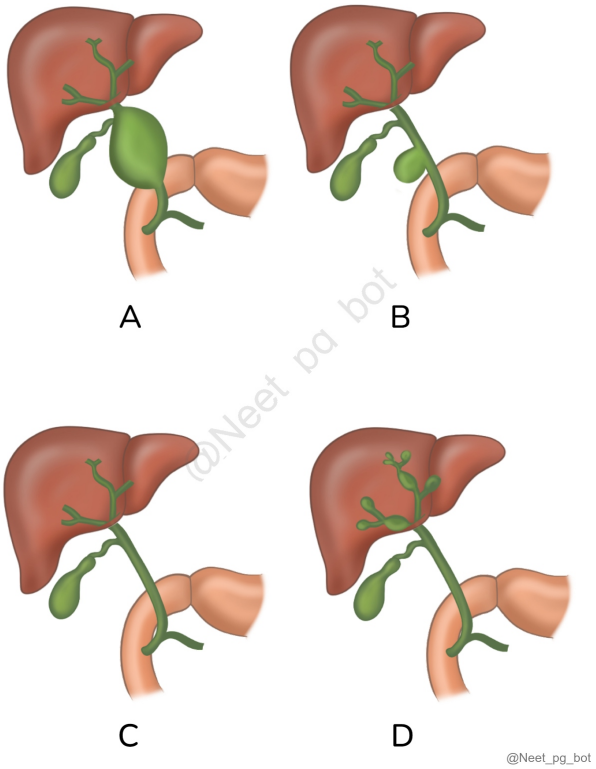
B. ERCP and stenting

C. Re-exploration and hepaticojejunostomy

D. Re-exploration and primary repair

See Answer in Part B → Q70

@Neet_pg_bot



Q71: Which of the following represents a type III choledochal cyst from the given image ? (Q793411)

A. A

B. B

C. C

D. D

See Answer in Part B → Q71

@Neet_pg_bot

Q72: Which neuroendocrine tumor of the pancreas is commonly linked with necrolytic erythema migrans ? (Q793855)

A. Insulinoma

B. Glucagonoma

C. Somatostatinoma

D. VIPoma

See Answer in Part B → Q72

@Neet_pg_bot

Q73: A 40-year-old man is brought to the casualty with severe abdominal pain radiating to the back for the past 1 day and has had 3 episodes of vomiting. The pain radiates to the back and is slightly relieved in the sitting forward position . The following signs are seen on examination and lab investigations reveal elevated lipase and amylase . Which of the following is the most likely diagnosis? (Q805008)

A. Acute appendicitis

B. Acute cholecystitis

C. Acute pancreatitis

D. Acute ischemic colitis

See Answer in Part B → Q73

Q25 (p. 302)					

Q1: A 45-year-old male presents to the emergency department with severe chest pain following forceful vomiting. Physical examination reveals subcutaneous emphysema. What is the most likely diagnosis? (Q849134)

A. Myocardial Infarction

B. Boerhaave's Syndrome

C. Acute Pancreatitis

D. Gastric Ulcer Perforation

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 45-year-old woman presents with fatigue, difficulty swallowing and pale skin. Investigation reveals a cervical esophageal web. Which of the following conditions is most likely? (Q849131)

A. Achalasia

B. Barrett’s Esophagus

C. Plummer-Vinson Syndrome

D. Esophageal Carcinoma

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 70-year-old male with a history of smoking presents with progressive dysphagia and weight loss. Endoscopy reveals a mass in the mid-esophagus. Biopsy confirms squamous cell carcinoma. Imaging shows the tumor invading the muscularis propria and metastasis to three regional lymph nodes. What is the TNM classification for this patient? (Q849128)

A. T2 N1 M0

B. T2 N2 M0

C. T3 N2 M0

D. T2 N3 M1

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old man presents with progressive dysphagia for both solids and liquids over the past year. He also reports occasional chest pain, especially after eating. Manometry is performed and analyzed using the Chicago Classification. The results show spastic contractions in the distal esophagus. Based on these findings, what type of achalasia is most likely? (Q849117)

A. Type I Achalasia

B. Type II Achalasia

C. Type III Achalasia

D. Diffuse Esophageal Spasm

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 40-year-old man complains of a burning sensation in his chest and regurgitation after meals. Symptoms improve with antacids and have no significant weight loss. What is the most likely diagnosis? (Q849123)

A. Peptic ulcer disease

B. Gastroesophageal reflux disease (GERD)

C. Gastritis

D. Esophageal spasm

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following findings are diagnostic of nutcracker esophagus? Distal esophageal contraction amplitude > 180 mmHg Distal esophageal contraction amplitude > 45 mmHg Distal esophageal peristaltic wave duration > 6 cm Distal esophageal contraction amplitude < 30 mmHg Distal esophageal contraction duration > 6 seconds Multiple simultaneous contractions with an amplitude of > 30 mmHg. (Q849125)

A. 1 and 5

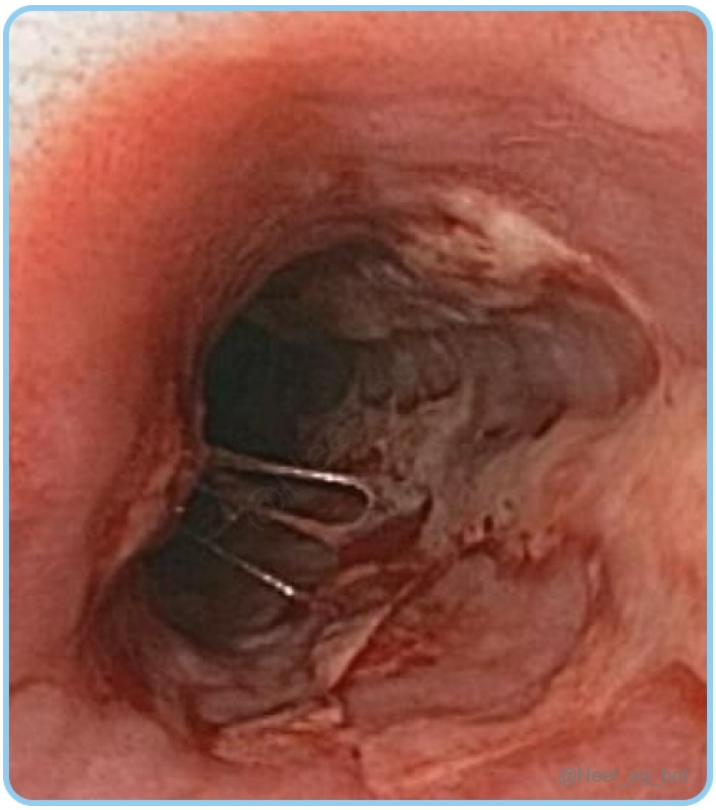
B. 2 and 3

C. 1, 3, and 5

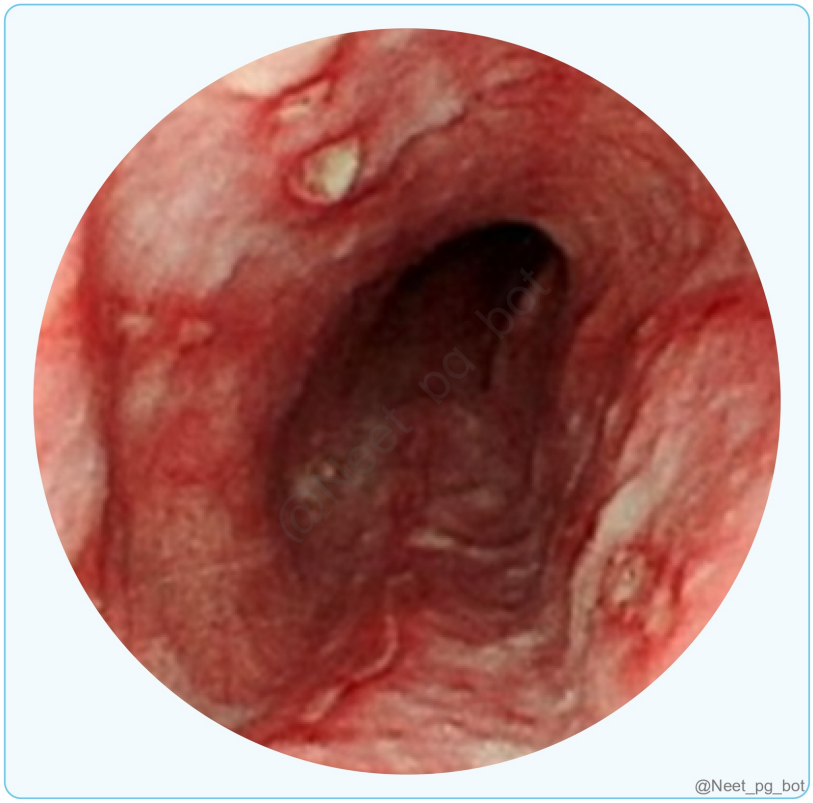
D. 2 and 6

See Answer in Part B → Q6

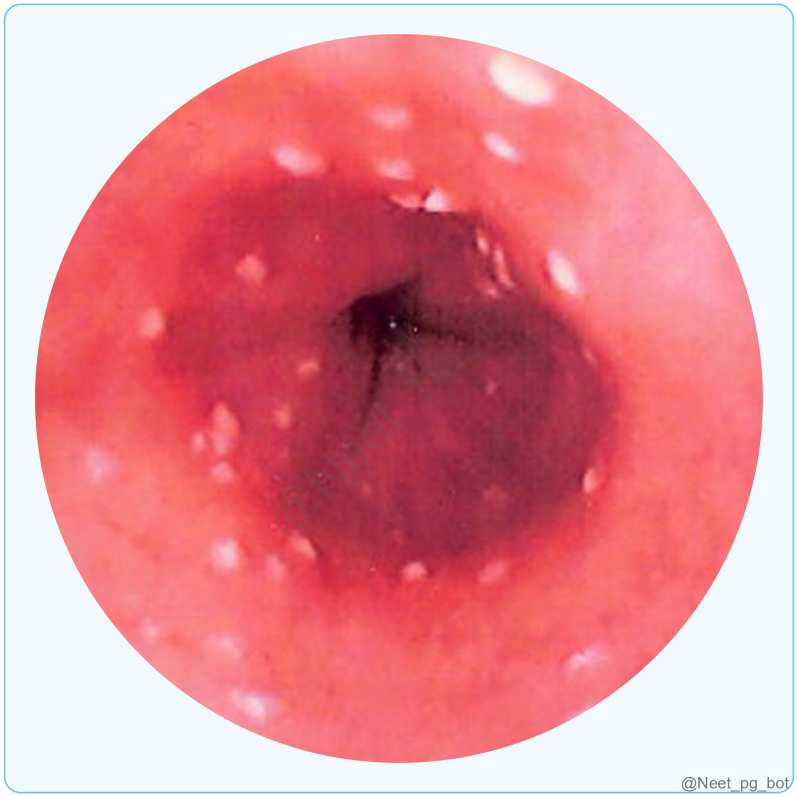
@Neet_pg_bot



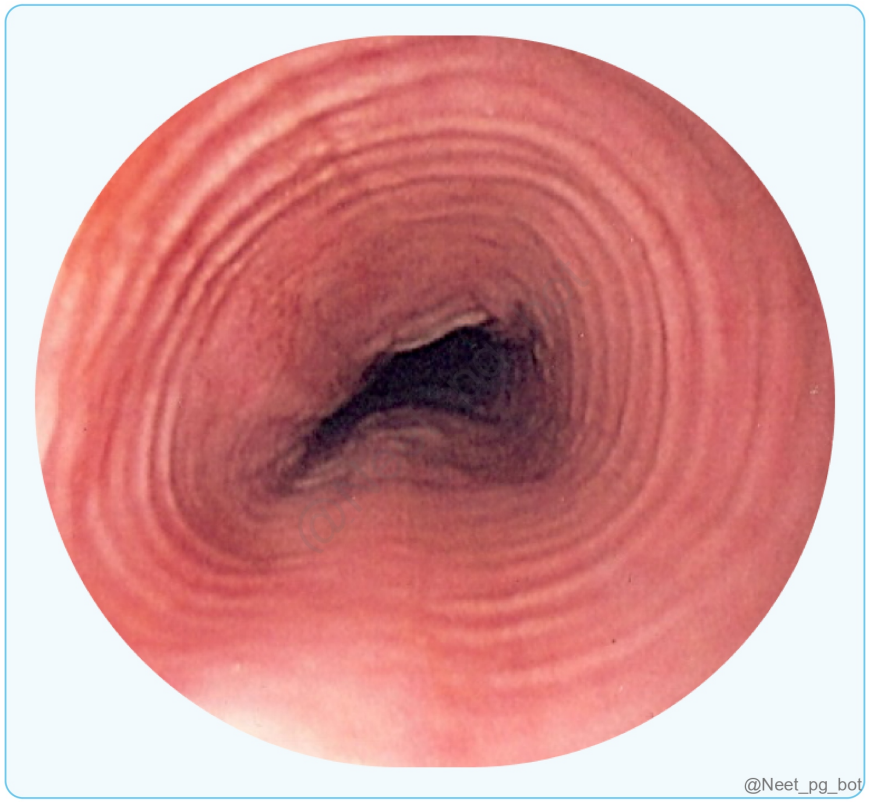
Q7: Match the following conditions with its endoscopy images A) Esophageal candidiasis 1) B) Feline esophagitis 2) C)Herpes simplex esophagitis 3) D)CMV esophagitis 4) (Q849135)



A. A-2, B-4, C-1, D-3



B. A-3, B-4, C-1, D-2



C. A-4, B-3, C-2, D-1

D. A-1, B-4, C-2, D-3

@Neet_pg_bot

@Neet_pg_bot

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is true regarding the esophagus? (Q849108)

A. The upper esophageal sphincter is composed of the thyropharyngeus and cricopharyngeus muscles

B. The lower esophageal sphincter is a physiological entity

C. The cervical esophagus is supplied by the inferior thyroid artery

D. All are true

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 60-year-old male patient complains of intermittent dysphagia and episodes of food obstruction. Endoscopy reveals a fibrous band at the gastroesophageal junction.

Which of the following is the most likely diagnosis? (Q849133)

A. Esophageal Web

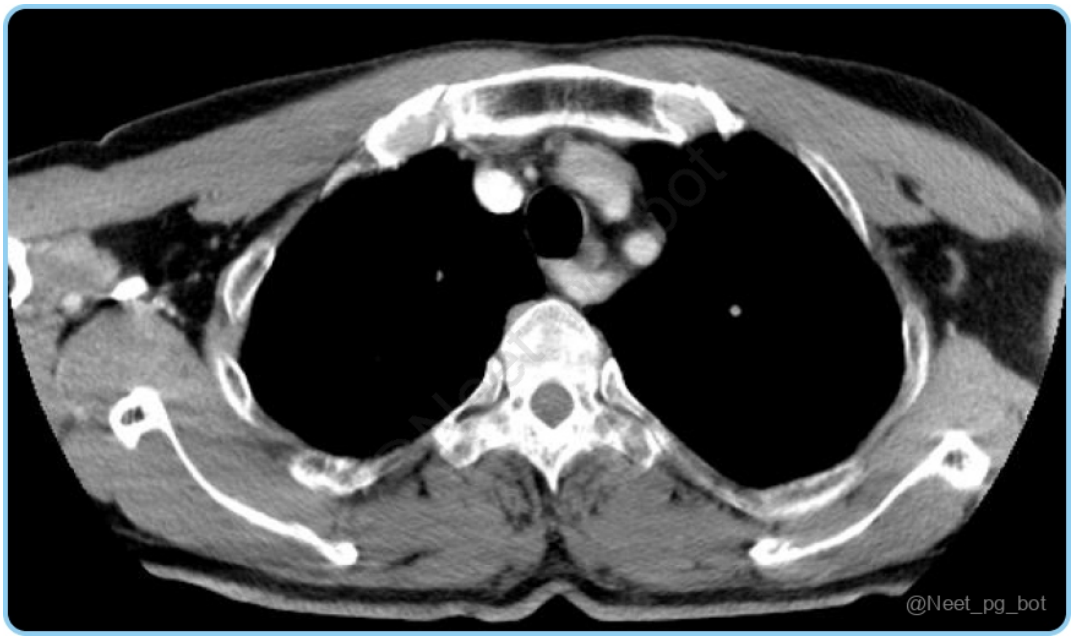
B. Zenker's Diverticulum

C. Barrett's Esophagus

D. Schatzki Ring

See Answer in Part B → Q9

@Neet_pg_bot



Q10: A 60-year-old patient presents with late-onset difficulty swallowing and significant weight loss. Imaging reveals an aberrant right subclavian artery compressing the esophagus. What is the most likely diagnosis? (Q849132)

A. Achalasia

B. Esophageal Cancer

C. Dysphagia Lusoria

D. Schatzki's Ring

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 45-year-old man undergoes an endoscopy for evaluation of dysphagia and an incidental mass is discovered in the esophagus. An endoscopic ultrasound (EUS) shows a hypoechoic mass originating from the muscularis propria. Which of the following statements regarding the esophageal lesion is most accurate? (Q849130)

A. Immediate biopsy and fine-needle aspiration (FNA) should be performed to confirm the diagnosis.

B. If the lesion is asymptomatic and small, it can be observed without biopsy.

C. The preferred treatment for small, symptomatic lesions is chemotherapy.

D. Large lesions (>5 cm) are best managed with radiofrequency ablation (RFA)

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 62-year-old male presents with progressive dysphagia and weight loss over the past 3 months. An endoscopy reveals a tumor in the lower third of the esophagus. Biopsy confirms adenocarcinoma. Further investigation reveals, the tumor has invaded the muscularis propria but no distant metastasis is detected. Which treatment option is most appropriate for this patient? (Q849129)

A. Endoscopic Mucosal Resection (EMR)

B. Endoscopic Submucosal Dissection (ESD)

C. Esophagectomy

D. Radiofrequency Ablation (RFA)

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 55-year-old male with a history of smoking and heavy alcohol consumption presents with progressive dysphagia and significant weight loss. Endoscopy reveals an

ulcerated lesion in the mid-esophagus, and biopsies confirm squamous cell carcinoma. What is the most appropriate initial diagnostic step to assess the extent of the disease? (Q849127)

A. Chromoendoscopy

B. Barium contrast study

C. Endoscopic Ultrasound (EUS)

D. FDG-PET scan

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 60-year-old man with chronic GERD undergoes endoscopy, which shows a 3 cm segment of salmon-colored mucosa above the gastroesophageal junction. Biopsy confirms intestinal metaplasia without dysplasia, and no nodularity or ulceration is seen.What is the most appropriate next step in management? (Q849126)

A. Annual surveillance endoscopy

B. Immediate endoscopic mucosal resection (EMR)

C. High-dose proton pump inhibitor (PPI) therapy and aspirin

D. Endoscopic ablation with radiofrequency ablation (RFA)

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 55-year-old man presents with intermittent chest pain and difficulty swallowing for the past few months. The chest pain is often severe and mimics angina but is not related to exertion. His symptoms often occur at night. Barium swallow reveals a typical finding given below. Which of the following disorders is most likely responsible for these findings? (Q849124)

A. Achalasia cardia

B. Gastroesophageal reflux disease (GERD)

C. Esophageal stricture

D. Diffuse esophageal spasm

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following is considered a minimally invasive procedure for treating achalasia cardia? (Q849119)

A. Laparoscopic Heller's Cardiomyotomy

B. Partial Fundoplication

C. Per-Oral Endoscopic Myotomy (POEM)

D. Esophagectomy

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 42-year-old man presents with progressive dysphagia for liquids more than solids for over six months, regurgitation of undigested food, nocturnal cough, and unintentional weight loss. The bird beak sign is seen on a barium swallow. Which investigation is the gold standard for diagnosing his condition? (Q849118)

A. Upper gastrointestinal endoscopy

B. High-resolution manometry

C. Barium swallow study

D. Chest X-ray

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following statements is true about the Zenker's diverticulum? (Q849116)

A. An enlarged diverticulum always results in desynchronization.

B. Halitosis is a symptom of an enlarged diverticulum.

C. Protrudes posteriorly below the cricopharyngeal sphincter.

D. Absence of a suture line increases the chance of a postoperative leak.

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 55-year-old woman with persistent GERD symptoms despite optimal medical therapy is considered for surgery. What is the most appropriate surgical procedure for her condition? (Q849115)

A. Nissen fundoplication

B. Fontan procedure

C. Hartmann procedure

D. Heineke–Mikulicz pyloroplasty

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which hormone is known to decrease LES pressure? (Q849114)

A. Gastrin

B. Cholecystokinin

C. Progesterone

D. Motilin

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 55-year-old man presented with difficulty swallowing and chest discomfort after meals, which improved after forceful belching. On physical examination, he appeared pale. Chest X-ray revealed a gas-filled structure within the thoracic cavity. Which of the following is the most likely diagnosis? (Q849113)

A. Peptic ulcer disease

B. Hiatus hernia

C. Esophageal cancer

D. Gastritis

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A newborn male presents with severe respiratory distress and a scaphoid abdomen. Chest X-ray reveals bowel loops in the left thoracic cavity. Immediate surgical intervention is planned to repair the diaphragmatic defect. Which of the following is the most likely diagnosis? (Q849112)

A. Bochdalek hernia

B. Morgagni hernia

C. Rolling hiatus hernia

D. Sliding hiatus hernia

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A newborn male, 1 day old, presents with persistent regurgitation of feeds and continuous drooling of saliva from the mouth. The baby exhibits frequent coughing and cyanosis, prompting an investigation that reveals a tracheoesophageal fistula. Which type is the most likely to be seen? (Q849111)

A. Type A

B. Type B

C. Type C

D. Type E

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 35-year-old man ingests a household cleaner and sustains a corrosive injury to esophagus. Which of the following is false in this case? (Q849110)

A. Neutralization with vinegar/citrus for alkali; antacids/milk/egg whites for acid

B. Early endoscopy is not preferred

C. Avoid emetics and sodium bicarbonate to prevent perforation

D. All are false

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 5-year-old boy swallowed a disk battery and an x-ray revealed that it was lodged in the esophagus. What is the next step in the management of this patient? (Q849109)

A. Observe

B. Immediate endoscopic removal

C. Endoscopic removal after 1 day of observation

D. Endoscopic removal after 2 days of observation

See Answer in Part B → Q25

Q1: A 58-year-old woman visits her primary care physician complaining of persistent upper abdominal pain that worsens after meals. She also reports experiencing nausea and occasional vomiting. After a thorough clinical evaluation, the physician suspects a gastric ulcer. What investigation should be done multiple times as a must in case of a gastric ulcer? (Q849029)

A. Endoscopy

B. Endoscopy with biopsy

C. Assessment for H pylori

D. Ultrasonography

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A patient with suspected gastric carcinoma undergoes an upper GI endoscopy. A large, malignant-appearing ulcer is noted. While there is a central crater, the endoscopist notes that its margins are ill-defined and blend into the surrounding gastric wall, causing localized rigidity. These findings are most characteristic of which Borrmann classification type? (Q849092)

A. Type I

B. Type II

C. Type III

D. Type IV

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A male patient comes to the clinic due to abdominal pain. He is a chronic smoker and has never been consistent with a healthy diet. An endoscopy and biopsy of the lesion in his stomach confirm gastric cancer. Which of the following statements regarding risk factors of gastric carcinoma is false? (Q849091)

A. High-salt foods like salted or smoked meat increase the risk of gastric carcinoma

B. H-pylori is the most common infectious cause of gastric carcinoma

C. Adenomatous polyps carry a risk of turning cancerous

D. Proton pump inhibitors have a protective effect against gastric cancer

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 50-year-old male comes to the OPD for a follow-up of peptic ulcer disease. He has had an upper gastrointestinal bleed in the recent past and was endoscopically and medically managed. A repeat endoscopy is done to assess his risk of rebleed and a flat pigmented spot is viewed in the duodenum. According to the Forrest classification system, what is the classification of the ulcer and risk of rebleed observed here? (Q849090)

A. IA, high risk

B. IIB, high risk

C. III, low risk

D. IIC, low risk

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 40-year-old patient is brought to the emergency department with melena and dizziness. Her BP is 100/ 80 mmHg, and her pulse rate is 100 bpm. Her lab investigations reveal Hb of 8 gm/dL and a blood urea nitrogen (BUN) of 25 mg/dL. Based on the Blatchford score, which of the following findings would most significantly increase her risk stratification score? a. Systolic blood pressure less than 100 mm of Hg b. High blood urea nitrogen level (> 25) c. Diagnosis of Mallory Weiss syndrome d. Heart rate more than 100 bpm (Q849089)

A. a and b only

B. a, b and c

C. a, c and d

D. a, b and d

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 60-year-old patient presents with sudden, massive hematemesis. An upper endoscopy identifies a small mucosal defect surrounded by normal gastric mucosa. Angiography reveals a large, tortuous artery in the left gastric artery distribution. What is the underlying pathophysiological mechanism of bleeding in Dieulafoy's lesion? (Q849088)

A. Erosion of the mucosa due to excessive acid secretion

B. Rupture of varices caused by portal hypertension

C. Erosion of mucosa due to pulsations from a large submucosal artery

D. Ulceration of the gastric mucosa due to chronic use of NSAIDs

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 62-year-old female with a history of liver cirrhosis presents with symptoms of chronic gastrointestinal bleeding, including anaemia and fatigue. Upper endoscopy is shown below. Which of the following is the most appropriate initial treatment for this condition? (Q849087)

A. Radiofrequency ablation

B. Hormonal therapy

C. Argon plasma coagulation

D. Reducing portal pressure

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 56-year-old man arrives in the emergency department with severe upper gastrointestinal bleeding. On examination, he is pale, hypotensive, and has a rapid pulse. Which of the following is the initial priority in managing this patient?

(Q849093)

A. Immediate endoscopy to identify the bleeding source

B. Assessment of airway, breathing, and circulation (ABCs) with intravenous access establishment

C. Administration of terlipressin for suspected variceal bleeding

D. Blood transfusion to raise hemoglobin above 10 g/dL

See Answer in Part B → Q8

@Neet_pg_bot

Q9: In patients with AIDS, which of the following organisms is a recognised cause of gastritis? (Q890664)

A. Histoplasmosis

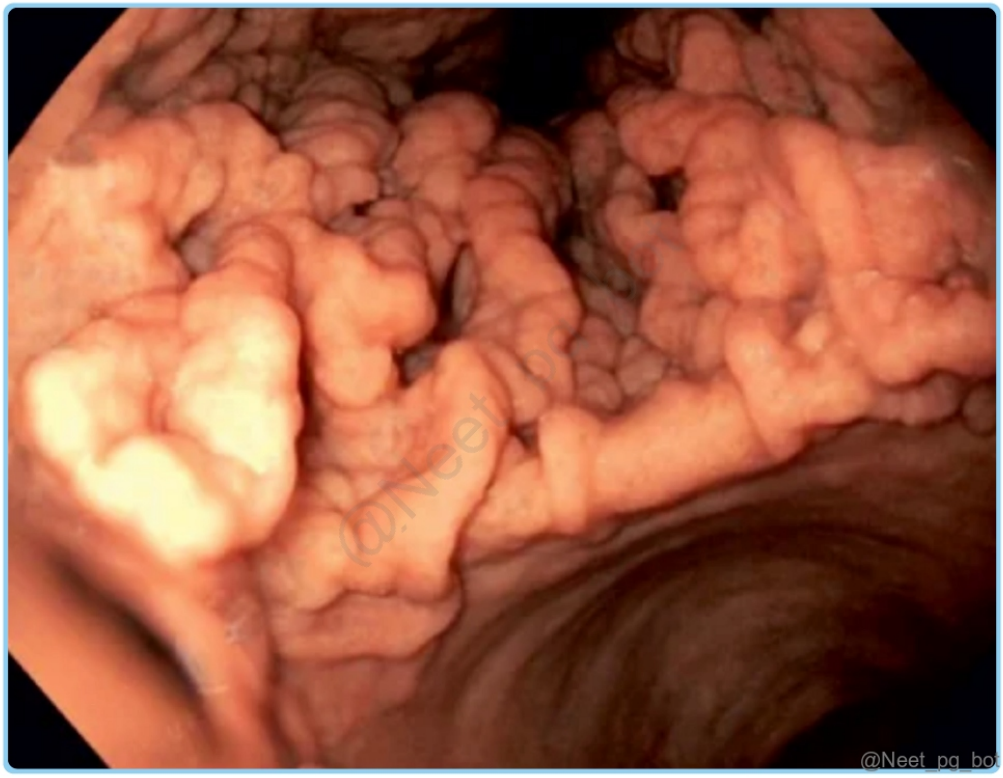
B. Cryptosporidiosis

C. Cytomegalovirus

D. Isospora belli

See Answer in Part B → Q9

@Neet_pg_bot



Q10: A 48-year-old man presents with progressive weight loss, early satiety, and bilateral pedal edema. Laboratory evaluation reveals hypoalbuminemia with normal liver function tests. Upper GI endoscopy shows the following appearance . Biopsy reveals foveolar hyperplasia with reduced parietal cells. Which of the following is the most likely underlying mechanism? (Q890677)

A. Autoimmune destruction of parietal cells leading to intrinsic factor deficiency

B. Overexpression of transforming growth factor-α causing mucous cell proliferation and reduced acid secretion

C. Increased gastrin secretion causing parietal cell hyperplasia and hyperchlorhydria

D. Chronic Helicobacter pylori infection causing antral-predominant inflammation

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 26-year-old male presents with persistent dyspepsia despite a 1-month course of PPIs. A urea breath test is positive. What is the most likely diagnosis? (Q890663)

A. Type A gastritis

B. Type B gastritis

C. Reflux gastritis

D. Erosive gastritis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: In hypovolemic shock, which part of the gastrointestinal tract is most vulnerable to ischemia due to poor collateral blood supply? (Q890660)

A. Griffith’s point

B. Sudeck’s point

C. Terminal ileum

D. Stomach

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A patient with severe burn injuries develops an upper gastrointestinal bleed. Endoscopy reveals multiple acute ulcers predominantly involving which part of the stomach? (Q890666)

A. Fundus and body

B. Antrum

C. Lesser curvature

D. Pyloric canal

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following surgical procedures is specifically indicated for a Type IV proximal gastric ulcer? (Q890668)

A. Maki’s pylorus-preserving gastrectomy

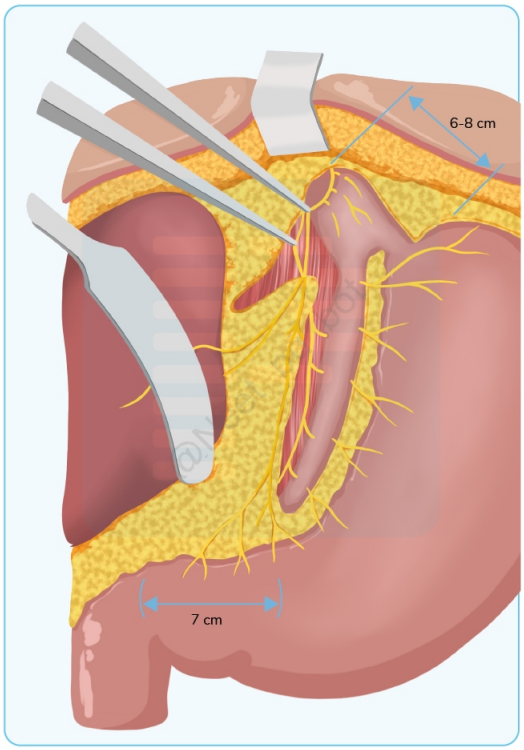
B. De Miguel’s antrectomy

C. Kelling-Madlener procedure

D. Highly selective vagotomy with ulcer excision

See Answer in Part B → Q14

@Neet_pg_bot



Q15: Which of the following statements is incorrect regarding the image shown below? (Q890670)

A. Ulcer recurrence rate is highest

B. Acid reduction is maximum

C. Nerve of Latarjet is spared

D. Postoperative complications are minimal

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 40-year-old man presents with sudden onset severe abdominal pain. On examination, he is tachycardic, hypotensive, and has board-like abdominal rigidity.

An erect chest X-ray reveals the following finding. What is the most appropriate immediate management? Ultrasound abdomen Intravenous fluid resuscitation Exploratory laparotomy Elective surgery Conservative management (Q890672)

A. 2, 3

B. 1, 4

C. 3, 4, 5

D. 1, 2, 5

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A patient develops sweating, tachycardia, colicky abdominal pain, and diarrhea within 30-40 minutes of meals following gastric surgery. Which of the following best explains the underlying mechanism? (Q890673)

A. Excess insulin secretion leading to hypoglycemia

B. Rapid entry of hyperosmolar chyme causing fluid shift into the intestinal lumen

C. Increased gastric acid secretion due to vagal overactivity

D. Delayed gastric emptying causing gastric distension

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following statements best describes organoaxial gastric volvulus? (Q890675)

A. Rotation occurs along the transverse (short) axis of the stomach

B. It is less common and usually not associated with diaphragmatic defects

C. It occurs along the longitudinal axis between the cardia and pylorus and is commonly associated with paraoesophageal hernia

D. It rarely requires surgical management

See Answer in Part B → Q18

@Neet_pg_bot

Q19: During a Billroth II procedure, the surgeon carefully dissects the pyloric region. Which of the following statements about this area's anatomy is most accurate? (Q849020)

A. The right gastric artery originates directly from the celiac trunk

B. The vagus nerve forms a single identifiable trunk in this region

C. Lymph nodes here drain exclusively into the pancreaticolienal group

D. The gastroduodenal artery passes posterior to the first part of the duodenum

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 45-year-old male with a history of chronic alcoholism presents to the emergency department after a night of intense vomiting following a drinking binge. He complains of severe upper abdominal pain and is found to have hematemesis. An urgent upper GI endoscopy is performed, revealing a mucosal laceration near the GE junction. Which of the following is not a management option for the above condition? (Q849086)

A. Multipolar electrocoagulation

B. Epinephrine injection

C. Endoscopic band ligation

D. Balloon tamponade

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following is NOT a cause of upper gastrointestinal bleeding? (Q849085)

A. Peptic Ulcer Disease

B. Esophageal Varices

C. Mallory-Weiss Tear

D. Angiodysplasia

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A patient presents with early satiety, weight loss, nausea, and vomiting. An upper endoscopy reveals a narrowing of the pylorus due to inflammation and scarring from peptic ulcer disease. What is the most appropriate initial step in managing this patient's gastric outlet obstruction? (Q849084)

A. Surgical antrectomy with reconstruction and vagotomy

B. Endoscopic dilation with stent placement

C. Placement of a nasogastric tube and correction of fluid/electrolyte imbalances

D. Immediate initiation of H. pylori eradication therapy

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 65-year-old man presents with severe epigastric pain and black, tarry stools. He has a history of chronic gastritis and NSAID use for osteoarthritis. Upper GI endoscopy reveals a gastric ulcer and a biopsy is taken for histological analysis. According to the modified Johnson's criteria, what type of ulcer is most likely? (Q849028)

A. Type I

B. Type IV

C. Type III

D. Type V

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 60-year-old male with a long-standing history of duodenal ulcer on treatment with proton pump inhibitors presents to the clinic with sudden severe epigastric pain, rebound tenderness, and air under the diaphragm. Based on this history, what is the complication? (Q849027)

A. Perforated duodenal ulcer

B. Pyloric stenosis

C. Gastric outlet obstruction

D. Hourglass deformity of stomach

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 35-year-old man comes to the clinic with pain in the epigastrium and uneasiness for 2 months, which is temporarily relieved by antacids. He has a history of smoking and takes nonsteroidal anti-inflammatory drugs (NSAIDs) occasionally for back pain. An upper gastrointestinal endoscopy reveals a duodenal ulcer. What would be the best line of treatment in this case? (Q849026)

A. H. pylori eradication

B. Proton pump inhibitors

C. Antacids like aluminium hydroxide

D. Highly selective vagotomy

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 50-year-old woman with a history of gastric carcinoma comes to the OPD with abdominal pain, early satiety, diarrhoea, and bloating. On examination, she is tachycardic and has palpitations. She also complains of headaches. She has undergone partial gastrectomy and Billroth type II reconstruction. What is the diagnosis here? (Q849025)

A. Recurrence of gastric carcinoma

B. Dumping syndrome

C. Gastric ulcer, Type V

D. Irritable bowel syndrome

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 60-year-old male with a history of peptic ulcer disease underwent partial gastrectomy with Roux-en-Y reconstruction five years ago. He presents with symptoms of severe diarrhoea, foul breath, and significant weight loss over the past few months. Which of the following is the most likely complication he is experiencing? (Q849024)

A. Gastrocolic fistula

B. Postvagotomy diarrhoea

C. Bilious vomiting

D. Nutritional deficiency

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 62-year-old woman is diagnosed with a T3N1M0 gastric adenocarcinoma located in the proximal third of the stomach, extending to the gastroesophageal junction. Which of the following gastrectomy procedures is most appropriate for curative intent? (Q849023)

A. Distal gastrectomy

B. Proximal gastrectomy

C. Total gastrectomy

D. Sleeve gastrectomy

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 55-year-old man undergoes a distal gastrectomy for gastric cancer. The surgeon wants to restore gastrointestinal continuity with a method that minimizes bile reflux gastritis. Which of the following reconstruction techniques is most appropriate? (Q849022)

A. Billroth I

B. Billroth II

C. Roux-en-Y gastrojejunostomy

D. Jejunal interposition

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 45-year-old man with refractory peptic ulcer disease is being considered for surgical intervention. Which of the following procedures will most likely preserve the vagal innervation of the gastric antrum and pylorus while reducing acid secretion? (Q849021)

A. Truncal vagotomy

B. Selective vagotomy

C. Truncal vagotomy with antrectomy

D. Highly selective vagotomy

See Answer in Part B → Q30

Q1: A 58 year old man is diagnosed with an adenocarcinoma located 4 cm below the gastroesophageal junction. According to the Siewert classification system, what type of tumour does he have, and how should it be treated if it does not extend into the GE junction? (Q849095)

A. Type I; treated as esophageal adenocarcinoma

B. Type II; treated as gastric adenocarcinoma

C. Type III; treated as gastric adenocarcinoma

D. Type III; treated as esophageal adenocarcinoma

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 60 year old woman presents with fatigue, loss of appetite, and a palpable mass in the upper abdomen. Endoscopic examination and biopsy confirmed diffuse large B-cell lymphoma of the stomach. What is the most appropriate treatment regimen for this patient? (Q849122)

A. H. pylori eradication therapy

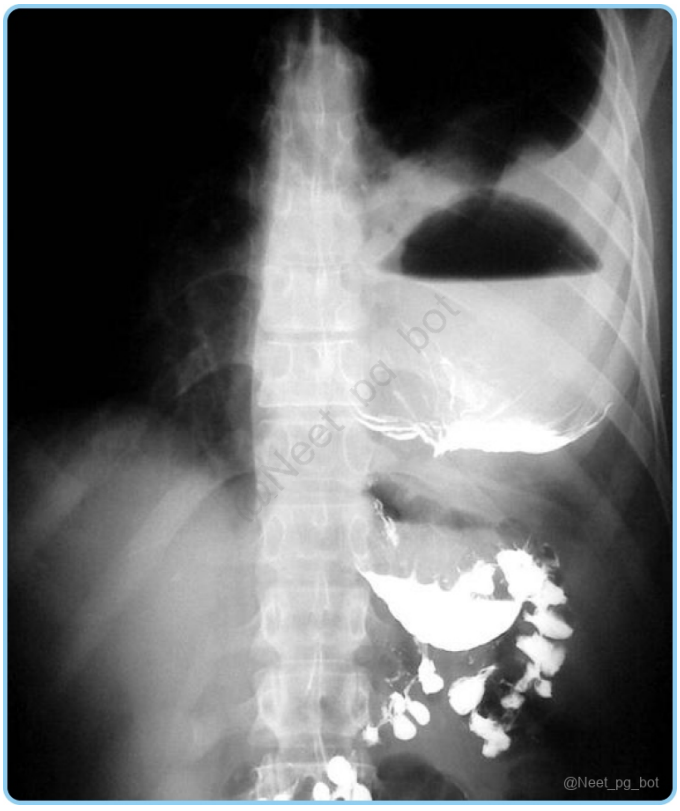
B. Radiation therapy alone

C. Chemotherapy with R-CHOP

D. Immunotherapy with checkpoint inhibitors

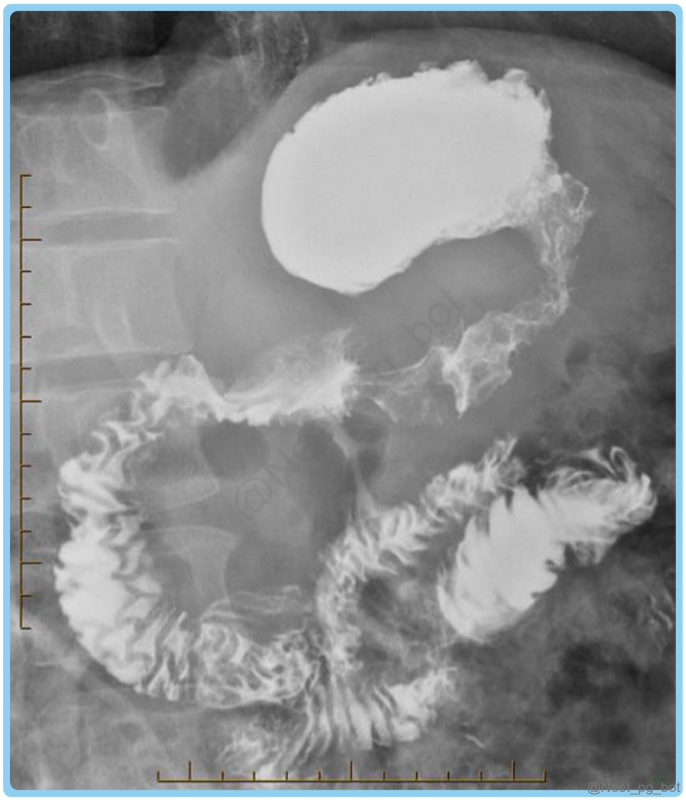
See Answer in Part B → Q2

@Neet_pg_bot



Q3: Match the following conditions with their corresponding X-ray findings: i) Teapot stomach a) ii) Hourglass stomach b) iii) Congenital Hypertrophic Pyloric Stenosis c) iv) Leather bottle stomach d) (Q849121)

A. i-a, ii-d, iii-c, iv-b



B. i-d, ii-a, iii-c, iv-b

C. i-d, ii-a, iii-b, iv-c

D. i-c, ii-b, iii-a, iv-d

@Neet_pg_bot

@Neet_pg_bot

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45 year old male presents with severe epigastric pain and inability to vomit despite repeated attempts. On examination, he has significant abdominal distention, and attempts to pass a nasogastric tube were unsuccessful. Which of the following best describes the condition represented by this clinical presentation? (Q849120)

A. Gastric cancer

B. Acute gastric volvulus

C. Peptic ulcer disease

D. Intestinal obstruction

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 17 year old girl with a history of depression presents with complaints of epigastric pain, early satiety, and vomiting of blood. She elicited a history of eating her hair due to stress. On examination, a palpable epigastric mass is noted. A CT scan of the abdomen reveals a large mass in the stomach. What is the most likely diagnosis? (Q849107)

A. Phytobezoar

B. Trichobezoar

C. Gastric carcinoma

D. Intestinal obstruction

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 2-week-old infant presents with vomiting, dehydration, and poor feeding. An abdominal X-ray shows a "double bubble" sign. Which of the following statements correctly differentiates Congenital Hypertrophic Pyloric Stenosis from Duodenal Atresia? (Q849106)

A. CHPS typically presents with bilious vomiting, while Duodenal Atresia presents with non-bilious vomiting.

B. In CHPS, infants are often hungry after vomiting, whereas in Duodenal Atresia, infants have no desire to feed.

C. Both conditions present with projectile vomiting, but CHPS is diagnosed by X-ray showing the "double bubble" sign.

D. Duodenal Atresia is commonly treated with Ramstedt's pyloromyotomy, whereas CHPS requires surgical correction of the duodenum.

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 3-week-old infant is diagnosed with Congenital Hypertrophic Pyloric Stenosis after presenting with projectile vomiting and signs of dehydration. The surgical team

plans to perform Ramstedt's pyloromyotomy. Which of the following statements about this condition and its management is true? (Q849105)

A. The incision during Ramstedt's pyloromyotomy should only involve the mucosal layer to avoid complications.

B. Infants with CHPS typically do not exhibit hunger after vomiting.

C. Postoperative intravenous fluids are administered until the infant can resume feeding, which usually occurs within 24 hours.

D. Persistent vomiting after surgery is primarily due to incomplete myotomy

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 3-week-old infant presents with persistent projectile non-bilious vomiting, dehydration, and weight loss. The physical examination reveals a palpable mass in the right upper quadrant. An abdominal ultrasound shows a thickened pylorus. Which of the following electrolyte imbalances is most likely to be seen in this patient? (Q849104)

A. Hyperkalemia

B. Hypernatremia

C. Hypokalemia

D. Hypocalcemia

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 65 year old male presents with complaints of persistent abdominal pain and weight loss. After evaluation, he is diagnosed with resectable gastric cancer. Based on the information provided, which of the following treatment options would likely offer the best median overall survival for this patient? (Q849103)

A. ECF (epirubicin, cisplatin, 5-fluorouracil) regimen

B. FLOT (fluorouracil, leucovorin, oxaliplatin, docetaxel) regimen

C. Palliative chemotherapy

D. Total gastrectomy without prior chemotherapy

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 55-year-old woman presents with abdominal pain and a palpable epigastric mass. CT shows a well-defined stomach mass. Biopsy confirms a gastrointestinal stromal tumor, with CD117 and DOG1 positivity. Which statement is most accurate about this patient? (Q849101)

A. CD117 positivity confirms the diagnosis of GIST, and DOG1 is not relevant

B. The primary treatment for GISTs is chemotherapy

C. Surgery is the mainstay of treatment for localized GISTs

D. GISTs most commonly occur in the small intestine and are rarely found in the stomach

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 52-year-old man presents with epigastric pain, weight loss, and early satiety for three months. On examination, mild epigastric tenderness is seen. Upper GI endoscopy reveals an ulcerated mass in the stomach antrum, confirmed as adenocarcinoma. Staging shows no distant metastases but involves perigastric lymph nodes. What is the next step in management? (Q849100)

A. Neoadjuvant chemotherapy followed by total gastrectomy

B. Subtotal gastrectomy with D1 lymph node dissection

C. Subtotal gastrectomy with D2 lymph node dissection

D. Palliative chemotherapy

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 55 year old patient is diagnosed with gastric cancer and is preparing for surgical treatment. The surgical team is reviewing the guidelines for lymph node resection to ensure optimal patient outcomes. According to current recommendations, what is the minimum number of lymph nodes that should be removed and examined during the surgery for gastric cancer? (Q849099)

A. 4 lymph nodes

B. 12 lymph nodes

C. 16 lymph nodes

D. 20 lymph nodes

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 62 year old male undergoes an endoscopic biopsy for a gastric mass. The pathology report reveals that the tumour invades the muscularis propria but does not extend into the subserosal connective tissue. What is the appropriate T classification for this tumour? (Q849098)

A. T1b

B. T2

C. T3

D. T4a

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 55 year old female presents with a palpable nodule in her umbilicus. She also has a history of weight loss and abdominal discomfort. Imaging reveals metastatic

spread of gastric cancer. Which of the following is the term for this clinical finding, and what is its typical route of spread? (Q849097)

A. Krukenberg tumor; hematogenous spread

B. Blumer shelf; transperitoneal spread

C. Sister Mary Joseph's nodule; transperitoneal spread

D. Virchow's node; retrograde lymphatic spread

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 28 year old man presents with recurrent abdominal pain and gastrointestinal bleeding. Imaging studies reveal the presence of multiple gastrointestinal stromal tumors (GISTs) in his stomach. His medical history includes a diagnosis of paragangliomas, and his mother has a history of lung tumors. What is the most likely genetic syndrome associated with this patient's findings? (Q849102)

A. Neurofibromatosis type 1

B. Carney’s Triad

C. Familial adenomatous polyposis

D. Peutz-Jeghers syndrome

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 65 year old male presents with vague epigastric discomfort and constant, non-radiating pain that is not related to food intake. He has a history of iron deficiency anaemia. Considering the regional differences in the prevalence of stomach cancer sites, what is the most likely location of his cancer if he resides in the West? (Q849094)

A. Distal stomach

B. Proximal stomach

C. Antrum of the stomach

D. Body of the stomach

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A patient with advanced gastric adenocarcinoma is found to have HER2/neu overexpression. Which targeted therapy is the drug of choice in this setting? (Q888695)

A. Bevacizumab

B. Cetuximab

C. Trastuzumab

D. Pembrolizumab

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A patient with a high-risk gastric gastrointestinal stromal tumour (GIST) undergoes complete surgical resection. What is the most appropriate next step in management? (Q888694)

A. Adjuvant external beam radiotherapy

B. Adjuvant chemotherapy with 5-fluorouracil

C. Adjuvant therapy with imatinib

D. Routine surveillance only

See Answer in Part B → Q18

@Neet_pg_bot

Q19: What is the most common metabolic complication observed in patients after a gastrectomy? (Q888693)

A. Vitamin B12 deficiency

B. Osteoporosis

C. Iron deficiency anaemia

D. Calcium deficiency

See Answer in Part B → Q19

@Neet_pg_bot

Q20: For which of the following clinical scenarios is surgery most appropriately indicated in a patient with gastric lymphoma? (Q888692)

A. Intractable pain without other complications

B. Asymptomatic, incidentally discovered gastric wall thickening

C. First-line chemotherapy failure with persistent symptomatic disease

D. Mild H. pylori-positive gastritis without lymphoma progression

See Answer in Part B → Q20

@Neet_pg_bot

Q21: What is the most common histological subtype of primary gastric non-Hodgkin lymphoma? (Q888691)

A. Gastric MALT lymphoma

B. Burkitt lymphoma

C. Diffuse large B-cell lymphoma

D. Follicular lymphoma

See Answer in Part B → Q21

@Neet_pg_bot

Q22: During curative surgical resection for gastric adenocarcinoma, what is the recommended minimum proximal and distal gross negative margin from the tumour edge? (Q888690)

A. 1 cm

B. 2 cm

C. 5 cm

D. 10 cm

See Answer in Part B → Q22

@Neet_pg_bot

Q23: According to the Japanese Gastric Cancer Association (JGCA) classification, suprapyloric lymph nodes correspond to which nodal station? (Q888689)

A. Station 1

B. Station 3

C. Station 5

D. Station 7

See Answer in Part B → Q23

@Neet_pg_bot

Q24: According to standard criteria, which of the following is an absolute contraindication for endoscopic mucosal resection (EMR) in early gastric cancer? (Q888686)

A. Tumour size 1.5 cm

B. Well-differentiated histology

C. Presence of ulceration

D. Tumour confined to the mucosa

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Troisier's sign, characterised by enlargement of the left supraclavicular lymph node (Virchow's node), is most indicative of metastasis from which primary cancer site? (Q888662)

A. Breast

B. Lung

C. Stomach

D. Colon

See Answer in Part B → Q25

@Neet_pg_bot

Q26: According to the Japanese classification, early gastric cancer is defined by tumour invasion limited to which layers of the gastric wall? (Q888661)

A. Mucosa and submucosa only

B. Muscularis propria

C. Serosa

D. Adjacent organs

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A patient presents with gastric outlet obstruction caused by a diffusely infiltrating gastric carcinoma. This presentation is classic for which condition, and how is it classified in the Bormann system? (Q888657)

A. Linitis plastica; Type III (Ulcerating)

B. Linitis plastica; Type IV (Diffuse infiltrating)

C. Krukenberg tumour; Type II (Ulcerofungating)

D. Gastric adenoma; Type I (Polypoid)

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which molecular alteration is characteristic of the intestinal type of gastric adenocarcinoma according to Lauren's classification? (Q888652)

A. Mutation of E-cadherin

B. Loss of heterozygosity in the APC gene

C. Inactivation of p53 only

D. KRAS mutation

See Answer in Part B → Q28

@Neet_pg_bot

Q29: According to Lauren's classification, which type of gastric adenocarcinoma is primarily associated with hematogenous spread? (Q888650)

A. Type II (Diffuse type)

B. Mixed type

C. Type I (Intestinal type)

D. Indeterminate type

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A patient with Helicobacter pylori infection is found to have gastric polyps. Which type of gastric polyp is most commonly associated with H. pylori and typically regresses after eradication therapy? (Q888648)

A. Adenoma

B. Fundic gland polyp

C. Hyperplastic polyp

D. Hamartomatous polyp

See Answer in Part B → Q30

@Neet_pg_bot

Q31: Which of the following is the most common location of gastric adenocarcinoma in Asian populations, and why? (Q888645)

A. Proximal stomach, due to the high prevalence of GERD

B. Antrum, due to the higher prevalence of H. pylori infections

C. Cardia, due to obesity-related factors

D. Fundus, due to autoimmune gastritis

See Answer in Part B → Q31

@Neet_pg_bot

Q32: A 35 year old male presents with severe weight loss and loss of appetite. Endoscopic examination reveals a thickened, rigid stomach with a "mother of pearl" appearance. Biopsy shows poorly differentiated cells with signet ring cells. What is the most appropriate treatment for his condition? (Q849096)

A. Partial gastrectomy

B. Chemotherapy alone

C. Total gastrectomy with oesophagojejunal anastomosis

D. Proton pump inhibitors and antibiotics

See Answer in Part B → Q32

@Neet_pg_bot

Q1: A 35-year-old female presents with painless swelling in the umbilical region. On physical examination, the swelling is found to be soft, smooth, and freely mobile in a direction perpendicular to the line of the mesentery. Imaging studies confirm the presence of a mesenteric cyst. Which of the following is not a component of Tillaux's triad? (Q849228)

A. Soft, smooth swelling in the umbilical region

B. Freely mobile in a direction perpendicular to mesentery

C. Presence of tenderness

D. Zone of resonance all around

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 52-year-old woman presents with abdominal distension, colicky pain that worsens after meals, and a gradual decline in her overall health. On examination, she has multiple hernias and ascites that do not demonstrate shifting dullness. Imaging reveals a jelly-like substance throughout the peritoneal cavity and mesentery. What is the most likely diagnosis for this patient? (Q849229)

A. Ovarian cystic tumor

B. Pseudomyxoma peritonei

C. Ascitic fluid due to liver cirrhosis

D. Colorectal carcinoma

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A CT scan reveals periaortic soft tissue mass encasing both ureters. Regarding retroperitoneal fibrosis, which of the following statements is false? (Q849231)

A. Methysergide use is a recognized etiology in some cases.

B. Bilateral ureteric obstruction is best managed initially with bilateral nephrostomies.

C. Tamoxifen is contraindicated in the medical management of this condition.

D. Laparoscopic ureterolysis with omental wrapping is a surgical option for persistent cases.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old male with a history of liver cirrhosis and ascites presents to the emergency department with fever, abdominal pain, and tenderness. Paracentesis is performed, and the ascitic fluid analysis shows an elevated white blood cell count. Which of the following organisms is the most common cause of spontaneous bacterial peritonitis in patients with ascites along with its source of infection? (Q849176)

A. Escherichia coli, Extraperitoneal source

B. Staphylococcus, Extraperitoneal source

C. Escherichia coli, Intraperitoneal source

D. Streptococcus pneumonia, Intraperitoneal source

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following statements is false regarding spontaneous bacterial peritonitis (Q849178)

A. Translocation of bacteria from the gut causes SBP

B. Neutrophil count >250/mm is present in SBP

C. Cefotaxime is the first-line treatment for SBP

D. SBP is a polymicrobial infection of ascitic fluid

See Answer in Part B → Q5

@Neet_pg_bot

Q6: What is the most common anaerobe responsible for Secondary Bacterial Peritonitis? (Q849180)

A. E. coli

B. Bacteroides fragilis

C. Klebsiella

D. Clostridium difficile

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following statements about continuous ambulatory peritoneal dialysis are true? (Q849225)

A. The most common organism causing peritonitis in CAPD is Staphylococcus saprophyticus

B. Treatment involves intraperitoneal instillation of first-generation cephalosporin via catheter for treating CAPD peritonitis

C. Recurrent attacks of peritonitis in CAPD should not be considered hemodialysis

D. None of the above

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old woman presents with a 3-day history of worsening lower abdominal pain, fever, and diarrhea with mucus. She reports a feeling of pressure in her pelvis and says that even sitting is excruciating. Her medical history is significant for diverticulitis, which was treated conservatively 6 weeks ago. Tenderness to palpation in the lower abdomen, and a rectal examination are present. What is the most likely diagnosis? (Q849226)

A. Acute appendicitis

B. Diverticulitis flare-up

C. Pelvic inflammatory disease

D. Pelvic abscess

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following statements are true about mesenteric cyst? (Q849227)

A. Enterogenous cyst has an independent vascular supply

B. Walls of chylolymphatic cysts are thicker than enterogenous cysts

C. Treatment of chylolymphatic cyst is resection and anastomosis

D. Fluid in enterogenous cyst is produced by goblet cells of viscera

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A male presents with bilateral flank pain, lower extremity edema, and elevated serum creatinine. CT scan reveals a retroperitoneal mass encasing both ureters. Biopsy shows dense fibrocollagenous tissue with chronic inflammation. Which of the following is the most likely etiology of this patient's condition? (Q849230)

A. IgG4-related disease

B. Metastatic prostate cancer

C. Methysergide use

D. Erdheim-Chester disease

See Answer in Part B → Q10

@Neet_pg_bot

Q1: A 3-year-old child with short bowel syndrome presents with severe malabsorption. Which surgical procedure involves stapling a dilated bowel into V shapes on alternating sides, decreasing the width and increasing the bowel length to improve nutrient absorption? (Q849162)

A. Bianchi procedure

B. Whipple Procedure

C. Billroth I and II Procedures

D. STEP procedure

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 6-year-old child with a history of extensive small bowel resection due to necrotizing enterocolitis is diagnosed with short bowel syndrome. Which among the following surgical procedures can help increase the bowel length and potentially reduce the dependency on parenteral nutrition? (Q849161)

A. Bianchi procedure

B. Whipple Procedure

C. Billroth I and II Procedures

D. Ileostomy

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old male presents with severe malnutrition and liver dysfunction even after subclavian parenteral nutrition for extensive small bowel resection. Which of the following is the most definitive treatment for his condition? (Q849160)

A. Jugular Parenteral Nutrition (TPN)

B. Small bowel transplantation

C. Serial transverse enteroplasty

D. Ileostomy

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 52-year-old male patient who underwent extensive resection of the small intestine for Crohn's disease presents with persistent diarrhea and worsening malnutrition. Despite following a strict dietary regimen, he is unable to maintain adequate nutritional status or fluid balance without intravenous support. What is the most appropriate management strategy for this patient? (Q849159)

A. Oral rehydration therapy

B. Enteral nutrition

C. Parenteral nutrition

D. Antidiarrheal medications

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 60-year-old woman with a history of extensive small bowel resection presents with persistent diarrhea, significant weight loss, and signs of malnutrition. She is unable to maintain adequate fluid and nutritional balance despite dietary modifications. what condition is she most likely experiencing? (Q849158)

A. Intestinal obstruction

B. Short bowel syndrome

C. Celiac disease

D. Crohn's disease

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 55-year-old patient with radiation enteritis undergoes bowel resection and develops short bowel syndrome. Which statement about bowel function is correct? (Q849157)

A. The jejunum compensates well for the loss of the ileum.

B. The ileum can compensate for a resected jejunum due to better absorption.

C. Short bowel syndrome is less severe with distal bowel loss.

D. The ileum's compensation is reduced due to looser junctions.

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 60-year-old man presents with complaints of fatigue, shortness of breath, and swelling in his legs. He has had a history of intermittent facial flushing and diarrhea for the past several years. Physical examination reveals a new heart murmur. Which of the following is the most likely diagnosis? (Q849155)

A. Aortic stenosis

B. Mitral regurgitation

C. Carcinoid heart disease

D. Pulmonary embolism

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following diagnostic steps is most appropriate to establish a definitive diagnosis of abdominal TB in this patient? (Q849150)

A. Serum-ascites albumin gradient (SAAG) measurement

B. Computed tomography (CT) with enterography protocol

C. Peritoneal fluid adenosine deaminase (ADA) level

D. Biopsy of the involved site with mycobacterial culture and nucleic acid amplification test (NAAT)

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 65-year-old male presents with sudden onset severe abdominal pain that started 30 minutes after his last meal. He is tachycardic and hypotensive and laboratory investigations reveal leukocytosis and elevated chromogranin A levels. A CT scan shows bowel wall enhancement and free fluid in the abdomen. Which of the following is the most preferred treatment? (Q849156)

A. Segmental resection + En-bloc lymphadenectomy

B. Chemotherapy regimen

C. Somatostatin analogue therapy

D. Total bowel resection

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 48-year-old woman presents with episodes of flushing, diarrhea, and abdominal pain over the past six months. She also reports intermittent wheezing and feels her symptoms worsen after consuming certain foods. On physical examination, she exhibits a rash on her face and neck. Imaging studies reveal a tumor in the ileum of the small intestine. What is the initial investigation of choice for localisation in this patient? (Q849154)

A. Contrast-enhanced CT abdomen

B. DOPA-PET

C. Urinary detention of 5-HIAA

D. Somatostatin receptor scintigraphy (SRS)

See Answer in Part B → Q10

@Neet_pg_bot

Q11: What is the most peculiar feature of gastric carcinoid tumor? (Q849153)

A. Abdominal pain

B. Abdominal distension

C. Bowel obstruction

D. Bright red patchy flushing of skin

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 55 y/o male presents with flushing, diarrhea, and recurrent episodes of bronchospasm. Imaging reveals multiple masses in the ileum. Laboratory tests show elevated serotonin levels. What is the most likely type of tumor responsible for his symptoms? (Q849152)

A. Foregut Carcinoid Tumor

B. Midgut Carcinoid Tumor

C. Hindgut Carcinoid Tumor

D. Non-Syndromic Neuroendocrine Tumor

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements is correct? (Q849151)

A. The most common small bowel tumor in adults is carcinoid tumor.

B. The most common small bowel tumor in children is a neuroendocrine tumor.

C. The most common primary malignant small bowel tumor is adenocarcinoma.

D. The most common small bowel tumor in adults is lymphoma.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 65 y/o male presents with chronic abdominal discomfort and bloating. Imaging shows multiple jejunal diverticula. The physician suspects these are due to increased intraluminal pressure. What is the most likely etiology of these diverticula? (Q849138)

A. Congenital origin due to incomplete recanalization of the duodenum

B. Acquired origin due to smooth muscle motor dysfunction

C. Remnant of the omphalomesenteric duct

D. Protrusion of the entire intestinal wall layers

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 28-year-old patient with gastrointestinal tuberculosis presents with abdominal pain and intermittent diarrhea. Imaging studies reveal a long, narrow filling defect in the terminal ileum. What is the most likely diagnosis based on these findings? (Q849149)

A. Ulcerative tuberculosis with subacute obstruction and perforation

B. Crohn’s disease with a narrowed segment and proximal distension

C. Hyperplastic tuberculosis with a filling defect in the terminal ileum and lymphadenopathy

D. Appendicitis with mass in the right iliac fossa

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A patient with pulmonary tuberculosis is diagnosed with ulcers in the terminal ileum. Which form of gastrointestinal tuberculosis is characterized by this presentation? (Q849148)

A. Hyperplastic tuberculosis with intestinal wall thickening.

B. Ulcerative tuberculosis with transverse ulcers and serosal thickening.

C. Crohn’s disease with abscesses and fistulas.

D. Hyperplastic tuberculosis with abscesses and fistulas.

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 35-year-old male presents with symptoms of abdominal pain and weight loss. He has a history of pulmonary tuberculosis. On examination, his abdomen is tender in the right iliac fossa. A barium follow-through study reveals a long, narrow filling defect in the terminal ileum. Which of the following is the most likely diagnosis? (Q849147)

A. Crohn's disease

B. Hyperplastic tuberculosis

C. Appendicitis

D. Carcinoma of the ileum

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 25-year-old female with a history of weight loss presents with intermittent abdominal pain, nausea, and vomiting. Imaging shows compression of the third portion of the duodenum between the aorta and the superior mesenteric artery. Conservative dietary management has failed. What is the next best step in management? (Q849146)

A. Laparoscopic duodenojejunostomy

B. Open duodenal bypass surgery

C. Continued conservative management

D. Open duodenojejunostomy

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 30 y/o male with a history of rapid weight loss presents with severe postprandial abdominal pain and vomiting. The physician suspects Superior Mesenteric Artery (SMA) syndrome. Which imaging technique is most suitable for visualizing the compression of the duodenum by the SMA and accurately measuring the aortomesenteric angle? (Q849145)

A. Endoscopy

B. Computed Tomography (CT) Scan

C. Barium X-ray Study

D. Abdominal Ultrasound

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following is NOT TRUE regarding superior mesenteric artery syndrome? (Q849144)

A. Early satiety and postprandial epigastric pain are present.

B. The knee to the chest or left lateral decubitus position alleviates symptoms.

C. Presentation is always acute, needing emergency intervention.

D. All of the above.

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which part of the duodenum is compressed in superior mesenteric artery syndrome? (Q849143)

A. First

B. Second

C. Third

D. Fourth

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 6-year-old boy is diagnosed with symptomatic Meckel's diverticulum after presenting with painless rectal bleeding. The diverticulum is found to be inflamed and with ulcers in the base. Which of the following surgical procedures is most appropriate for this patient? (Q849142)

A. Amputation at base and invagination.

B. Resection of small bowel with diverticulum.

C. Ileostomy.

D. Diverticulectomy.

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 7-year-old boy presents with intermittent episodes of blood in his stools without pain. On examination, there are no signs of acute abdomen. Blood investigations reveal he is anemic. Which is the investigation of choice in this case for Meckel's diverticulum? (Q849141)

A. USG abdomen

B. Colonoscopy

C. Tc-pertechnetate scan

D. CT abdomen

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 2-year-old boy presents with painless rectal bleeding. CT scans show a diverticulum 2 inches long located around 2 feet proximal to the ileocaecal valve. A Technetium-99m pertechnetate scan shows an area of increased uptake in the right lower quadrant. What is the most likely type of ectopic mucosal tissue found in the diverticulum that can explain these findings? (Q849140)

A. Gastric

B. Pancreatic

C. Colonic

D. Jejunal

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following characteristics is true regarding Meckel's diverticulum? (Q849139)

A. Located approximately 30 cm from the ileocecal valve.

B. Always lined with ectopic pancreatic tissue

C. Arises from the mesenteric border of the ileum.

D. Contains all the layers of the bowel wall.

See Answer in Part B → Q25

@Neet_pg_bot

Q1: Which of the following statements regarding intraoperative findings for treatment of large bowel obstruction is incorrect? (Q849076)

A. A distended caecum during laparotomy indicates a large bowel obstruction.

B. Emergency caecostomy can be done to stabilize the patient.

C. A collapsed caecum during laparotomy suggests a large bowel obstruction.

D. Resection and anastomosis are appropriate treatments for Crohn's disease

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 45-year-old patient with a history of previous abdominal surgeries presents with severe abdominal pain that initially started as crampy but has become constant and steady. The patient has a temperature of 102 degrees, 128 beats per minute heart rate, and elevated white blood cell count. Which diagnostic test is most appropriate for confirming in this patient? (Q849077)

A. Abdominal X-ray

B. CECT

C. USG abdomen

D. MRI abdomen

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 55-year-old female patient presents with a history of abdominal surgery performed 3 days ago. She reports worsening abdominal distension and has not passed stool since the surgery. On examination her abdomen is distended, and bowel sounds are absent. Which of the following statements is correct regarding this condition? (Q849078)

A. Caused by increased peristaltic activity.

B. Surgery is the first-line treatment.

C. X-ray shows dilated bowel loops and air-fluid levels

D. Associated with hyperkalemia.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 4-year-old boy is brought with intermittent episodes of severe abdominal pain, during which he pulls his knees to his chest and cries inconsolably. He passed a small amount of "red, jelly-like" stool. On examination, the child appears pale, lethargic, and mildly dehydrated. What is the most likely abdominal CT finding seen in this condition? (Q849079)

A. Target sign

B. Claw sign

C. Coiled spring sign

D. Coffee bean sign

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 75-year-old male patient, bedridden after hip surgery, presents with a 4-day history of progressive abdominal distension, nausea, and constipation. On physical examination, his abdomen is distended but non-tender, with decreased bowel sounds.

An abdominal X-ray shows dilated loops of colon, particularly in the cecum, but no air-fluid levels or evidence of mechanical obstruction. His vital signs are stable, and there is no fever. Which of the following drugs is commonly used in pharmacologic treatment of this condition? (Q849080)

A. Loperamide

B. Neostigmine

C. Stimulant laxatives

D. Osmotic laxatives

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 72-year-old male presents with a 2-day history of progressive abdominal distension, constipation, and colicky pain. He has a history of chronic constipation and has been bedridden for the past few months due to a hip fracture. On examination, his abdomen is distended and tympanic, with mild tenderness. Abdominal guarding and rigidity not observed. X-ray of the abdomen is shown below. Which of the following factors does not predispose to this condition? (Q849081)

A. Chronic constipation with laxative abuse

B. Anticholinergic drugs

C. Mentally-retarded individuals

D. Short pelvic mesocolon

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following options is not true regarding caecal volvulus? (Q849082)

A. Rotation is more commonly seen in clockwise direction

B. Caecal volvulus involves the terminal ileum and the right colon

C. In caecal bascule, there is axial twisting

D. Clinically, it may manifest as small bowel obstruction

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is/are components of Hartmann’s procedure? (Q849083)

A. Sigmoidectomy

B. Closure of rectal stump

C. Descending colostomy

D. All of the above

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old man with a history of abdominal surgery presents with severe crampy abdominal pain and bilious vomiting. On examination, his abdomen is distended, and he has not had a bowel movement for three days. Which of the following is the most likely cause of his obstruction? (Q849073)

A. Pelvic Adhesions

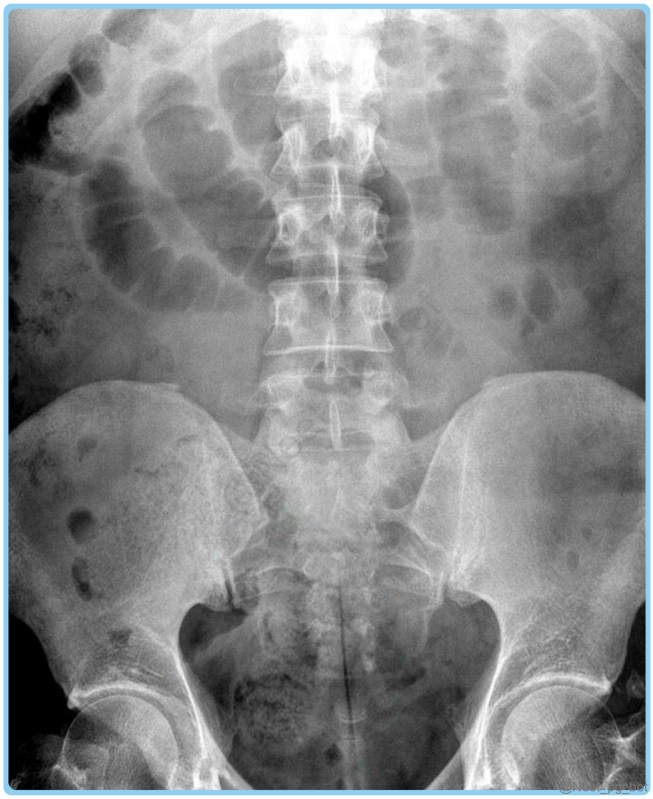
B. Colorectal Cancer

C. Inguinal Hernia

D. Crohn's Disease

See Answer in Part B → Q9

@Neet_pg_bot



Q10: A 50-year-old man presents with acute abdominal pain, and bilious vomiting. Physical examination reveals a distended abdomen, and he has not had a bowel movement for three days. An abdominal X-ray is shown below. What is the most appropriate next step in management ? (Q849074)

A. Administer oral laxatives

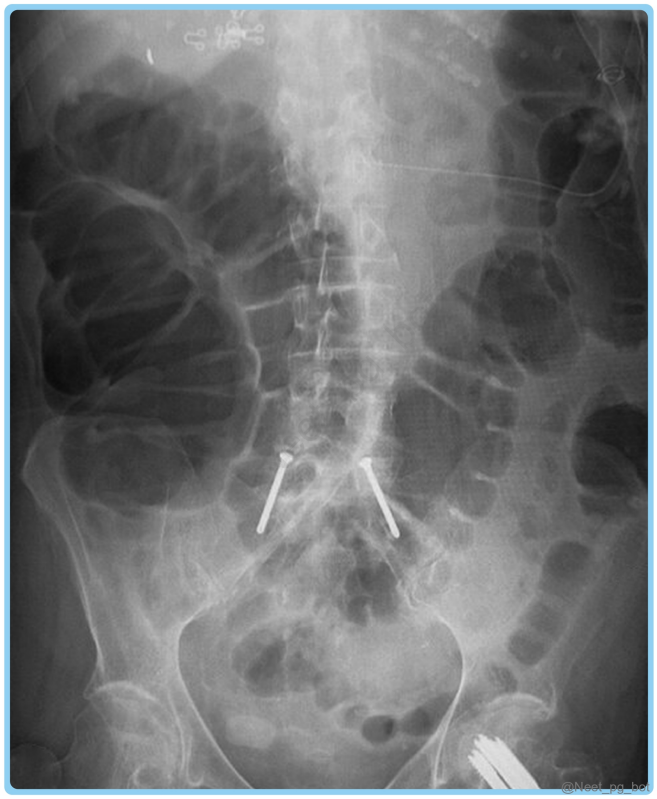
B. Start IV fluids (RL)

C. Exploratory laparotomy

D. IV Prokinetics

See Answer in Part B → Q10

@Neet_pg_bot



Q11: Based on the findings visible in the X-ray, all of the following are true, except: (Q849075)

A. Haustral folds are irregularly spaced and do not span the full lumen

B. Dilated bowel loops are typically peripheral in location on a supine film

C. Haustral markings do not form complete mucosal rings across the bowel

D. Presence of centrally located featureless loops without haustra is typical of large bowel obstruction

See Answer in Part B → Q11

Q1: Which of the following statements about diverticulitis is incorrect? Diverticulitis often presents with abdominal pain localized to the lower left side. A barium enema is a preferred imaging method for diagnosing diverticulitis. Colostomy is often performed as a first-line treatment. Stage Ib of the Modified Hinchey Classification refers to a pericolic abscess. Complications of diverticulitis may include fistula formation, such as colovesical fistula. (Q849048)

A. 1 and 5

B. 2 and 4

C. 4 and 5

D. 2 and 3

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which variant of Familial Adenomatous Polyposis is associated with both colorectal cancer and brain tumors? (Q849052)

A. Classic FAP

B. Attenuated FAP

C. Gardner's Syndrome

D. Turcot Syndrome

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old woman presents with a history of recurrent colorectal cancer. Her family history reveals that her mother was diagnosed with endometrial cancer at age 50, and her aunt had ovarian cancer. Genetic testing is recommended. What is the most likely diagnosis? (Q849053)

A. Cowden Syndrome

B. Lynch Syndrome

C. Peutz-Jeghers Syndrome

D. MUTYH-Associated Polyposis (MAP)

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 35-year-old woman presents with multiple oral papillomas, facial trichilemmomas, and a history of thyroid nodules. She also reports that her mother had breast cancer at a young age. On examination, multiple small, wart-like growths on her hands is noted. What is the most likely diagnosis? (Q849054)

A. Neurofibromatosis

B. Cowden disease

C. Peutz-Jeghers syndrome

D. Gardner syndrome

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following endoscopic findings is considered the earliest and most characteristic lesion seen in Crohn's disease? (Q883976)

A. Cobblestoning mucosa

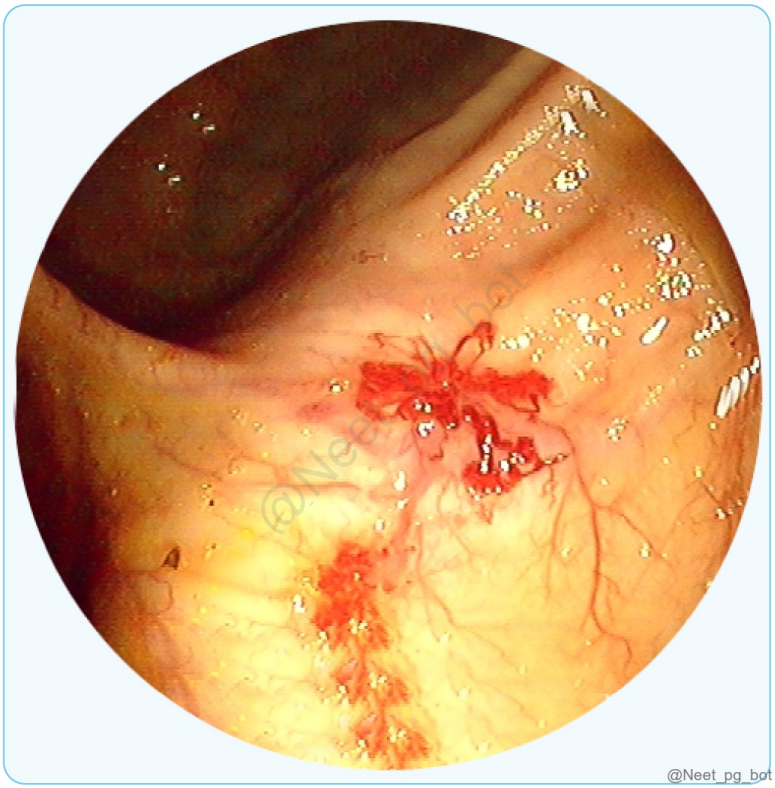
B. Deep serpiginous ulcers

C. Aphthous ulcers

D. Pseudopolyps

See Answer in Part B → Q5

@Neet_pg_bot



Q6: A 75-year-old patient presents with recurrent episodes of painless lower gastrointestinal bleeding. Colonoscopy is performed, and the image above is obtained. What is the most likely diagnosis? (Q883989)

A. Diverticular bleeding

B. Colonic carcinoma

C. Angiodysplasia

D. Ulcerative colitis

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which colonic region is most vulnerable to ischemic colitis due to its watershed vascular supply? (Q883988)

A. Cecum

B. Hepatic flexure

C. Rectum

D. Splenic flexure

See Answer in Part B → Q7

@Neet_pg_bot

Q8: The radiographic finding of "thumbprinting" on a plain abdominal X-ray is most indicative of which pathological process? (Q883987)

A. Intraluminal faecal impaction

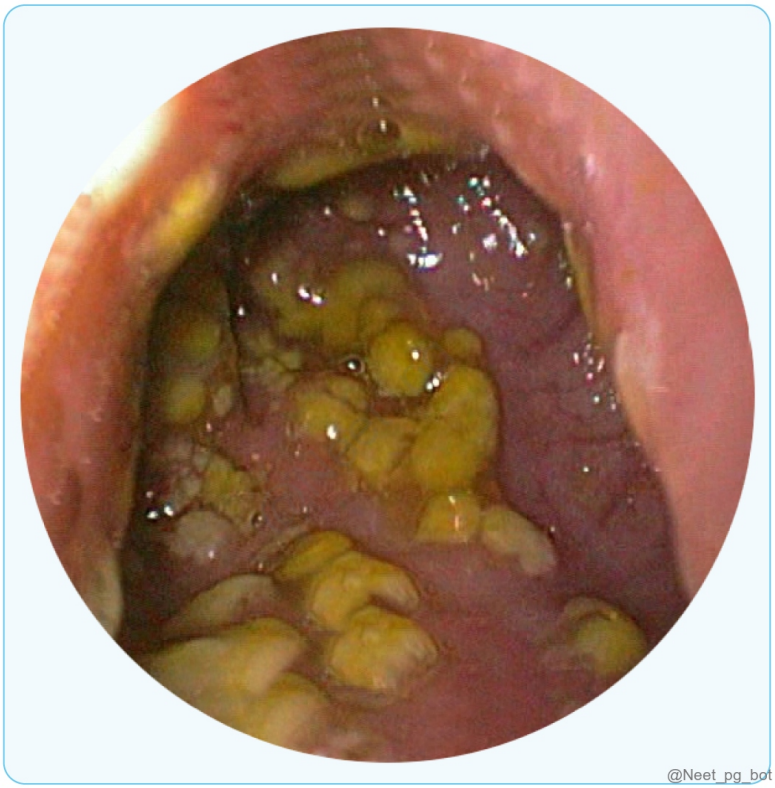
B. Colonic submucosal oedema or haemorrhage

C. Extrinsic compression by an abdominal mass

D. Pneumatosis intestinalis

See Answer in Part B → Q8

@Neet_pg_bot



Q9: A 64-year-old woman was recently treated for antibiotic-associated diarrhea and initially improved. Two weeks later, she returns with recurrent abdominal cramps and foul-smelling watery diarrhea. Stool toxin assay is positive for Clostridioides difficile. Sigmoidoscopy findings are shown above. What is the preferred antibiotic for management at this stage? (Q883986)

A. Oral metronidazole

B. Intravenous vancomycin

C. Oral fidaxomicin

D. Oral ciprofloxacin

See Answer in Part B → Q9

@Neet_pg_bot

Q10: In which patient population is a colovesical fistula due to diverticulitis most commonly seen? (Q883985)

A. Young women

B. Men and women equally

C. Women who have had a hysterectomy

D. Men

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A patient with multiple episodes of diverticulitis develops UTIs and says the urine sometimes contains air and particles resembling stool. What is the likely complication? (Q883984)

A. Emphysematous cystitis

B. Colovesical fistula

C. Pericolic abscess

D. Diverticular bleeding

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A patient presents with generalised peritonitis due to perforated sigmoid diverticulitis with faecal contamination. Which surgical procedure is most appropriate in this emergency setting? (Q883983)

A. Primary anastomosis without diversion

B. Loop ileostomy

C. Hartmann’s procedure

D. Total colectomy with ileorectal anastomosis

See Answer in Part B → Q12

@Neet_pg_bot

Q13: An elderly patient with multiple comorbidities presents with acute complicated diverticulitis and a pericolic abscess measuring 7 cm on CT scan. What is the most appropriate initial intervention? (Q883982)

A. Immediate surgical resection

B. CT-guided percutaneous drainage and intravenous antibiotics

C. Outpatient oral antibiotics and liquid diet

D. Colonoscopic drainage

See Answer in Part B → Q13

@Neet_pg_bot

Q14: According to the Hinchey classification of acute diverticulitis, which stage is characterised by faecal peritonitis? (Q883981)

A. Stage I

B. Stage II

C. Stage III

D. Stage IV

See Answer in Part B → Q14

@Neet_pg_bot

Q15: What is currently the preferred initial imaging modality for evaluating suspected acute diverticulitis? (Q883980)

A. Barium enema

B. Plain abdominal radiography

C. Computed tomography

D. Colonoscopy

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 62-year-old man presents with intermittent lower abdominal discomfort and altered bowel habits. A contrast radiographic study of the colon is performed, and the image is shown above. The outpouchings seen in this condition are best described as which of the following? (Q883979)

A. True diverticula involve all bowel layers

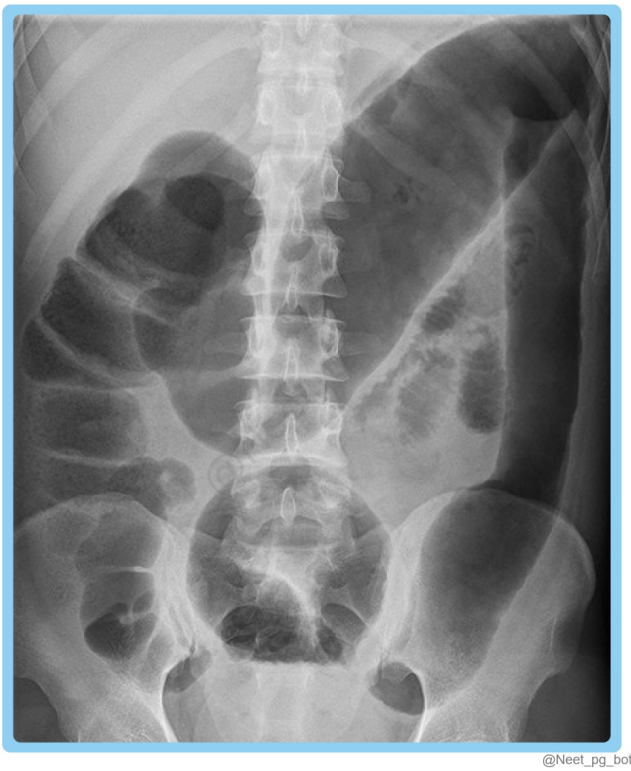
B. False diverticula involving mucosa and submucosa only

C. Congenital outpouchings are most common in the cecum

D. Inflammatory pseudopolyps associated with ulcerative colitis

See Answer in Part B → Q16

@Neet_pg_bot



Q17: A patient with severe ulcerative colitis presents with high fever, abdominal distension, and tenderness. An abdominal X-ray shows the following findings. What is the most likely diagnosis? (Q883978)

A. Sigmoid volvulus

B. Crohn's disease flare

C. Toxic megacolon

D. Ogilvie's syndrome

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following statements is TRUE regarding the postoperative recurrence of Crohn's disease? (Q883977)

A. The risk of relapse is highest immediately after surgery and decreases over time.

B. The presence of active disease at the resection margins guarantees early recurrence.

C. The probability of symptomatic relapse increases with time since resection

D. Surgery is curative in the majority of patients with ileocecal Crohn's disease

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 45-year-old male presents with severe abdominal pain, vomiting, and abdominal distension along with tenderness. X-ray shows dilated bowel loops with air-fluid levels. The patient is taken for exploratory laparotomy. Which of the following structures is most likely to be visualized first to differentiate between small intestine and large intestine obstruction? (Q849042)

A. Cecum

B. Ileum

C. Ascending Colon

D. Sigmoid Colon

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 16-year-old boy is brought to the clinic by his mother due to rectal bleeding. His father died of colon cancer at age 40. Colonoscopy reveals hundreds of polyps throughout the colon. Which of the following is the most likely diagnosis? (Q849051)

A. Crohn's disease

B. Familial adenomatous polyposis (FAP)

C. Lynch syndrome

D. Juvenile polyposis syndrome

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 16-year-old girl presents with intermittent abdominal pain, occasional rectal bleeding, and pigmented macules on her lips, buccal mucosa, and digits. Her mother had similar pigmented spots. What is the most likely diagnosis? (Q849050)

A. Familial Adenomatous Polyposis (FAP)

B. Lynch Syndrome

C. Peutz-Jeghers Syndrome

D. Cowden Syndrome

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following correctly identifies a type of non-neoplastic polyp? (Q849049)

A. Tubular adenomatous polyp

B. Sessile serrated polyp

C. Juvenile polyp

D. Villous adenomatous polyp

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 55-year-old patient presents with symptoms of abdominal pain and changes in bowel habits. A barium enema is performed, which reveals a characteristic finding on imaging given below. Which of the following is the most likely diagnosis? (Q849047)

A. Diverticulosis

B. Colon Cancer

C. Pseudomembranous Colitis

D. Ischemic colitis

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 55-year-old male presents to the clinic with complaints of intermittent chest pain and difficulty swallowing. He gives a history of gastrointestinal discomfort and was recently diagnosed with both hiatal hernia and diverticulosis during a routine endoscopic examination. Given his current history, what is the other condition that has the highest probability for which he should be evaluated? (Q849046)

A. Gallstones

B. Peptic ulcer disease

C. Inflammatory bowel disease

D. Chronic pancreatitis

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 2-day-old neonate presents with abdominal distension, vomiting, and failure to pass meconium within the first 48 hours of life. On physical examination, the abdomen is distended, and a digital rectal examination reveals a tight anal sphincter with an explosive discharge of stool upon withdrawal of the finger. What is the best step of investigation to confirm the exact pathology? (Q849045)

A. Abdominal X-ray

B. Barium enema

C. Rectal biopsy

D. Anorectal manometry

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Assertion: The colon plays a significant role in the production of short-chain fatty acids (SCFAs) from dietary fibers. Reason: Fermentation of dietary fibers by gut bacteria in the colon produces SCFAs like butyrate, acetate, and propionate, which serve as metabolic fuel for colon cells. (Q849044)

A. Both Assertion and Reason are true, and the Reason is the correct explanation for the Assertion.

B. Both Assertion and Reason are true, but the Reason is not the correct explanation for the Assertion.

C. The Assertion is true, but the Reason is false.

D. Both Assertion and Reason are false

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 60-year-old male presents with severe abdominal pain, distension, and constipation. A CT scan reveals a large intestinal obstruction at the level of the descending colon. Which of the following arteries is primarily responsible for providing collateral circulation in this situation? (Q849043)

A. Superior Mesenteric Artery

B. Inferior Mesenteric Artery

C. Marginal Artery of Drummond

D. Arc of Riolan

See Answer in Part B → Q27

Q1: Which of the following is the most accurate screening method for colon cancer? (Q849056)

A. Flexible sigmoidoscopy

B. Colonoscopy

C. Fecal Occult Blood Test

D. Virtual Colonoscopy

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 15-year-old patient is diagnosed with juvenile polyposis syndrome (JPS). Which of the following statements accurately describes the management and characteristics of JPS? (Q849072)

A. The initial colonoscopy screening should be started by age 10

B. JPS is caused by mutations in the SMAD4 or BMPR1A genes

C. Prophylactic colectomy is indicated only when iron-deficiency anemia is present

D. Best managed with immediate total colectomy regardless of the number of polyps

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 65-year-old male presents with acute lower gastrointestinal bleeding. He is hemodynamically stable but has a significant amount of blood in his stool. What is the next best step in management? (Q849071)

A. Outpatient colonoscopy

B. Immediate surgery

C. CT angiogram

D. Inpatient colonoscopy

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 65-year-old woman presents to the emergency department with a sudden onset of severe abdominal pain, bloody diarrhea, and low-grade fever. Her medical history includes hypertension and a recent episode of congestive heart failure. An abdominal CT scan reveals signs of bowel ischemia. Which of the following is the most likely diagnosis? (Q849070)

A. Acute mesenteric ischemia

B. Ischemic colitis

C. Diverticulitis

D. Crohn's disease

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 65-year-old male presents with a 5-day history of watery diarrhea, abdominal cramping, and low-grade fever. He was recently treated with cephalosporins for a respiratory infection. Upon examination, the patient is dehydrated but stable.

Endoscopy reveals raised yellowish-white plaques on the colonic mucosa. What is the most likely diagnosis? (Q849069)

A. Ulcerative colitis

B. Crohn’s disease

C. Pseudomembranous colitis

D. Ischemic colitis

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 45-year-old woman, recently diagnosed with colon and bladder cancer, presents with a notable family history; her mother also had both cancers and succumbed to them. Additionally, she has a history of sebaceous adenomas. Which other malignancy should she be evaluated for, considering the potential hereditary cancer syndrome? (Q849068)

A. Thyroid cancer

B. Liver cancer

C. Breast carcinoma

D. Pancreatic cancer

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following statements regarding the therapy for colon carcinoma are correct? Statements: 1. Chemotherapy is often used in the adjuvant setting after surgery to reduce the risk of recurrence in patients with Stage III colon cancer 2. Immunotherapy is typically used as a first-line treatment for patients with colon cancer who have microsatellite instability-high (MSI-H) or mismatch repair deficiency 3. Chemotherapy with FOLFOX (5-Fluorouracil, Leucovorin, and Oxaliplatin) is commonly used for Stage IV colon cancer to achieve a cure 4. Checkpoint inhibitors

like Pembrolizumab are effective in colon cancer patients with microsatellite instability-high (MSI-H) or mismatch repair deficiency 5. Radiotherapy is not preferred for colon cancer due to its limited benefit in local control (Q849067)

A. 1, 2, and 4

B. 2, 4, and 5

C. 1, 4, and 5

D. 3, 4, and 5

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 62-year-old male underwent a right hemicolectomy for carcinoma of the colon. On the fourth postoperative day, he developed severe abdominal pain, fever, tachycardia, and hypotension. On physical examination, his abdomen is distended and diffusely tender with guarding and rigidity. Laboratory results show elevated white blood cell count. A CT scan of the abdomen reveals free fluid and air in the peritoneal cavity. Considering the clinical presentation and imaging findings, what is the most likely cause of his current condition? (Q849066)

A. Surgical site infection

B. Anastomotic leak

C. Bowel obstruction

D. Ileus

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 55-year-old male presents with fatigue, weight loss, and intermittent abdominal pain. He has a history of occasional rectal bleeding. On examination, he has mild pallor, and there is a palpable mass in the right upper quadrant. A colonoscopy is performed, revealing a large ulcerative mass at the hepatic flexure of the colon. Biopsy

confirms the diagnosis of adenocarcinoma. What is the most appropriate next step in the management of this patient? (Q849065)

A. Segmental resection of the hepatic flexure

B. Right hemicolectomy

C. Extended right hemicolectomy

D. Total colectomy

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which chemotherapy regimen is standard for adjuvant treatment in a patient with stage III colon cancer? (Q849063)

A. Capecitabine

B. FOLFOX

C. FOLFIRI

D. Bevacizumab

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 72-year-old female is found to have a 3 cm mass in the ascending colon during colonoscopy. A CT scan of the abdomen and pelvis shows no evidence of lymph node involvement or distant metastases. What is the most appropriate management for this patient? (Q849062)

A. Perform a right hemicolectomy with en-bloc lymph node dissection.

B. Recommend adjuvant chemotherapy following the surgical resection.

C. Proceed with endoscopic mucosal resection of the tumor.

D. Recommend Endoscopic polypectomy

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following is a possible description of a T3 colon tumour? (Q849061)

A. Tumour invades submucosa

B. Tumour invades subserosa

C. Tumour invades adjacent organs or structures

D. Tumour confined to the mucosa

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following best describes the Modified Dukes' Staging System for colorectal cancer? (Q849060)

A. Dukes A: Tumour invades the muscularis propria but no lymph node involvement

B. Dukes B: Tumour penetrates through the muscularis propria with positive lymph nodes

C. Dukes C: Tumour invades beyond the bowel wall, no lymph node involvement

D. Dukes D: Tumour has distant metastasis regardless of lymph node status

See Answer in Part B → Q13

@Neet_pg_bot

Q14: On barium enema investigation of a 54-year-old male with colon cancer an apple core lesion was found. What is the location of the carcinoma? (Q849059)

A. Left

B. Right

C. Transverse colon

D. Any of the above

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Arrange the steps in the pathogenesis of colon cancer Dysplasia Intermediate adenoma DNA methylation 18q loss DCC (Q849058)

A. 1,3,2,4

B. 1,2,3,4

C. 4,3,2,1

D. 3,2,1,4

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 62-year-old male with a history of long-standing ulcerative colitis presents with rectal bleeding, unintentional weight loss, and altered bowel habits. A colonoscopy reveals a large, ulcerated mass in the sigmoid colon, and a biopsy confirms adenocarcinoma. Which of these factors in his history would not have served as risk factors for developing colon cancer? (Q849057)

A. Long-standing ulcerative colitis

B. Smoking

C. Use of NSAIDs

D. Red meat in the diet

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 54-year-old female with intractable diarrhea and pigmentation was diagnosed with Cronkhite-Canada syndrome. Which of the following statements regarding the disease are true? Hamartomatous polyp of colon Seen only in females Polyps can be present in the stomach and duodenum as well 15% can turn malignant (Q849055)

A. 1,4

B. 2,3,4

C. 1,2

D. 1,2,3,4

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 62-year-old patient is diagnosed with a large, invasive adenocarcinoma of the splenic flexure of the colon. The colorectal surgeon recommends surgical resection. Which of the following colectomy procedures would be most appropriate for this patient? (Q849064)

A. Left hemicolectomy

B. Extended left hemicolectomy

C. Subtotal colectomy

D. Total proctocolectomy

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which diagnostic modality can detect active gastrointestinal bleeding at the lowest rate of blood loss? (Q883999)

A. CT angiography

B. Selective mesenteric angiography

C. 99m Tc-labelled red blood cell scintigraphy

D. Colonoscopy

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A guaiac-based faecal occult blood test (gFOBT) is most sensitive for detecting bleeding originating from which part of the gastrointestinal tract? (Q883998)

A. Upper GI tract (e.g., stomach)

B. Small intestine

C. Oesophagus

D. Colon

See Answer in Part B → Q20

@Neet_pg_bot

Q21: In a hemodynamically stable patient presenting with acute hematochezia, what is the appropriate initial diagnostic step? (Q883997)

A. Immediate angiography

B. Urgent exploratory laparotomy

C. Colonoscopy after bowel preparation

D. Upper endoscopy (EGD)

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Along which anatomical structure are the paracolic lymph nodes primarily located? (Q883996)

A. Superior mesenteric artery

B. Marginal artery of Drummond

C. Inferior mesenteric vein

D. Middle colic artery

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A flexible sigmoidoscope is typically designed to visualise the colon up to what approximate length from the anal verge? (Q883995)

A. 25 cm

B. 40 cm

C. 60 cm

D. 100 cm

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 2-year-old boy undergoes a pull-through procedure for Hirschsprung disease. What is the most common postoperative complication overall? (Q883994)

A. Enterocolitis

B. Faecal incontinence

C. Constipation

D. Anastomotic leak

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 3-month-old infant presents with chronic constipation, abdominal distension, and failure to pass meconium within the first 48 hours of life. A rectal biopsy confirms aganglionosis of the distal colon, consistent with Hirschsprung disease. Which surgical procedure is considered a definitive treatment for this condition? (Q883993)

A. Duhamel pull-through

B. Nissen fundoplication

C. Heineke-Mikulicz pyloroplasty

D. Whipple procedure

See Answer in Part B → Q25

@Neet_pg_bot

Q26: When performing a rectal biopsy to diagnose Hirschsprung disease, at what distance above the dentate line should the sample ideally be taken to avoid a false-positive result? (Q883992)

A. 0.5 cm

B. 1.0 cm

C. 2.0 cm

D. 5.0 cm

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Hirschsprung disease is most frequently associated with mutations in which gene? (Q883991)

A. APC

B. RET

C. BRCA1

D. CFTR

See Answer in Part B → Q27

@Neet_pg_bot

Q28: What combination of clinical features is typically seen in Heyde’s syndrome? (Q883990)

A. Aortic stenosis, colonic diverticulosis, and iron deficiency anaemia

B. Mitral stenosis, angiodysplasia, acquired von Willebrand disease

C. Aortic stenosis, angiodysplasia, acquired von Willebrand disease

D. Aortic regurgitation, peptic ulcer disease, thrombocytopenia

See Answer in Part B → Q28

Q1: Which of the following macroscopic features is most characteristic of Crohn's disease compared to ulcerative colitis? (Q849290)

A. Continuous inflammation from the rectum extending proximally

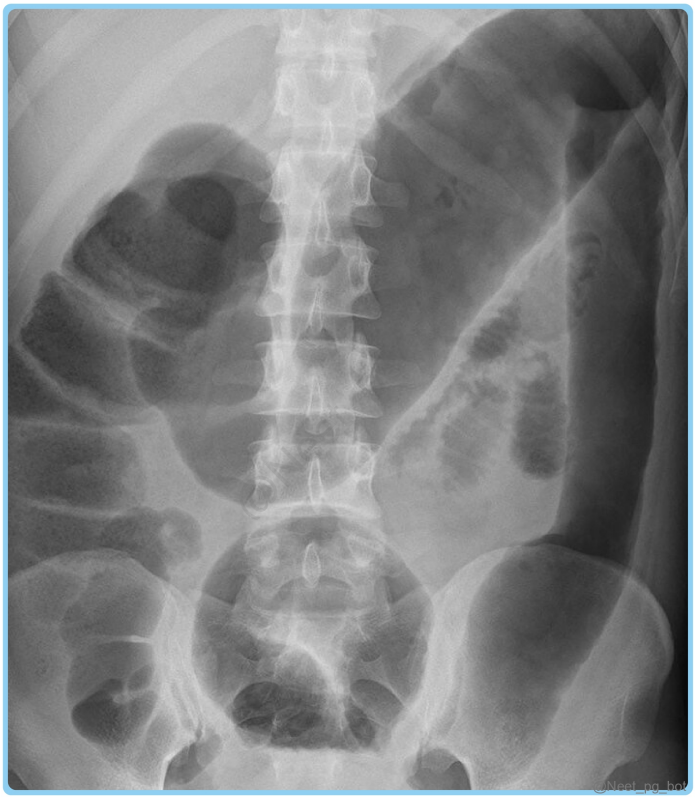
B. Erythematous, granular mucosa with superficial ulcerations

C. Transmural inflammation in UC

D. Thickened bowel wall and mesenteric fat wrapping

See Answer in Part B → Q1

@Neet_pg_bot



Q2: A 52-year-old male with a history of ulcerative colitis presents with severe abdominal pain and distention, fever, and tachycardia. He appears ill and is in significant discomfort. Lab tests show leukocytosis and electrolyte imbalances. An X-ray of the abdomen is taken. Which of the following surgical procedures is the most appropriate for this patient? {{caption_text}} (Q849289)

A. Segmental Colectomy

B. Total Abdominal Colectomy with End Ileostomy

C. Diverting Loop Ileostomy with Colonic Lavage

D. Laparoscopic Colonic Decompression

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 38-year-old male presents with severe abdominal distension and diarrhea. His vitals show a heart rate of 125 beats/min, fever of 38.9°C, and a white blood cell count of 13,800/microL. A radiograph reveals colonic dilation of 7 cm. Which of the following additional findings would not confirm the diagnosis of toxic megacolon? (Q849288)

A. Anemia

B. Altered sensorium

C. Hypotension

D. Electrolyte disturbances

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 32-year-old patient diagnosed with mild Crohn's disease affecting the ileocecal region presents to your clinic. The patient has mild symptoms with no significant systemic involvement. What is the most appropriate first-line drug to prescribe for this patient to induce remission in mild Crohn's disease? (Q849267)

A. Prednisone

B. Azathioprine

C. Infliximab

D. Budesonide

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A patient with chronic ulcerative colitis who had undergone total proctocolectomy with ileal pouch-anal anastomosis has come to the department complaining of diarrhoea, abdominal pain, fever and malaise. On examination, hematochezia is noted. What is the first line of treatment here? (Q849287)

A. Antibiotic therapy

B. Biologic agents

C. Probiotics

D. Pouch excision

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 45-year-old male with a long-standing history of chronic inflammatory bowel disease presents for routine follow-up. He undergoes a colonoscopy, during which suspicious lesions are identified. A biopsy confirms the presence of malignancy. Which of the following types of cancer is more commonly associated with Crohn's disease than with ulcerative colitis? (Q849280)

A. Colon carcinoma

B. Small intestine carcinoma

C. Cholangiocarcinoma

D. Gastric cancer

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following would be a differentiating feature of Colitis-associated colon carcinoma (CAC) from sporadic colon cancer? (Q849279)

A. Sporadic colon cancer develops due to chronic inflammation and dysplasia

B. CAC has a lower mortality

C. CAC is more common after the age of 30

D. Sporadic colon cancer is associated with young individuals

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 58-year-old male comes to the hospital complaining of intermittent pain in the anal region and intermittent diarrhea for 6 months. On examination, he was found to have complex perianal fistulas bilaterally, with skin tags, as shown in the image. His blood investigations reveal anemia. What could be the possible diagnosis leading to this? {{caption_text}} (Q849278)

A. Crohn’s disease of anorectum

B. Ulcerative colitis

C. Carcinoma rectum

D. Hemorrhoids

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A patient with a history of ulcerative colitis (UC) has undergone a total proctocolectomy with ileal pouch-anal anastomosis (TPA + IPAA) as part of their treatment. Which of the following is not a possible complication of the procedure? (Q849277)

A. Anastomotic leak

B. Pouchitis

C. Pelvic sepsis

D. Peritonitis

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following procedures is the definitive management of Ulcerative colitis? (Q849276)

A. Total Proctocolectomy with End Ileostomy(TPA+EI)

B. Total Proctocolectomy with Ileal Pouch-Anal Anastomosis (TPA+IPAA)

C. Total Proctocolectomy with mucosectomy with hand-sewn IPAA

D. Total abdominal colectomy with very low Hartmann closure with end ileostomy

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 45-year-old patient presents with a history of chronic abdominal pain, frequent bloody diarrhea, and an urgent need to defecate. Colonoscopy reveals continuous inflammation starting from the rectum and extending through the colon. Despite receiving the highest doses of medical therapy, the symptoms have worsened. Which of the following would not be considered an indication for surgery in this patient? (Q849269)

A. Failure of maximum medical therapy

B. Multiple bowel movements

C. Fulminant colitis

D. Enteroenteric fistula

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 35-year-old patient with moderate to severe ulcerative colitis has achieved clinical remission with a biologic agent. Which of the following drugs is used in the maintenance therapy for moderate to severe ulcerative colitis? (Q849268)

A. Mesalamine

B. Adalimumab

C. Sulfasalazine

D. Hydrocortisone

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 55-year-old male patient presents with a low rectal tumor and requires bowel diversion. The surgeon is considering the type of stoma to be created. Which of the following indications best matches the need for an ileostomy rather than a colostomy? (Q849254)

A. To relieve bowel obstruction when resection is not feasible.

B. To protect a distal anastomosis after low anterior resection.

C. To manage inflammatory diseases with severe perianal disease.

D. Permanent fecal diversion following total colectomy

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 39-year-old male with a 12-year history of ulcerative colitis presents with worsening symptoms despite maximum medical therapy. He experiences >10 bowel movements per day, urgency, tenesmus, and significant weight loss. Biopsies show high-grade dysplasia. The surgical team plans a total proctocolectomy with ileal pouch-anal anastomosis (IPAA). What is the primary goal of the planned surgery for this patient? (Q849266)

A. Palliative

B. Curative

C. Remission

D. Maintenance

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following statements regarding ulcerative colitis is correct? (Q849265)

A. Backwash ileitis, where there is secondary inflammation in the terminal ileum, is a common finding in all patients with ulcerative colitis.

B. Extraintestinal manifestations such as arthritis are more likely to occur in patients with proctitis alone.

C. 8 bloody stools per day and associated joint pain are classified as moderate ulcerative colitis.

D. Fulminant ulcerative colitis is characterized by >10 bowel movements daily, continuous bleeding, and evidence of systemic toxicity.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 38-year-old patient with a history of chronic diarrhea and rectal bleeding undergoes a barium enema for evaluation. The radiological image shows changes in the colonic mucosa. Based on the findings of the barium enema, which of the following radiological features is most indicative of Ulcerative colitis (UC)? {{caption_text}} (Q849264)

A. Narrowed, constricted colon with a "hose pipe" appearance

B. Multiple deep ulcers with surrounding inflammation

C. Discontinuous patches of inflammation with normal segments in between

D. Presence of pseudopolyps

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 30-year-old patient presents with persistent and worsening chronic diarrhea, rectal bleeding, and abdominal pain for the past several months. An endoscopic examination reveals continuous mucosal inflammation starting at the rectum and extending proximally. Which of the following findings is most characteristic of ulcerative colitis (UC) and helps differentiate it from Crohn's disease? (Q849263)

A. Patchy inflammation with skip lesions

B. Continuous inflammation starting from the rectum

C. Transmural inflammation with cobblestone appearance

D. Presence of granulomas in the mucosal layer

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which extraintestinal manifestation is most commonly associated with Crohn's disease? (Q849262)

A. Uveitis

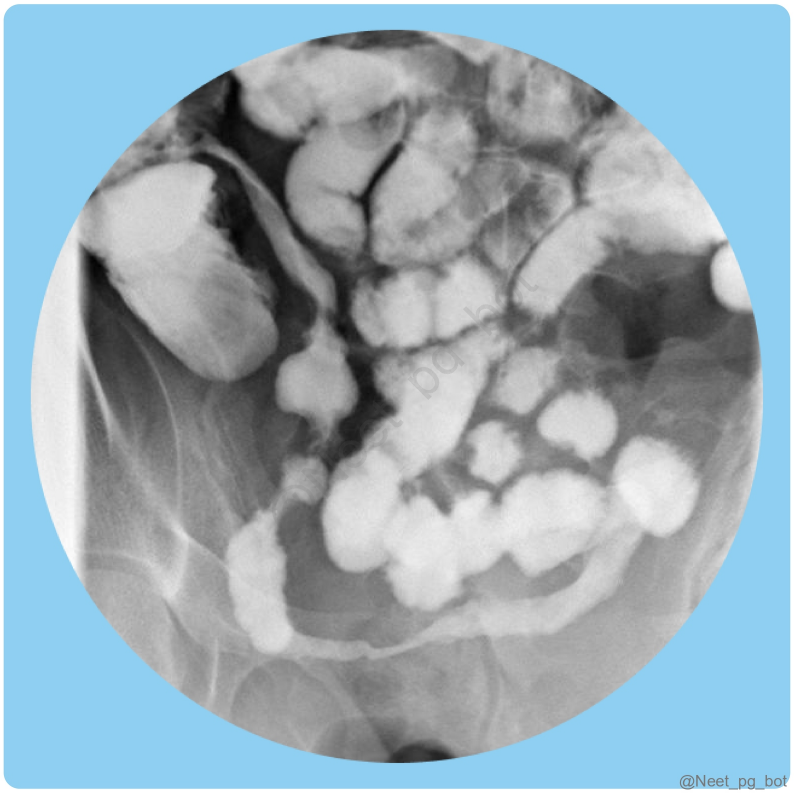
B. Pyoderma gangrenosum

C. Erythema nodosum

D. Nephrotic syndrome

See Answer in Part B → Q18

@Neet_pg_bot



Q19: A 45-year-old patient with a history of long-standing Crohn's disease presents for a follow-up examination. An abdominal X-ray with barium contrast is performed to evaluate the current state of the small bowel. Based on the barium radiographic image provided, which of the following signs is depicted below? {{caption_text}} (Q849261)

A. String Sign of Kantor

B. Apple-Core Sign

C. Lead-Pipe Appearance

D. Bird-Beak Sign

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 34-year-old female with a known diagnosis of Crohn's disease presents with symptoms of abdominal pain, weight loss, and intermittent diarrhea. Imaging studies reveal significant inflammation and strictures in the gastrointestinal tract. Which part of the gastrointestinal tract is most commonly affected by Crohn's disease, leading to ulcers and strictures? (Q849260)

A. Duodenum

B. Jejunum

C. Ileum

D. Colon

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 35-year-old patient presents with chronic diarrhea, abdominal pain, and weight loss. A resection of the terminal ileum is performed, and the findings are shown in the image below. Which of the following findings is most characteristic of this disease? {{caption_text}} (Q849258)

A. Continuous mucosal lesions and crypt abscesses

B. Cobblestone appearance and transmural inflammation

C. Superficial ulceration and loss of haustrations

D. Pseudopolyps and mucosal inflammation

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 40-year-old male presents with chronic diarrhea, abdominal pain, and recent weight loss. On examination, there is tenderness in the right lower quadrant, and a colonoscopy revealed patchy inflammation in the terminal ileum with skip lesions.

Which of the following combinations of risk factors and etiological factors is most consistent with the diagnosis? (Q849257)

A. NOD2/CARD15 gene mutation, smoking

B. HLA-DR2 association, appendectomy

C. Autoimmune etiology, non-smoker

D. Milk allergy, personality disorders

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 65-year-old woman undergoes an emergency ileostomy following bowel obstruction. Two weeks postoperatively, she presents with increased pain and swelling around the stoma site. On examination, a bulge is noted adjacent to the stoma. The stoma itself appears healthy, with no signs of necrosis or ischemia. What is the most likely diagnosis? (Q849256)

A. Stoma Stenosis

B. Stoma Retraction

C. Parastomal Hernia

D. Stoma Prolapse

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 55-year-old male patient undergoes emergency abdominal surgery for a perforated sigmoid diverticulitis with peritonitis. The surgeon decides to create a stoma as part of the management plan. Which of the following stomas is most appropriate for diverting fecal content and allowing distal bowel healing while planning for potential future reconnection? (Q849255)

A. End colostomy

B. Loop ileostomy

C. Double-barrel colostomy

D. Permanent ileostomy

See Answer in Part B → Q24

Q1: A 34-year-old male undergoes an open appendectomy for acute appendicitis. The choice of incision was McBurney's incision. Postoperatively, after a few days, he presents with pain and bulging in the right lower quadrant, which is diagnosed as an indirect inguinal hernia. Which nerve injury during the appendectomy is most likely responsible for this complication? (Q849041)

A. Ilioinguinal nerve

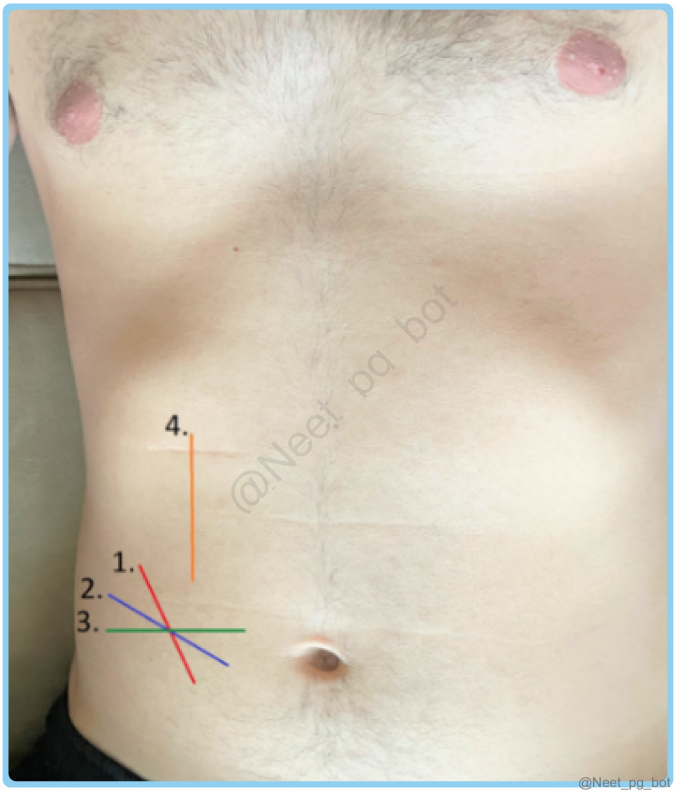
B. Femoral nerve

C. Genitofemoral nerve

D. Pudendal nerve

See Answer in Part B → Q1

@Neet_pg_bot



Q2: A 25-year-old male presents with right lower quadrant abdominal pain and is diagnosed with acute appendicitis. The surgical team plans to perform an appendectomy. Which of the following correctly represents the type of Incision used in appendicectomy? a-Rutherford Morrison b-Lanz c-McBurney’s d-Battle (Q849039)

A. 1-a, 2-c, 3-b, 4-d

B. 1-a, 2-b, 3-c, 4-d

C. 1-c, 2-b, 3-a, 4-d

D. 1-c, 2-a, 3-b, 4-d

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 25-year-old male presents with right lower quadrant abdominal pain and is diagnosed with acute appendicitis. He undergoes an open appendectomy. Which of the following statements regarding the steps of an open appendectomy is incorrect? (Q849040)

A. The incision is made at McBurney's point and extended down to the external oblique aponeurosis.

B. Cecum is identified with the help of taenia coli and ileocecal junction.

C. Mesoappendix and appendicular artery are ligated to prevent bleeding.

D. A lock-stitch suture is placed around the base of the appendix which is used to bury the stump after excision of the appendix.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 24-year-old man presents with acute onset of right lower abdominal pain, fever, and nausea. During physical examination, the manoeuvre shown in the image is performed, which elicits pain in the right lower quadrant. This clinical finding is known as: (Q884006)

A. Obturator sign

B. Rovsing's sign

C. Psoas sign

D. Murphy's sign

See Answer in Part B → Q4

@Neet_pg_bot

Q5: What is the typical initial location and character of abdominal pain at the onset of acute appendicitis? (Q884004)

A. Right lower quadrant, sharp and constant

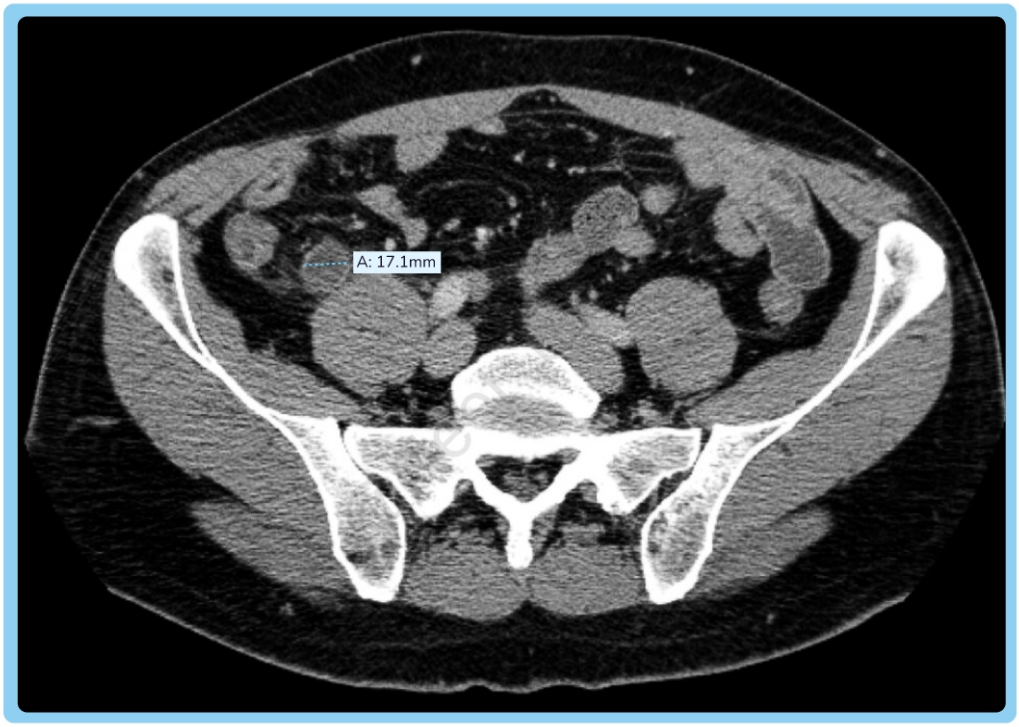
B. Epigastric, burning

C. Periumbilical, colicky and poorly localised

D. Diffuse, crampy

See Answer in Part B → Q5

@Neet_pg_bot



Q6: A 26-year-old patient presents with acute right lower quadrant abdominal pain, nausea, and low-grade fever. A contrast-enhanced CT scan of the abdomen is obtained and is shown above. Which of the following physical examination findings is not typically associated with this condition? (Q884007)

A. Psoas sign

B. Rovsing's sign

C. Ballance sign

D. McBurney's sign

@Neet_pg_bot

See Answer in Part B → Q6

@Neet_pg_bot

Q7: In a pediatric patient with suspected acute appendicitis, what is the preferred initial imaging modality to avoid radiation exposure? (Q884008)

A. Plain abdominal X-ray

B. CT scan of the abdomen and pelvis

C. Ultrasound of the abdomen

D. MRI of the abdomen

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 28-year-old man presents with fever, right lower quadrant pain, and signs of peritonitis. Exploratory laparotomy reveals a perforated appendix with purulent peritoneal fluid. Cultures are obtained. Which anaerobic organism is most commonly isolated in this scenario? (Q884009)

A. Escherichia coli

B. Bacteroides fragilis

C. Clostridium perfringens

D. Klebsiella pneumoniae

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A patient with a palpable, tender right lower quadrant mass and a history of abdominal pain for 5 days is diagnosed with an appendiceal mass. The patient is hemodynamically stable. What is the most appropriate initial management?

(Q884010)

A. Immediate appendectomy

B. Ochsner-Sherren regimen

C. Percutaneous drainage of the mass

D. Laparoscopic exploration

See Answer in Part B → Q9

@Neet_pg_bot

Q10: When converting a gridiron (McBurney) incision to a Rutherford Morison incision during an appendectomy, which of the following muscle layers are divided? (Q884011)

A. Only the external oblique muscle

B. External oblique, internal oblique, and transversus abdominis muscles

C. Rectus abdominis muscle only

D. External oblique and transversus abdominis muscles only

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A surgeon performing an appendectomy ensures that only a very short appendiceal stump is left behind to avoid stump appendicitis. What is the recommended maximum length of the residual appendiceal stump? (Q884012)

A. 1 mm

B. 3 mm

C. 5 mm

D. 10 mm

See Answer in Part B → Q11

@Neet_pg_bot

Q12: During an open appendectomy, which instrument is specifically designed for atraumatic grasping of delicate structures like the appendix or fallopian tube? (Q884013)

See Answer in Part B → Q12

@Neet_pg_bot

Q13: What is the most common site within the appendix for a carcinoid tumour to arise? (Q884014)

A. Base of the appendix

B. Mid-appendix

C. Tip (distal third) of the appendix

D. Appendiceal orifice

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 1.8 cm carcinoid tumour is found at the tip of the appendix on histopathology after an appendectomy. There is no invasion of the mesoappendix, and margins are clear. What is the most appropriate next step in management? (Q884015)

A. Observation only

B. Completion of right hemicolectomy

C. Chemotherapy

D. Repeat appendectomy with wider margins

See Answer in Part B → Q14

@Neet_pg_bot

Q15: An incidental 0.5 cm carcinoid tumour at the tip of the appendix with clear margins and no high-risk features is discovered after an appendectomy. What is the appropriate management? (Q884016)

A. Completion of right hemicolectomy

B. Adjuvant chemotherapy

C. Observation only

D. Radiation therapy

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which pathogen is classically associated with mesenteric lymph node enlargement producing symptoms similar to acute appendicitis? (Q884017)

A. Salmonella typhi

B. Campylobacter jejuni

C. Mycobacterium tuberculosis

D. Yersinia enterocolitica

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Pseudomyxoma peritonei most commonly arises from rupture or leakage of which type of tumour? (Q884018)

A. Colonic adenocarcinoma

B. Appendiceal mucinous cystadenoma

C. Ovarian serous cystadenocarcinoma

D. Gastric signet ring carcinoma

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which physical examination manoeuvre, when performed in the left lower quadrant, elicits pain in the right lower quadrant and is suggestive of acute appendicitis? (Q884005)

A. Psoas sign

B. Obturator sign

C. Murphy's sign

D. Rovsing's sign

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 28-year-old woman presented with a 3-day history of vague lower abdominal pain, low-grade fever, and urinary frequency. Initial pelvic examination and urinalysis were inconclusive. CT scan revealed acute appendicitis with an inflamed appendix located in the pelvis. The delayed diagnosis in this case was most likely due to: (Q849031)

A. The appendix's pelvic location masking classic right lower quadrant signs

B. Misinterpretation of urinary symptoms as a primary urological issue

C. Lack of characteristic migration of pain from periumbilical to right iliac fossa

D. Absence of typical anorexia and vomiting in early appendicitis

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which pathological process marks the starting point in the evolution of acute appendicitis? (Q884003)

A. Luminal obstruction

B. Ischemic injury due to arterial embolism

C. Bacterial translocation from the colon

D. Autoimmune inflammation

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which anatomical structure serves as a surgical landmark to identify the ileocecal junction during appendectomy? (Q884002)

A. Jackson membrane

B. Gerlach valve

C. Fold of Treves

D. Mesoappendix

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A patient undergoes an appendectomy. While separating the mesoappendix, the operating surgeon cauterises and ligates the vessel within it. Which artery is this? (Q884001)

A. Ileocolic artery

B. Right colic artery

C. Appendicular artery

D. Middle colic artery

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A surgeon performing an appendectomy notes the appendix in its typical location. Which anatomical position is this most likely to be? (Q884000)

A. Pelvic

B. Retrocaeal

C. Subcaecal

D. Pre-ileal

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 30-year-old female presents with right lower quadrant abdominal pain and is diagnosed with acute appendicitis. During surgery, a small mass is found at the tip of the appendix, which is subsequently identified as a carcinoid tumour. Which of the following statements about carcinoid tumours in the appendix is correct? (Q849038)

A. They are most commonly found at the base of the appendix.

B. They typically produce excessive amounts of insulin.

C. For carcinoid tumors >2cm, right hemicolectomy is the preferred modality of treatment

D. They are associated with a high risk of metastasis.

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 55-year-old male with a history of appendicitis presents with severe right lower quadrant pain, fever, tachycardia, and tenderness. An ultrasound shows an

appendix mass. Despite conservative treatment, his condition worsens. Which sign or symptom indicates the need for surgical intervention? (Q849037)

A. Increased white blood cell count with stable abdominal findings

B. Rising pulse rate with increasing size of the appendix mass

C. Localized right iliac fossa pain with no change in pulse rate

D. Generalized abdominal pain with no fever

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 45-year-old male presents with a 3-day history of right lower quadrant pain, fever, and anorexia. His examination is significant for a palpable mass in the right lower quadrant with guarding and rebound. A CT scan demonstrates an appendiceal mass. He was admitted to the hospital and started on intravenous antibiotics. After 48 hours, his fever has resolved, and his abdominal pain has significantly improved. What is the most appropriate next step in management? (Q849036)

A. Discharge home on oral antibiotics

B. Continue IV antibiotics and observe

C. Laparoscopic appendectomy

D. Colonoscopy

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Which of the following statements is true about acute appendicitis? (Q849035)

A. Diagnosis in children can be done by clinical signs only

B. Diagnosis in adults requires additional imaging modalities

C. The gold standard test is the USG abdomen

D. A shift to the left in the leukocyte count is seen

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 16-year-old male presents to the emergency department with a 12-hour history of abdominal pain. The pain was initially periumbilical and colicky in nature but has since localized to the right iliac fossa. He has also experienced one episode of vomiting and has no appetite. His Alvarado score is 5. What is the inference of this score? (Q849034)

A. Negative for acute appendicitis

B. Diagnosis for acute appendicitis is confirmed

C. CECT is indicated in this patient

D. None of the above

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 22-year-old male presents with right lower quadrant pain for the past 24 hours. On examination, the surgeon demonstrates cutaneous hyperesthesia in an area bounded by a line joining the anterior superior iliac spine, the umbilicus, and the pubic symphysis. Which of the following statements is most accurate regarding this clinical sign? (Q849033)

A. This sign is known as Sherren's triangle and is specific to retro-cecal appendicitis

B. The hyperesthesia is due to irritation of the T10-L1 nerve roots by the inflamed appendix

C. This sign is highly specific for appendicitis and rules out other causes of right lower quadrant pain

D. The presence of this sign contraindicates the use of laparoscopy for appendectomy

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 28-year-old male presents with right lower quadrant pain, nausea, and low-grade fever. Upon examination, he exhibits rebound tenderness at McBurney's point. Which of the following is the most likely initial event in the pathogenesis of this patient's condition? (Q849032)

A. Bacterial invasion of the appendiceal wall

B. Obstruction of the appendiceal lumen

C. Thrombosis of appendiceal vessels

D. Perforation of the appendix

See Answer in Part B → Q30

Q25 (p. 422)	*Q26 (p. 422)*				

Q1: A 28 y/o female presents with a history of chronic constipation, rectal pain, and bleeding. On examination, an ulcer is found on the anterior wall of the rectum, 7 cm from the anal verge. Proctography reveals rectal intussusception. Which is the most appropriate treatment for this patient's condition? (Q849210)

A. STARR Procedure

B. Abdominal Rectopexy

C. Histology

D. Colostomy

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 55 y/o male presents with rectal bleeding and pain during defecation. O/E, a firm mass is palpable in the anal canal. A biopsy confirms carcinoma of the anal canal. Imaging shows no distant metastasis, but inguinal nodes are enlarged. Which of the following is the most appropriate initial treatment for this patient? (Q849209)

A. Abdominoperineal Resection (APR) with Colostomy

B. Chemoradiation

C. Radiotherapy alone

D. Neoadjuvant Chemotherapy followed by surgery

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 60 y/o patient is diagnosed with anal canal cancer. A tumour of size 3cm invades through the muscularis propria into the perirectal tissue, involving 4-6 regional lymph nodes without distant metastasis. Which of the following stages correctly describes this condition? (Q849208)

A. Stage I (T1-T2, N0, M0)

B. Stage II (T1-T2, N1, M0)

C. Stage III (T1-T4, N2, M0)

D. Stage IV (T1-T4, N1-N3, M1)

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 58 y/o woman presents with anal pain, bleeding during bowel movements, and the presence of a palpable mass. She has a history of multiple sexual partners and was recently diagnosed with human papillomavirus (HPV) infection. Which of the following risk factors is most strongly associated with the development of anal canal cancer in this patient? (Q849207)

A. HPV infection leads to anal condylomata.

B. Immunosuppression due to a recent organ transplant.

C. History of vulvar intraepithelial neoplasia (VIN).

D. Chronic constipation resulting in haemorrhoids.

See Answer in Part B → Q4

@Neet_pg_bot

Q5: .A 78-year-old woman with a history of chronic constipation and faecal incontinence presents with a complaint of a mass that protrudes circumferentially from her anus, which she can manually reduce. She also reports occasional bleeding and difficulty with bowel movements. Which of the following is the most appropriate management for this patient's rectal prolapse? (Q849192)

A. Perineal rectopexy

B. Rubber band ligation

C. Abdominal rectopexy

D. Infrared photocoagulation

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 58 y/o man presents with bright red blood in his stool, tenesmus, and intermittent abdominal pain for one month. A digital rectal exam reveals a hard mass 5 cm from the anal verge. Rigid sigmoidoscopy confirms a neoplasm. What is the next step to evaluate the extent of his disease? (Q849205)

A. Perform a CT scan of the abdomen and pelvis.

B. Schedule a colonoscopy.

C. Obtain a biopsy of the rectal mass.

D. Surgical intervention

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 35-year-old woman experiencing severe pain during bowel movements, bright red blood on toilet paper, and chronic anal fissures has not improved with conservative treatment and is being referred for surgery. Which surgical procedure is aimed at reducing anal sphincter tone to promote healing of the fissure while

maintaining continence? (Q849202)

A. Fissurectomy

B. Lateral Internal Sphincterotomy

C. Anal Advancement Flap

D. Botulinum toxin injection

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 35-year-old woman with a recurrent anal abscess has developed an anal fistula. She is concerned about continence after surgery. Which surgical option is best to treat her condition while minimizing incontinence risk? (Q849199)

A. Fistulotomy

B. Fistulectomy

C. Setons

D. Ligation of the Intersphincteric Fistula Tract (LIFT)

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 1-week-old girl with a newly diagnosed rectovestibular fistula is undergoing evaluation. Which of the following is the most appropriate initial treatment for a newborn with a rectovestibular fistula? (Q849211)

A. Single-stage anoplasty

B. Initial colostomy followed by definitive pull-through operation

C. Wangenstein's Invertogram to determine the level of the rectal pouch

D. Aspiration of meconium and dye injection for fistula assessment

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 62 y/o woman diagnosed with rectal carcinoma is being evaluated for treatment options. Which of the following statements regarding the treatment strategies for rectal carcinoma is true? (Q849206)

A. Total mesorectal excision (TME) is a method of palliative care in patients with advanced rectal cancer.

B. Neoadjuvant chemoradiotherapy is used after surgical resection to minimize the risk of local recurrence.

C. Local excision is indicated for early-stage rectal cancers with good prognostic factors.

D. Abdominoperineal excision (APR) is the preferred surgical approach for all cases of rectal carcinoma.

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 60-year-old male presents with bright red, painless rectal bleeding and a feeling of incomplete evacuation. Digital rectal examination (DRE) reveals a firm, irregular, palpable mass located 6 cm from the anal verge. Which statement about the clinical features of rectal carcinoma is most accurate? (Q849204)

A. Tenesmus is a late symptom.

B. Rectal carcinoma typically presents without any changes in bowel habits.

C. Rectal carcinoma is most common in patients under 55 years of age.

D. The presence of a hard mass within 7-8 cm of the anal verge.

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 24-year-old male presents with recurrent painful swelling and discharge at the natal cleft. He has coarse hair and reports worsening after prolonged sitting. On examination, a tender fluctuant swelling with a midline pit is noted.What is the most appropriate initial management? (Q849203)

A. Complete surgical excision of the sinus

B. Cauterization using silver nitrate

C. Drainage through a midline incision

D. Lateral internal sphincterotomy

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 32 y/o woman presents with severe pain during bowel movements and bright red blood on toilet paper for 2 weeks. She describes the pain as excruciating and sharp, akin to "passing glass." Based on this clinical scenario, which of the following statements is correct? (Q849201)

A. It mainly presents with anal itching & discharge

B. The hallmark symptom is severe pain during defecation that usually subsides after bowel movements.

C. This condition is characterized by a thickened anal papilla and a skin tag.

D. The majority of cases occur in the anterior midline in women due to childbirth.

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 35 y/o woman presents with severe pain during bowel movements and bright red blood on toilet tissue. Upon examination, the physician suspects an anal fissure. Which of the following characteristics is most likely associated with a chronic anal fissure? (Q849200)

A. Presence of bright red blood only after bowel movements.

B. Severe sharp pain during bowel movements that subside afterwards.

C. Thickened anal papilla and skin tag are present at the fissure site.

D. Extensive oedema and inflammation

See Answer in Part B → Q14

@Neet_pg_bot

Q15: During a detailed anatomical study, a researcher examines the fascia layers associated with the rectum. Which of the following structures separates the rectum from the prostate in males? (Q849184)

A. Presacral fascia

B. Fascia propria

C. Denonvilliers' fascia

D. Waldeyer's fascia

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 32 y/o male presents with intermittent discharge of pus from an external opening near the anus, accompanied by discomfort and occasional blood in the discharge. He has a history of anorectal abscess treated six months ago and reports pain during bowel movements. Which of the following is the investigation of choice in this case? (Q849198)

A. Fistulography (X-ray)

B. Endoscopic Ultrasound

C. Anoscopy

D. MRI

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 45 y/o male presents to the clinic with a persistent anal discharge and discomfort. He has a history of recurrent perianal abscesses over the past year. O/E an external opening is noted near the anal margin. Which of the following is the most likely cause of the anal fistula in this patient? (Q849197)

A. Crohn's disease

B. Tuberculosis

C. Actinomycosis

D. Cryptoglandular infection

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 38-year-old man presents with severe anal pain and a tender, indurated lump at the anal margin. He reports a two-day history of progressively localized pain but has no systemic symptoms such as fever or malaise. What is the next best step in managing this patient? (Q849196)

A. Immediate antibiotic therapy

B. Surgical drainage under anaesthesia

C. Observation and follow-up in 48 hours

D. Imaging studies to confirm diagnosis

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 45-year-old diabetic male reports deep, intense pain "inside" the anal area that worsens with coughing or sneezing. The examination shows minimal external swelling, but the significant discomfort prevents a complete digital rectal exam. Given this clinical picture, which type of anorectal abscess is most likely present in this patient? (Q849194)

A. Perianal Abscess

B. Ischiorectal Abscess

C. Intersphincteric Abscess

D. Supralevator Abscess

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 55-year-old man presents with difficulty urinating and lower abdominal discomfort. The doctor advises a digital rectal examination (DRE) to assess for potential prostate enlargement or other rectal abnormalities. Which of the following is not an external inspection finding? (Q849193)

A. Anal fissures

B. Rectal polyps

C. Pilonidal sinus

D. External hemorrhoids

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 72-year-old multiparous woman presents with a painless mass protruding from her anus along with occasional bleeding and fecal incontinence. O/E the mass is circumferential, red in colour, and reducible. Which of the following is the most likely type of rectal prolapse? (Q849191)

A. Partial prolapse

B. Mucosal prolapse

C. Complete prolapse

D. Internal haemorrhoids

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 45-year-old man presents with persistent bleeding from haemorrhoids despite dietary changes and non-operative treatments. Examination reveals third-degree internal haemorrhoids. Which of the following is not an indication of hemorrhoidectomy? (Q849190)

A. Third-degree haemorrhoids

B. Second-degree haemorrhoids

C. 'Mixed' haemorrhoids with a well-defined external component

D. Fourth-degree haemorrhoids

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 50-year-old woman presents with bright red bleeding during defecation and a prolapsed haemorrhoid that cannot be reduced manually. What is the most suitable management for this patient? (Q849188)

A. Dietary and lifestyle changes

B. Rubber band ligation

C. Sclerotherapy

D. Hemorrhoidectomy

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 45-year-old man reports experiencing bright red bleeding during bowel movements and a mass that protrudes from his anus, which he can manually reduce but does not reduce spontaneously. On examination, no thrombosed haemorrhoids are observed. Which degree of internal haemorrhoids is this patient most likely suffering from? (Q849187)

A. First degree

B. Second degree

C. Third degree

D. Fourth degree

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 55 y/o woman presents with complaints of rectal bleeding and discomfort during bowel movements. She mentions experiencing chronic constipation and frequent straining. Which pathophysiological mechanism is most likely contributing to her haemorrhoids? (Q849186)

A. High-fiber diet

B. Well-supported suspensory tissues

C. Excess venous drainage

D. Increased intra-abdominal pressure

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 58 y/o male presents with rectal cancer located just distal to the dentate line. During his evaluation for metastatic spread, which lymph nodes are most likely to be

involved given the location of his cancer? (Q849185)

A. Internal iliac lymph nodes

B. Inferior mesenteric lymph nodes

C. Para-aortic lymph nodes

D. Inguinal lymph nodes

See Answer in Part B → Q26

Q1: A 65-year-old male presents with a painful, irreducible groin hernia, severe colicky pain, bilious vomiting, and absence of faeces or flatus for 24 hours. The hernia is tense and extremely tender, with reddish-blue skin discolouration and no cough impulse. What is the immediate next step in management? (Q849330)

A. Administer IV antibiotics and fluids and proceed with surgery

B. Immediate surgical repair with synthetic mesh

C. Apply cold compresses to the hernia to reduce swelling

D. Start oral antibiotics and monitor the hernia for changes

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A patient presents with an incisional hernia located just above the umbilicus in the midline of the abdomen. According to the EHS classification, how is this hernia classified? (Q849338)

A. M1

B. M2

C. M3

D. L2

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is NOT typically considered an indication for surgical repair of an umbilical hernia in adults? (Q849337)

A. Incarceration or strangulation of hernia contents

B. Hernia size >2 cm in diameter

C. Symptomatic hernia causing pain or discomfort

D. Hernia in a patient with a BMI of 32

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 75-year-old thin woman presents with intermittent pain and paresthesia along the medial aspect of her right thigh. She reports nausea and vomiting over the past few days. On examination, hip flexion and external rotation exacerbate her thigh pain. Which of the following signs is most specific for the likely diagnosis? (Q849335)

A. Cough impulse

B. Howship-Romberg sign

C. Carnett's sign

D. Murphy's sign

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 55-year-old woman presents with a painful lump in her lower right abdomen, lateral to the rectus muscle. The swelling becomes more prominent when she stands or coughs. CT scan shows a defect in the transversus abdominis aponeurosis. What is the most likely diagnosis? (Q849334)

A. Epigastric hernia

B. Umbilical hernia

C. Spigelian hernia

D. Incisional hernia

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 60-year-old male patient presents with right lower abdominal swelling and is diagnosed with a sliding hernia. After discussing the risks, his surgery is planned for hernia repair. Which of the following statements regarding sliding hernia is true? (Q849333)

A. More common in females than males

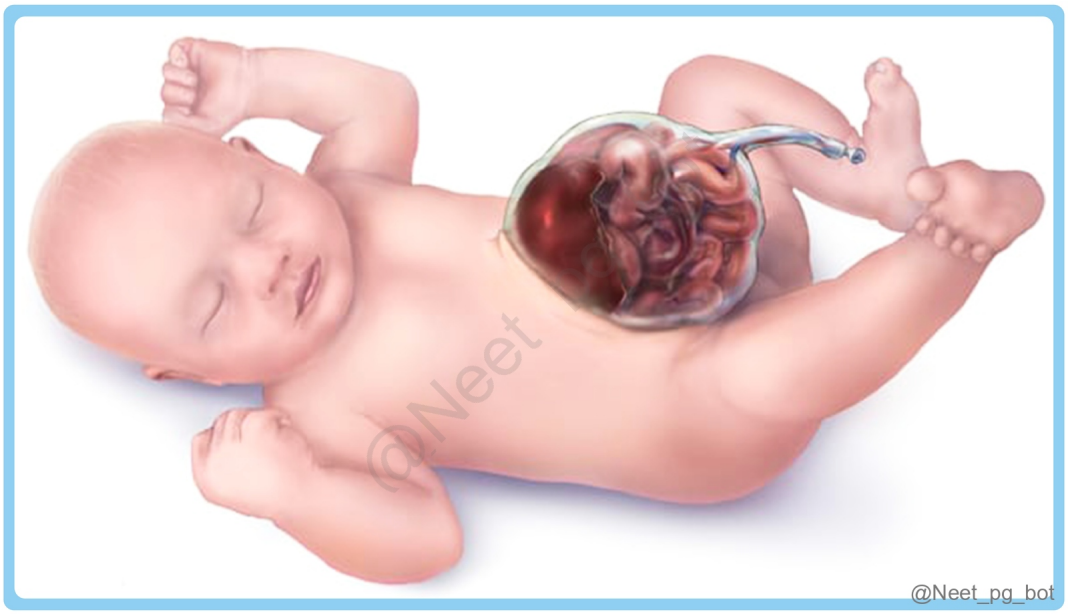
B. Anterior wall of the sac is formed by the viscera

C. There is an increased risk of bowel injury during management.

D. Most common content is the appendix.

See Answer in Part B → Q6

@Neet_pg_bot



Q7: Which of the following is NOT a feature associated with the image shown below? (Q849340)

A. Covered by amnion and peritoneum layers

B. Higher incidence of associated chromosomal abnormalities like Trisomy 13, 18, and 21

C. The defect is usually located to the right of the umbilical cord insertion

D. Can be associated with Beckwith-Wiedemann Syndrome

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old woman presents with a reducible swelling in the left groin below the inguinal ligament, suggesting a femoral hernia. The surgeon opts for a low approach to access the femoral canal directly without entering the inguinal canal. Which technique is most appropriate for this approach? (Q849331)

A. Lockwood's technique

B. McEvedy's technique

C. Lotheissen's technique

D. McVay repair

See Answer in Part B → Q8

@Neet_pg_bot

Q9: During laparoscopic inguinal hernia repair, which critical structure should the surgeon avoid to prevent significant bleeding? (Q849329)

A. Obturator Artery

B. Accessory Obturator Artery

C. Corona Mortis artery

D. Superficial Epigastric Artery

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 42-year-old woman with a history of Gardner's syndrome presents with persistent abdominal pain and a palpable mass in the left lower quadrant. She has previously undergone an open proctocolectomy. Imaging studies reveal an infiltrative mass in the mesentery. What is the most appropriate management strategy for her recurrent intra-abdominal mass? (Q849341)

A. Immediate systemic chemotherapy without further surgical intervention.

B. Wide local excision with a 2 cm margin, potentially followed by radiotherapy.

C. Hormonal therapy to manage the tumor.

D. Laparoscopic surgery to remove the tumor, given its lower risk of recurrence.

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 55-year-old woman with sudden groin pain and diarrhoea is found to have a small bulge in the right groin. She describes the pain as colicky and has symptoms resembling acute gastroenteritis. Which type of hernia is most likely associated with these symptoms? (Q849342)

A. Littre's hernia

B. Amyand's hernia

C. Maydl's hernia

D. Richter's hernia

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 62-year-old male has a right groin bulge that worsens with standing and reduces when lying down. The bulge is medial to the inferior epigastric vessels. Based on the Nyhus classification, which type of hernia does this patient have? (Q849215)

A. Type I

B. Type II

C. Type III A

D. Type III B

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A newborn is diagnosed with a congenital diaphragmatic hernia (CDH) and presents with severe respiratory distress. Physical examination revealed a scaphoid abdomen and a chest X-ray showed bowel loops in the thoracic cavity and a mediastinal shift. What is the most appropriate initial intervention to stabilise the infant before surgical repair? (Q849345)

A. Bag-mask ventilation to ensure adequate oxygenation.

B. Placement of an Orogastric tube to decompress the stomach

C. IV Antibiotics to prevent infection in the herniated bowel.

D. Immediate surgery, irrespective of the status

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 12-year-old girl presents with abdominal pain and intermittent nausea. Physical examination reveals a large, non-tender abdominal mass in the left lower quadrant, contiguous with the small intestine in the mesentery. Based on the findings, which type of mesenteric cyst is most likely, and what is the preferred management approach? (Q849346)

A. Enterogenous cyst; Resection and anastomosis

B. Chylolymphatic cyst; Enucleation

C. Hydatid cyst; Anti-parasitic therapy

D. Traumatic cyst; Observation

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Match the following hernias with their respective defects. Hernia Defect 1. Berger's Hernia a) Defect in the conjoint tendon 2. Beclard's Hernia b) Hernia into the pouch of Douglas 3. Ogilvie's Hernia c) Hernia behind the Roux limb 4. Stammer's Hernia d) Through the saphenous opening 5. Peterson Hernia e) Through transverse mesocolon after retro colic gastro-jejunostomy (Q849343)

A. 1-b, 2-d, 3-a, 4-e, 5-c

B. 1-b, 2-c, 3-d, 4-a, 5-e

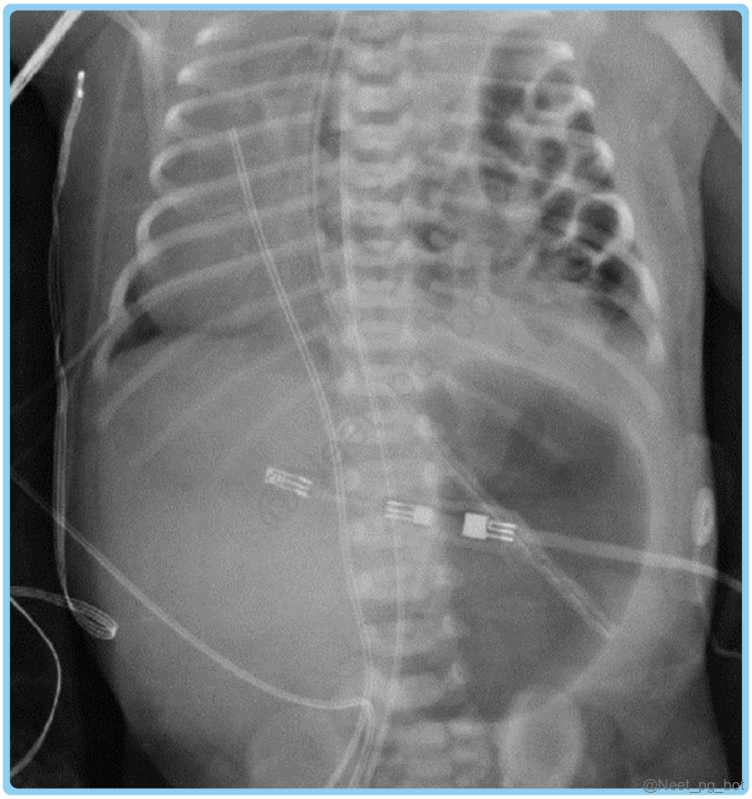
C. 1-d, 2-a, 3-e, 4-b, 5-c

D. 1-a, 2-d, 3-c, 4-e, 5-b

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A day-old preterm infant is admitted with severe respiratory distress. Physical examination shows a scaphoid abdomen and chest X-rays reveal bowel loops in the thorax and a mediastinal shift. Despite intensive care, the infant's condition deteriorates rapidly and leads to death. Which of the following accurately describes a



characteristic feature of the most common type of this condition? (Q849344)

A. Left-sided posteromedial defect with herniation of small intestine

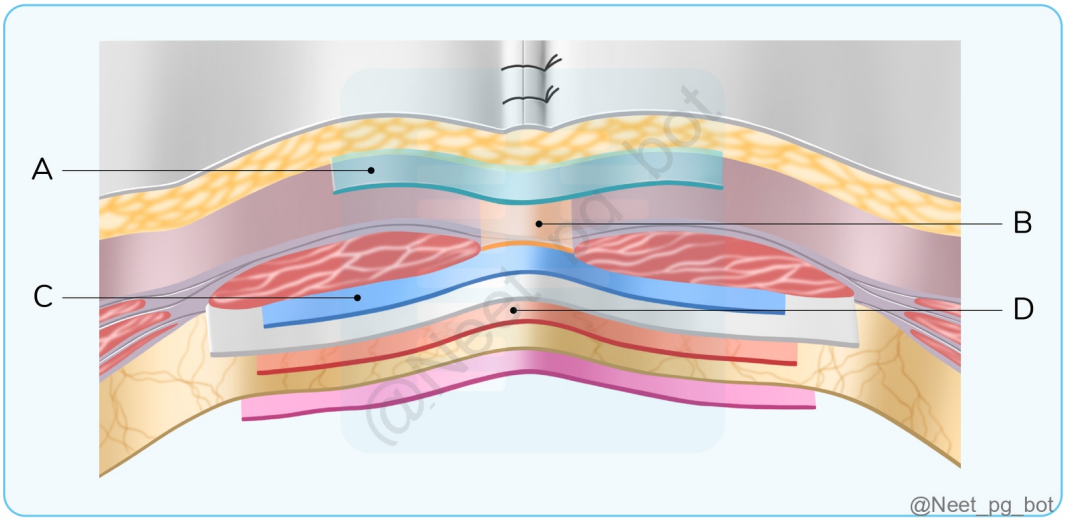
B. Right-sided anterolateral defect associated with herniation of the liver

C. Defective central tendon of the diaphragm

D. Persistence of the pleuroperitoneal canal

See Answer in Part B → Q16

@Neet_pg_bot



Q17: Which technique of incisional hernia is done at point B? (Q849339)

A. Onlay

B. Inlay

C. Retromuscular

D. Preperitoneal

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 58-year-old male with chronic bronchitis, smoking history, and recent steroid use presents with a lower abdominal bulge that worsens with prolonged standing and heavy weight lifting. Which of these factors contributes to the risk of his condition? Chronic bronchitis Heavy weight lifting Smoking Steroid use (Q849212)

A. 1, 2, 3

B. 1, 3, 4

C. 2, 3, 4

D. 1, 2, 3, 4

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which type of lumbar hernia is characterized by a protrusion just below the 12th rib? (Q849336)

A. Petit's lumbar hernia

B. Grynfeltt-Lesshaft hernia

C. Gibbon's hernia

D. Pantaloon hernia

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 55-year-old woman presents with a small, reducible swelling in her right groin area. Upon examination, you noticed that the swelling was located lateral to the femoral vessels. Which variant of femoral hernia is this most likely to be? (Q849332)

A. Narath's hernia

B. Cloquet's hernia

C. Velpeau's hernia

D. Laugier's hernia

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 55-year-old man undergoes emergency inguinal hernia surgery. Postoperatively, he experiences persistent groin pain, raising concerns about nerve injury. Which nerve is most commonly injured during open inguinal hernia surgery? (Q849328)

A. Iliohypogastric nerve

B. Ilioinguinal nerve

C. Genitofemoral nerve

D. Femoral nerve

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A laparoscopic surgeon is repairing an inguinal hernia and wants to avoid using electrocautery in certain areas to prevent injury. Which anatomical region should the surgeon avoid? (Q849327)

A. Triangle of Doom

B. Triangle of Pain

C. Triangle of Hesselbach

D. Triangle of Scarpa

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 62-year-old male presents with a progressively worsening right groin bulge over 6 months, causing discomfort during lifting or prolonged standing. The hernia is reducible, and he is scheduled for elective repair. What is the gold standard surgical technique for his inguinal hernia repair? (Q849217)

A. Shouldice Repair

B. Lichtenstein Repair

C. Herniotomy

D. Stoppa Repair

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 72-year-old female presents with a non-reducible right groin bulge below the inguinal ligament, confirmed by ultrasound to extend into the femoral canal. According to the Gilbert classification, which type best describes this condition? (Q849216)

A. Type 1

B. Type 3

C. Type 6

D. Type 7

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 67-year-old male presents with a gradually increasing bulge in his right groin, which becomes more prominent when standing and straining and can be reduced when lying down. The bulge is medial to the inferior epigastric vessels. Which statement best describes this inguinal condition? (Q849214)

A. Direct hernia, passing through a defect in the abdominal wall.

B. Indirect hernia, passing through the deep inguinal ring into the scrotum.

C. Direct hernia, passing through the deep inguinal ring.

D. Indirect hernia, passing through a defect in the abdominal wall.

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 72-year-old man presents with a bulge in his lower abdomen that worsens with heavy lifting or coughing. Physical examination reveals a direct inguinal hernia. Which of the following correctly describes the boundaries of the involved anatomical triangle? (Q849213)

A. Lateral: Inferior epigastric vessels; Medial: Rectus abdominis; Inferior: Inguinal ligament

B. Lateral: Rectus abdominis; Medial: Inguinal ligament; Inferior: Femoral vessels

C. Lateral: Femoral vessels; Medial: Rectus abdominis; Inferior: Superior epigastric vessels

D. Lateral: Inguinal ligament; Medial: Femoral vessels; Inferior: Rectus abdominis

See Answer in Part B → Q26

« Back to Folder Directory

[05_Gastrointestinal Surgery] 031 Spleen — Quick Jump

Q1 (p. 438) *Q2 (p. 438)* *Q3 (p. 438)* *Q4 (p. 439)* *Q5 (p. 439)* *Q6 (p. 440)*
Q7 (p. 440) *Q8 (p. 440)* *Q9 (p. 441)* *Q10 (p. 441)*

Q1: Which of the following statements about the spleen is not true? (Q849317)

A. Normal adult spleen weights 75–250 g.

B. The long axis lies along the 10th rib.

C. It develops from the mesenchymal cells of the ventral mesogastrium.

D. It is an intraperitoneal organ

See Answer in Part B → Q1

@Neet_pg_bot

Q2: What is the most common indication for a splenectomy? (Q849318)

A. Hereditary spherocytosis

B. Idiopathic thrombocytopenic purpura (ITP)

C. Trauma

D. Abscess

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old male is planned for an elective splenectomy due to hereditary spherocytosis. Which of the following vaccination strategies is most appropriate to prevent infections post-splenectomy? (Q849319)

A. 10-12 weeks before surgery

B. Only if the patient shows signs of infection

C. Delay all vaccinations until 6 months after surgery

D. 1 week before the surgery

See Answer in Part B → Q3

@Neet_pg_bot

Q4: An elderly male undergoes an open splenectomy due to splenic rupture following a car accident. In the postoperative room, he complains of shortness of breath and chest discomfort. What is the MOST common immediate complication after a splenectomy? (Q849320)

A. Pulmonary embolism

B. Left basal atelectasis

C. Pleural effusion

D. Pneumonia

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 25-year-old woman with thalassemia major undergoes an elective splenectomy. She is informed about potential complications and the need for vaccinations. When is the most common Fatal late complication of splenectomy most likely to occur? (Q849321)

A. Within the first 6 months

B. 1-2 years post-splenectomy

C. 2-5 years post-splenectomy

D. 5-10 years post-splenectomy

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 4-year-old boy is brought to the clinic with a history of sudden onset of petechial hemorrhages and purpuric patches on the skin. The mother also reports episodes of spontaneous epistaxis over the past few days. He had a flu-like illness a few weeks ago. Laboratory investigations show isolated thrombocytopenia. Which of the following statements is most accurate about the disease? (Q849322)

A. Equal incidence in both males and females

B. Predominantly seen in females aged 15-50

C. Associated with renal dysfunction

D. Associated with hemolytic anemia and jaundice

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 45-year-old patient presents with persistent petechiae, frequent nosebleeds, and heavy menstrual bleeding over the past 7 months. She is being considered for splenectomy. Which statement accurately reflects the current approach to this treatment? (Q849323)

A. Laparoscopic splenectomy is preferred.

B. Long-term steroid therapy is the primary approach.

C. Approximately 50% of patients will achieve complete remission post-splenectomy.

D. All patients receive pre-splenectomy transfusions immediately

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old patient undergoes a splenectomy for an incidental finding. Histological examination of the spleen reveals a vascular tumor. Which of the following is the most likely type of tumor identified? (Q849325)

A. Histiocytic Lymphoma

B. Hemangioendothelioma

C. Non-Hodgkin's Lymphoma

D. Plasmacytoma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 45-year-old patient presents with a one-week history of persistent left upper abdominal pain. The patient exhibits fever, left upper quadrant tenderness, and leukocytosis. Which of the following is the investigation of choice for confirming the diagnosis? (Q849326)

A. Chest X-ray

B. Abdominal Ultrasound

C. Computed Tomography (CT)

D. Radioisotope Scanning

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 30-year-old patient presents with an abdominal mass. Imaging studies reveal a cystic structure in the spleen. Based on the imaging characteristics and the absence of an epithelial lining, which of the following is the most likely diagnosis? (Q849324)

A. Cystic hemangioma

B. Mesenchymal Inclusion Cyst

C. Secondary cyst

D. Dermoid cyst

See Answer in Part B → Q10

Q1: A 2-month-old male infant presents with a scrotal swelling that has been present since birth. Now, the swelling has become suddenly painful, red, and irreducible. What is the most likely diagnosis? (Q866898)

A. Acute epididymo-orchitis

B. Testicular torsion

C. Strangulated inguinal hernia

D. Incarcerated inguinal hernia

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is a recommended treatment for esophageal varices? (Q866901)

A. Endoscopic ligation

B. Transjugular intrahepatic portosystemic shunt (TIPS)

C. Intravenous labetalol

D. Oral amoxicillin

See Answer in Part B → Q2

@Neet_pg_bot

Q3: What is the most appropriate treatment for an 8cm chylolymphatic mesenteric cyst? (Q866911)

A. Aspiration

B. Enucleation

C. Resection of the cyst along with the adjacent bowel

D. Conservative

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A follow-up patient of GERD on endoscopy was having a nodule in the 2nd part of the duodenum, which hormone are you suspecting to be raised? (Q866920)

A. Gastrin

B. Inulin

C. VIP

D. Glucagon

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A neonate has intestines protruding from the abdomen without any covering. Initial management is done. If the viscera cannot be reduced into the abdomen, what is the appropriate next step in management? (Q866922)

A. Surgical correction

B. Conservative management with higher antibiotics

C. Silo placement → Serial reduction → Operative fascial closureCover the content with a Silo bag and wait

D. Cover with NS-soaked gauze

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 16-year-old boy presents with multiple episodes of abdominal pain and a history of passing blood in his stools. On examination, he has darkly pigmented spots on his lips and oral mucosa. Endoscopy reveals multiple hamartomatous polyps in the small intestine. What is the most likely diagnosis? (Q866926)

A. Familial Adenomatous Polyposis

B. Peutz-Jeghers Syndrome

C. Juvenile Polyposis Syndrome

D. Cronkhite-Canada Syndrome

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Identify the pathology in the child. (Q866930)

A. Umbilical Hernia

B. Spigelian Hernia

C. Inguinal Hernia

D. Femoral Hernia

@Neet_pg_bot

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following veins are involved in the formation of esophageal varices? (Q866934)

A. Left gastric vein

B. Right gastric vein

C. Left gastroepiploic vein

D. Right gastroepiploic vein

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 22-year-old male presents to the emergency department with a 12-hour history of abdominal pain that started around the umbilicus and has now localised to the right lower quadrant. He also reports nausea and loss of appetite. On examination, he has tenderness in the right iliac fossa with rebound tenderness. His temperature is 38.2°C. Laboratory investigations reveal a white blood cell count of 14,000/mm 3 with a left shift. What is his pain score? (Q865323)

A. 5

B. 7

C. 8

D. 10

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 65-year-old patient undergoes colonoscopy for evaluation oc altered bowel habits. A 6cm colonic mass is identified and biopsied. Histopathology confirms adenocarcinoma that is confined to the mucosal layer, with no evidence of invasion into the submucosa or beyond. Imaging studies show no lymph node involvement or distant metastasis. Based on this information, what is the most appropriate TNM stage of this tumour? (Q865328)

A. Stage I

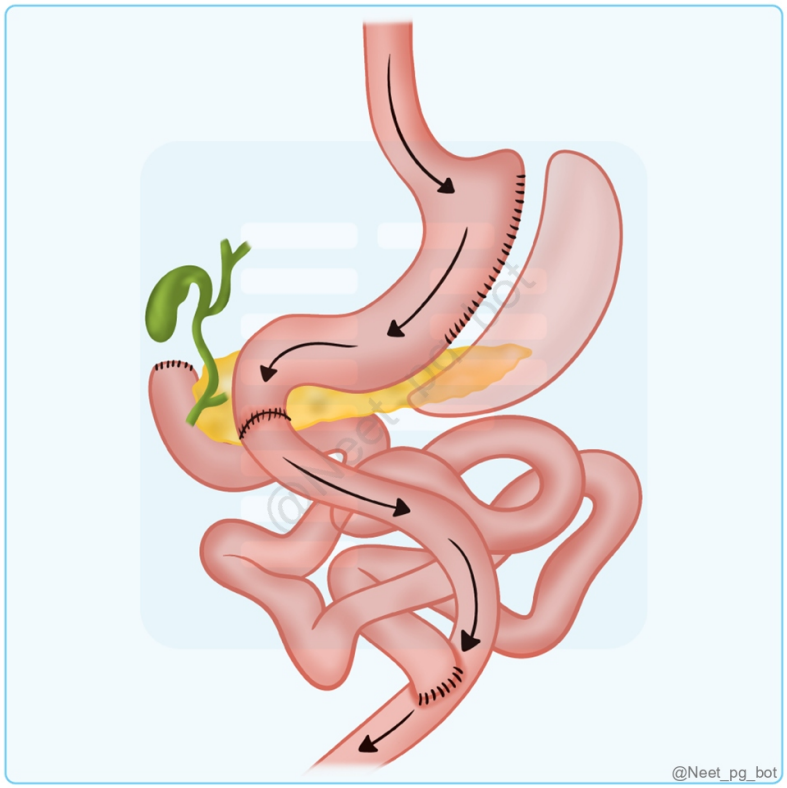
B. Stage IIA

C. Stage IIB

D. Stage 0

See Answer in Part B → Q10

@Neet_pg_bot



Q11: Identify the procedure done? (Q865332)

A. Single Anastamosis Duodenal-Ileal Bypass with Gastrectomy

B. Gastric bypass

C. Sleeve Gastrectomy

D. Adjustable gastric banding

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 35-year-old patient presents with a history of diarrhea associated with blood in stool for several weeks. On examination, the patient is febrile and has abdominal distension and tenderness. A CT scan (coronal view) shows a grossly dilated colon with loss of haustrations. Laboratory investigations reveal leukocytosis and elevated inflammatory markers. Based on the clinical and radiological findings, what is the most likely diagnosis? (Q865369)

A. Ulcerative colitis

B. Crohn's disease

C. Colonic carcinoma

D. Intestinal tuberculosis

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is incorrectly matched with its corresponding scoring or classification system? (Q865384)

A. Pancreatitis -Atlanta classification

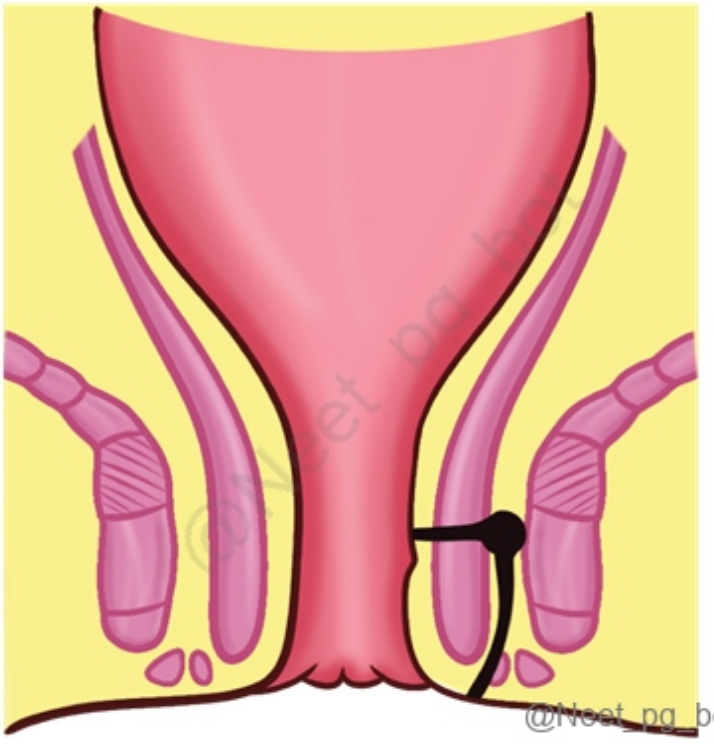
B. Achalasia - Los Angeles Score

C. Colonoscopy - Boston Score

D. Parathyroid - Miami criteria

See Answer in Part B → Q13

@Neet_pg_bot



Q14: Identify the fistula according to park's classification? (Q866417)

A. Intersphincteric

B. Supra-sphincteric

C. Extra-sphincteric

D. Trans-sphincteric high

See Answer in Part B → Q14

@Neet_pg_bot

Q15: During ward rounds, you encounter a patient who has been admitted with esophageal carcinoma. What is the most likely presentation for this patient? (Q853041)

A. Dysphagia of liquids followed by solids

B. Dysphagia of solids followed by liquids

C. Chest pain

D. Neck mass

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 30-year-old patient with peptic ulcer disease presents with persistent abdominal pain despite treatment at multiple hospitals. He has ulcers in the jejunum and ileum. His gastric pH is <2, and after discontinuing PPIs, his gastrin levels are 10 times higher than normal. What is the likely lesion, and what are the boundaries of the triangle containing it? (Q853042)

A. Insulinoma; triangle formed

B. ■■■Insulinoma; triangle formed by cystic duct, junction of D2-D3, neck and body of pancreas

C. Gastrinoma; triangle formed by cystic duct, junction of D2-D3, neck and body of pancreas

D. Gastrinoma; triangle formed by only common bile duct, junction of D2-D3, neck and body of pancreas

See Answer in Part B → Q16

@Neet_pg_bot

Q17: An intern assists in laparoscopic surgery, and the resident explains the instruments and operating ports. The surgeon then asks, "What is the angle between the camera port and the working port called?" (Q853044)

A. Azimuth's angle

B. ■■■Elevation angle

C. Crossing angle

D. Manipulation angle

See Answer in Part B → Q17

@Neet_pg_bot

Q18: What is the Truelove and Witts classification used for? (Q853059)

A. ■■■Acute severe ulcerative colitis

B. ARDS

C. Acute encephalitis

D. Acute pancreatitis

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Match the following diseases with their respective gene mutation: A. Familial adenomatous polyposis i. SMAD4 B. Juvenile polyposis ii. STK11 C. Tuberous sclerosis iii. APC gene D. Peutz-Jeghers syndrome iv. TSC1 (Q853060)

A. A-i, B-ii, C-iii, D-iv

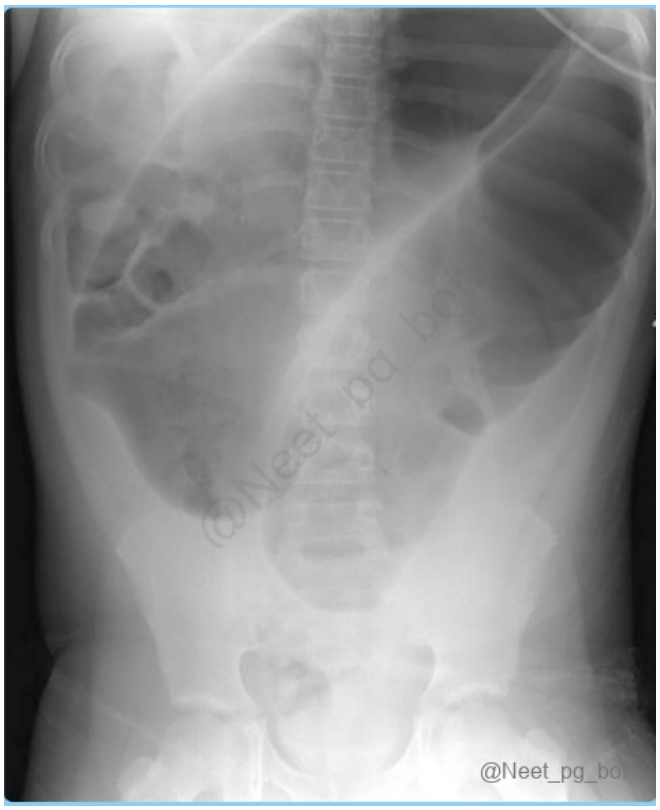
B. A-ii, B-iii, C-i, D-iv

C. A-iii, B-i, C-iv, D-ii

D. A-iv, B-ii, C-iii, D-i

See Answer in Part B → Q19

@Neet_pg_bot



Q20: A 33-year-old male presents with sudden onset acute abdominal pain, constipation for 1 day, persistent hiccups, and occasional vomiting. An abdominal X-ray was performed. Identify the pathology. (Q852686)

A. Sigmoid volvulus

B. Caecal volvulus

C. Intussusception

D. Dynamic obstruction

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 34-year-old male undergoes an open appendectomy for acute appendicitis. The choice of incision was McBurney's incision. Postoperatively, after a few days, he presents with pain and bulging in the right lower quadrant, which is diagnosed as an indirect inguinal hernia. Which nerve injury during the appendectomy is most likely responsible for this complication? (Q852703)

A. Ilioinguinal nerve

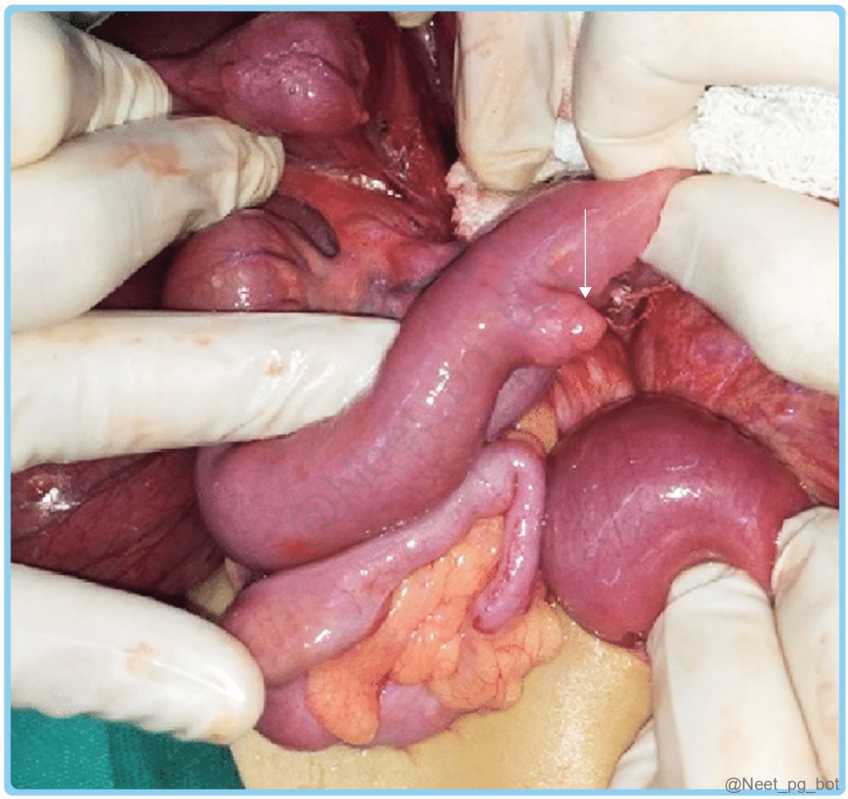
B. Femoral nerve

C. Genitofemoral nerve

D. Pudendal nerve

See Answer in Part B → Q21

@Neet_pg_bot



Q22: A 4-year-old boy was brought to the emergency department with complaints of melena that contains gastric mucosa and acute intermittent pain in the right iliac region. On surgical exploration, the following structure was found, what is the diagnosis? (Q852679)

A. Meckel's diverticulum

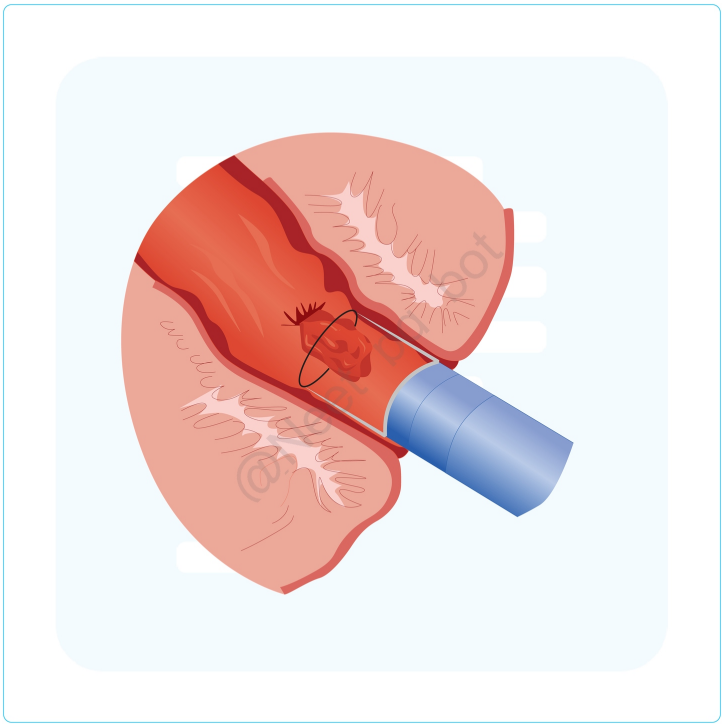
B. Appendicular lump

C. Carcinoid

D. Obstructed bowel loops

See Answer in Part B → Q22

@Neet_pg_bot



Q23: A patient with grade 4 hemorrhoids underwent surgery, identify the instrument. (Q852681)

A. Haemorrhoids resection kit

B. Stapler kit

C. Haemorrhoids band kit

D. CO2 laser

@Neet_pg_bot

See Answer in Part B → Q23

@Neet_pg_bot

Q24: What is the most likely cause of lower right abdominal pain and rebound tenderness in a patient with Meckel's diverticulum? (Q852725)

A. Perforation

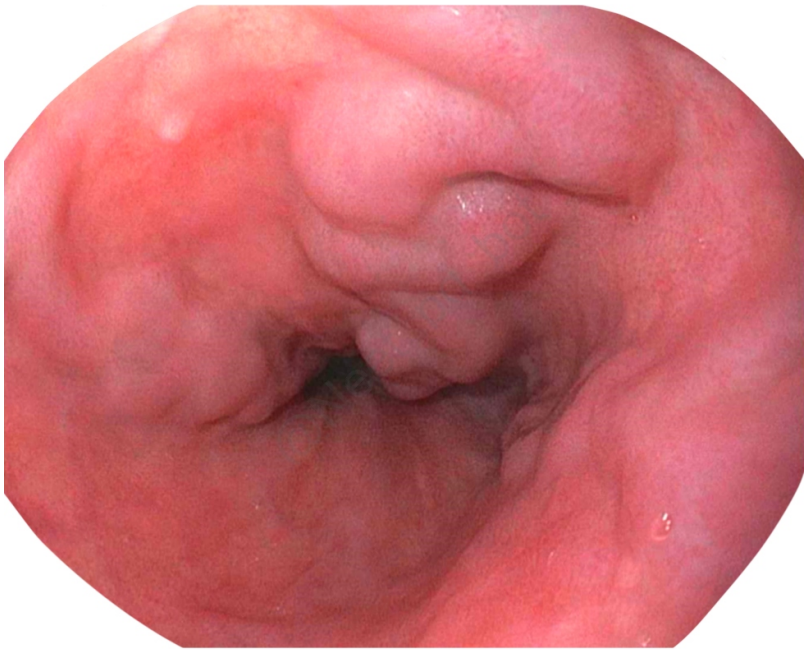
B. Intestinal obstruction

C. Appendicitis

D. Cholecystitis

See Answer in Part B → Q24

@Neet_pg_bot



Q25: The endoscopic image shows the following finding. What is the diagnosis? (Q844309)

A. Barretts esophagus

B. Esophageal varices

C. Gastric erosion

D. Chronic GERD

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A patient presents with an umbilical hernia that was previously reducible but has now become irreducible. Which of the following is the most appropriate management option? (Q844312)

A. Umblical excision

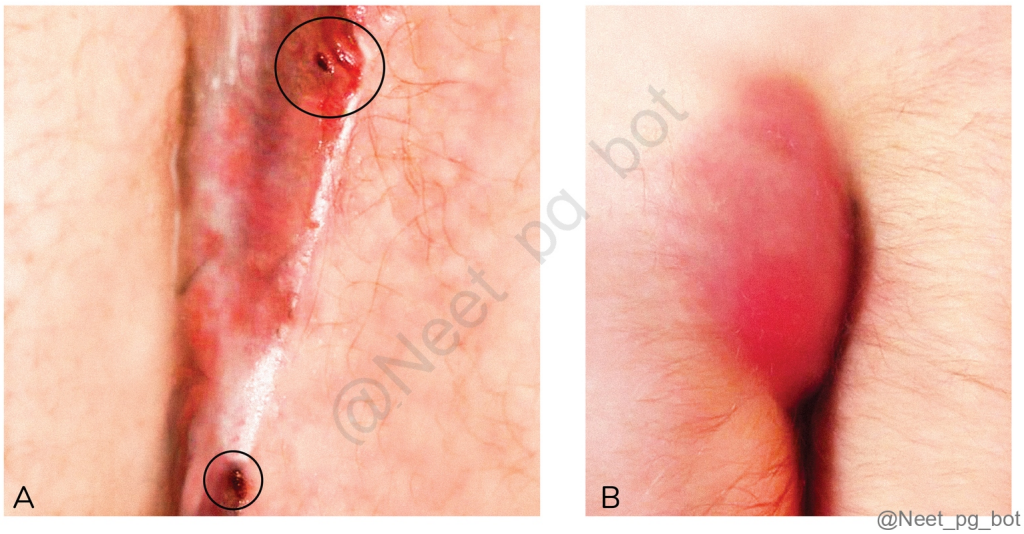
B. Umbilical excision with mesh hernioplasty

C. Mesh hernioplasty

D. Conservative management

See Answer in Part B → Q26

@Neet_pg_bot



Q27: A jeep driver presented with pain in the gluteal region along with swelling. What is the most likely diagnosis? (Q844317)

A. Pilonidal sinus

B. Fistula in ano

C. Fissure in ano

D. Gluteal abscess

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A patient presents to the outpatient department (OPD) with recurrent diarrhea, abdominal pain, and foul-smelling stools. Following finding was observed on colonoscopy. what is the diagnosis? (Q844298)

A. Pseudomembranous colitis

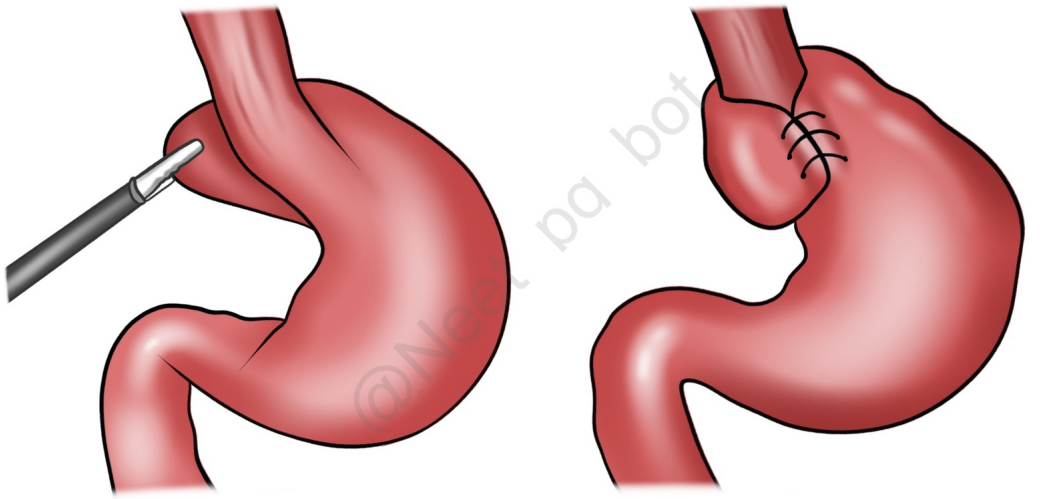
B. FAP

C. Ulcerative colitis

D. Acute gastritis

See Answer in Part B → Q28

@Neet_pg_bot



Q29: Identify the procedure commonly performed in patients with recurrent gastroesophageal reflux disease (GERD): (Q844301)

A. 360-degree Nissen fundoplication

B. Partial gastrectomy

C. Esophageal banding

D. 270-degree Nissen fundoplication

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A child with recurrent vomiting undergoes an x-ray, as shown below. What is the most likely electrolyte imbalance in this patient? (Q860358)

A. Hypokalemia

B. Hyperkalemia

C. Hyponatremia

D. Hypernatremia

See Answer in Part B → Q30

@Neet_pg_bot

Q31: Which nerve is most commonly injured during indirect inguinal hernia surgery? (Q860378)

A. Femoral nerve

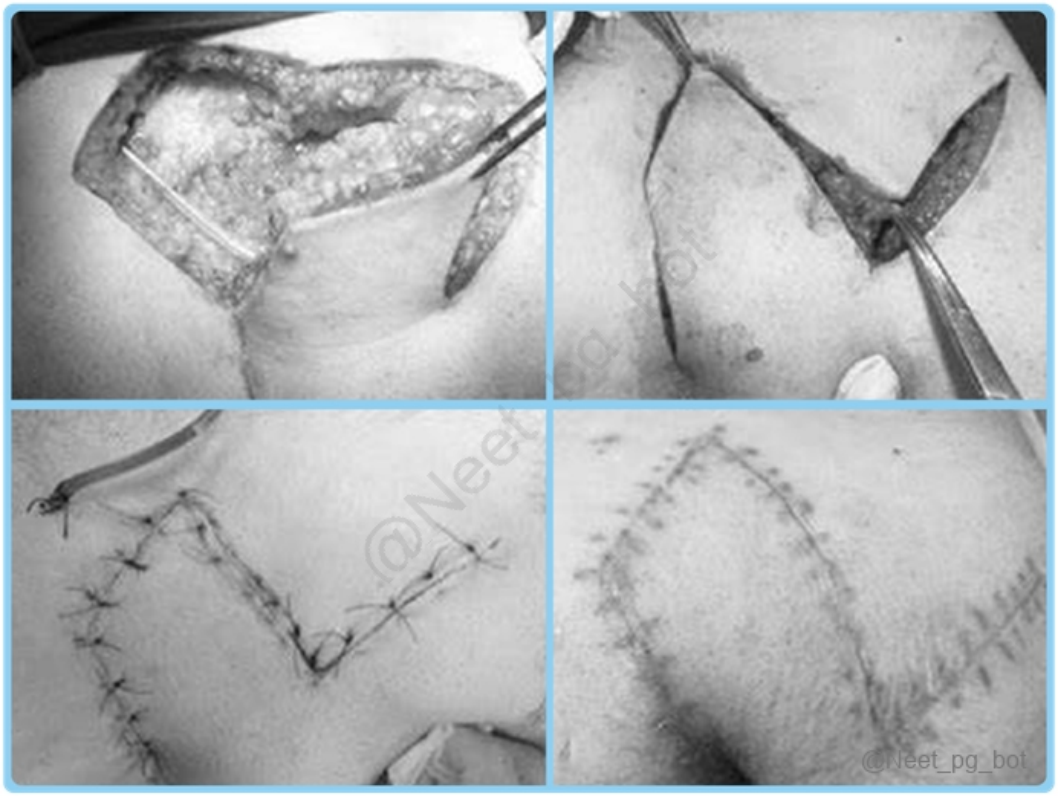
B. Genitofemoral nerve

C. Obturator nerve

D. Ilioinguinal nerve

See Answer in Part B → Q31

@Neet_pg_bot



Q32: A patient underwent surgery for pilonidal sinus, which type of flap is used in this surgery? (Q860379)

A. Rhomboid flap

B. Advanced flap

C. Rotational flap

D. Free flap

See Answer in Part B → Q32

@Neet_pg_bot

Q33: Which incision is most commonly used for an appendectomy? (Q860386)

A. McBurney incision

B. Kocher's incision

C. Midline incision

D. Battle incision

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A 54-year-old male with a history of multiple episodes of vomiting, binge drinking, and heavy meals presents to the emergency department with sudden onset of severe left-sided chest pain radiating to the left shoulder. Pneumoperitoneum is noted on X-ray. What is the most likely diagnosis? (Q860410)

A. Mediastinal air leak

B. Esophageal perforation

C. Pneumoperitoneum

D. Peptic ulcer

See Answer in Part B → Q34

@Neet_pg_bot

Q35: Which of the following is not an indication for splenectomy? (Q860413)

A. Iatrogenic splenic trauma

B. Thrombocytopenia

C. Hairy cell leukemia

D. Bone marrow failure

See Answer in Part B → Q35

@Neet_pg_bot

Q36: A 60-year-old male patient presents with a left groin swelling for a few years, which increases in size on standing and decreases when lying down. On examination, the swelling shows a positive cough impulse. What is the appropriate management?

(Q860416)

A. Incision and drainage

B. Herniotomy

C. Herniorrhaphy

D. Reduction of contents, repair defects and reinforcement with mesh

See Answer in Part B → Q36

@Neet_pg_bot

Q37: Which of the following structures does not form the boundary of Hesselbach's triangle? (Q860425)

A. Inferior epigastric artery

B. Vas deferens

C. Rectus abdominis

D. Inguinal ligament

See Answer in Part B → Q37

@Neet_pg_bot

Q38: What is the type of hernia in which the internal organ forms a portion of the wall of the hernia sac? (Q860428)

A. Lumbar hernia

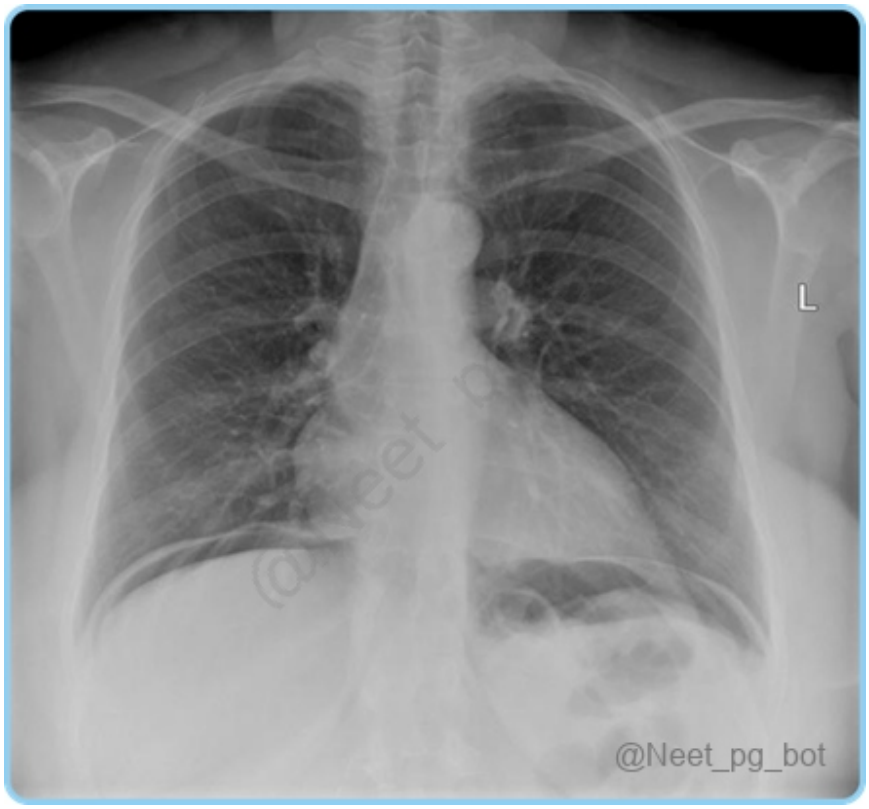
B. Sliding hernia

C. Spigelian hernia

D. Richter hernia

See Answer in Part B → Q38

@Neet_pg_bot



Q39: A 35-year-old male presents to the ER with complaints of epigastric pain for 1 day. On examination, his heart rate is 120/min, and blood pressure is 100/60 mmHg. There is tenderness, guarding, and rigidity on palpation. Based on the clinical presentation and the X-ray findings, what is the most likely cause of this patient's condition? (Q860453)

A. Acute cholecystitis

B. Hollow viscus perforation

C. Sigmoid volvulus

D. Small bowel obstruction

See Answer in Part B → Q39

@Neet_pg_bot

Q40: During laparoscopic surgery, while inserting the trocar, which of the following is most prone to injury? (Q860456)

A. Abdominal aorta

B. Superior epigastric artery

C. Both superior and inferior epigastric arteries

D. Inferior epigastric artery

See Answer in Part B → Q40

@Neet_pg_bot

Q41: A 40-year-old male presents with diffuse abdominal pain. Physical examination reveals rigidity and guarding. Abdominal X-ray shows air under the diaphragm. The patient is taken up for surgery, and an ileal perforation is noted intraoperatively with gross contamination of the abdomen with enteric and purulent content. What is the appropriate management of this patient? (Q860486)

A. Resection and anastomosis

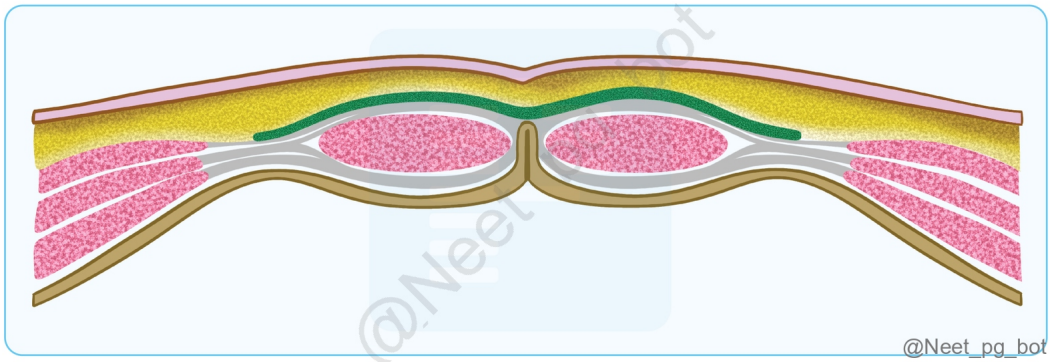
B. Primary repair

C. Urgent surgical exploration with ileostomy

D. Omental patch closure

See Answer in Part B → Q41

@Neet_pg_bot



Q42: A 60-year-old female presents with a gradually progressive swelling over the abdomen for 1.5 years. She has a history of midline surgery. On examination, the swelling is 4 cm and is reducible with a palpable cough impulse. She is planning to undergo fascial closure with mesh repair. What is the most likely location of the mesh shown in the image? (Q860489)

A. Inlay

B. Sublay

C. Onlay

D. Intraperitoneal repair

See Answer in Part B → Q42

@Neet_pg_bot

Q43: Which of the following is the most common hernia in females? (Q840009)

A. Direct Inguinal hernia

B. Indirect inguinal hernia

C. Femoral hernia

D. Obturator hernia

See Answer in Part B → Q43

@Neet_pg_bot

Q44: A 45-year-old patient presents to the clinic with complaints of food regurgitation and weight loss over the past several months. A barium swallow test is performed. What is the diagnosis? (Q840035)

A. Achalasia cardia

B. Esophageal carcinoma

C. Zenker's diverticulum

D. Diffuse esophageal spasm

See Answer in Part B → Q44

@Neet_pg_bot

Q45: Which of the following are risk factors for cholangiocarcinoma? Hepatitis B PSC Caroli's disease Opisthorchis viverrini (Q840038)

A. 1, and 2 only

B. 2, 3, and 4 only

C. 4 only

D. 1, 2, 3, and 4

See Answer in Part B → Q45

@Neet_pg_bot

Q46: A 20-year-old chronic alcoholic presents with severe hematemesis. USG shows distention of the portal vein and the liver appears hyperechoic. Pantoprazole has been initiated. What is the next appropriate step in management? (Q840054)

A. Initiate a course of broad-spectrum antibiotics

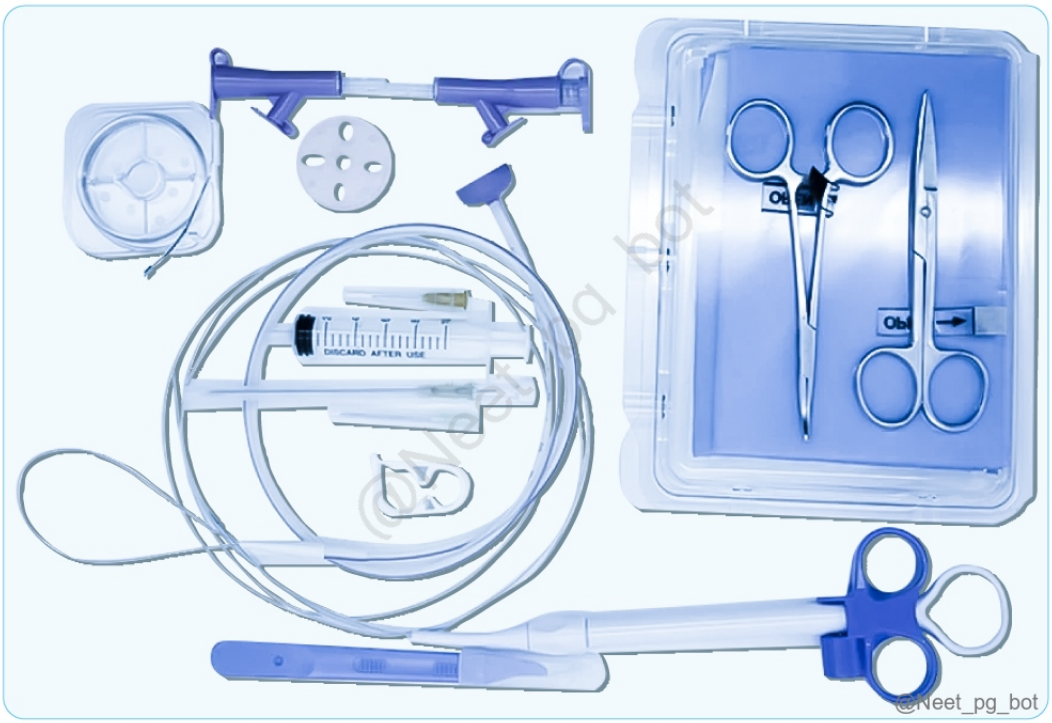
B. Order a liver biopsy to assess for fibrosis

C. Administer intravenous fluids and electrolyte replacement

D. Perform an endoscopy to look for varices

See Answer in Part B → Q46

@Neet_pg_bot



Q47: Identify the image given below? (Q840055)

A. PEG tube

B. Central line

C. Orogastric tube insertion

D. ICD

See Answer in Part B → Q47

@Neet_pg_bot

Q48: A 28-year-old pregnant woman presents with a history of decreased fetal movements and respiratory distress in her newborn. On examination, the neonate appeared cyanotic, with increased breathing work. Auscultation reveals bowel sounds in the left hemithorax. A chest x-ray is given in the image. Which of the following congenital anomalies is most likely responsible for these findings? (Q860177)

A. Congenital diaphragmatic hernia

B. Tetralogy of Fallot

C. Transposition of the Great Vessels

D. Tracheoesophageal fistula

See Answer in Part B → Q48

@Neet_pg_bot

Q49: During an endoscopy, a man is found to have the squamocolumnar junction located more proximally than normal. Which of the following conditions is most likely responsible for this finding? (Q860181)

A. Achalasia cardia

B. Sliding hernia

C. Rolling hernia

D. Gastroesophageal reflux disease

See Answer in Part B → Q49

@Neet_pg_bot

Q50: Which appendicular carcinoma is most commonly associated with pseudomyxoma peritonei? (Q860183)

A. Mucinous cystadenocarcinoma

B. Adenocarcinoma

C. Carcinoid tumour

D. Serous cystadenoma

See Answer in Part B → Q50

@Neet_pg_bot

Q51: Which of the following is the treatment of choice in a pregnant woman with an anal wart, as shown in the image given below? (Q860185)

A. Trichloroacetic acid application

B. Excision

C. Cryotherapy with liquid nitrogen

D. Oral acyclovir

See Answer in Part B → Q51

@Neet_pg_bot

Q52: A 70-year-old male patient who underwent gastrointestinal surgery one month ago, presents with a palpable abdominal bulge at the surgical site. Physical examination reveals a reducible 12 cm incisional hernia. What is the most appropriate next step in the management of this patient? (Q860195)

A. Schedule for laparoscopic mesh repair

B. Prescribe an abdominal belt for daily use

C. Advise observation and reassessment in six months

D. Laparoscopic closure without mesh

See Answer in Part B → Q52

@Neet_pg_bot

Q53: A neonate is diagnosed with gastroschisis. What is the most appropriate management strategy for this condition? (Q860202)

A. Surgical wall repair

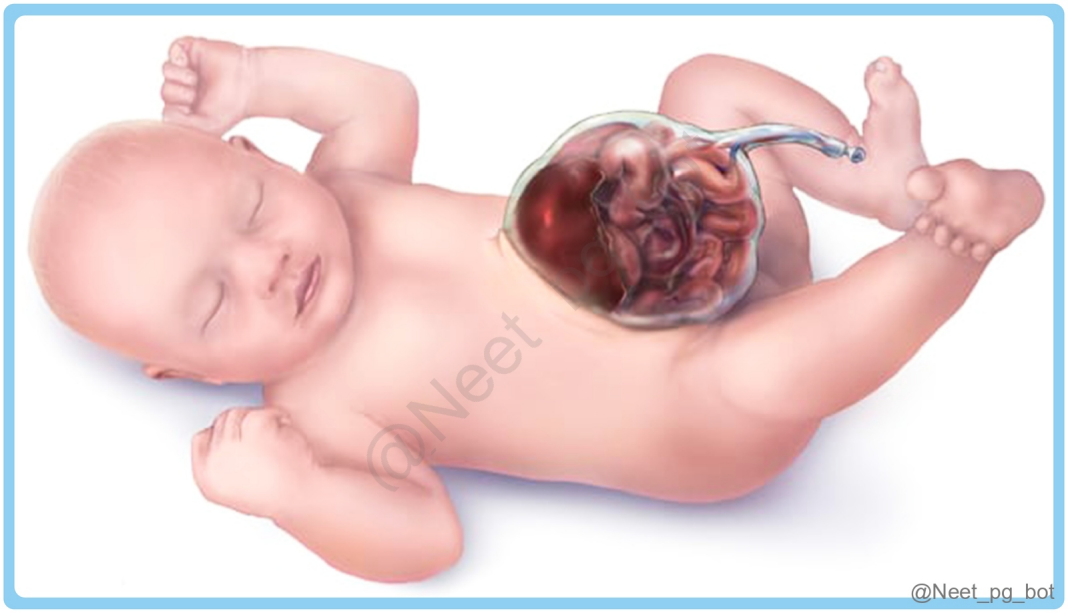
B. Wait and watch

C. Slowly putting it inside

D. Surgical excision

See Answer in Part B → Q53

@Neet_pg_bot



Q54: Identify the image: (Q860206)

A. Omphalocele

B. Urachal cyst

C. Umbilical hernia

D. Umbilical adenoma

See Answer in Part B → Q54

@Neet_pg_bot

Q55: In a seat belt injury, which of the following organs is most commonly affected? (Q860228)

A. Liver

B. Spleen

C. Pancreas

D. Hollow viscus

See Answer in Part B → Q55

@Neet_pg_bot

Q56: A young patient in the first decade of life presents with grade II splenic injury with no active bleeding. What is the management? (Q860297)

A. Splenectomy

B. Splenorrhaphy

C. Embolization

D. Conservative

See Answer in Part B → Q56

@Neet_pg_bot

Q57: What is the most likely diagnosis for an adult male patient with a history of intermittent purulent discharge with a slight blood tinge from an external opening located in the perianal region? (Q860300)

A. Hemorrhoids

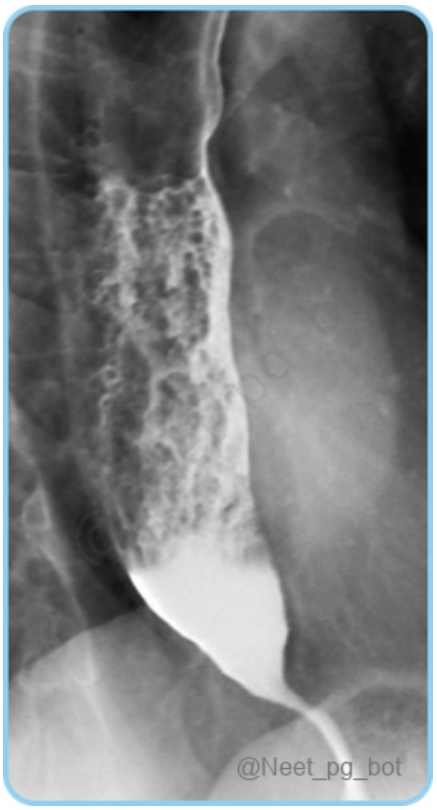
B. Pilonidal sinus

C. Perianal abscess

D. Fistula in ano

See Answer in Part B → Q57

@Neet_pg_bot



Q58: A barium swallow radiographic image of a woman with dysphagia is given below. What is the diagnosis? (Q860304)

A. Achalasia

B. Distal esophageal spasm

C. Jackhammer esophagus

D. None of the above

See Answer in Part B → Q58

@Neet_pg_bot

Q59: A patient underwent bronchoscopy, during the procedure a perforation occurred at 25 cm. Which structure is most likely to be damaged? (Q860306)

A. Diaphragm

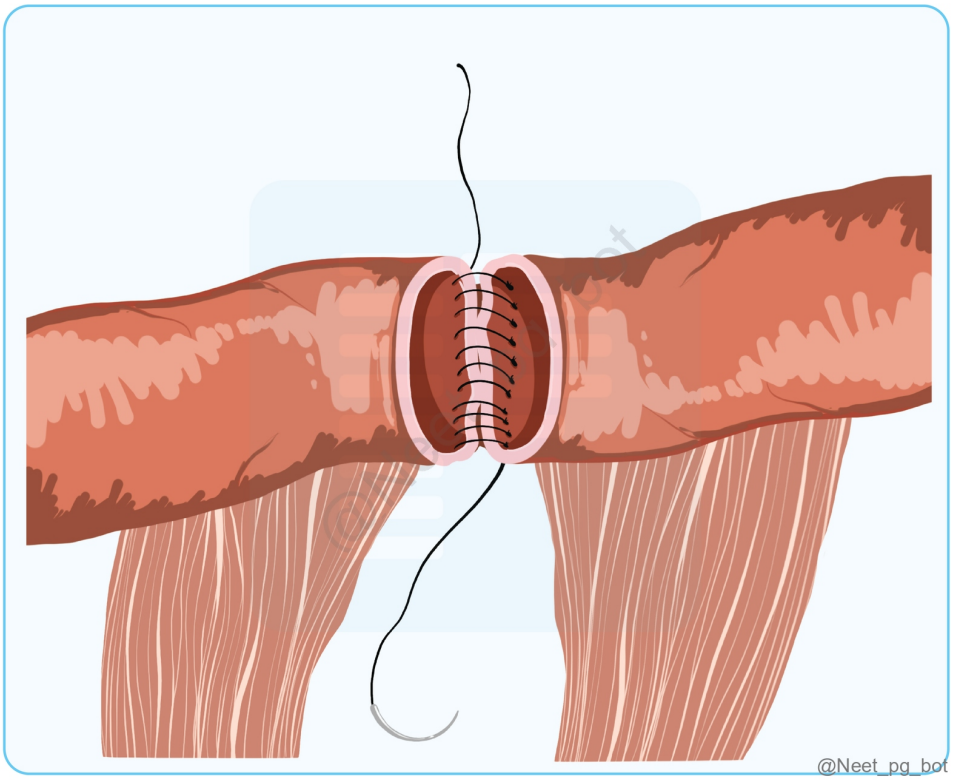
B. Arch of aorta

C. Pharyngoesophageal junction

D. T10

See Answer in Part B → Q59

@Neet_pg_bot



Q60: Identify the operative procedure shown in the image. (Q860308)

A. Primary closure of perforation

B. Resection and Anastomosis

C. Ileostomy

D. Resection alone

See Answer in Part B → Q60

@Neet_pg_bot

Q61: A young female presents with pain and vomiting in the ER. Clinical examination reveals a swelling lateral and below the pubic tubercle. X-ray shows intestinal obstruction. What is the most probable diagnosis? (Q857243)

A. Adhesions

B. Strangulated Inguinal Hernia

C. Strangulated Femoral Hernia

D. Appendicular mass

See Answer in Part B → Q61

@Neet_pg_bot

Q62: A 55-year-old male presents with complaints of dysphagia, halitosis, and regurgitation . Radiological imaging shows a blind pouch at the level of the pharynx. What is the likely diagnosis ? (Q820101)

A. Pulsion diverticula

B. Achalasia cardia

C. CA Esophagus

D. GERD

See Answer in Part B → Q62

@Neet_pg_bot

Q63: A 60-year-old man, a smoker, presented to the OPD with complaints of fatigue. He is known to be anemic and his sister had a history of endometrial cancer. The physician is considering appropriate colorectal cancer screening methods for this patient. Which screening method should be recommended for colorectal malignancy in this patient? (Q820105)

A. Barium enema

B. Colonoscopy every 10 years

C. Check for occult blood in stool

D. Flexible sigmoidoscopy yearly

See Answer in Part B → Q63

@Neet_pg_bot

Q64: What type of material is in the mesh used in Lichtenstein hernioplasty? (Q820106)

A. Polypropylene

B. Polyglactin

C. Polydioxanone

D. Polyacrilamide

See Answer in Part B → Q64

@Neet_pg_bot

Q65: A 20-year-old male presents with a 5-day history of abdominal pain, fever and vomiting . On examination, there is a palpable mass in right iliac fossa with leukocytosis . What is the management plan for this condition? (Q820127)

A. Ochsner-Sherren regime

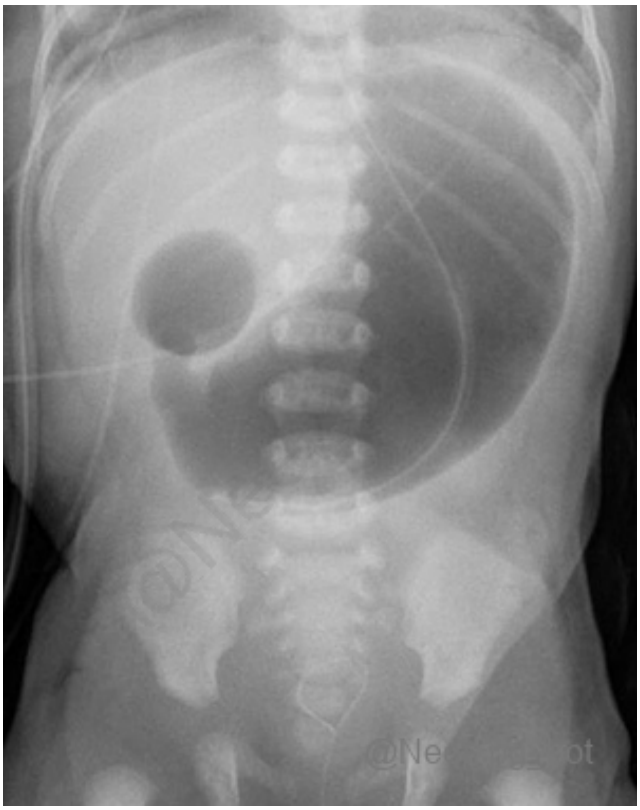
B. Alvarado scoring

C. Laparoscopic appendectomy

D. Cholecystectomy

See Answer in Part B → Q65

@Neet_pg_bot



Q66: A newborn baby presents with bilious vomiting and abdominal distension within 2 days of birth . An X-ray abdomen was performed which is shown below. What is the most probable diagnosis? (Q820131)

A. Duodenal atresia

B. Pyloric stenosis

C. Esophageal atresia

D. Gas in bowel

See Answer in Part B → Q66

@Neet_pg_bot

Q67: A 70-year-old male patient presents with progressive dysphagia to solids and liquids and the manometry findings include uncoordinated or absent peristalsis with increased LES resting pressure . What is the most likely diagnosis for this patient? (Q820145)

A. Stomach cancer

B. Cancer esophagus

C. GERD

D. Achalasia cardia

See Answer in Part B → Q67

@Neet_pg_bot

Q68: A 45-year-old patient presents after undergoing a Billroth II gastrectomy operation and complains of symptoms suggestive of dumping syndrome , including vomiting and diarrhea occurring approximately 20 minutes after meals. What should be the initial management for this patient's condition? (Q820171)

A. Low fat diet

B. Small frequent meals

C. Insulin and protein

D. Reverse Billroth II to Billroth I

See Answer in Part B → Q68

@Neet_pg_bot

Q69: A 35-year-old patient is scheduled to undergo laparoscopic surgery. The surgical team plans to create a pneumoperitoneum to facilitate the procedure. Which gas is commonly used for creating the pneumoperitoneum in laparoscopic surgeries? (Q820240)

A. Helium

B. Oxygen

C. Nitrogen

D. Carbon dioxide

See Answer in Part B → Q69

@Neet_pg_bot

Q70: A male patient complains of loss of appetite and dysphagia, with a weight loss of approximately 6 kg over the last three months. He had a previous diagnosis of esophageal cancer and underwent treatment. What might be the cause of his current symptoms? (Q830818)

A. Esophageal cancer recurrence

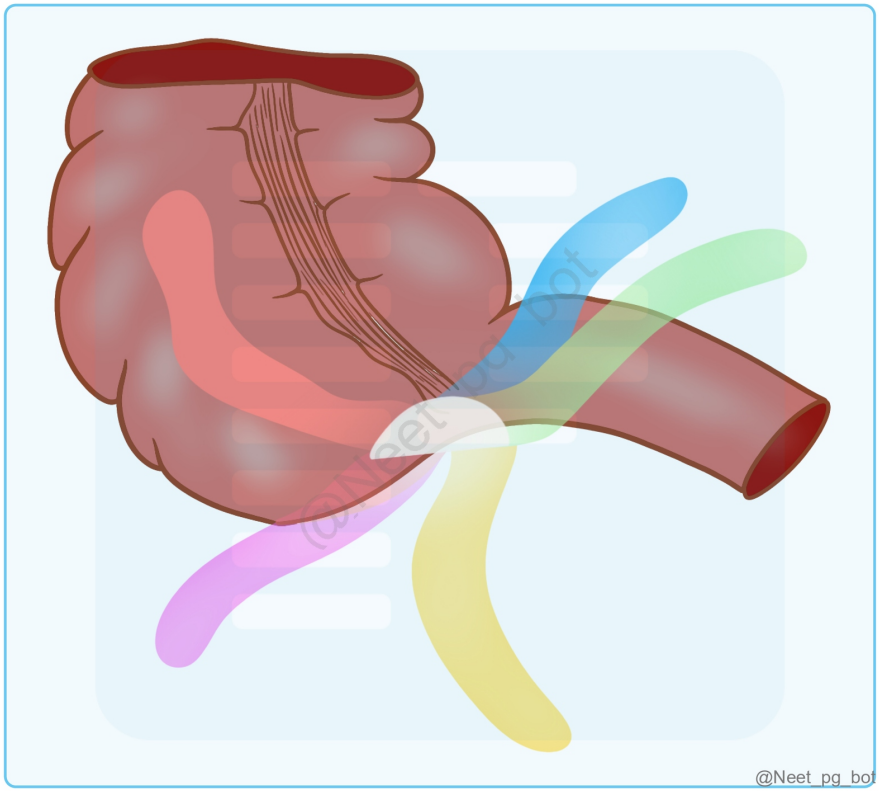
B. Fibrosis

C. Achalasia cardia

D. GERD

See Answer in Part B → Q70

@Neet_pg_bot



Q71: What is the position of the appendix marked in red colour? (Q854748)

A. Retrocecal

B. Preileal

C. Subcecal

D. Pelvic

See Answer in Part B → Q71

@Neet_pg_bot

Q72: A surgeon examines a case of hernia and is able to retract the hernial sac but not its contents. Based on this examination, which type of hernia is most likely? (Q854750)

A. Incarcerated hernia

B. Reduction en masse

C. Sliding hernia

D. Maydl's hernia

See Answer in Part B → Q72

@Neet_pg_bot

Q73: A 53-year-old patient presents with a complaint of per rectal bleeding. The surgeon suspects a possible colorectal pathology and wants to determine the most appropriate investigation for this patient. Which of the following options would be the best choice? (Q854758)

A. Colonoscopy

B. CEA levels

C. CA-19-9 levels

D. CECT

See Answer in Part B → Q73

@Neet_pg_bot

Q74: Which of the following is not a perineal approach for rectal prolapse? (Q854766)

A. Altemeir

B. Frykman and Goldberg's

C. Thiersch

D. Delorme

See Answer in Part B → Q74

@Neet_pg_bot

Q75: Which of the following is the most common complication following ligation of the first vessel during abdominoperineal resection for rectal carcinoma? (Q855169)

A. Parasympathetic - bladder dysfunction and retrograde ejaculation

B. Sympathetic - bladder dysfunction and impotence

C. Sympathetic - retrograde ejaculation and bladder dysfunction

D. Sympathetic - impotence and loss of cutaneous sensation in the perineal region

See Answer in Part B → Q75

@Neet_pg_bot

Q76: A 45-year-old male presents with right thigh pain after undergoing bilateral laparoscopic hernia repair for an inguinal hernia. Which nerve entrapment is most likely responsible for this symptom? (Q855178)

A. Ilioinguinal nerve

B. Iliohypogastric nerve

C. Femoral nerve

D. Lateral cutaneous nerve of thigh

See Answer in Part B → Q76

@Neet_pg_bot

Q77: A patient presents with swelling in the groin region, diagnosed as a direct inguinal hernia . Weakness in which of the following structures is most likely to cause this condition? (Q855239)

A. Pectineal ligament

B. Conjoint tendon

C. Reflected part of inguinal ligament

D. Lacunar ligament

See Answer in Part B → Q77

@Neet_pg_bot

Q78: A 4-year-old child presents with a rectal polyp and painless rectal bleeding. Histopathological examination reveals enlarged and inflamed glands filled with mucin. The child is diagnosed with a juvenile rectal polyp. Which of the following best describes the polyp in this case? (Q855247)

A. Adenoma

B. Choristoma

C. Hamartoma

D. Carcinoma

See Answer in Part B → Q78

@Neet_pg_bot

Q79: A 20-year-old female patient consumed a cleaning product containing 90% sodium hydroxide. She is having complete dysphagia. What is the best step in management? (Q855272)

A. Esophagojejunostomy

B. Stent placement

C. Feeding jejunostomy

D. Gastrojejunostomy

See Answer in Part B → Q79

@Neet_pg_bot

Q80: Which of the following is not true about Congenital Hypertrophic Pyloric Stenosis? (Q857791)

A. Presents with non-bilious vomiting

B. Caused by hypertrophy of longitudinal muscles

C. USG is the gold standard investigation for this condition

D. Hypokalemic metabolic alkalosis seen

See Answer in Part B → Q80

@Neet_pg_bot

Q81: Which of the following is the most common type of anorectal fistula? (Q857797)

A. Intersphincteric

B. Trans-sphincteric

C. Suprasphincteric

D. Extrasphincteric

See Answer in Part B → Q81

@Neet_pg_bot

Q82: During an endoscopy, when a constriction is detected at the esophageal junction approximately 25 cm from the incisor, what is the likely cause? (Q857827)

A. Inferior vena cava

B. Arch of aorta

C. Right bronchus

D. Diaphragmatic opening

See Answer in Part B → Q82

@Neet_pg_bot

Q83: A homosexual man presents with painful defecation and a protruding mass from the anal canal. Biopsy confirms squamous cell carcinoma of the anus. What is the appropriate course of action for managing this patient? (Q857833)

A. Chemotherapy

B. Abdominoperineal repair

C. Combined chemoradiation

D. Wide local excision

See Answer in Part B → Q83

@Neet_pg_bot

Q84: A man came with complaints of recurrent discharge and pain due to lesions around the anus for 3 years. A diagnosis of fistula-in-ano is made. What is the gold standard investigation for this condition? (Q857874)

A. Fistulography

B. USG

C. CECT

D. MRI

See Answer in Part B → Q84

@Neet_pg_bot

Q85: Which of the following procedures has the highest risk of causing the recurrence of duodenal ulcers? (Q857899)

A. Selective Vagotomy

B. Highly selective vagotomy

C. Truncal vagotomy

D. Truncal Vagotomy with Antrectomy

See Answer in Part B → Q85

@Neet_pg_bot

Q86: An elderly woman underwent surgical resection of her bowel; after a few months, she presents with easy fatigability and tiredness. Blood smear evaluation shows macrocytic anaemia. Resection of all of the following can cause this, except: (Q855654)

A. Jejunum

B. Duodenum

C. Ileum

D. Stomach

See Answer in Part B → Q86

@Neet_pg_bot

Q87: Which of the following statements regarding acute cholecystitis is false? (Q855683)

A. Gall bladder thickness >3 mm on USG

B. Murphy’s sign positive

C. Leukocytosis

D. Gold standard investigation is CT scan

See Answer in Part B → Q87

@Neet_pg_bot

Q88: Which of the following is not a perineal approach for the condition shown in the image? (Q855689)

A. Rip stein's procedure

B. Delorme’s operation

C. Thiersch operation

D. Altemeier’s procedure

See Answer in Part B → Q88

@Neet_pg_bot

Q89: A patient who had grade 3 splenic trauma was managed conservatively in the ICU. Which of the following signs on day 2 would indicate a need for surgery? (Q855694)

A. Hemoglobin falls from 12 mg/dL to 10 mg/dL

B. Extraperitoneal bladder rupture

C. Pneumoperitoneum

D. Air in gallbladder

See Answer in Part B → Q89

@Neet_pg_bot

Q90: A female patient was diagnosed with gastric cancer. On immunohistopathology, the biopsy sample was positive for CD117 and negative for LCA, cytokeratin, and S100. What is the diagnosis? LCA - Leucocyte common antigen GIST - Gastrointestinal stromal tumors SCC - Squamous cell carcinoma (Q855697)

A. GIST

B. Adenocarcinoma

C. Hodgkin’s lymphoma

D. SCC

See Answer in Part B → Q90

@Neet_pg_bot

Q91: A female patient is planned for cholecystectomy. Which of the following is not an advantage of laparoscopic surgery? (Q855698)

A. Lesser post-operative pain

B. Cosmetically better

C. Earlier return to normal physiological function

D. Longer duration of stay in hospital

See Answer in Part B → Q91

@Neet_pg_bot

Q92: Severe, intractable pain in advanced rectum cancers is due to: (Q855699)

A. Anterior infiltration in prostate

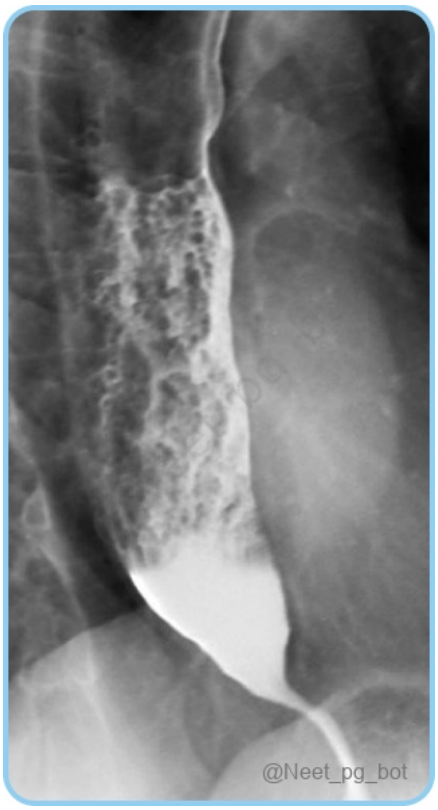
B. Anterior infiltration in the bladder

C. Posterior infiltration in sacral plexus

D. All of the above

See Answer in Part B → Q92

@Neet_pg_bot



Q93: Which investigation is not necessary for the following condition? (Q855153)

A. Timed barium study

B. Endoscopy

C. Esophageal manometry

D. 24-hour pH monitoring

See Answer in Part B → Q93

@Neet_pg_bot

Q94: Which of the following causes maximum malnutrition? (Q855159)

A. Pancreatic fistula

B. Duodenal fistula

C. Distal ileal fistula

D. Colonic fistula

See Answer in Part B → Q94

@Neet_pg_bot

Q95: Which of the following nerves would be involved if a patient experiences a loss of sensations over the root of the penis after undergoing open hernia surgery? (Q855162)

A. Iliohypogastric nerve

B. Ilioinguinal nerve

C. Genitofemoral nerve

D. Medial cutaneous nerve to thigh

See Answer in Part B → Q95

@Neet_pg_bot

Q96: A 10-year-old child with hereditary spherocytosis and hypersplenism presents to the hospital. A splenectomy is planned for this child. All the following vaccines are recommended before splenectomy except? (Q855165)

A. Pneumococcal vaccine

B. Typhoid vaccine

C. Haemophilus influenza B vaccine

D. Meningococcal vaccine

See Answer in Part B → Q96

@Neet_pg_bot

Q97: Which of the following statements about psoas abscess are true? Fluctuant swelling in the hip Cold abscess can develop from Pott's abscess Pain on the passive extension of the hip joint is seen It develops more commonly through the hematogenous route in immunocompromised patients and elderly. (Q855170)

A. 1 and 2

B. 1, 3 and 4

C. 1, 2, 3 and 4

D. 2, 3 and 4

See Answer in Part B → Q97

@Neet_pg_bot

Q98: Which of the following would be the most commonly encountered ectopic tissue in Meckel’s diverticulum? (Q855203)

A. Gastric and pancreatic

B. Colonic and pancreatic

C. Gastric and colonic

D. Thyroid and lung

See Answer in Part B → Q98

@Neet_pg_bot

Q99: What is true about gall bladder carcinoma? (Q855210)

A. Palpable abdominal lump is the earliest sign

B. Earliest sign is jaundice

C. Gallstones and gallbladder cancer are easily distinguished clinically

D. Median survival is less than 6 months

See Answer in Part B → Q99

@Neet_pg_bot

Q100: A patient who had undergone appendectomy 2 days ago presents with severe abdominal pain. On exploration, there is a collection of blood in the abdomen. Which of the following arteries should have been ligated during surgery? (Q855212)

A. Ileocolic artery

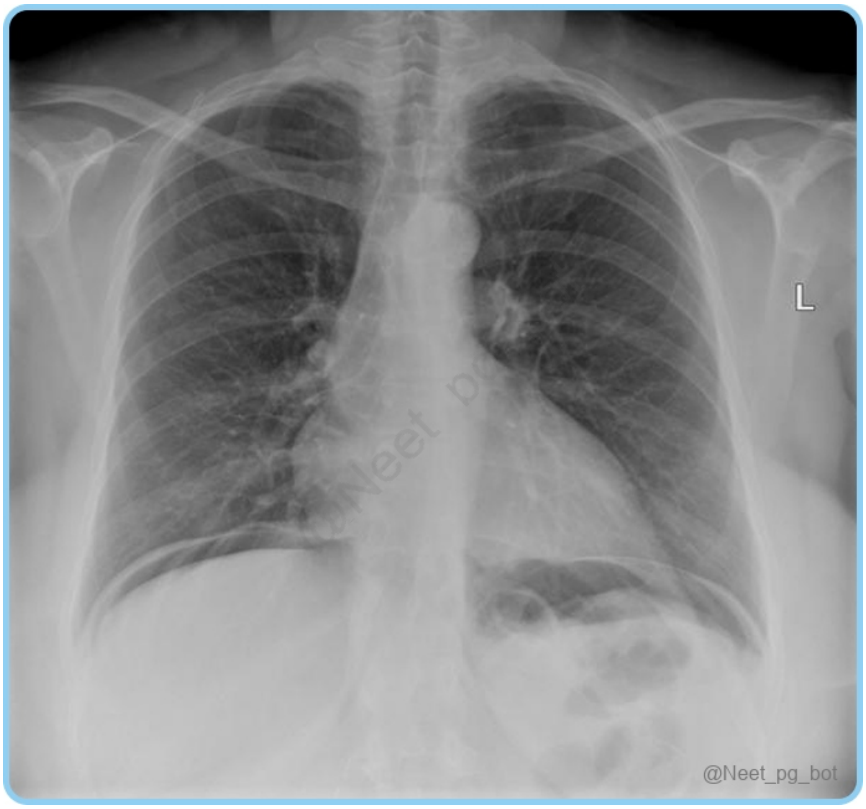
B. Right colic artery

C. Superior rectal artery

D. Superior mesenteric artery

See Answer in Part B → Q100

@Neet_pg_bot



Q101: What should be the subsequent step in managing a 32-year-old male patient who comes to the surgical emergency department with a 2-day history of peptic ulcer disease, experiencing abdominal pain, bloating, and difficulty passing stools? IV fluids CECT abdomen Exploratory laparotomy Upper GI endoscopy Below is the provided X-ray film image (Q855215)

A. 1 and 2

B. 1 and 3

C. 1 and 4

D. 1, 2 and 3

See Answer in Part B → Q101

@Neet_pg_bot

Q102: Identify the correct statement regarding gastric carcinoma: It is mostly hereditary E-cadherin adhesion defect is seen in diffuse types of gastric CA. Wnt signaling pathway defect is seen in intestinal-type gastric CA. Depth of cancer has no role in prognosis. (Q855250)

A. A, C, D

B. B, C

C. B, C, D

D. A, D

See Answer in Part B → Q102

@Neet_pg_bot

Q103: A patient presented with large intra-abdominal fluid accumulation and was found to have pancreatic necrosis. Which of the following are included in the management of the condition? Antibiotics IV IV fluids Culture MRI Assisted drainage Laparotomy (Q855349)

A. 1, 2, 3, 4 and 5

B. 2, 4, 5 and 6

C. 1, 2, 3, 5 and 6

D. 1, 2, 3, 4, 5 and 6

See Answer in Part B → Q103

@Neet_pg_bot

Q104: What is the most prevalent condition that leads to the occurrence of heartburn and chest pain in a patient? (Q857174)

A. Barrett's esophagus

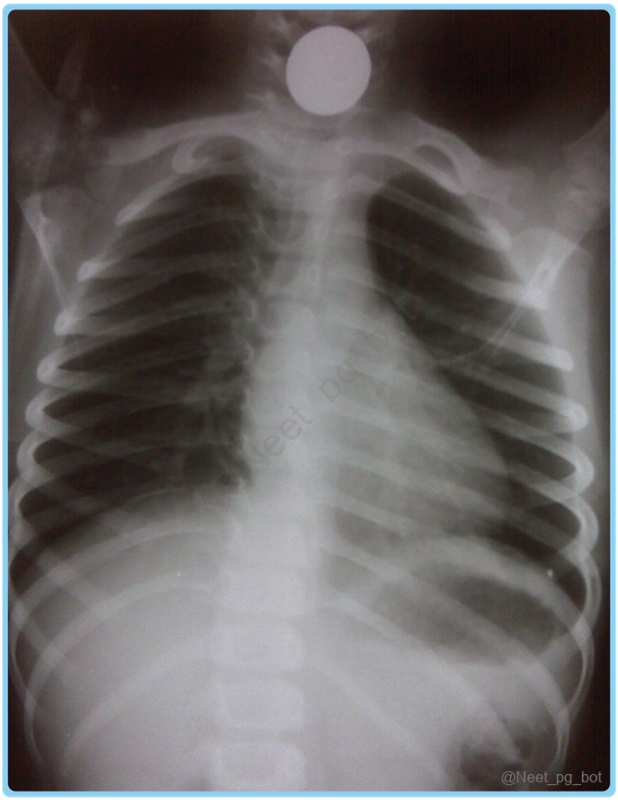
B. Pneumonia

C. Myocardial infarction

D. Esophagitis

See Answer in Part B → Q104

@Neet_pg_bot



Q105: A baby playing unsupervised was brought with complaints of difficulty in swallowing for the last few hours. The x-ray image is given below. What is the diagnosis? (Q857178)

A. Foreign body in the trachea

B. Foreign body in the esophagus

C. Foreign body in lungs

D. Foreign body in pleura

See Answer in Part B → Q105

@Neet_pg_bot

Q106: What is the most appropriate next course of action in managing a male patient, aged 40, who presents with widespread abdominal pain and has a confirmed history of Crohn's disease, as well as rigidity and guarding observed during a physical examination, with ileal perforation being detected on imaging? (Q857216)

A. Antibiotics and NPO

B. Upper GI endoscopy

C. Urgent surgical exploration with ileostomy

D. CT abdomen

See Answer in Part B → Q106

@Neet_pg_bot

Q107: A 34-year-old male presented with a painless mass in the right inguinal region. On examination, there is a cough impulse on the index finger. The swelling reaches the scrotum and is reduced completely by pressing it through the deep inguinal ring with a gurgling sound. What is the likely diagnosis? (Q857238)

A. Femoral hernia

B. Direct inguinal hernia

C. Indirect inguinal hernia

D. Umbilical hernia

See Answer in Part B → Q107

@Neet_pg_bot

Q108: What is the likely diagnosis for a 40-year-old patient who has experienced the passage of mucus and blood in their stool, with inflammation predominantly observed in the rectum during sigmoidoscopy, and the presence of crypt abscess detected during biopsy? (Q857240)

A. Ulcerative colitis

B. Irritable bowel syndrome

C. Crohn disease

D. Pseudomembranous colitis

See Answer in Part B → Q108

@Neet_pg_bot

Q109: An elderly male patient presented with purulent discharge from an opening located in the perianal region. The patient is put in a lithotomy position, and the opening is located at the 11 o'clock position, 2 cm from the anal margin. What will be the likely position of the internal opening, and where does the internal opening start? (Q857258)

A. 12 o'clock and at the external anal sphincter

B. 11 o'clock and at the internal anal sphincter

C. 9 o'clock and at anal verge

D. 6 o'clock and crypt of the dentate line

See Answer in Part B → Q109

@Neet_pg_bot

Q110: What is the most probable outcome for the patient after undergoing gastrectomy? (Q857271)

A. Folic acid deficiency

B. Vitamin B12 deficiency

C. Gastric ulcer

D. Constipation

See Answer in Part B → Q110

@Neet_pg_bot

Q111: What is the diagnosis for a patient who exhibits symptoms of dysphagia, experiencing pain behind the breastbone, and regurgitation accompanied by coughing following meals? (Q857274)

A. Brown Patterson Kelly syndrome

B. Achalasia

C. Esophageal diverticula

D. Reflux esophagitis

See Answer in Part B → Q111

@Neet_pg_bot

Q112: In a patient with ascites visiting your clinic for diagnostic paracentesis, you opt for a midline approach to remove the fluid. Which of the following size needles is used during this procedure? (Q857276)

A. 14 gauge

B. 16 gauge

C. 17 gauge

D. 22 gauge

See Answer in Part B → Q112

@Neet_pg_bot

Q113: A patient presented with retrosternal chest pain radiating to the jaw and dysphagia. A barium swallow was performed, and the following image was shown. Which of the following is the most likely diagnosis? (Q857438)

A. Infectious esophagitis

B. Diffuse esophageal spasm

C. Barrette's esophagus

D. Esophageal stricture

See Answer in Part B → Q113

@Neet_pg_bot

Q114: The provided barium swallow indicates (Q857453)

A. Achalasia cardia

B. Diffuse esophageal spasm

C. Nutcracker oesophagus

D. Hypertensive lower esophageal sphincter

See Answer in Part B → Q114

@Neet_pg_bot

Q115: Which of the following conditions has a barium enema as shown in the picture below? (Q857454)

A. Multiple colonic polyps

B. Ulcerative colitis

C. Diverticulosis

D. Irritable bowel syndrome

See Answer in Part B → Q115

@Neet_pg_bot

Q116: A gross specimen of the colon obtained from a 14-year-old boy is shown below. Which of the following is the most likely diagnosis? (Q857499)

A. Crohn's disease

B. Familial adenomatous polyposis (FAP)

C. Lynch syndrome

D. Juvenile polyposis syndrome

See Answer in Part B → Q116

@Neet_pg_bot

Q117: During a routine check-up, an elderly male was discovered to have a rectal mass during a digital rectal examination, indicating the possibility of rectal carcinoma. Despite normal bowel habits, the next course of action for managing this patient should be: (Q857519)

A. CT scan of the abdomen

B. Rigid sigmoidoscopy and biopsy

C. Full colonoscopy and biopsy

D. Barium enema

See Answer in Part B → Q117

@Neet_pg_bot

Q118: A 30-year-old female presented with a low-grade fever of 1-week duration associated with loss of appetite and weight loss. Barium meal follow-through image of the patient is given below. What is the probable diagnosis? (Q857520)

A. Ileocaecal TB

B. Ulcerative colitis

C. Crohn's disease

D. Carcinoma caecum

See Answer in Part B → Q118

@Neet_pg_bot

Q119: A 35-year-old man arrives at the emergency department with a concern of vomiting blood. He mentions a recent pattern of excessive alcohol consumption. Upon examination, his vital signs are steady, and he has a pale appearance. There are no indications of ongoing bleeding. The results of his liver function tests are within the normal range. To further assess the situation, an upper gastrointestinal endoscopy is

scheduled. What is the most probable diagnosis? (Q857523)

A. Esophageal varices

B. Gastric ulcer

C. Mallory-Weiss tear

D. Alcoholic gastritis

See Answer in Part B → Q119

@Neet_pg_bot

Q120: Which of the following accurately represents Bormann's classification for gastric carcinoma? (Q857524)

A. Type I: Polypoid tumor with a small ulcerated component

B. Type II: Ulcerated tumor with infiltrative margins

C. Type III: Diffusely infiltrative tumor with linitis plastica appearance

D. Type IV: Mucinous carcinoma with extensive peritoneal metastases

See Answer in Part B → Q120

@Neet_pg_bot

Q121: A 60-year-old male presents to the emergency department with abdominal pain and vomiting. He reports a 2-day history of constipation and bloating. On examination, he appears uncomfortable, and his abdomen is distended with high-pitched bowel sounds. X-ray reveals dilated loops of the small bowel. What is the most likely cause of his symptoms? (Q857525)

A. Colonic malignancy

B. Small bowel obstruction

C. Acute pancreatitis

D. Gastric ulcer

See Answer in Part B → Q121

@Neet_pg_bot

Q122: Which of the following findings of colonoscopy is highly malignant? (Q857526)

A. Multiple flat polyps about 100

B. Single pedunculated polyp

C. Multiple pedunculated polyps

D. Solitary flat polyp

See Answer in Part B → Q122

@Neet_pg_bot

Q123: Which of the following statements accurately describes McBurney's point in cases of acute appendicitis? (Q857527)

A. McBurney point is located in the left lower quadrant of the abdomen.

B. McBurney point corresponds to the site of maximal tenderness in acute appendicitis.

C. McBurney point is used to assess rebound tenderness in acute appendicitis.

D. McBurney point is located at the umbilicus in acute appendicitis.

See Answer in Part B → Q123

@Neet_pg_bot

Q124: What is the likely diagnosis for a patient who has been experiencing fever and pain in the lower right abdomen for the past 5 days, with the presence of a tender mass in the right iliac fossa and an elevated leukocyte count? (Q857528)

A. Appendicitis

B. Hydronephrosis

C. Tuberculosis

D. Carcinoma colon

See Answer in Part B → Q124

@Neet_pg_bot

Q125: What is the diagnosis of a female patient who presents with a mass in the inguinal area that can be reduced from the deep inguinal ring accompanied by a gurgling sound? (Q857530)

A. Direct inguinal hernia

B. Indirect inguinal hernia

C. Femoral hernia

D. Pantaloon hernia

See Answer in Part B → Q125

@Neet_pg_bot

Q126: All of the following are true about Crohn’s disease except (Q857554)

A. Rectum is involved

B. Serpiginous ulcers are formed

C. Transmural involvement

D. Recurrence is more common

See Answer in Part B → Q126

@Neet_pg_bot

Q127: Which of the following statements are true about colon cancer? 1. Right and left colon cancers can behave differently 2. Colon cancers can be hereditary 3. Colon

cancer risk can be reduced by metformin 4. Colon cancers frequently metastasize to the liver (Q858355)

A. 1, 2 and 3 only

B. 2, 3 and 4 only

C. 2 and 4 only

D. 1, 2, 3 and 4

See Answer in Part B → Q127

@Neet_pg_bot

Q149: A middle-aged man presents with a gradual onset of swallowing difficulties for both solid and liquid foods, persisting for 8 months. The barium swallow test results are presented below. The patient undergoes upper gastrointestinal endoscopy and manometry. Which of the following statements is not true regarding this condition? (Q859597)

A. Loss of lower esophageal sphincter pressure causing reflux

B. <75% relaxation of the lower esophageal sphincter

C. It is a primary motility disorder

D. Esophageal peristalsis is absent

See Answer in Part B → Q149

@Neet_pg_bot

Q150: What would be the subsequent course of action for managing a 35-year-old woman who has been experiencing swelling in her right groin for the past six months, as determined during her arrival at the emergency department? Upon examination, a reducible hernia is observed in the right groin without any signs of strangulation. (Q859599)

A. Exploratory laparotomy

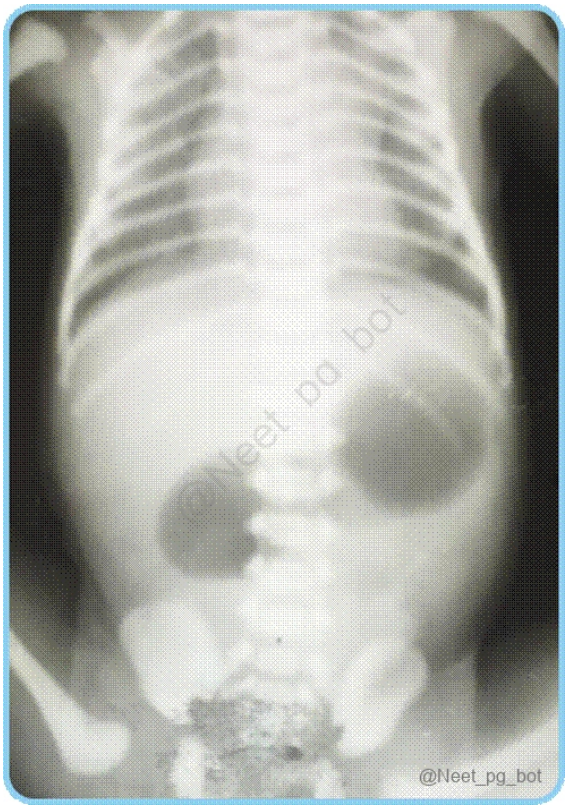
B. Reduce the swelling and later observe

C. Reduce the swelling and do elective surgery

D. Do a CT abdomen

See Answer in Part B → Q150

@Neet_pg_bot



Q151: The likely diagnosis for a newborn infant presenting with signs of intestinal obstruction, as indicated by the x-ray image and CT abdomen showing an annular pancreas, is: (Q859607)

A. Jejunoileal atresia

B. Esophageal atresia

C. Duodenal atresia

D. Colonic atresia

See Answer in Part B → Q151

@Neet_pg_bot

Q152: A patient who underwent Nissen's fundoplication was seen in the ward during evening rounds. He is asymptomatic at present and has stable vitals. What is the next line of management for this patient? (Q859609)

A. Nasogastric tube to prevent gas bloat syndrome

B. Insert chest tube to prevent pneumothorax

C. Monitor vitals

D. Imaging to rule out perforation

See Answer in Part B → Q152

@Neet_pg_bot

Q153: Which of the following do not require instruments to examine? (Q859610)

A. Acute anal fissure

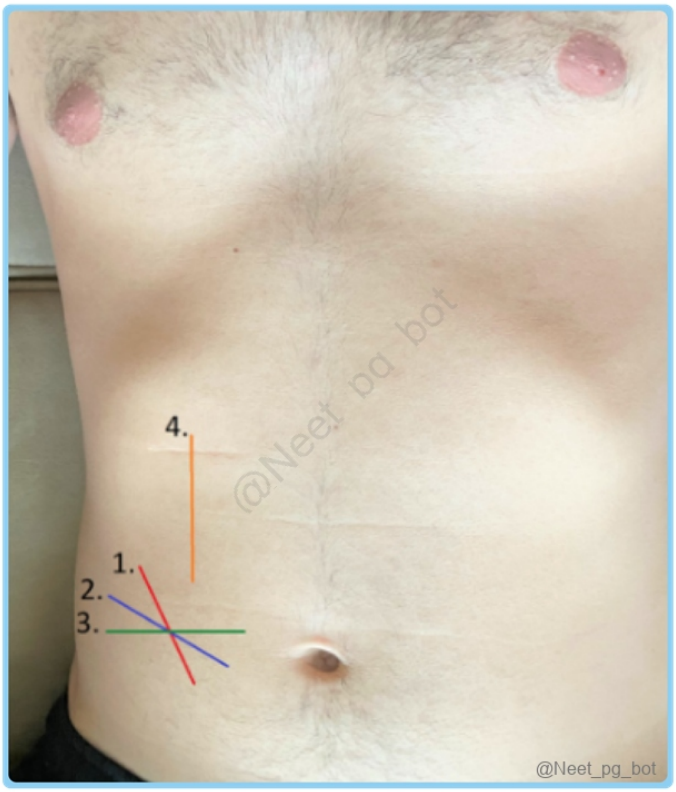
B. Carcinoma rectum

C. Hemorrhoids

D. Rectal polyp

See Answer in Part B → Q153

@Neet_pg_bot



Q154: Identify the incision marked as 4. (Q859611)

A. Gridiron incision

B. Lanz incision

C. Rutherford - Morison incision

D. Paramedian incision

See Answer in Part B → Q154

@Neet_pg_bot

Q155: Which of the following statements about carcinoid tumours in the appendix is false? (Q859612)

A. Size appears to be the best predictor of malignant behaviour and metastatic potential

B. Arise from Kulchitsky cells of the crypts of Leiberkuhn

C. Most common location is the base of the appendix

D. Most common tumor of the appendix

See Answer in Part B → Q155

@Neet_pg_bot

Q156: The most common type of gastric sarcoma: (Q859623)

A. GIST

B. Liposarcoma

C. Leiomyosarcoma

D. Epithelioid sarcoma

See Answer in Part B → Q156

@Neet_pg_bot

Q157: What structures are contained within the anterior pararenal space? Head, neck, and body of the pancreas Adrenal gland, kidney, ureters Aorta, inferior vena cava Ascending and descending colon (Q859825)

A. 1,4

B. 3,4

C. 2,3

D. 1,2

See Answer in Part B → Q157

@Neet_pg_bot

Q158: What electrolyte imbalance is commonly observed in patients with this postoperative condition, as depicted in the provided x-ray? (Q859829)

A. Hypocalcemia

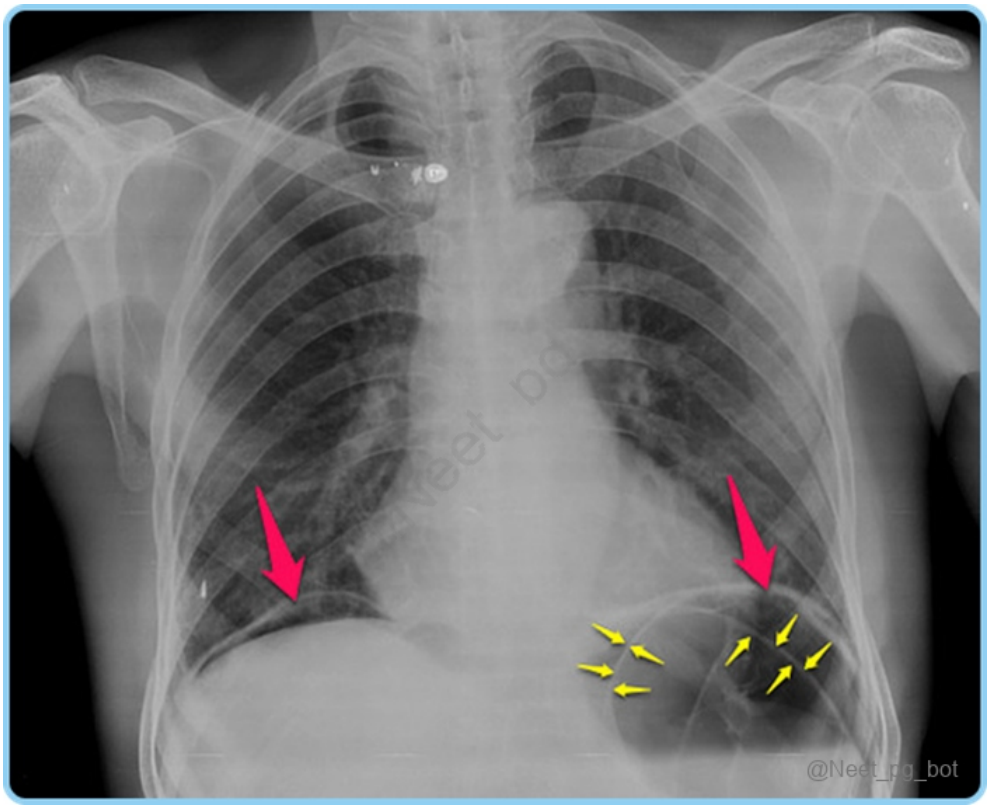
B. Hypokalemia

C. Hyperkalemia

D. Hypercalcemia

See Answer in Part B → Q158

@Neet_pg_bot



Q159: A 40-year-old male presents with diffuse abdominal pain. He has a past history of peptic ulcer disease. Physical examination reveals rigidity. An X-ray of the abdomen is shown below. What is the next best step in the management of this patient? (Q859831)

A. Antibiotics and NPO (nothing by mouth)

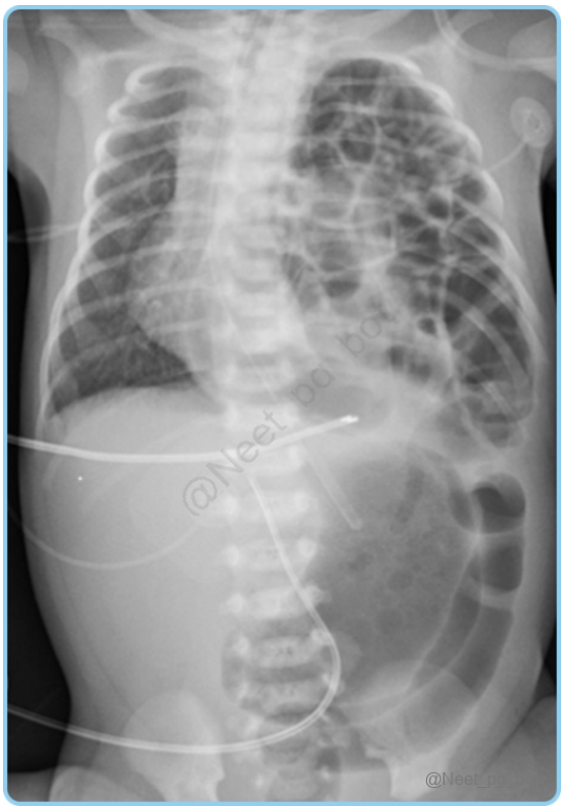
B. Upper GI endoscopy

C. Urgent surgical exploration

D. CT abdomen

See Answer in Part B → Q159

@Neet_pg_bot



Q160: A neonate presented with mild intermittent upper abdominal pain. On examination, the infant has a scaphoid abdomen and breath sounds are decreased on both sides. The X-ray is given below. What is the diagnosis? (Q859848)

A. Bochdalek hernia

B. Pneumonia

C. Gastric volvulus

D. Eventration of diaphragm

See Answer in Part B → Q160

@Neet_pg_bot

Q161: What is the diagnosis of a neonate who is brought to the hospital with complaints of forceful vomiting that is not accompanied by bile after feeding? The child appears lethargic and dehydrated, and abdominal examination shows visible movements of the stomach. A barium meal was conducted, and the image provided is shown below. (Q859853)

A. Hirschsprung’s disease

B. Congenital hypertrophic pyloric stenosis

C. Jejunal atresia

D. Duodenal atresia

See Answer in Part B → Q161

@Neet_pg_bot

Q162: What is the probable diagnosis for a 5-year-old child with abdominal swelling, mild discomfort, no pain or vomiting, and a fluctuant soft swelling that moves freely in a plane perpendicular to the mesentery attachment, as seen in the outpatient department? (Q859866)

A. Peritoneal cyst

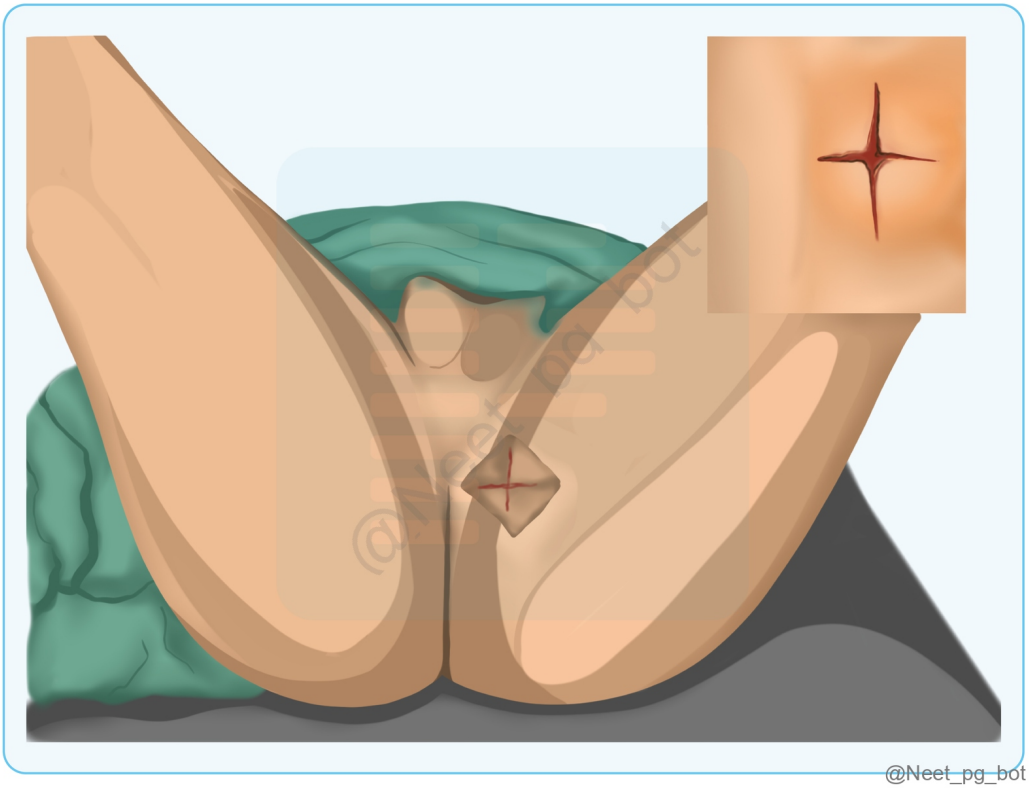
B. Lipoma

C. Chylolymphatic cyst

D. Pseudocyst

See Answer in Part B → Q162

@Neet_pg_bot



Q163: The image below shows an image of the anus. What is the most likely diagnosis, and it occurs when one of your anus glands becomes clogged and infected? Pus and fluid accumulate in the anal gland, resulting in an excruciatingly painful abscess around your anus? (Q859870)

A. Hemorrhoids

B. Pelvirectal abscess

C. Perianal abscess

D. Pilonidal sinus

See Answer in Part B → Q163

@Neet_pg_bot

Q164: Which of the following is the most probable diagnosis for a 38-year-old male patient who visited the surgery OPD with a history of occasional discharge of pus with a slight presence of blood from an external opening in the perianal region, despite multiple attempts at drainage? The examination of the perianal region is depicted

below. (Q859872)

A. Pilonidal sinus

B. Perianal abscess

C. Hemorrhoids

D. Fistula-in-ano

See Answer in Part B → Q164

@Neet_pg_bot

Q165: An infant of 12 weeks presented with the following defect in the umbilical area. Identify the condition. (Q859875)

A. Omphalocele

B. Gastroschisis

C. Umbilical hernia

D. Paraumbilical hernia

See Answer in Part B → Q165

@Neet_pg_bot

Q166: A patient, after heavy drinking of alcohol presents with multiple episodes of vomiting and hematemesis. The most likely diagnosis is: (Q859898)

A. Mallory-Weiss syndrome

B. Esophageal carcinoma

C. Achalasia cardia

D. Boerhaave's syndrome

See Answer in Part B → Q166

@Neet_pg_bot

Q167: The treatment of choice for inguinal hernia in infants is: (Q859899)

A. Herniotomy

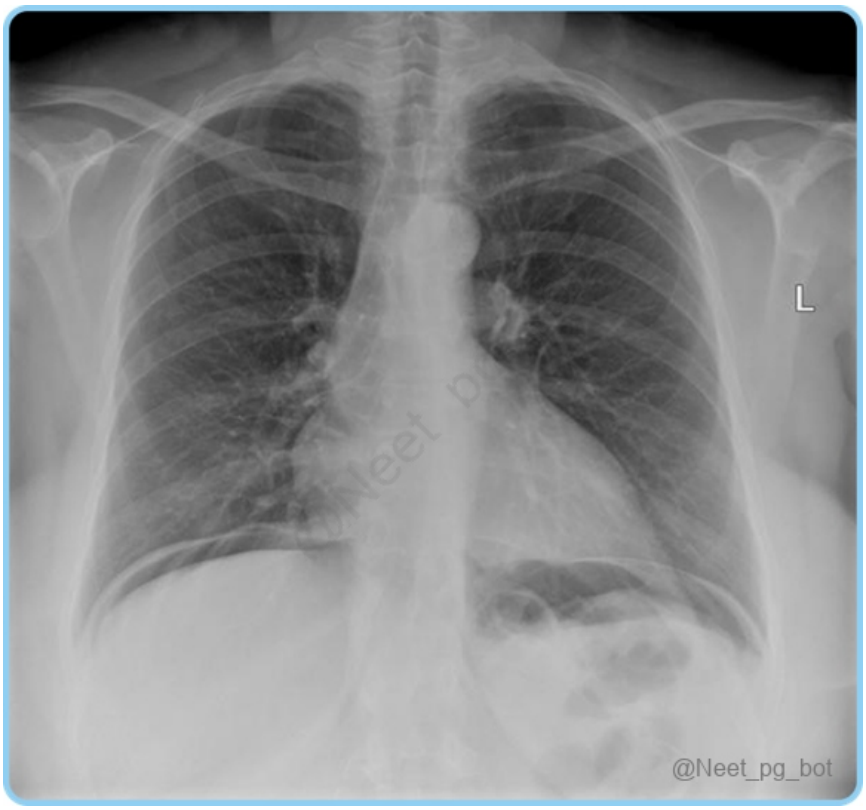
B. Herniorrhaphy

C. TRUSS

D. Hernioplasty

See Answer in Part B → Q167

@Neet_pg_bot



Q168: A patient presents with acute-onset, severe abdominal pain. He is hemodynamically stable. A chest X-ray is shown below. What is the next step in management? (Q855778)

A. Gastric lavage

B. Chest tube insertion

C. Tracheostomy

D. Resuscitation and laparotomy

See Answer in Part B → Q168

@Neet_pg_bot

Q169: A 1.5-month-old male infant presents to the outpatient department with vomiting after feeding and failure to thrive . On examination, a firm, olive-shaped mass is palpated in the upper abdomen . What is the most likely diagnosis? (Q852714)

A. Subacute Intestinal Obstruction

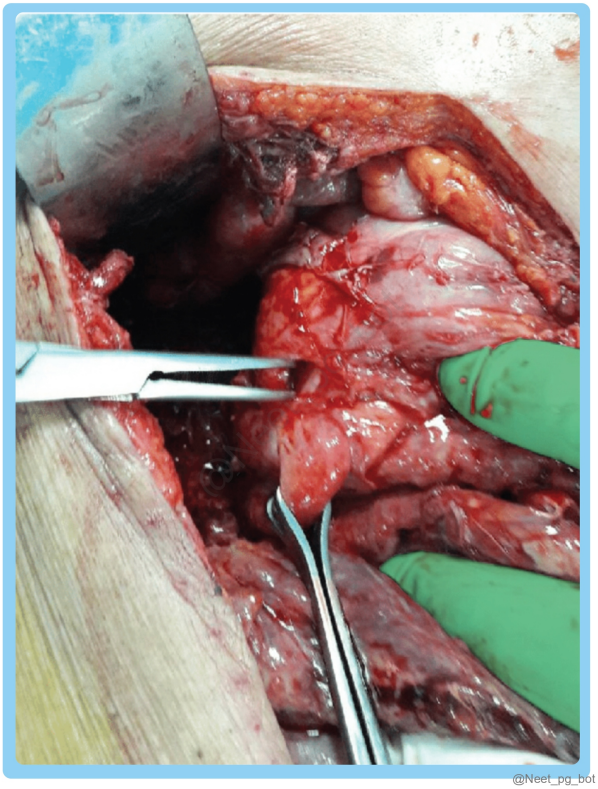
B. Pyloric Stenosis

C. GERD

D. Esophageal Atresia

See Answer in Part B → Q169

@Neet_pg_bot



Q170: An alcoholic male patient diagnosed with hollow viscus perforation is taken up for laparotomy. Intraoperatively, a 2 cm perforation is seen in the duodenal region, as shown below. How can this patient be managed? (Q860458)

A. Primary closure of the defect

B. Omental pedicle repair

C. Billroth I

D. Billroth II

See Answer in Part B → Q170

@Neet_pg_bot

Q171: Which of the following is/are complications associated with GERD? Asthma Laryngitis Pulmonary Fibrosis Chronic cough (Q839982)

A. 1,2

B. 1,2,4

C. 1,2,3

D. 1,2,3,4

See Answer in Part B → Q171

@Neet_pg_bot

Q172: Which of the following is not a layer of esophagus? (Q820123)

A. Mucosa

B. Submucosa

C. Serosa

D. Muscularis

See Answer in Part B → Q172

@Neet_pg_bot

Q173: Which of the following gene mutations are involved in carcinoma of the colon? (Q856243)

A. APC, BRCA, k-ras

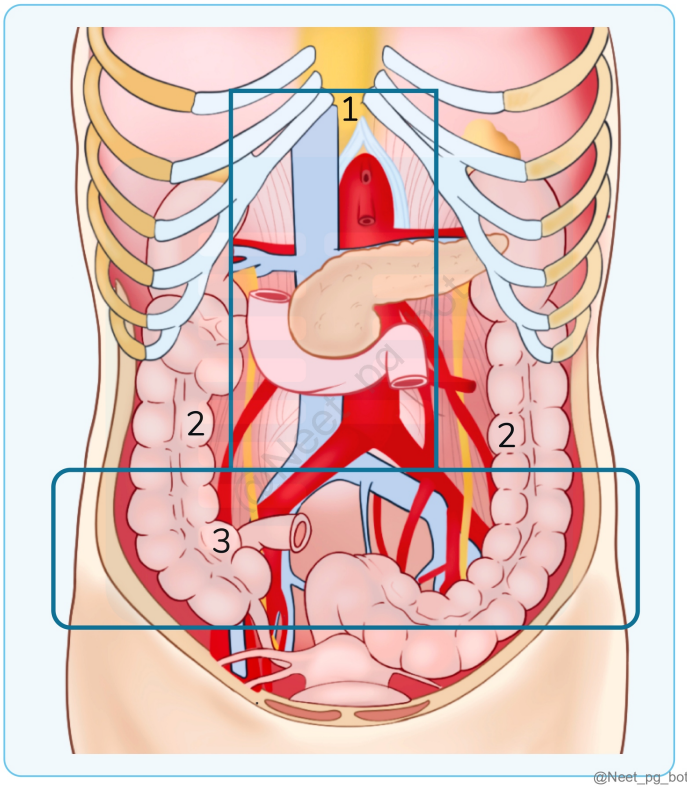
B. APC, k-ras, p53

C. MYh, K-RAS, APC

D. MYH, p53, DCC

See Answer in Part B → Q173

@Neet_pg_bot



Q174: Mandatory exploration is required in the injuries. Which zones of retroperitoneum are required? (Q859819)

A. 1

B. 2

C. 3

D. 1 & 3

See Answer in Part B → Q174

@Neet_pg_bot

Q175: A 45-year-old man complained of recurrent discharge and pain due to lesions around the anus for 3 years. What is the diagnosis? (Q855580)

A. Pilonidal sinus

B. Carbuncle

C. Boil

D. Fistula in ano

See Answer in Part B → Q175

@Neet_pg_bot

Q176: A 35-year-old man with a history of ulcerative colitis presents with fatigue and pruritus. Laboratory investigations show a cholestatic liver function test pattern. MRCP reveals multifocal strictures and beading of intrahepatic and extrahepatic bile ducts. Liver biopsy demonstrates concentric "onion-skin" fibrosis around bile ducts. What is the most likely diagnosis? (Q879028)

A. Primary biliary cholangitis

B. Primary sclerosing cholangitis

C. Autoimmune hepatitis

D. Secondary biliary cirrhosis

See Answer in Part B → Q176

@Neet_pg_bot

Q177: The angle between two working ports in laparoscopic surgery? (Q879104)

A. Azimuth angle

B. Elevation angle

C. Manipulation angle

D. Extreme angle

See Answer in Part B → Q177

@Neet_pg_bot

Q178: All of the following statements about stomas are true except? (Q879107)

A. Patients with a colostomy are at a higher risk of fluid and electrolyte imbalance

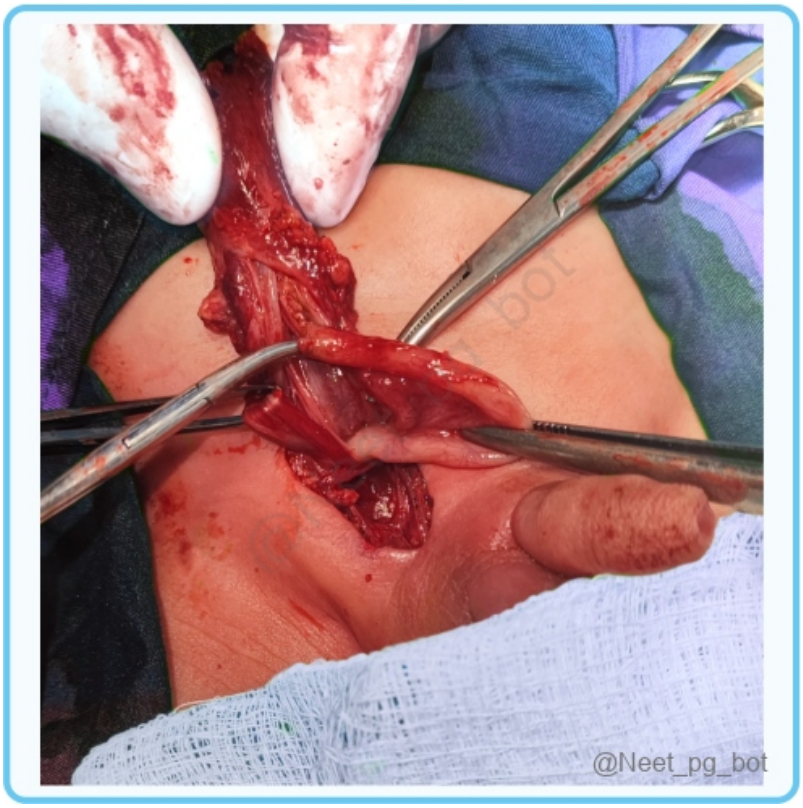
B. Ileostomy stoma is spouted

C. Temporary stomas are fashioned as a loop

D. Colostomy stoma is everted and flushed

See Answer in Part B → Q178

@Neet_pg_bot



Q179: During surgery for an inguinal hernia, the appendix is found inside the hernia sac. What type of hernia is this? (Q879118)

A. Litter’s hernia

B. Amyand’s hernia

C. Gibbons hernia

D. Richter’s hernia

See Answer in Part B → Q179

@Neet_pg_bot

Q180: A patient with recurrent history of gastric ulcers presented with severe pain abdomen on evaluation a small mass is found on the anterior wall of duodenum. Which investigation will help in the diagnosis? (Q879137)

A. Insulin levels

B. Gastrin level

C. Urea breath test

D. 24 hr PH monitoring

See Answer in Part B → Q180

@Neet_pg_bot

Q181: Arrange the steps of hernioplasty: 1. Skin incision 2. Identify the sac and reduce the content 3. Place the mesh 4. Close the wound (Q879145)

A. 1 → 2 → 3 → 4

B. 1 → 3 → 2 → 4

C. 2 → 1 → 3 → 4

D. 1 → 2 → 4 → 3

See Answer in Part B → Q181

@Neet_pg_bot

Q182: A 20-year-old male presents with pain in the right iliac fossa for 4 days, associated with fever and vomiting. On examination, a tender, palpable mass is felt in the right iliac fossa. He is diagnosed with an appendicular lump. Which of the following statements is incorrect regarding this condition? (Q879226)

A. Ochsner– Sherren regimen is the initial treatment

B. Ultrasonography is useful in evaluation

C. Interval appendectomy is mandatory in all cases

D. Appendicular lump is a complication of acute appendicitis

See Answer in Part B → Q182

@Neet_pg_bot

Q183: What type of hernia is a funicular hernia ? (Q32236)

A. Direct inguinal hernia

B. Indirect inguinal hernia

C. Femoral hernia

D. Umbilical hernia

See Answer in Part B → Q183

@Neet_pg_bot

Q184: Which of the following is the most common type of anorectal fistula ? (Q513252)

A. Intersphincteric

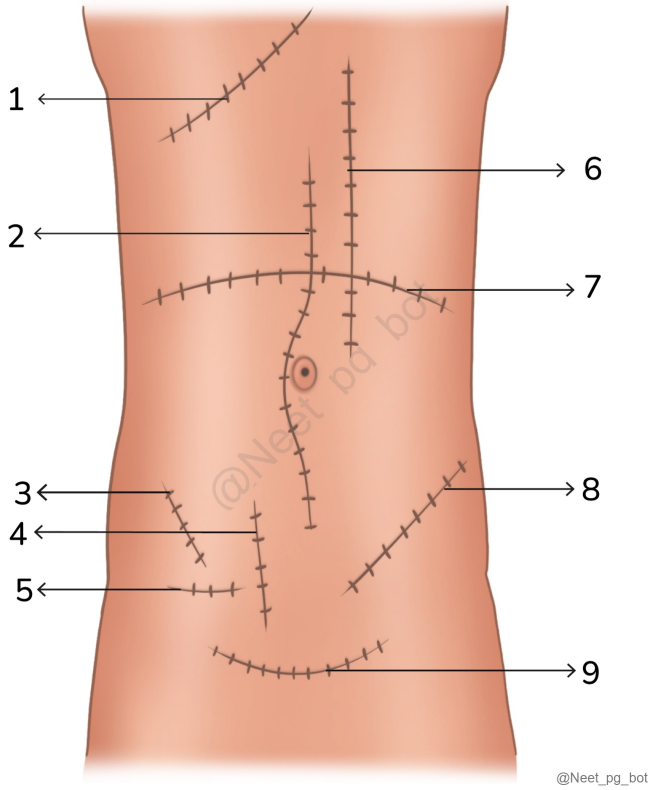
B. Trans-sphincteric

C. Suprasphincteric

D. Extrasphincteric

See Answer in Part B → Q184

@Neet_pg_bot



Q185: A 23-year-old male had acute appendicitis 3 days ago and presented to the surgery department with abdominal pain and tenderness . Which of the following incisions would be appropriate for this condition? (Q793366)

A. 1

B. 2

C. 3

D. 5

See Answer in Part B → Q185

@Neet_pg_bot

Q186: A 45-year-old alcoholic with a history of binge drinking presents with an episode of vomiting bright red blood . His vitals are stable. An endoscopy was performed, an image of which is given below; what is the probable diagnosis here? (Q793397)

A. Tension pneumothorax

B. Boerhaave syndrome

C. Mallory Weiss Tear

D. Gastric ulcer perforation

See Answer in Part B → Q186

@Neet_pg_bot

Q187: What is the most probable cause of massive, sudden onset hematemesis in a 50-year-old patient with a history of chronic liver disease and chronic alcoholism, who has arrived at the emergency department? (Q793399)

A. Mallory Weiss tear

B. Bleeding esophageal varices

C. Boerhaave's syndrome

D. Perforated ulcer

See Answer in Part B → Q187

@Neet_pg_bot

Q188: A 3-day old neonat e presents abdominal distension and bilious vomiting . Among the following, which is the most appropriate investigation to diagnose the condition? (Q793487)

A. Barium swallow

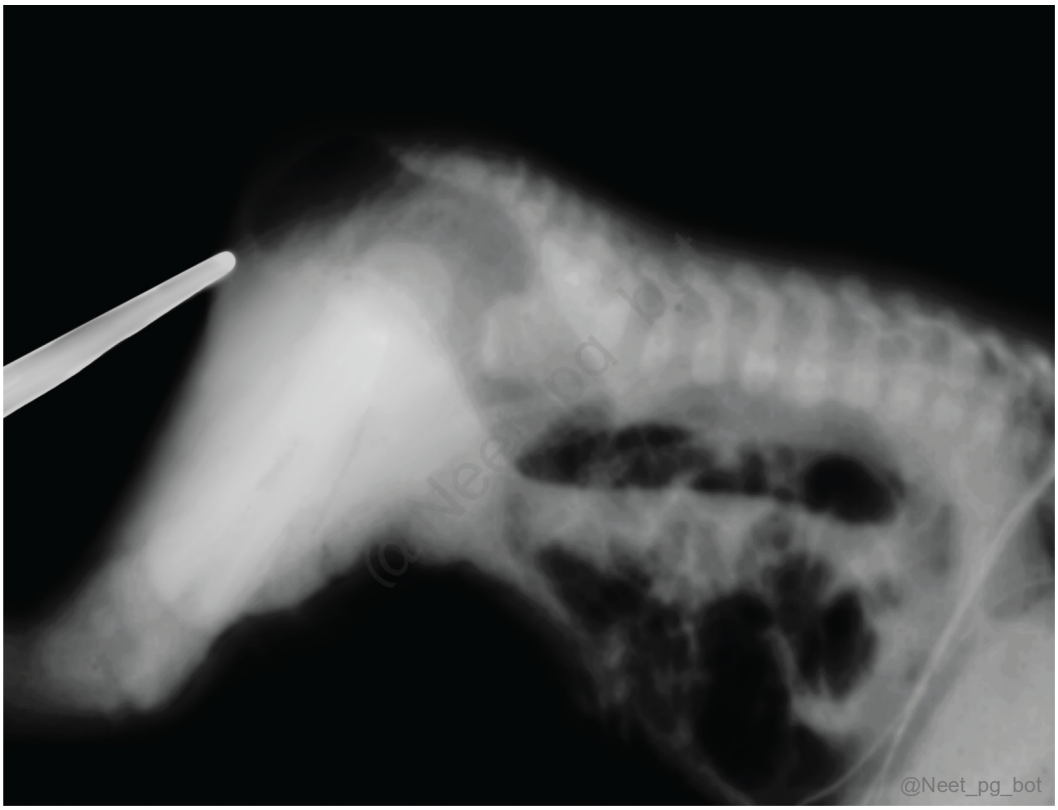
B. Barium meal

C. Barium meal follow through

D. CECT abdomen

See Answer in Part B → Q188

@Neet_pg_bot



Q189: Identify the pathology in the given radiograph of a newborn .: (Q793490)

A. Meningocele

B. Imperforate anus

C. Congenital megacolon

D. Pyloric stenosis

See Answer in Part B → Q189

@Neet_pg_bot

Q190: Which of the following is the best investigation to establish a diagnosis of GERD ? (Q793499)

A. 24 hours ambulatory pH monitoring

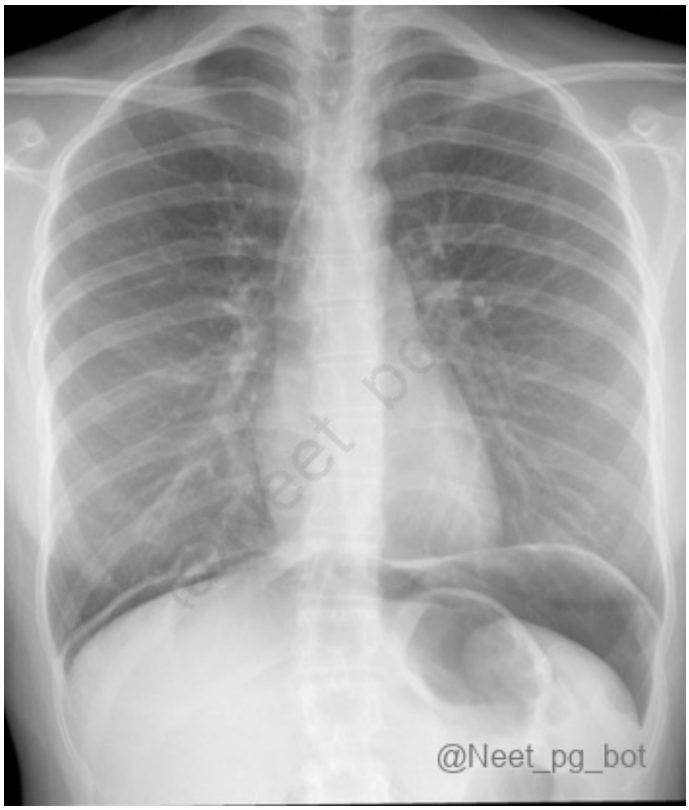
B. Upper GI endoscopy

C. CECT

D. MRI

See Answer in Part B → Q190

@Neet_pg_bot



Q191: A 42-year-old alcoholic and a chronic smoker presented with bouts of vomiting and stabbing pain in the epigastrium . He was binge drinking shortly before the symptoms started. He is febrile and tachycardic . The given findings were seen on bedside radiological imaging. Which among the following is a likely cause of this? (Q793502)

A. Tension pneumothorax

B. Peptic ulcer perforation

C. Boerhaave syndrome

D. Mallory Weiss tear

See Answer in Part B → Q191

@Neet_pg_bot

Q192: Which of the following is the most common deficiency observed after gastric bypass /bariatric surgery ? (Q793518)

A. Iron

B. Copper

C. Zinc

D. Calcium

See Answer in Part B → Q192

@Neet_pg_bot

Q193: An elderly man underwent Roux-en-Y gastric bypass surgery for obesity . He now presents to his physician with complaints of dizziness, fatigue, and tremors 2 hours after the ingestion of a carbohydrate-rich meal . His symptoms occur mainly due to 1. Hypoglycemia 2. Small volume of food intake 3. High osmotic load of food 4. Increased release of insulin 5. Increased release of glucagon (Q793528)

A. 1, 2 and 5

B. 1, 3 and 5

C. 1 and 4

D. 3 and 5

See Answer in Part B → Q193

@Neet_pg_bot

Q194: A young adult with gastric outlet obstruction presents with vomiting . Which of the following fluids is preferred in this patient for initial resuscitation ? (Q793531)

A. Normal saline

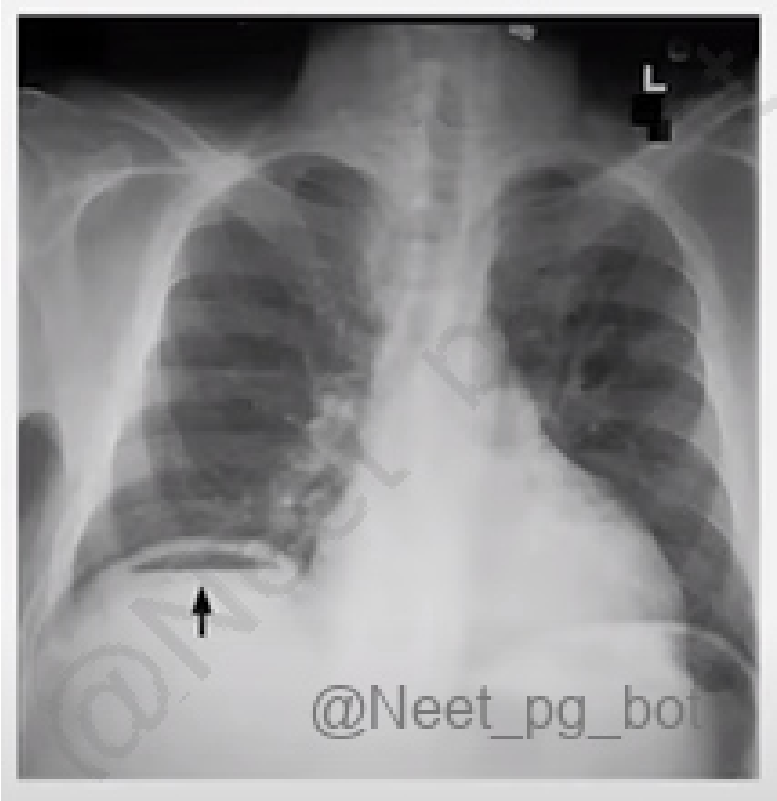
B. Ringer lactate

C. 5% dextrose in water

D. 20% dextrose in water

See Answer in Part B → Q194

@Neet_pg_bot



Q195: A 34 years old female with a history of alcohol intake was taking NSAIDs for abdominal pain . She developed severe pain in the whole abdomen . A radiograph is given below. What is the diagnosis? (Q793857)

A. Rupture of ectopic pregnancy

B. Acute pancreatitis

C. Perforated liver abscess

D. Hollow viscus perforation

See Answer in Part B → Q195

@Neet_pg_bot

Q196: What is the diagnosis of a patient who had a bronchospasm history, and was found to have a tumor in their ileum along with elevated levels of 5-hydroxy

indoleacetic acid in their urine? (Q793867)

A. Carcinoid tumor

B. Neuroblastoma

C. Leiomyoma

D. Chromaffinoma

See Answer in Part B → Q196

Q1: A urologist is teaching medical students about the causes of hydronephrosis. When discussing bilateral hydronephrosis, which of the following conditions is not typically associated with this presentation? (Q849270)

A. Bladder neck stenosis

B. Benign prostatic hyperplasia

C. Posterior urethral valve

D. Retrocaval ureter

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A male presents with a 3 cm stone in the middle calyx of the left kidney. Which of the following statements regarding the use of percutaneous nephrolithotomy (PCNL) in the management of this patient is correct? (Q849250)

A. PCNL involves creating a large flank incision to directly access the renal pelvis and remove the stone

B. PCNL is indicated for the treatment of renal stones larger than 2 cm in diameter or stones resistant to ESWL

C. PCNL is performed under general anesthesia, and the patient is required to remain immobilized for several days postoperatively

D. PCNL is contraindicated in patients with severe hydronephrosis or anatomical abnormalities of the urinary tract

See Answer in Part B → Q2

@Neet_pg_bot

Q3: In a 55-year-old male with sterile pyuria, flank pain, and a "moth-eaten" renal calyx appearance on CT, which test is the gold standard for confirming genitourinary tuberculosis? (Q849274)

A. Retrograde Pyelogram

B. Urine Culture & Sensitivity

C. Intravenous Pyelogram

D. Contrast-Enhanced CT

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old man with a history of renal tuberculosis presents with increased urinary frequency and lower abdominal discomfort that has gradually worsened over the past few months. Imaging studies reveal significant fibrosis and a reduced bladder size. Which of the following features is present in the advanced stage, where the bladder is contracted? (Q849273)

A. Golf hole around the ureteric orifice

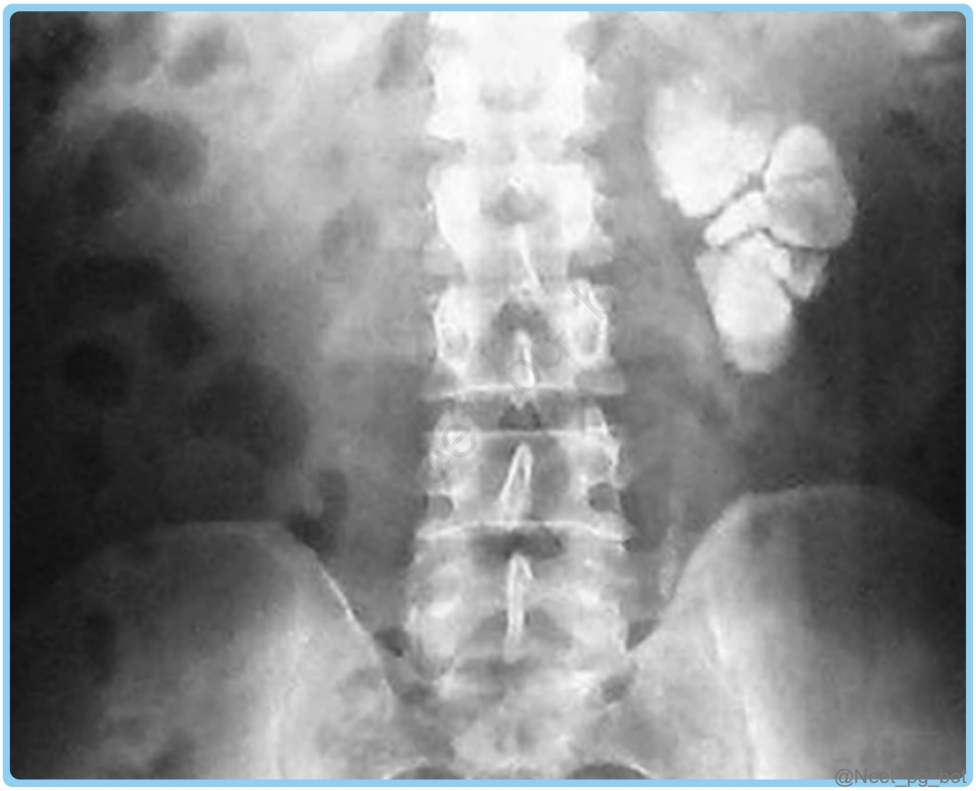
B. Calcification of bladder wall

C. The beaded appearance of the distal ureter

D. None of the above

See Answer in Part B → Q4

@Neet_pg_bot



Q5: A 38-year-old male with a history of untreated pulmonary tuberculosis presents with symptoms of dysuria, hematuria, and flank pain, and noticed a gradual worsening of his symptoms. His laboratory tests are consistent with renal impairment. Which of the following features are seen in this condition? (Q849272)

A. Caseous necrosis and tissue destruction

B. Dystrophic calcification

C. Ureteric strictures and obstruction

D. All of the above

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 35-year-old man presents with intermittent right flank pain and a palpable mass in his right loin. His urinalysis shows microscopic hematuria. Imaging reveals the presence of unilateral hydronephrosis. Which of the following correctly describes the condition known as Dietl's crisis? (Q849271)

A. Sudden onset of flank pain accompanied by fever and pyuria

B. Intermittent flank pain with a palpable abdominal mass that resolves after voiding large volume of urine

C. Constant dull ache in the loin with progressive renal failure

D. Acute anuria associated with bilateral ureteric obstruction

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 62-year-old diabetic man presents with fever, flank pain, and a palpable mass in his left loin. Initial ultrasound reveals a fluid collection associated with the left kidney. Which of the following statements is incorrect with respect to the probable diagnosis of this patient? (Q849259)

A. Pyonephrosis is commonly seen in patients with hydronephrosis due to renal obstruction

B. Pyonephrosis can spread by cortical extension & hematogenous route

C. Pyonephrosis involves the collection of pus inside the kidney

D. Percutaneous nephrostomy is the treatment of choice for elderly and diabetic patients

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old female with poorly controlled diabetes presents with fever, flank pain, and vomiting. Initial investigations reveal a kidney infection. Which of the following findings is likely to be seen in Emphysematous Pyelonephritis but not in Xanthogranulomatous Pyelonephritis? (Q849252)

A. Presence of Proteus as the causative organism

B. Air within the kidney or perinephric region on imaging

C. Association with struvite stones

D. Foamy lipid-laden histiocytes in renal parenchyma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 60-year-old patient with a history of recurrent renal stones is scheduled for laser-based intracorporeal lithotripsy to treat a 2 cm stone in the renal pelvis. Which of the following lasers is most commonly used for intracorporeal lithotripsy procedures? (Q849251)

A. Carbon dioxide laser

B. Neodymium: YAG laser

C. Holmium: YAG laser

D. Helium laser

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is the most common type of radiolucent renal stone? (Q849241)

A. Calcium Oxalate Stones

B. Uric Acid Stones

C. Cystine Stones

D. Xanthine Stones

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A male underwent ESWL for a 2 cm renal stone 4 weeks ago. Imaging now reveals multiple small stone fragments (street of stone) in the ureter. Which of the

following statements regarding the management of this condition is correct? (Q849249)

A. Urgent ureteroscopy should be performed to remove the obstructing stone fragments

B. Conservative management with alpha-blocker therapy is the first-line approach

C. Repeat ESWL is the preferred option to further fragment the retained stone pieces

D. Percutaneous nephrolithotomy is the treatment of choice to clear the Steinstrasse

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A male presents with a 10 mm stone in the lower pole of the left kidney. Regarding the use of extracorporeal shock wave lithotripsy (ESWL) for this patient, which of the following statements is false? (Q849248)

A. ESWL works by generating focused shock waves that pass through the body and fragment the stone

B. ESWL is contraindicated in patients with significant skeletal deformities or obesity

C. ESWL can be performed on stones less than 2 cm in diameter for optimal fragmentation

D. Post-ESWL, the patient is encouraged to ambulate soon after the procedure to facilitate stone passage

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A male presents with a 5 mm lower-ureteric stone and no hydronephrosis. Which of the following is the most appropriate initial management strategy for this patient? (Q849247)

A. Urgent ureteroscopic stone extraction

B. Extracorporeal shock wave lithotripsy

C. Percutaneous nephrostomy tube placement

D. Trial of conservative management with medical expulsive therapy

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 30 years old male presents with recurrent episodes of right flank pain and hematuria. Ultrasonography and plain abdominal radiography are inconclusive for renal stones. Which of the following statements regarding the use of radionuclide scans in the evaluation of this patient is correct? (Q849246)

A. Technetium-99m dimercaptosuccinic acid (DMSA) scan is the preferred modality to diagnose renal stones

B. Gallium-67 citrate scan has higher sensitivity and specificity than DMSA scan for detecting renal stones

C. Radionuclide scans are exclusively reserved for patients with impaired renal function

D. Radionuclide scans can distinguish between obstructing and non-obstructing renal stones

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following investigations is considered the gold standard for diagnosing renal stones and can identify both radiopaque and radiolucent stones? (Q849245)

A. Kidney, Ureter, and Bladder X-ray

B. Ultrasound

C. Non-contrast computed tomography

D. Intravenous urogram

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 35-year-old woman presents with recurrent urinary tract infections (UTIs), persistent back pain, and hematuria. Imaging reveals a large, branched stone occupying a significant portion of her right kidney. Urinalysis shows alkaline pH, the presence of bacteria, and crystals as shown below. Which of the following is the most likely composition of this stone? (Q849244)

A. Calcium oxalate

B. Uric acid

C. Struvite

D. Cystine

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 42-year-old male presents to the emergency department with severe abdominal pain. Imaging reveals that he has a renal stone lodged in the middle third of his ureter. He describes the pain as radiating to his hypogastrium. Which nerve is

responsible for the radiation of pain to the hypogastrium? (Q849243)

A. Ilioinguinal Nerve

B. Iliohypogastric Nerve

C. Genitofemoral Nerve

D. Femoral Nerve

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 50-year-old man with a history of HIV, on ART, presents to the emergency department with severe flank pain, hematuria, and difficulty urinating. Recent imaging studies reveal the presence of renal stones. Which of the following ART drugs is commonly associated with the development of renal stones? (Q849242)

A. Indinavir

B. Efavirenz

C. Nevirapine

D. None of the above

See Answer in Part B → Q18

Q19 (p. 576)	*Q20 (p. 576)*				

Q1: A 55-year-old male presents with painless hematuria and weight loss over the past six months. CECT reveals a 9 cm enhancing mass in the right kidney, with evidence of invasion into the renal vein. Histopathology shows cells with clear cytoplasm and a delicate network of vasculature. Which of the following is the most likely variant of renal cell carcinoma? (Q849283)

A. Chromophobe renal cell carcinoma

B. Papillary renal cell carcinoma

C. Clear cell renal cell carcinoma

D. Collecting duct carcinoma

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 70-year-old male with a history of hypertension is diagnosed with renal cell carcinoma (RCC) after a CT scan reveals a 5 cm tumor confined to the right kidney. His renal function is normal, and there is no evidence of metastasis. What is the most appropriate initial treatment for this patient? (Q849286)

A. Partial Nephrectomy

B. Radical Nephrectomy

C. Radiofrequency Ablation

D. Targeted Therapy

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 28-year-old woman is incidentally found to have a horseshoe kidney during an abdominal CT scan. She has no symptoms. Which of the following complications is she at highest risk for developing? (Q849300)

A. Pelviureteric junction obstruction

B. Renal cell carcinoma

C. Renal artery stenosis

D. Nephroptosis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A newborn presents with abdominal distension and respiratory distress. Ultrasound reveals bilaterally enlarged kidneys with multiple small cysts. Which of the following statements regarding the diagnosis is incorrect? (Q849296)

A. It follows an autosomal recessive pattern of inheritance

B. The gene involved is the PKHD1 gene on chromosome 7

C. USG shows enlarged, echogenic kidneys, with poor corticomedullary differentiation

D. Hepatic fibrosis is the cause of death

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following statements is incorrect regarding the investigations and treatment of Autosomal Dominant Polycystic Kidney Disease? (Q849295)

A. CECT is the investigation of choice for ADPKD

B. IVP may show a "spider leg" or "bell-shaped" appearance in ADPKD

C. Rovsing's operation is the gold standard for management which involves the opening and evacuation of fluid from cysts in ADPKD

D. Treatment is only done when cysts are overdistended causing pain, hemorrhage & infection

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 6-month-old child undergoes a micturating cystourethrogram for suspected vesicoureteric reflux. The radiologist notes reflux into the renal pelvis with mild distention of the collecting system. Which grade of vesicoureteric reflux does this finding represent? (Q849304)

A. Grade IV

B. Grade II

C. Grade III

D. Grade I

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 4-year-old boy presents with recurrent urinary tract infections and a palpable kidney mass in the loin region. Further, the patient is diagnosed with vesicoureteric reflux on both sides. Which of the following is an incorrect statement regarding the management of this condition? (Q849303)

A. Most cases resolve spontaneously without treatment

B. The investigation of choice is Intravenous Pyelogram

C. Symptomatic cases require surgical correction via ureteric reimplantation

D. Severe cases may require nephrectomy and renal transplantation

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 5-year-old girl is brought to the pediatric urology clinic by her mother, who reports that the child has "never been dry" since birth. The mother notes that urine dribbles continuously via the vagina, but the child can also pass urine normally. An intravenous urogram is performed which is attached below. Which of the following is the most likely diagnosis? (Q849302)

A. Vesicoureteral reflux

B. Posterior urethral valves

C. Ectopic ureter from duplicated collecting system

D. Ureterocele

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 6-year-old boy presents with recurrent urinary tract infections and a palpable abdominal mass. Imaging reveals a cystic dilation near the ureteral orifice within the bladder. Which of the following best describes the underlying condition? (Q849301)

A. Ureterocele

B. Bladder diverticulum

C. Ectopic ureter

D. Vesicoureteral reflux

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 40-year-old male presents with right-sided flank pain and persistent hematuria. An intravenous urogram is done and given below. What is the definitive management of this condition? (Q849299)

A. Observation with serial imaging

B. Ureteric stent placement

C. Surgical repositioning of the ureter

D. Percutaneous nephrostomy

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 35-year-old woman presents with intermittent left flank pain and episodes of gross hematuria. Imaging reveals a dilated renal pelvis with a narrowed ureteropelvic junction. Which of the following is the most appropriate long-term management? (Q849298)

A. Percutaneous nephrostomy

B. Watchful waiting with regular monitoring

C. Pyeloplasty

D. Ureteric balloon dilatation

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 20-year-old pregnant woman undergoes an ultrasound at 22 weeks' gestation. The scan reveals severe oligohydramnios and the fetal kidneys are not visualized. Which of the following additional findings is most likely to be present in the fetus? (Q849297)

A. Pulmonary hypoplasia

B. Normal lung development

C. Medullary sponge kidney

D. Enlarged fetal bladder

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 45-year-old woman with a history of tuberous sclerosis complex with angiomyolipoma (AML) presents with a sudden onset of severe left flank pain. On examination, she is hypotensive and has a tender left flank. Imaging reveals a large hemorrhage in the left kidney extending into the perirenal space. Which of the following is the most likely diagnosis? (Q849281)

A. Pyelonephritis

B. Renal cell carcinoma

C. Wunderlich syndrome

D. Acute appendicitis

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following statements is incorrect regarding Autosomal Dominant Polycystic Kidney Disease? (Q849294)

A. The disease involves a mutation in the PKD1 and PKD2 genes on chromosomes 4 and 16 respectively

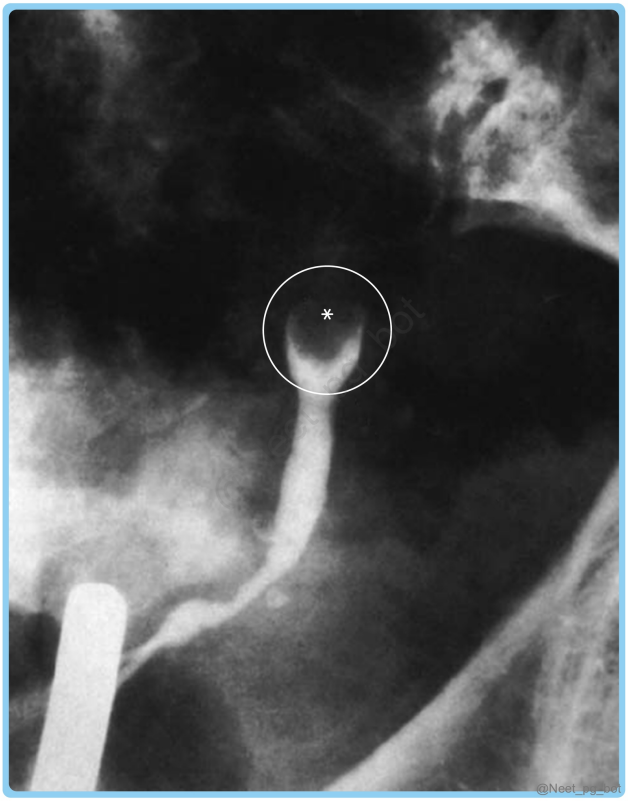
B. Hypertension is the most common manifestation

C. Cysts can be seen in the organs such as the ovary, and pancreas in patients with ADPKD

D. The most common extrarenal manifestation is polycystic liver disease

See Answer in Part B → Q14

@Neet_pg_bot



Q15: A 65-year-old man with a history of working in a dye factory for 30 years presents with flank pain and gross hematuria. Urinalysis confirms the presence of blood, and cytology shows atypical cells. A retrograde urogram was done given in the image below. He was diagnosed with carcinoma of the renal pelvis. Which of the following statements is incorrect regarding the diagnosis? (Q849293)

A. The radiographic image shows the Goblet sign.

B. Patients most commonly present with flank pain

C. CT urography is the investigation of choice for diagnosis

D. The most common histological type is transitional cell carcinoma

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 4-year-old girl is brought to the pediatrician with a palpable abdominal mass. Imaging studies reveal a large renal tumor and a biopsy confirms the diagnosis of Wilms tumor. Which of the following statements regarding Wilms tumor is correct? (Q849292)

A. Chemotherapy is contraindicated in Wilms tumor due to the young age of the patients

B. The most common site of metastasis in patients with Wilms tumor is the Liver.

C. A multimodal approach including surgery, chemotherapy, and radiation is typically used.

D. The route of spread is mostly lymphatic for metastasis of tumor foci.

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 2-year-old male child presents with severe proteinuria, ambiguous genitalia, and hypertension. His karyotype is 46XY, and genetic testing reveals a missense mutation in the WT1 gene. Imaging studies show a unilateral renal mass. Which of the following is the most likely explanation for the patient's clinical presentation? (Q849291)

A. Beckwith-Wiedemann syndrome with Wilms' tumor

B. Denys-Drash syndrome with gonadal dysgenesis

C. Frasier syndrome with gonadoblastoma

D. Perlman syndrome with nephroblastomatosis

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 55-year-old man presents with painless hematuria and a palpable mass in the left flank. Imaging studies reveal a renal mass measuring 8 cm with evidence of invasion into the renal vein but no involvement of surrounding lymph nodes or distant metastasis. According to the TNM staging system, what is the most appropriate stage of this renal cell carcinoma? (Q849285)

A. Stage I

B. Stage II

C. Stage III

D. Stage IV

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 62-year-old woman with a history of smoking presents with a sudden onset of headaches and visual disturbances. A CT scan shows a 5 cm mass in the left kidney. Which of the following is most likely associated with her condition? (Q849284)

A. Addison's disease

B. Hypocalcemia

C. Hypotension

D. Polycythemia

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 65-year-old male presents with an incidental finding of a renal mass on imaging. The mass shows an enhancing appearance on cross-sectional imaging with a central stellate scar. A biopsy is inconclusive, and the mass is surgically removed. Histopathological examination reveals granular, eosinophilic cytoplasm within the tumor cells, negative for cytokeratin 7. What is the most likely diagnosis? (Q849282)

A. Clear Cell Renal Cell Carcinoma

B. Renal Oncocytoma

C. Chromophobe Renal Cell Carcinoma

D. Papillary Renal Cell Carcinoma

See Answer in Part B → Q20

Q19 (p. 588)	*Q20 (p. 588)*				

Q1: A 74-year-old man was diagnosed with squamous cell carcinoma of the bladder. Which of the following is the most likely risk factor for this type of bladder cancer? (Q849368)

A. History of schistosomiasis.

B. Previous bladder augmentation surgery.

C. Occupational exposure to aromatic hydrocarbons.

D. Use of drugs like cyclophosphamide

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A patient who had undergone cystectomy and urinary diversion with an ileal conduit after being diagnosed with muscle-invasive bladder cancer comes for follow-up. His blood investigations revealed an electrolyte imbalance. Which of the following is not a possible imbalance in this condition? (Q849377)

A. Hypokalemia

B. Hyponatremia

C. Hypocalcemia

D. Hypomagnesemia

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A new mother comes to the outpatient department with her neonate as she notices intermittent fluid leaking from the umbilicus of the baby. On examination, the umbilicus is inflamed, enlarged, and there is delayed healing of the cord stump. What is the diagnosis? (Q849376)

A. Patent urachus

B. Urachal cyst

C. Umbilical-urachal sinus

D. Vesico-urachal diverticulum

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 55-year-old male with non-muscle invasive bladder carcinoma is advised TURBT and BCG immunotherapy due to a high risk of recurrence. Which condition is not a contraindication for BCG therapy? (Q849375)

A. Immunocompromised

B. Immediately after TURBT

C. Total urinary incontinence

D. Previous history of tuberculosis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: During a radical cystectomy for bladder cancer in males, which of the following structures is typically spared and not removed? (Q849374)

A. Seminal Vesicles

B. Prostate

C. Urethra

D. Testes

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is the preferred initial therapy for a patient with carcinoma in situ (Tis) urinary bladder cancer after TURBT? (Q849373)

A. Intravesical Gemcitabine (single instillation)

B. Intravesical Mitomycin (single instillation)

C. Intravesical BCG therapy

D. Immediate Cystectomy

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is not a tumor marker for urinary bladder cancer? (Q849372)

A. Hyaluronidase (HYAL-1)

B. Nuclear Matrix Protein 22

C. Bladder Tumor Antigen

D. Alpha-fetoprotein

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 62-year-old male with a bladder tumor invading the muscle layer is classified as which TNM stage? (Q849371)

A. Ta

B. T1

C. T2

D. T3

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 62-year-old patient with muscle-invasive bladder cancer is undergoing evaluation for metastasis. What is the most common lymphatic node involved in bladder cancer metastasis? (Q849370)

A. Supraclavicular nodes

B. Pelvic Nodes

C. Retroperitoneal Nodes

D. Intrathoracic Nodes

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 65-year-old male with a history of smoking presents with frequent urination and microscopic hematuria. Cystoscopy reveals a flat, high-grade lesion confined to the bladder epithelium. What is the most likely diagnosis? (Q849369)

A. Papillary tumor

B. Carcinoma in situ

C. Stage T1 urothelial carcinoma

D. Squamous cell carcinoma of bladder

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 7-year-old boy with recurrent urinary tract infections (UTIs) is brought with a few episodes of hematuria and bladder discomfort. Imaging shows a diverticulum near the ureteric orifice. Which of the following statements is most accurate based on the clinical scenario? (Q849367)

A. Congenital diverticulum due to its location and UTIs.

B. Occurs secondary to high intravesical pressure.

C. Immediate surgery is needed regardless of symptoms.

D. Thick-walled bladder with multiple diverticula.

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 34-year-old male presents with severe abdominal pain and inability to urinate after a car accident. On examination, he has diffuse abdominal tenderness with guarding and rigidity. A cystogram reveals urine leakage into the peritoneal cavity. What is the next best step in management? (Q849366)

A. Foley’s catheterisation and observation

B. Emergency laparotomy

C. IV antibiotics and close monitoring

D. Delayed surgical repair

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 48-year-old female presents with chronic pelvic pain, urinary urgency, and frequency. On cystoscopy, a characteristic bladder lesion with a small capacity and visible mucosal breaks is noted. What is the most likely diagnosis? (Q849364)

A. Bladder Cancer

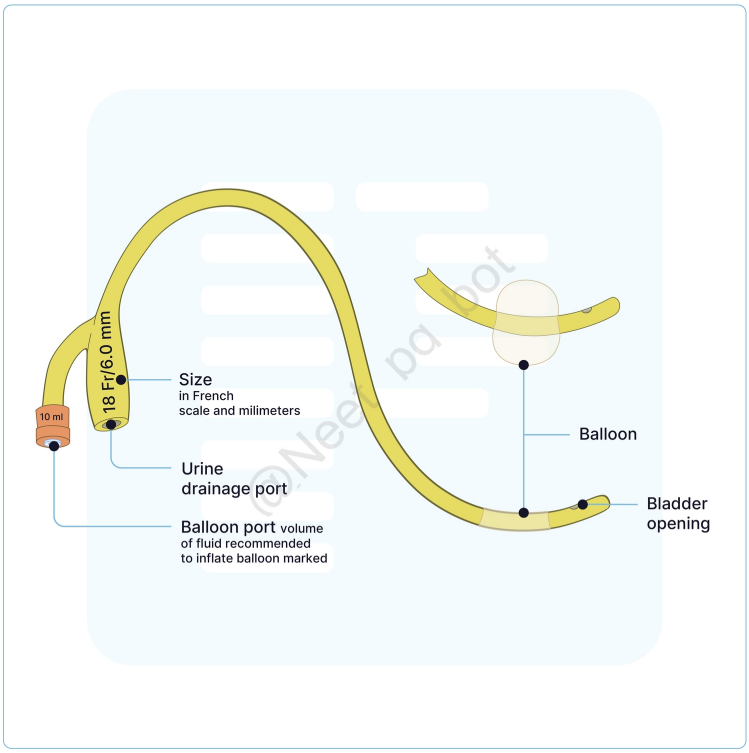
B. Radiation Cystitis

C. Interstitial Cystitis with Hunner’s Lesion

D. Urinary Tract Infection

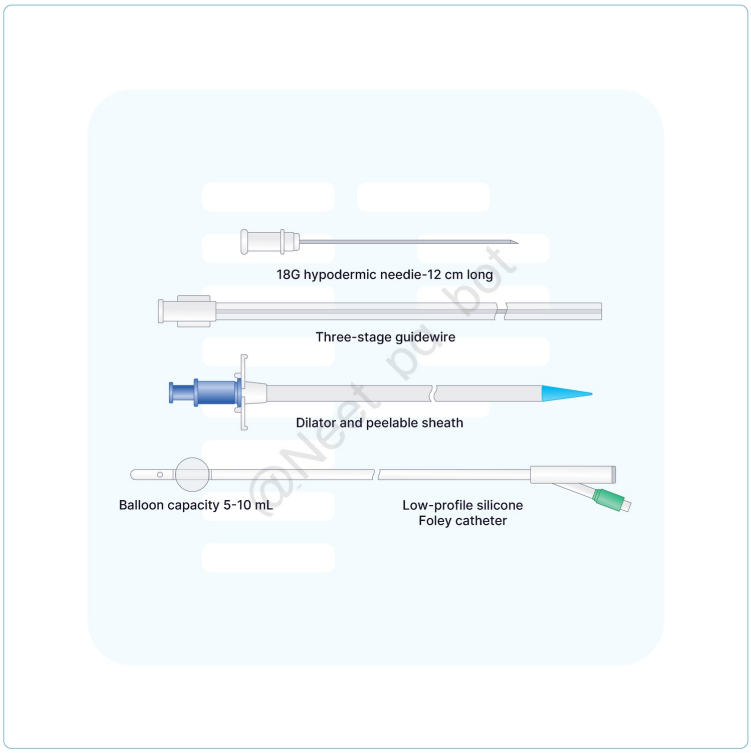
See Answer in Part B → Q13

@Neet_pg_bot



Q14: Based on the images provided, where would each of the shown catheters be used? Image 1: Image 2: (Q849358)

A. Image 1:Used for patients with acute urinary retention; Image 2:Used only in neurogenic bladder



B. Image 1: Used for patients with an enlarged prostate causing retention; Image 2: Used in cases of urethral stricture or trauma

C. Image 1: Used for short-term postoperative bladder drainage; Image 2:Used only when Foley's catheterization is contraindicated

D. Image 1: Used for patients with acute urinary retention; Image 2:Used for continuous bladder irrigation

@Neet_pg_bot

@Neet_pg_bot

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 35-year-old male presents to the emergency department after a motor vehicle accident with a pelvic fracture and gross hematuria. The CT cystogram showed the following characteristic findings. Which of the following statements regarding the diagnosis of this patient is incorrect? {{caption_text}} (Q849365)

A. Retrograde cystography demonstrates extravasation of contrast limited to the perivesical space.

B. Catheter drainage for 10-14 days is the treatment of choice for uncomplicated cases.

C. Immediate surgical repair in cases of bladder neck injury.

D. Both urethral and suprapubic catheters are recommended in all cases.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 60-year-old female with recurrent UTIs and a history of chronic immunosuppression after a renal transplant presents with non-tender abdominal

nodules. The biopsy shows histiocytes with basophilic inclusions staining positive for PAS and von Kossa stains. Which of the following is the most accurate statement regarding the diagnosis? (Q849363)

A. Commonly associated with Gram-negative bacteria like E. coli

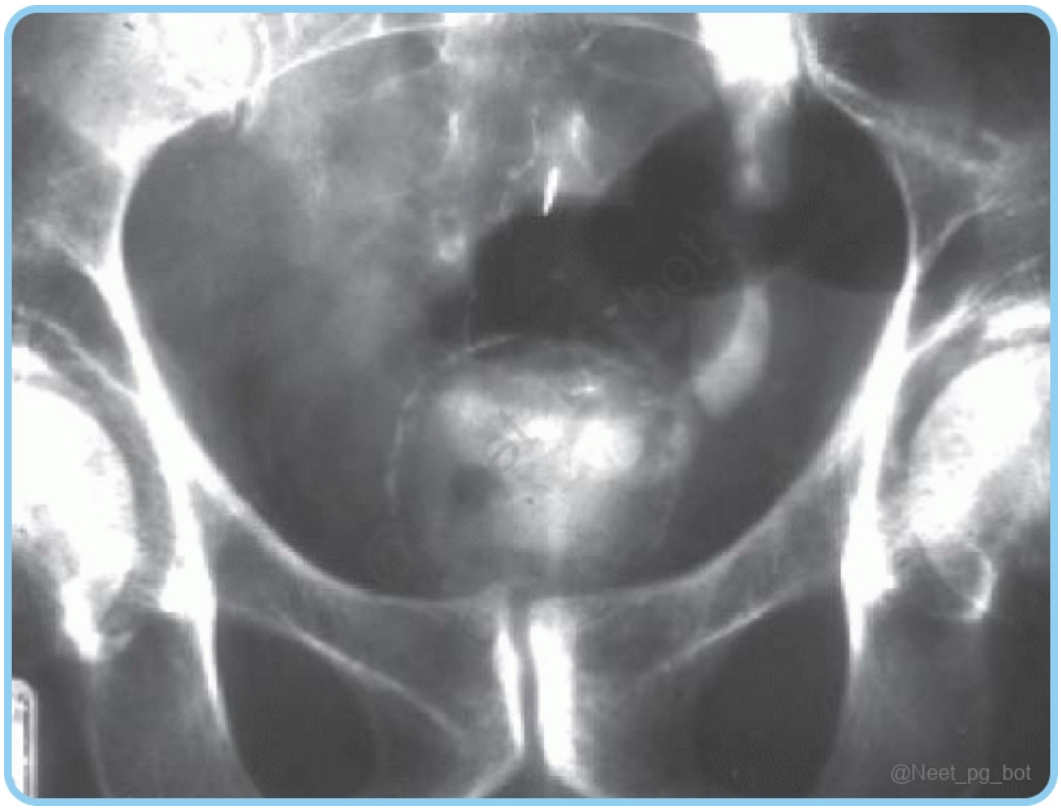
B. Characteristic histological feature is Langhans giant cells

C. Treated primarily with high-dose corticosteroids

D. Usually self-limiting and resolves without treatment

See Answer in Part B → Q16

@Neet_pg_bot



Q17: A 45-year-old male tourist from rural Egypt presents with recurrent hematuria and lower abdominal pain. A pelvic radiograph shows a circular calcification resembling a fetal head in the pelvis with associated faint calcification of the distal right ureter. What is the most likely diagnosis and appropriate next step? (Q849362)

A. Bladder stones; perform cystoscopy

B. Chronic schistosomiasis; obtain urine microscopy for ova

C. Pelvic tuberculosis; order interferon-gamma release assay

D. Calcified bladder tumor; schedule CT urography

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 9-year-old boy from a rural area presents with suprapubic pain, increased urinary frequency, and occasional hematuria, with no incontinence or systemic symptoms. He appears thin, has normal external genitalia, and has no significant medical history. Imaging shows multiple small, smooth bladder stones. What is the most likely cause? (Q849361)

A. Bladder outlet obstruction leading to urinary stasis

B. Infection with urease-producing bacteria

C. Nutritional deficiency

D. Foreign body presence in the bladder

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following statements about ectopia vesicae is correct? (Q849360)

A. More common in females than males

B. Presents with normal urinary continence

C. Increased risk of urinary bladder adenocarcinoma

D. Resolves on its own without surgery

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 70-year-old male with diabetes and Parkinson's disease presents with a 6-month history of difficulty urinating, incomplete bladder emptying, and frequent nighttime urination. A post-void residual volume test shows significant urine retention. Which of the following conditions is least likely the primary cause of his chronic urinary retention? (Q849359)

A. Parkinson's disease

B. Diabetic neuropathy

C. Benign Prostatic Hyperplasia (BPH)

D. Overactive Bladder

See Answer in Part B → Q20

Q1: An elderly male is identified to have a well-circumscribed lesion within the prostate suspicious of cancer. Based on the McNeal classification, in which prostatic zone is the lesion most likely to be located? (Q849305)

A. Transitional Zone

B. Peripheral Zone

C. Central Zone

D. Anterior Fibromuscular Stroma

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 75-year-old man presents with difficulty in urination, weak stream, and increased frequency. On digital rectal examination, his prostate is found to be enlarged, and his PSA levels are mildly elevated. Which enzyme converts testosterone to dihydrotestosterone, a hormone responsible for the pathogenesis of his condition? (Q849306)

A. Aromatase

B. 17-β Hydroxysteroid dehydrogenase

C. 5 ■ reductase

D. 21-Hydroxylase

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 68-year-old male presents with complaints of urinary frequency, nocturia, and a weak urinary stream. The International Prostate Symptom Score (IPSS) assessment reveals a score of 22. Which of the following best describes the severity of his symptoms according to the IPSS? (Q849307)

A. Mild

B. Moderate

C. Severe

D. Asymptomatic

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 65-year-old male presents with urinary frequency, nocturia, and a weak urinary stream for 6 months. His prostate is symmetrically enlarged, prostate-specific antigen (PSA) is slightly elevated and Qmax (Uroflowmetry) is 7 ml/sec. Which of the following is the most appropriate initial management for this patient? (Q849308)

A. Transurethral resection of the prostate

B. Tamsulosin

C. Immediate catheterization

D. Finasteride

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following is the most common complication of TURP (Trans urethral resection of prostate)? (Q849309)

A. Retrograde ejaculation

B. TURP syndrome

C. Incontinence

D. Erectile dysfunction

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 70-year-old man is undergoing transurethral resection of the prostate (TURP) for benign prostatic hyperplasia. Postoperatively, he gets agitated and complains of severe headache, nausea, and blurred vision. His lab results show a serum sodium level of 118 mEq/L. Which of the following is the most appropriate initial management? (Q849310)

A. Administer intravenous hypertonic saline

B. Start oral furosemide

C. Administer intravenous normal saline

D. Oral fluid restriction

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 65-year-old male is undergoing surgery for Benign Prostatic Hyperplasia with distressing LUTS (lower urinary tract symptoms). Prostate gland is significantly enlarged, measuring over 100 grams. Which among the following surgical approach is most appropriate? (Q849311)

A. Transurethral incision of prostate

B. Open prostatectomy

C. Frayer’s suprapubic prostatectomy

D. Young’s perineal prostatectomy

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 55-year-old male, known diabetic presents to the emergency department with a high-grade fever, perineal pain, and difficulty urinating. He has a history of acute bacterial prostatitis, treated two weeks ago with antibiotics. On examination, the prostate is tender and swollen. What is the most likely diagnosis and investigation to confirm the same? (Q849312)

A. Prostatic abscess and Transrectal ultrasound

B. Chronic prostatitis and urine culture

C. Acute prostatitis and urine microscopy

D. Benign prostatic hyperplasia and PSA levels

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 60-year-old male undergoes evaluation for a urinary tract infection. Imaging studies reveal multiple small stones within the prostate gland. Laboratory analysis of these prostatic calculi will most likely show which of the following compositions? (Q849313)

A. Uric acid

B. Struvite

C. Calcium oxalate

D. Calcium phosphate

See Answer in Part B → Q9

@Neet_pg_bot

Q10: An elderly male presents with urinary hesitancy, weak stream, nocturia, weight loss, and back pain. DRE reveals a hard, irregular prostate. Which of the following is the common genetic alteration observed in his condition? (Q849314)

A. Mutation of the BRCA1 gene

B. Hypermethylation of GSTP1

C. Overexpression of HER2

D. Mutation of the RB1 gene

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 70-year-old male presents with an elevated PSA level of 12 ng/mL. A transrectal ultrasound-guided biopsy reveals a Gleason score of 9 (4 + 5). Which of the following is the most appropriate initial management approach for this patient? (Q849315)

A. Active surveillance with regular PSA monitoring and repeat biopsies

B. Radical prostatectomy

C. Hormone therapy and possibly radiation

D. Observation with no immediate treatment

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 65-year-old male patient undergoes a transurethral resection of the prostate (TURP) for benign prostatic hyperplasia. During the procedure, a tumor is discovered, which involves less than 5% of the resected tissue and is well-differentiated. The tumor was an incidental finding and was not palpable during a digital rectal examination. Based on the TNM staging system for prostate cancer, what is the most appropriate stage for this tumor? (Q849316)

A. T1a

B. T1b

C. T2a

D. T3a

See Answer in Part B → Q12

Q1: A 28-year-old male was involved in a high-speed road traffic accident. He reports severe pelvic pain and difficulty in passing urine. On examination, there is blood at the urethral meatus, and the patient complains of suprapubic tenderness. The bladder appears to be distended, and there is a high-riding prostate on a digital rectal examination. Which of the following investigations is the most appropriate to confirm the suspected injury of this patient? (Q849422)

A. Retrograde Urethrography (RGU)

B. Cystoscopy

C. Voiding Cystourethrography

D. Intravenous Pyelography (IVP)

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following statements are true regarding urethral carcinoma? (Q849431)

A. Bloody discharge present without infection

B. Prostatic urethral tumor is treated with laser ablation

C. Squamous carcinoma has a poor prognosis

D. All are true

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old male presents with a carcinoma penis. After discussing treatment options, he is informed that his management plan may include partial penectomy. What is the nature of his cancer? (Q849430)

A. Localized tumor of glans

B. Proximal penile tumor

C. T1 stage

D. T2 stage

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old male presents with a noninvasive, localized squamous cell carcinoma on the glans penis. The lesion is well-demarcated and has not invaded deeper tissues. What is the TNM stage of his cancer? (Q849429)

A. T1

B. T2

C. T3

D. Ta

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 52-year-old male presents with a large, dry, verrucae-like growth on the penis. Biopsy confirms it as a Buschke-Lowenstein tumor. Which of the following is the wrong statement regarding the disease? (Q849428)

A. Caused by HPV

B. Radiotherapy is contraindicated

C. Can spread through blood

D. It is curable

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Bowen's disease, erythroplasia of Queyrat, and bowenoid papulosis are examples of: (Q849427)

A. Premalignant penile lesions

B. Benign tumors of the penise

C. Penile malignancies

D. None of the above

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following statements are correct regarding Peyronie's Disease? Is characterized by fibrous plaques in the tunica albuginea of the penis. The plaques are typically found on the ventral aspect of the penis. Can be associated with Dupuytren's contracture. Oral medications like pentoxifylline and vitamin E are used in medical management. The primary treatment involves immediate surgical intervention (Nesbit Operation). (Q849426)

A. 1, 2, and 4 are correct

B. 2, 3, and 5 are correct

C. 1, 3, and 4 are correct

D. 2, 4, and 5 are correct

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 45-year-old man presents with symptoms of urinary obstruction, including difficulty in starting urination, weak urinary stream, and frequent urinary tract infections. On physical examination, he has a history of trauma to the pelvic region. A retrograde urethrogram (RGU) reveals a stricture in the anterior urethra measuring more than 2 cm. Which of the following is the most appropriate management option for this patient? (Q849425)

A. Urethral Dilatation

B. Optical Internal Urethrotomy

C. Excision and reconstruction with buccal mucosa

D. Urethral Stenting

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Assertion: Eggplant deformity is a clinical manifestation observed in penile fracture cases. Reason: It is caused by a tear in the corpus spongiosum layer of the penis. (Q849424)

A. Both Assertion and Reason are correct, and the Reason is the correct explanation for the Assertion

B. Both Assertion and Reason are correct, but the Reason is not the correct explanation for the Assertion

C. The Assertion is correct, but the Reason is incorrect

D. The Assertion is incorrect, but the Reason is correct

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 28-year-old male was involved in a high-speed motor vehicle accident. On examination, he has a high-riding prostate on rectal exam, and blood is noted at the urethral meatus. He complains of difficulty in urination, and imaging reveals a pelvic fracture. Retrograde urethrography confirms a complete disruption of the posterior urethra. After initial stabilization, Which of the following is the most definitive method of management for this patient? (Q849423)

A. Immediate Surgical Repair of the Urethra

B. Suprapubic Catheter Placement Alone

C. Delayed Urethroplasty 3 months post-injury

D. Long-term Foley Catheterization

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is the least dilatable part of the male urethra? (Q849378)

A. Prostatic urethra

B. Membranous urethra

C. Penile (spongy) urethra

D. Urethral meatus

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 35-year-old male presents with an erection lasting over 6 hours and initial aspiration fails to resolve the condition. What is the next appropriate step in the management of this patient? (Q849387)

A. Oral phosphodiesterase inhibitors

B. Observation

C. Intracavernosal phenylephrine injection

D. Penile prosthesis placement

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 30 year old male presents with a painless erection following a penile trauma. Doppler ultrasound confirms the presence of blood flow and blood gas analysis shows arterial blood characteristics. What is the most likely type of priapism? (Q849386)

A. Ischaemic priapism

B. Non-ischaemic priapism

C. Neurogenic priapism

D. Recurrent priapism

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 60-year-old male presents to the emergency department with severe pain and swelling of the glans penis after retracting his foreskin for catheterization. The foreskin is stuck behind the glans with visible constriction. What is the most appropriate initial management? (Q849385)

A. Circumcision

B. Manual reduction using compression methods

C. Topical corticosteroid application

D. Oral antibiotics

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 5 year old boy presents with a non-retractable foreskin that has a fibrotic ring around the preputial orifice. His parents report that he experiences pain and irritation during urination. What is the most likely diagnosis? (Q849384)

A. Physiologic phimosis

B. Paraphimosis

C. Pathologic phimosis

D. Balanitis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A newborn male presents with urinary retention, lethargy and a distended bladder. Antenatal ultrasound showed a "keyhole sign" with a thickened bladder wall. Which of the following is the most likely diagnosis? (Q849383)

A. Hypospadias

B. Vesicoureteral reflux

C. Posterior urethral valves

D. Neurogenic bladder

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 4-year-old boy presents with complaints of recurrent UTI and difficulty urinating as mentioned by their parents.Upon examination, the physician notes that the urethral opening is located on the dorsal (top) aspect of the penis rather than at the tip. What is the most likely diagnosis? (Q849382)

A. Hypospadias

B. Peyronie’s disease

C. Epispadias

D. Phimosis

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 4-year-old boy presents with recurrent urinary tract infections and a history of abnormal urination. Physical examination reveals an abnormal opening on the perineum instead of the tip of the penis. What is the most likely diagnosis? (Q849381)

A. Hypospadias

B. Epispadias

C. Ectopic vesicae

D. Phimosis

See Answer in Part B → Q18

@Neet_pg_bot

Q19: What is the correct sequence of steps for hypospadias repair? (Q849380)

A. Degloving, orthoplasty, urethroplasty, and glanuloplasty

B. Orthoplasty, degloving, urethroplasty, and glanuloplasty

C. Degloving, urethroplasty, orthoplasty, and glanuloplasty

D. Degloving, urethroplasty, glanuloplasty, and orthoplasty

See Answer in Part B → Q19

@Neet_pg_bot

Q20: What is the most common type of hypospadias? (Q849379)

A. Scrotal hypospadias

B. Glanular hypospadias

C. Penoscrotal hypospadias

D. Perineal hypospadias

See Answer in Part B → Q20

Q19 (p. 611)	*Q20 (p. 611)*				

Q1: A 45-year-old man presents with bilateral scrotal swelling. On examination, tense clusters that feel like bunches of grapes are palpable posterior to the testis and positive transillumination seen. Which of the following is the most appropriate management option if the patient reports discomfort? (Q849482)

A. Aspiration of the cysts

B. Total epididymectomy

C. Ultrasound-guided drainage

D. Excision of the cysts

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 35-year-old man presents with a painless, firm scrotal mass. Serum alpha-fetoprotein (AFP) and human chorionic gonadotropin (hCG) levels are elevated. What is the most likely diagnosis? (Q849491)

A. Epididymal cyst

B. Orchitis

C. Chimney sweep cancer

D. Hydrocele

See Answer in Part B → Q2

@Neet_pg_bot

Q3: For a patient with Stage I seminoma, which of the following is the most appropriate treatment? (Q849490)

A. Radical Orchidectomy followed by adjuvant chemotherapy

B. Radical Orchidectomy followed by adjuvant radiotherapy

C. High-dose chemotherapy

D. Radical Orchidectomy alone

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Match the tumor markers with their associated testicular tumor types: Tumor Markers Tumor Types 1. AFP (Alpha-fetoprotein) a. Seminoma 2. HCG (Human Chorionic Gonadotropin) b. Yolk Sac Tumor 3. LDH (Lactate Dehydrogenase) c. Choriocarcinoma 4. CA-125 d. Ovarian cancer (Q849489)

A. 1-b,2-c,3-a,4-d

B. 1-d,2-b,3-c,4-a

C. 1-a,2-d,3-b,4-c

D. 1-c,2-a,3-d,4-b

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 25 years old man presents with a painless testicular mass. On examination, non-tender 3 cm mass in the right testicle is found.Ultrasound reveals a homogeneous, hypoechoic intratesticular mass. Serum tumor markers show elevated beta-hCG and LDH but normal AFP. Which of the following is the most likely diagnosis? (Q849488)

A. Leydig cell tumor

B. Embryonal carcinoma

C. Seminoma

D. Teratoma

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 28-year-old man undergoes a radical orchiectomy for a painless,enlarging testicular mass. Histopathology reveals neoplastic cells confined to the seminiferous tubules without stromal invasion.Serum tumor markers are within normal limits.Which of the following is the most likely diagnosis? (Q849487)

A. Seminoma

B. Yolk sac tumor

C. Leydig cell tumor

D. Intratubular germ cell neoplasm (ITGCN)

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Match the following WHO classification of tumors with its corresponding tumor :- 1. Germ cell tumors derived from germ cell neoplasia in situ A. Gonadoblastoma 2. Germ cell tumors unrelated to germ cell neoplasia in situ B. Prepubertal-type teratoma 3. Sex cord-stromal tumors C. Sertoli cell tumor 4.Nonseminomatous germ cell tumors D. Choriocarcinoma (Q849486)

A. 1 - A; 2 - B; 3 - C; 4 - D

B. 1 - B; 2 - A; 3 - C; 4 - D

C. 2 - B; 1 - C; 3 - D; 4 - A

D. 4 - A; 3 - B; 2 - C; 1 - D

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 30-year-old male presents with a painless testicular mass. On physical examination, a solid intratesticular mass is palpable, and there is difficulty in palpating the epididymis. Which of the following associated findings would most likely be present in this patient? (Q849485)

A. Cough and dyspnea

B. Gynecomastia

C. Lower extremity swelling

D. Lumbar back pain

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 28-year-old man presents for a routine physical exam. He has a history of cryptorchidism corrected by orchidopexy in childhood. What is his relative risk of developing testicular cancer compared to the general population? (Q849484)

A. No increased risk

B. 1.5 to 3.5 times higher

C. 2 times higher

D. 3.7 to 7.5 times higher

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 60-year-old male with a history of diabetes presents with intense pain, swelling, and erythema of the scrotum. Physical examination reveals dusky skin and

subcutaneous crepitation. What is the most appropriate initial management? (Q849483)

A. Oral antibiotics

B. Immediate surgical debridement

C. Observation and pain management

D. Aspiration of the affected area

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 35-year-old man presented with a swelling of the scrotum, which was diagnosed as a spermatocele. Which of the following features of the swelling would have led to this diagnosis? (Q849478)

A. Location of the swelling at the head of the epididymis, above and behind the body of the testis

B. Soft, cystic, and transilluminant

C. Barley water-like fluid with spermatozoa on aspiration cytology

D. All of the above

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 25-year-old tall, thin male presents with a dull, aching pain in his left groin and scrotum, describing a "bag of worms" sensation on palpation. He was suggested to undergo Palomo's Operation. Which of the following describes the procedure? (Q849477)

A. Suprainguinal extraperitoneal ligation of the testicular vein

B. Extraperitoneal excision of testicular vein

C. Excision of pampiniform plexus

D. None of the above

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements on hydrocele is false? (Q849476)

A. Fluid is collected between the two layers of the tunica vaginalis

B. Primary vaginal hydrocele is common in middle-aged men

C. Lord's plication is done for large hydrocele

D. Congenital hydrocele is reduced on lying down

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 15-year-old boy presented with a sudden onset of pain in the scrotum, groin, and lower abdomen. On examination of the scrotum, he is showing Deming's sign. What is Deming's sign? (Q849475)

A. The affected testis is positioned high

B. The affected testis lies horizontally

C. Opposite testis is placed horizontally

D. The affected testis is positioned low

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 27-year-old male is presented with a swollen, red, and painful epididymis. On examination, his vas deferens has a beaded texture and epididymis is craggy. A diagnosis of epididymo-orchitis was made. What is the most likely causative organism? (Q849473)

A. Mumps

B. Filaria

C. Tuberculosis

D. Gonococci

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 4-year-old boy has a right testis that intermittently moves between the scrotum and the groin, especially during physical activity. The testis is retractable but can be brought down into the scrotum upon gentle manipulation, while the left testis is normally positioned. What is the most likely physiological explanation for this intermittent movement of the testis? (Q849472)

A. Patent processus vaginalis

B. Undescended testis

C. Overactive dartos muscle

D. Increased tone of the cremasteric muscle

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 2 year old boy underwent surgery for an ectopic testis, followed by an orchidopexy. Several weeks later, he presents with symptoms including swelling and pain in the scrotum, along with fever. On examination, the scrotum is tender, and the affected testis appears to be positioned higher than normal. What is the most likely cause for these symptoms? (Q849471)

A. Abscess formation

B. Scrotal hematoma

C. Testicular atrophy

D. Testicular torsion

See Answer in Part B → Q17

@Neet_pg_bot

Q18: An 8 months old infant is undergoing surgical exploration for an undescended testis. The surgeon follows the standard approach and examines the inguinal canal but does not find the testis in the usual tract. Which location should the surgeon check next? (Q849470)

A. Superficial inguinal pouch

B. Perineum

C. Femoral canal

D. Retroperitoneum

See Answer in Part B → Q18

@Neet_pg_bot

Q19: All are true regarding undescended testis, except? (Q849469)

A. Seminoma is the most common tumor associated with undescended testis

B. Elevated abdominal temperature impairs sperm production

C. Orchidopexy is typically performed between 6-18 months of age.

D. Undescended testis causes loss of secondary sexual characteristics due to Leydig cell impairment.

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following factors are responsible for testicular descent? Testosterone Gubernaculum Intra-abdominal Pressure CGRP (Calcitonin Gene-Related Peptide) INSL3 (Insulin-like 3) Processus Vaginalis (Q849468)

A. 1, 2, and 3

B. 1, 2, and 6

C. 1, 3, 4, and 6

D. 1,2,3,4,5,6

See Answer in Part B → Q20

Q1: A 13-year-old boy presents to the OPD with sudden onset severe pain in the right testis 2 hours after being hit by a cricket ball. On examination: Severe tenderness of the right testis, absent cremasteric reflex & testis is high-riding. What is the next best step in management? (Q866925)

A. USG Arterial Doppler

B. NSAIDS

C. USG Venous Doppler

D. Surgical exploration

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is not a recognised cause of recurrent renal stone formation? (Q865361)

A. Hyperoxaluria

B. Hypercalciuria

C. Hypercitraturia

D. Hyperuricosuria

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 3 year old child was brought to OPD with complain of dysuria and ballooning on micturition and examination as given below, what is the diagnosis? (Q866452)

A. Balanitis xerotica obliterans

B. True phimosis

C. Recurrent balanoposthitis

D. Recurrent urinary tract infections

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A middle-aged woman presents with flank pain and dysuria. The pain was temporarily relieved by intravenous analgesics administered at a nearby primary healthcare center. She is diagnosed with ureteric colic secondary to ureteric calculi. What is the most appropriate diagnostic modality in this case? (Q853039)

A. NCCT KUB

B. ■■■■■■■

C. USG KUB

D. ■■■Ureteroscopy

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Identify the structure on prostate biopsy: (Q853040)

A. Psammoma bodies

B. Corpora arenacea

C. ■■■Amyloid

D. Corpora amylacea

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A newborn male presents with urinary retention, lethargy and a distended bladder. Antenatal ultrasound showed a "keyhole sign" with a thickened bladder wall. Which of the following is the most likely diagnosis? (Q852715)

A. Hypospadias

B. Vesicoureteral reflux

C. Posterior urethral valves

D. Neurogenic bladder

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 22-year-old male presents to the emergency department with a strong urge to urinate but is unable to do so. He has a history of perineal trauma. On examination, blood is noted at the external urethral meatus. Which structure is most likely injured? (Q852718)

A. Bulbar urethra

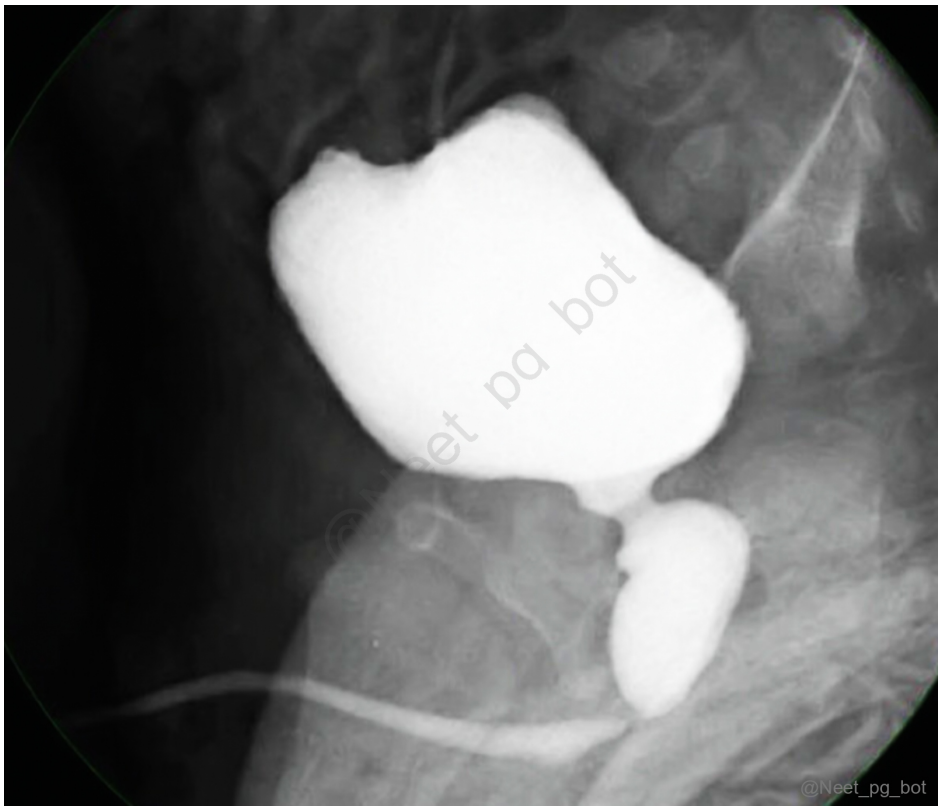
B. Posterior urethral valve

C. Intraperitoneal Bladder rupture

D. Membranous urethra

See Answer in Part B → Q7

@Neet_pg_bot



Q8: A child presents to the outpatient department (OPD) with a radiological image as given. What is the most appropriate management for this condition? (Q844289)

A. Endoscopic ablation

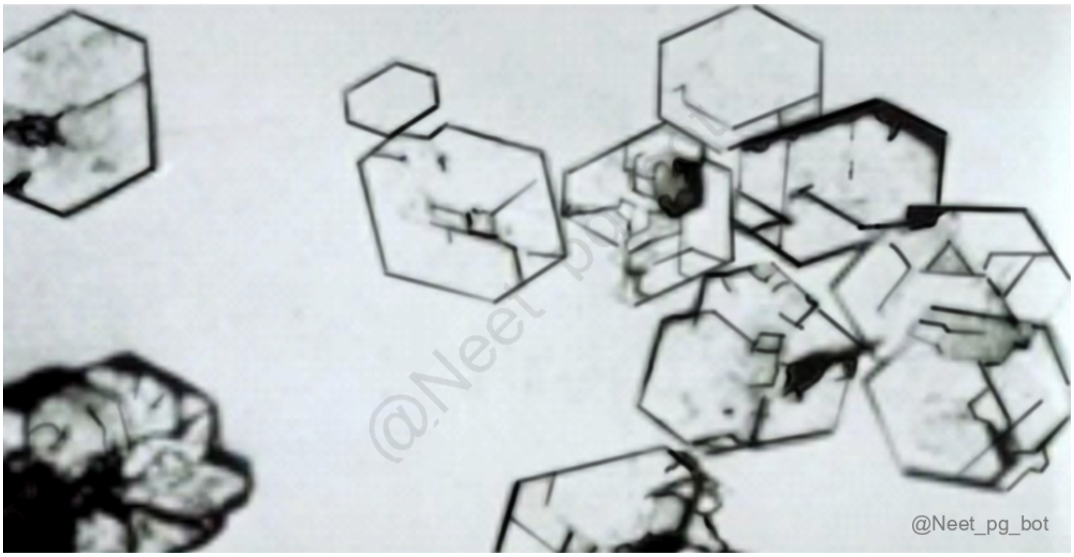
B. Dilation of urethra

C. Dilation of urethra and bladder

D. Conservative

See Answer in Part B → Q8

@Neet_pg_bot



Q9: A young patient presents to the outpatient department (OPD) with recurrent colicky abdominal pain. Urine examination reveals the presence of red blood cells (RBCs). What is the most likely diagnosis? (Q844290)

A. Glomerulonephritis

B. Oxalate stone

C. Polycystic kidney disease

D. Cystine stone

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 12-year-old child presents to the outpatient department (OPD) with a complaint of scrotal pain, with a history of trauma 6 hours prior. Upon surgical exploration, the findings suggest significant damage. What is the most likely diagnosis? (Q844297)

A. Testicular torsion with gangrene

B. Torsion of testicular appendages with gangrene

C. Gangrene

D. Hematoma

See Answer in Part B → Q10

@Neet_pg_bot

Q11: What instrument is used to insert this tube? (Q844311)

A. Nephroscope

B. Cysto urethroscope

C. Ureteroscope

D. Endoscope

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A patient was brought to the emergency department with a history of fall and head injury. What is the diagnosis? (Q844292)

A. EDH

B. SDH

C. SAH

D. Contusion

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Identify the procedure done. (Q844299)

A. Orchidectomy

B. Total penectomy

C. Partial penectomy

D. None of the above

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A patient presents with a growth over the penis that is classified as a T3 lesion, with no enlarged inguinal lymph nodes detected. What is the best method of management? (Q844305)

A. Penectomy

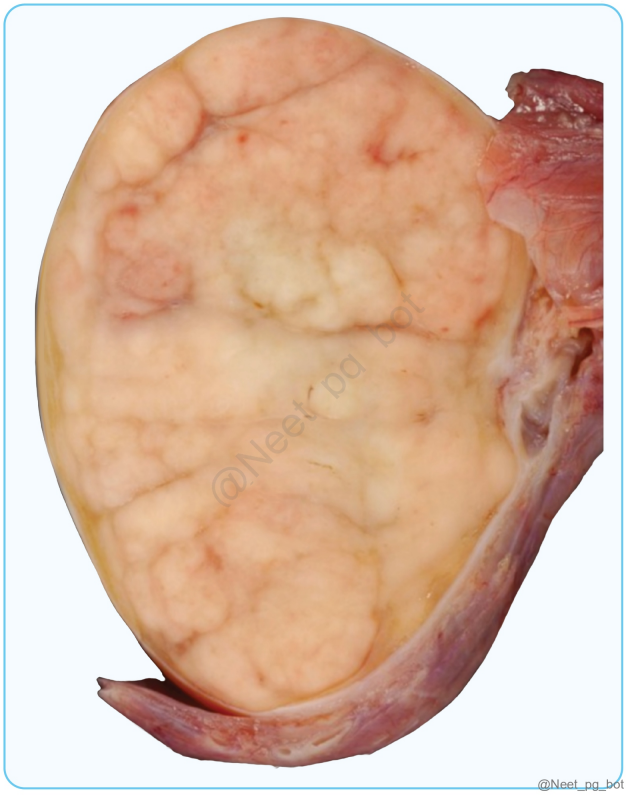
B. Penectomy with orchidectomy

C. Penectomy with superficial / modified inguinal lymph node dissection

D. Penectomy with deep inguinal lymph node dissection

See Answer in Part B → Q14

@Neet_pg_bot



Q15: A 35-year-old male presents with a bulky scrotal swelling. On evaluation, malignancy is suspected, and an orchidectomy is performed. The gross section of the testicular mass is shown in the image. What is the most likely diagnosis? (Q860402)

A. Seminoma

B. Teratoma

C. Yolk sac tumour

D. Endodermal sinus tumor

See Answer in Part B → Q15

@Neet_pg_bot

Q16: An adult male presents to the outpatient department with a painful scrotal swelling accompanied by fever. The swelling is associated with the tunica vaginalis and is characterized by fluid accumulation. What is the likely diagnosis? (Q860406)

A. Varicocele

B. Hydrocele

C. Cystocele

D. Torsion testis

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 40-year-old man presents with gynecomastia. Ultrasound reveals a 1 cm solid mass within the body of the testis. Serum testosterone is 600 ng/dL, and estradiol is 35 pg/mL. What is the most likely diagnosis? (Q860423)

A. Spermatocytic tumor

B. Sertoli cell tumor

C. Granulosa cell tumor

D. Leydig cell tumor

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 55-year-old man presents with abdominal pain. A CECT (Contrast Enhanced CT) abdomen was done. What is the likely source of pain? (Q860459)

A. Gall bladder

B. Spleen

C. Kidney

D. Liver

See Answer in Part B → Q18

@Neet_pg_bot

Q19: All of the following statements regarding Wilms tumor are true, except? (Q840019)

A. Presents as an abdominal mass

B. Most commonly seen <5yrs of age

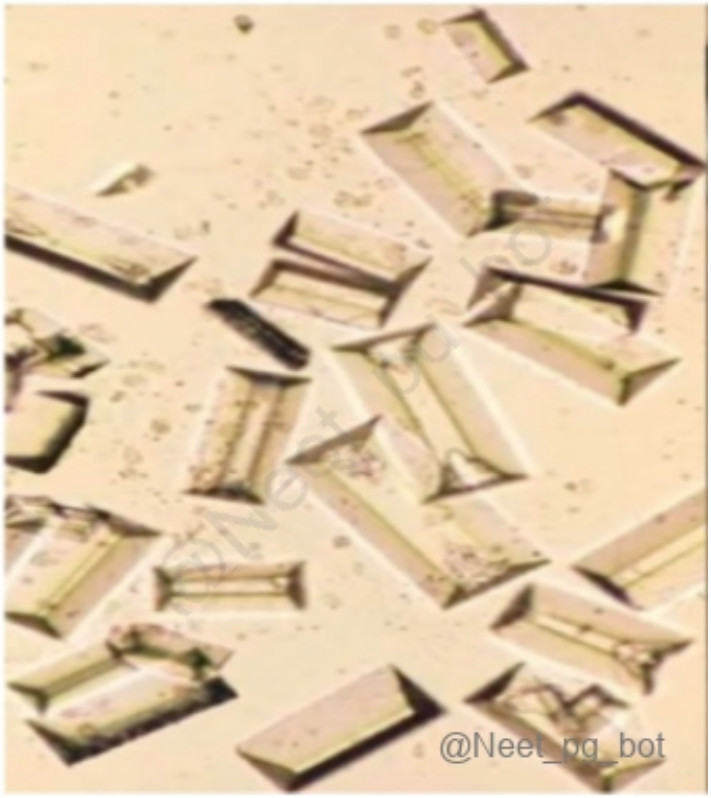
C. Majority patients recover due to chemotherapy and radiotherapy

D. Lung involvement in uncommon and occurs late

See Answer in Part B → Q19

@Neet_pg_bot

Q20: 45-year-old female presents with recurrent episodes of right flank pain, hematuria, and a history of urinary tract infections. Urine analysis shows alkaline



urine with a pH of 8.0. Microscopy revealed the following finding. Which of the following is the most likely underlying cause of this patient's condition? (Q840022)

A. Triple phosphate stone

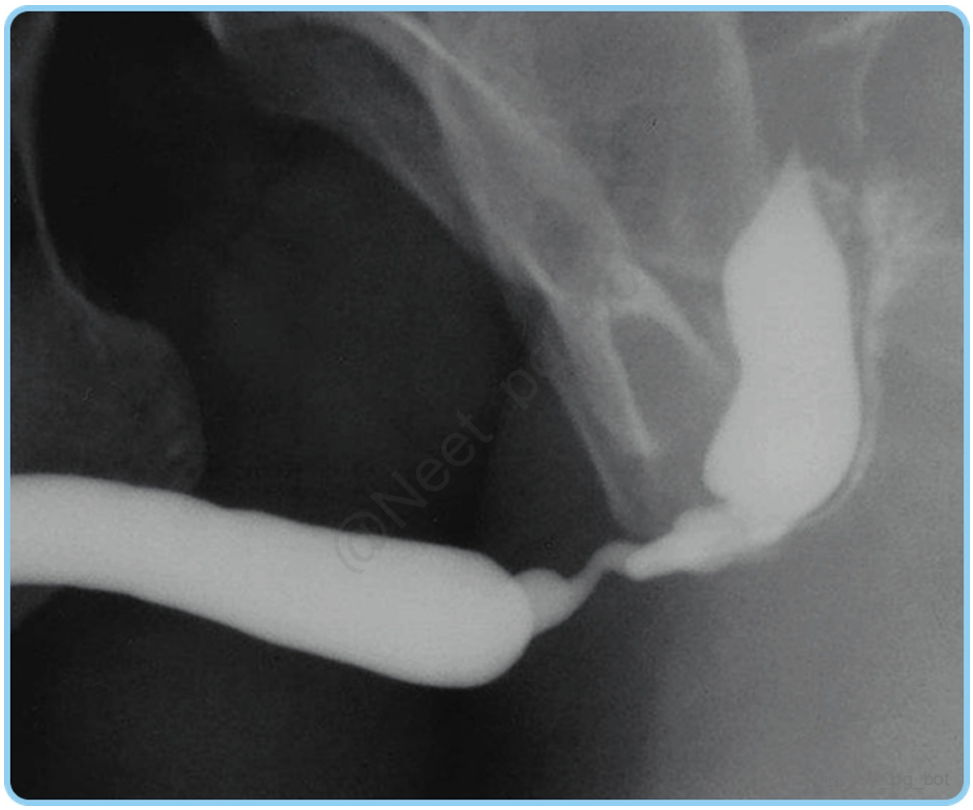
B. Ca Oxalate Stones

C. Uric Acid Stones

D. Cystine Stones

See Answer in Part B → Q20

@Neet_pg_bot



Q21: Identify the condition in the image: (Q860209)

A. Bulbar urethral stricture

B. Membranous urethral injury

C. Urethral tear

D. Prostate hyperplasia

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A patient develops a severe infection and necrosis in the scrotal region after 5 days of catheterization. Based on the clinical presentation, what is the most likely diagnosis? (Q860214)

A. Fournier’s gangrene

B. Gas gangrene

C. Wet gangrene

D. Scrotal hematoma

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 35-year-old male presents with a painless testicular mass. After orchidectomy, histopathological examination reveals the presence of Reinke's crystals within the tumor cells. What is the most likely diagnosis? (Q860215)

A. Sertoli cell tumor

B. Leydig cell tumor

C. Seminoma

D. Yolk sac tumor

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Post-orchidectomy, the specimen shows Reinke's Crystals. What is the diagnosis? (Q857248)

A. Seminoma

B. Leydig Cell Tumor

C. Metastasis

D. Yolk sac tumour

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 45 year old patient with a history of kidney stones that were surgically removed 2 years ago presents with complaints of fever and flank pain. Imaging done is shown here. What would be the most appropriate next step in the management of this patient? (Q820137)

A. Laparotomy to remove the stones

B. Lithotripsy to remove recurrent stone

C. Leave the foreign body inside

D. Cystoscopic retrieval of foreign Body

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 65-year-old male patient presents with urinary complaints. He has a history of working in a dye factory in the past. On USG examination, his bladder walls are found to be thickened and irregular. What is the most appropriate management for this patient? (Q820175)

A. Instillation of BCG

B. Cystoscopy with tumor removal

C. Intravesical mitomycin C

D. Radical cystectomy

See Answer in Part B → Q26

@Neet_pg_bot

Q27: What is the best investigation to assess renal perfusion? (Q820191)

A. DTPA scan

B. DMSA scan

C. RGU

D. CT urogram

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 4-year-old child is brought to the emergency department with a painless abdominal swelling noticed by the parents. On examination, a large, firm, mobile

abdominal mass is noted. The mass is unilateral and does not cross the midline. There is no associated hematuria, fever, or weight loss. What is the most probable diagnosis? (Q830828)

A. Neuroblastoma

B. Angiomyolipoma

C. Renal cell carcinoma

D. Wilm’s tumor

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 45-year-old patient presents with complaints of dysuria and intermittent back pain. On examination, there are no palpable abdominal masses or tenderness. An X-ray image of the abdomen is shown. What is the most likely diagnosis? (Q854769)

A. PTH adenoma

B. Wilm's tumour

C. Renal cell carcinoma

D. Lipoma

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 55-year-old male presented with verrucous carcinoma around the glans of the penis. Examination reveals that the inguinal lymph nodes are not enlarged. What is the appropriate management for this patient? (Q855147)

A. Total penectomy

B. CO2 laser excision

C. Topical 5-fluorouracil

D. Partial penectomy

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A diabetic patient presents with sudden-onset perineal pain. On examination, foul-smelling discharge and necrotic tissue, as seen in the image, are noted. Which of the following is true about the given condition? (Q855167)

A. Anti-gas gangrene serum is indicated for all cases

B. Urinary diversion is the next step

C. A bilateral orchidectomy must be done

D. Mixed aerobic and anaerobic infection

See Answer in Part B → Q31

@Neet_pg_bot

Q32: Which of the following statements is not true regarding the provided medical condition? (Q855208)

A. Repeated radical surgery every 24 hours may be required to adequately manage this condition

B. This is a case of Meleney's gangrene

C. The condition is caused by β-hemolytic streptococcus and may sometimes be polymicrobial

D. Hyperbaric oxygen has no role in the treatment of this condition.

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A 55-year-old male patient presents with hematuria and a neovascular mass in the left kidney on a CT scan, as shown below. What is the diagnosis? (Q857778)

A. Renal cell carcinoma

B. Renal oncocytoma

C. Renal angiomyolipoma

D. Renal cyst

See Answer in Part B → Q33

@Neet_pg_bot

Q34: Which lymph node is most commonly involved in prostate cancer? (Q857794)

A. Deep inguinal

B. Retroperitoneal

C. Superficial inguinal

D. Pelvic

See Answer in Part B → Q34

@Neet_pg_bot

Q35: Which of the following statements is false about the following image? (Q857795)

A. Staphylococcus aureus is the causative organism

B. Common in diabetic patients

C. High mortality

D. The testes remain unaffected

See Answer in Part B → Q35

@Neet_pg_bot

Q36: What type of hernia is a funicular hernia? (Q857796)

A. Direct inguinal hernia

B. Indirect inguinal hernia

C. Femoral hernia

D. Umbilical hernia

See Answer in Part B → Q36

@Neet_pg_bot

Q37: A 50-year-old male patient came to the outpatient department with complaints of hematuria. A 2x2 cm bladder mass is seen which is low-grade transitional cell carcinoma. Which among the following is the ideal management? (Q857799)

A. Transurethral resection of the tumor

B. Resection with ileal conduit

C. Partial cystectomy with bladder reconstruction

D. Neoadjuvant chemotherapy

See Answer in Part B → Q37

@Neet_pg_bot

Q38: Which of the following will have unilateral hydronephrosis? (Q857801)

A. Urethral atresia

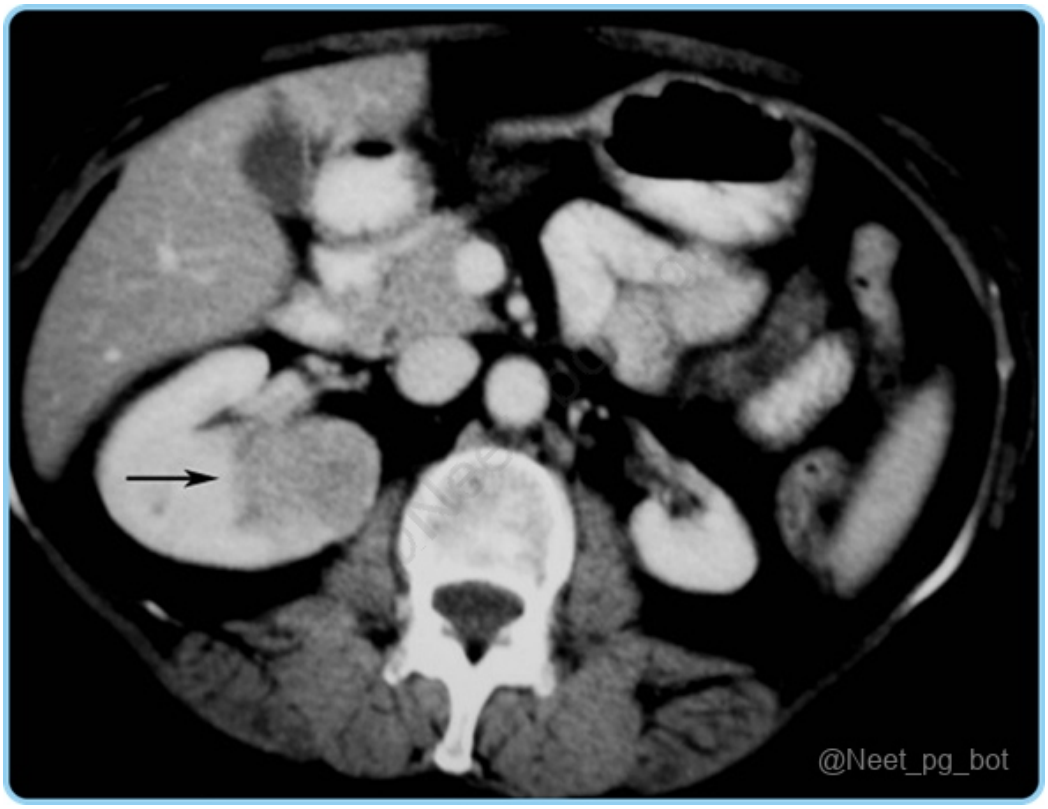
B. Posterior urethral valves

C. Benign Prostatic Hyperplasia

D. Retrocaval ureter

See Answer in Part B → Q38

@Neet_pg_bot



Q39: A 44-year-old female presents with an incidentally discovered 4 cm solid, hyper-enhancing mass in the lower pole of the right kidney on CT imaging. The contralateral kidney is normal, and there is no evidence of lymphadenopathy or distant metastasis. What is the most appropriate management for this patient? (Q857802)

A. Partial nephrectomy

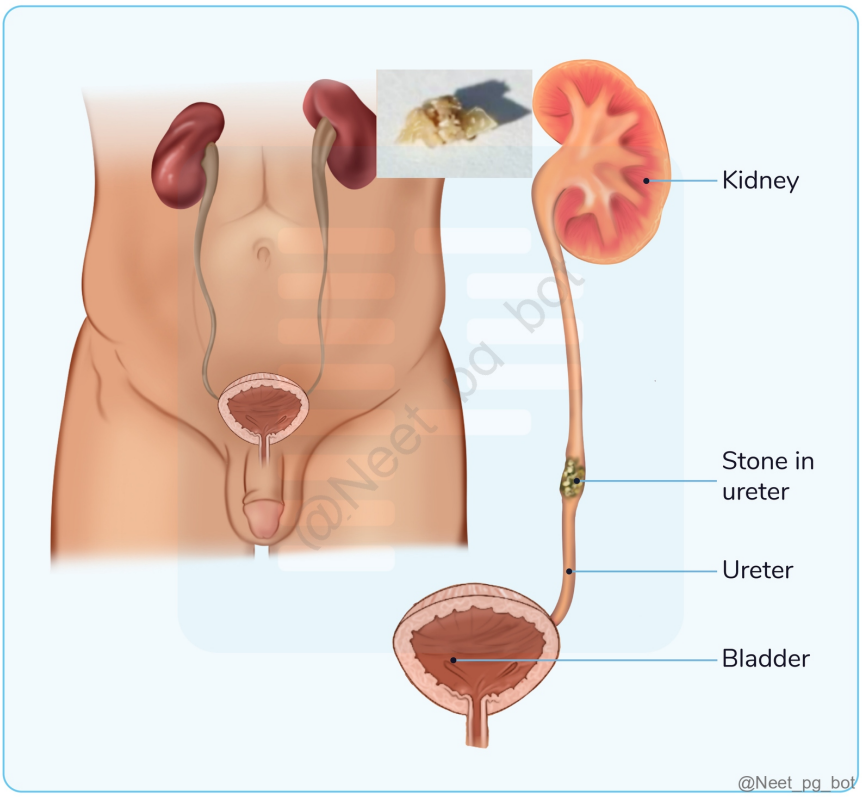
B. Partial nephrectomy + Neoadjuvant chemotherapy

C. Radical nephrectomy

D. Radical nephrectomy + Postoperative radiotherapy

See Answer in Part B → Q39

@Neet_pg_bot



Q40: Which of the following is the recommended treatment for the condition shown in the image, where the size of the stone is 1.5 cm? (Q857820)

A. Percutaneous nephrolithotomy

B. Ureteroscopy

C. ESWL

D. Wait and watch

See Answer in Part B → Q40

@Neet_pg_bot

Q41: What is the initial management approach for urinary symptoms in a patient with benign prostatic hyperplasia (BPH)? (Q857822)

A. TURP: Transurethral resection of prostate

B. Tamsulosin

C. Finasteride

D. Observation

See Answer in Part B → Q41

@Neet_pg_bot

Q42: Which of the following are true about nephroblastoma except: (Q857825)

A. Treatment is chemotherapy followed by surgery

B. Lung metastasis is common

C. Hematogenous spread

D. Most common intra-abdominal malignancy in children

See Answer in Part B → Q42

@Neet_pg_bot

Q43: A 25-year-old patient presents to the surgical OPD with a painless left inguinal reducible mass. On examination cough impulse is positive. After further investigations, the patient is diagnosed with an inguinal hernia. What is the surgical management of this patient? (Q857831)

A. Herniotomy

B. Hernioplasty

C. Wait and watch

D. Emergency laparotomy

See Answer in Part B → Q43

@Neet_pg_bot

Q44: A male patient presented with complaints of hematuria and recurrent urinary tract infection. You notice the following finding in his CT. What is the likely condition indicated by the arrow in the image? (Q857867)

A. Polycystic kidney disease

B. Horseshoe kidney

C. Hydronephrosis

D. Pancake kidney

See Answer in Part B → Q44

@Neet_pg_bot

Q45: Which is the correct sequence for the correction of hypospadias? Urethroplasty Penile de-gloving Orthoplasty Glanuloplasty (Q855696)

A. 1,3,2,4

B. 2,3,1,4

C. 3,1,4,2

D. 1,3,4,2

See Answer in Part B → Q45

@Neet_pg_bot

Q46: A 30-year-old male patient presents with a pelvic fracture following blunt abdominal trauma. No blood is seen at the meatus. Catheterisation does not produce significant urine output. The radiological image is given below. What is the next step in management? (Q855183)

A. Suprapubic cystostomy

B. Per Urethral catheterisation

C. Laparotomy

D. Pelvic packing along with B/L percutaneous nephrostomy

See Answer in Part B → Q46

@Neet_pg_bot

Q47: What is the most likely diagnosis for a young girl who presents with continuous dribbling of urine despite voiding normally, as reported by her parents, who mention her never being completely dry since birth? (Q857151)

A. Ectopic ureter

B. Ureterocele

C. Congenital megaureter

D. Vesicoureteric reflux

See Answer in Part B → Q47

@Neet_pg_bot

Q48: A 1-month-old child is brought to the OPD for consultation regarding an empty scrotal sac. On examination B/L inguinal masses are palpable. What is the next step of management for this child? (Q857163)

A. Perform karyotyping

B. Surgical exploration within the next 2 weeks

C. Perform orchidopexy now

D. Wait and watch for spontaneous descent within the next 6 months.

See Answer in Part B → Q48

@Neet_pg_bot

Q49: Which of the following is the most common type of radiolucent renal stone? (Q857202)

A. Calcium Oxalate Stones

B. Uric Acid Stones

C. Cystine Stones

D. Xanthine Stones

See Answer in Part B → Q49

@Neet_pg_bot

Q50: For which of the following conditions is the Whitaker test recommended? (Q857211)

A. Hydronephrosis

B. Posterior urethral valve

C. Urethral atresia

D. Urethral stricture

See Answer in Part B → Q50

@Neet_pg_bot

Q51: A 33-year-old man was referred to the surgery OPD from the infertility clinic. On palpation, a bag of worms sensation was felt with dilated veins. What is the most likely diagnosis? (Q857251)

A. Hydrocele

B. Varicocele

C. Testicular torsion

D. Epididymo Orchitis

See Answer in Part B → Q51

@Neet_pg_bot

Q52: What would be the best treatment option for a patient who has been diagnosed with renal cell carcinoma and has a tumour measuring 10 cm in size, located at the lower part of the kidney, and has negative regional lymph nodes? (Q857266)

A. Radical nephrectomy

B. Partial nephrectomy

C. Radiotherapy

D. Chemotherapy

See Answer in Part B → Q52

@Neet_pg_bot

Q53: What is the most likely diagnosis for a patient who has a scrotal mass on the left side that is hard in texture, has uneven edges, does not decrease in size when lying down or manipulated, does not have a cough impulse, but shows enlargement in the para-aortic lymph nodes? (Q857268)

A. Hydrocele

B. Direct inguinal hernia

C. Indirect inguinal hernia

D. Metastasising testicular tumor

See Answer in Part B → Q53

@Neet_pg_bot

Q54: A 10-month-old male baby presented with an empty scrotum. Ultrasonography revealed that the right testis was found in the right inguinal canal, while the left testis was found in the perineum. Comment on the diagnosis of this baby. (Q857500)

A. Bilateral undescended testis

B. Bilateral ectopic testis

C. Right-side undescended testis and left-sided ectopic testis

D. Right side ectopic testis and left side undescended testis

See Answer in Part B → Q54

@Neet_pg_bot

Q55: What is the most probable diagnosis for a 14-year-old boy who is experiencing sudden scrotal pain, where physical examination reveals a swollen and red scrotum

with the right testes being retracted, absent cremasteric reflex, and negative Prehn's sign? (Q857504)

A. Right-sided hydrocele

B. Strangulated inguinal hernia

C. Right testicular torsion

D. Right epididymo orchitis

See Answer in Part B → Q55

@Neet_pg_bot

Q56: What is the likely diagnosis for an elderly male patient who has come to the hospital with lower back pain, a movable mass in the lower back that becomes more prominent when breathing in and a general feeling of weakness? The lab tests show the presence of red blood cells in the urine, with no sign of pus cells. (Q857531)

A. Polycystic kidney disease

B. Hydronephrosis

C. Renal cell carcinoma

D. Chronic pyelonephritis

See Answer in Part B → Q56

@Neet_pg_bot

Q57: What is the likely diagnosis for a 60-year-old male who is experiencing lower back pain and has sclerotic lesions in the vertebrae? (Q857532)

A. Carcinoma prostate

B. Tuberculosis

C. Renal cell carcinoma

D. Carcinoma colon

See Answer in Part B → Q57

@Neet_pg_bot

Q58: A patient with a history of trauma has a ruptured bulbar urethra. What is the location for the accumulation of urine? (Q857534)

A. Superficial pouch

B. Deep pouch

C. Rectouterine pouch

D. Uterovesical pouch

See Answer in Part B → Q58

@Neet_pg_bot

Q59: In a newborn male with an undeveloped scrotum, the testis was observed to be located near the peritoneum. Which of the following factors aids in the descent of the testis into the scrotum? (Q857536)

A. GnRH Analogues

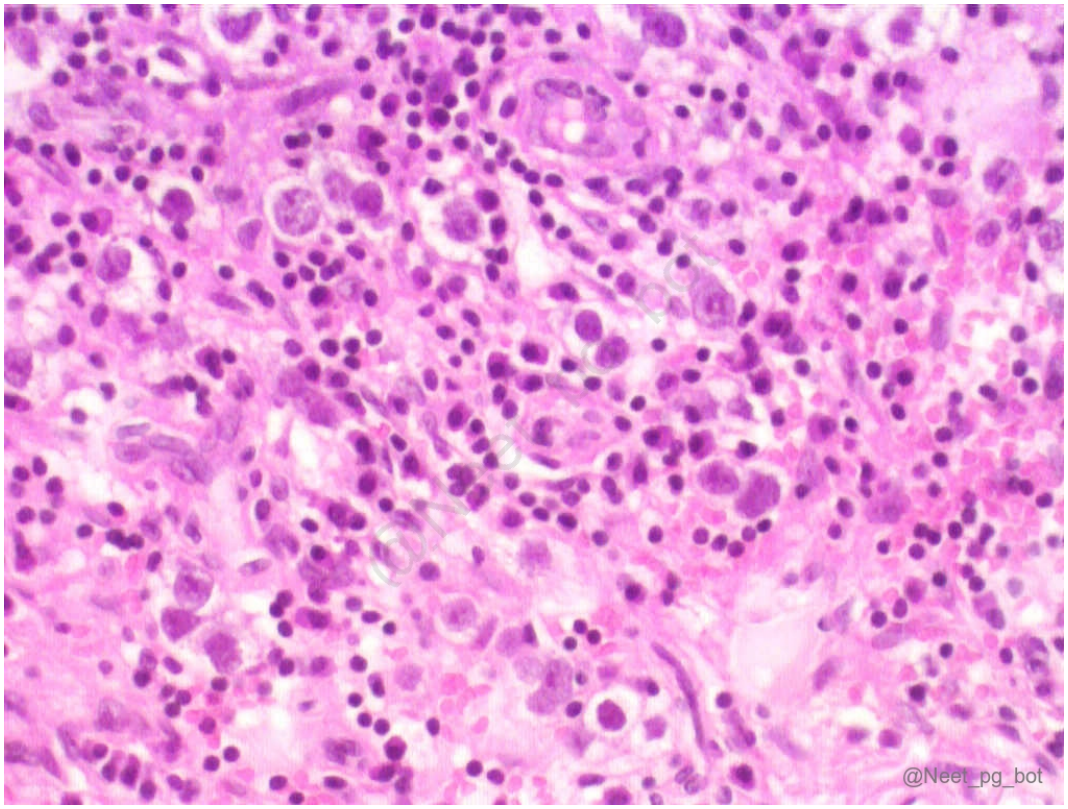
B. Testosterone

C. Cold Compressions

D. Manually bring the testis down to the bottom of scrotum.

See Answer in Part B → Q59

@Neet_pg_bot



Q60: A 35-year-old man presents with scrotal enlargement. His LDH levels are notably elevated, while HCG and alpha-fetoprotein levels remain within normal ranges. Upon histopathological examination, the findings are as shown below. What is the most probable diagnosis? (Q857537)

A. Leydig cell tumor

B. Embryonal carcinoma

C. Seminoma

D. Teratoma

See Answer in Part B → Q60

@Neet_pg_bot

Q61: A young male underwent lumbar sympathectomy, and bilateral L1 ganglions were removed. What will be the most common side effect? (Q857538)

A. Impotence

B. Retrograde ejaculation

C. Bladder dysfunction

D. Incontinence

See Answer in Part B → Q61

@Neet_pg_bot

Q62: All the following are features of polycystic disease of kidneys except: (Q857543)

A. Hematuria

B. Hypertension

C. Renal failure

D. Erythrocytosis

See Answer in Part B → Q62

@Neet_pg_bot

Q63: A 26 year old male presented with a painless large round firm right testicular swelling, with a dragging sensation. The left testis was normal. AFP was around 3000U. What is the next best step in the management? (Q858337)

A. FNAC

B. Scrotal true cut biopsy

C. High inguinal orchidectomy

D. Repeat tumor markers

See Answer in Part B → Q63

@Neet_pg_bot

Q64: A 20-year-old was brought to the ER after falling off his bicycle. His vitals were stable, but he had a bruise over the perineum, and he had not passed urine yet. Blood was seen at the meatus and the bladder was not palpable. How do you manage him? (Q858339)

A. Wait and send him home

B. Immediate insertion of a Foley catheter

C. Suprapubic aspiration of urine

D. Wait for bladder to fill and urge to urinate

See Answer in Part B → Q64

@Neet_pg_bot

Q65: What is the primary reason for bladder outlet obstruction in male children? (Q858352)

A. Posterior urethral valve

B. Urethral atresia

C. Anterior urethral valve

D. Ureterocele

See Answer in Part B → Q65

@Neet_pg_bot

Q66: A 3-year-old boy is brought by his mother with right-sided abdominal swelling noticed during bathing. He had a history of hematuria 2 weeks ago, which resolved spontaneously. On examination, a right-sided reniform, ballotable mass is palpable. What is the investigation of choice for confirming the diagnosis? (Q856530)

A. CECT abdomen

B. PET-CT

C. 24-hour urinary VMA

D. FNAC

See Answer in Part B → Q66

@Neet_pg_bot

Q67: A 50-year-old male patient came to the outpatient department with complaints of hematuria. A 2x2 cm bladder mass is seen which is low grade transitional cell carcinoma. Which among the following is the ideal management? (Q856567)

A. Transurethral resection of the tumor

B. Resection with ileal conduit

C. Partial cystectomy with bladder reconstruction

D. Neoadjuvant chemotherapy

See Answer in Part B → Q67

@Neet_pg_bot

Q68: Which of the following statements is true regarding the condition mentioned below? {{caption_text}} (Q856203)

A. Patient must be started on anti-gas gangrene serum therapy

B. It is a mixed flora aerobic and anaerobic infection

C. Bilateral orchiectomy is generally performed

D. Compulsory urinary diversion is performed

See Answer in Part B → Q68

@Neet_pg_bot

Q69: In a patient with abdominal pain and sterile pyuria, what is the finding shown in the image given? (Q856205)

A. Putty kidney

B. Nephrocalcinosis

C. Staghorn calculus

D. Psoas calcification

See Answer in Part B → Q69

@Neet_pg_bot

Q70: A 75-year-old man with prostate carcinoma presents to you with a PSA of 9 ng/mL with a small tumour focus. His Gleason score is 6. What will be your most likely management? (Q856232)

A. Radical prostatectomy

B. External beam radiation

C. Brachytherapy

D. Active surveillance

See Answer in Part B → Q70

@Neet_pg_bot

Q71: A patient arrives after being involved in a motorcycle road traffic accident. The patient does not report any pain or injury. Upon examination, there is evidence of blood at the urethral meatus. What would be your subsequent course of action in terms of managing this patient? (Q856251)

A. Foley's catheterization

B. Wait and watch

C. Nephrogram

D. Suprapubic cystostomy

See Answer in Part B → Q71

@Neet_pg_bot

Q72: What is the probable diagnosis for a girl who has experienced continuous urinary dribbling and persistent bladder fullness since birth? (Q856227)

A. Stress incontinence

B. Ureterocele

C. Ectopic ureter

D. Vesicovaginal fistula

See Answer in Part B → Q72

@Neet_pg_bot

Q73: Identify the investigation and the lesion depicted in the image given below: (Q854923)

A. Retrograde cystourethrogram with membranous urethra stricture

B. Retrograde cystourethrogram with penile urethral stricture

C. Micturating cystourethrography with bulbar stricture

D. Micturating cystourethrography with prostatic urethra stricture

See Answer in Part B → Q73

@Neet_pg_bot

Q74: A male patient was brought to the emergency department following a fall into a manhole, resulting in injury to his perineum. He experiences a strong urge to urinate but is unable to do so. During examination, blood is observed at the opening of the urethra, and there is swelling of the penis and scrotum. Which specific area is affected by the injury? (Q854961)

A. Membranous urethra rupture

B. Bulbar urethra injury

C. Prostatic urethra injury

D. Urinary bladder rupture

See Answer in Part B → Q74

@Neet_pg_bot

Q75: Which of the following should be the treatment of choice for renal cell carcinoma with a tumour less than 4 cm in size? (Q854970)

A. Partial nephrectomy

B. Partial nephrectomy + Neoadjuvant chemotherapy

C. Radical nephrectomy

D. Radical nephrectomy + Postoperative radiotherapy

See Answer in Part B → Q75

@Neet_pg_bot

Q76: A 65-year-old man presented to his primary care physician with a 3-month history of increasing urinary frequency without burning and nocturia four times each day. He has limited his fluid consumption and caffeine intake in the evening without much benefit. On prostate examination, the swelling was palpated with a smooth surface, and a firm, non-tender rubber-like consistency was found. The physician thinks of benign prostate hypertrophy. All are characteristic features of benign prostate hypertrophy except: (Q859601)

A. Increased trabeculations in the bladder

B. J-shaped/ fish hook proximal ureter

C. J-shaped/ fish hook distal ureters

D. Bilateral hydronephrosis

See Answer in Part B → Q76

@Neet_pg_bot

Q77: A 68-year-old man presents to OPD with a low backache. His PSA level is 100 ng/ml. Which of the following drugs is indicated for treatment? (Q859617)

A. Somatostatin

B. Terlipressin

C. Goserelin

D. Testosterone

See Answer in Part B → Q77

@Neet_pg_bot

Q78: A 25-year-old morbidly obese male patient presented with complaints of severe abdominal pain and urinary disturbances. His urine microscopy shows the following type of crystals, and an ultrasound of the kidney revealed a renal stone of size 2.5 cm. What is the treatment of choice? (Q859621)

A. Extracorporeal shockwave lithotripsy (ESWL)

B. Percutaneous nephrolithotomy (PCNL

C. Open surgery

D. Ureteroscopy-assisted removal

See Answer in Part B → Q78

@Neet_pg_bot

Q79: According to Weigert Meyer's rule of duplication of the ureter, the lower pole ureter in the urinary bladder is: (Q859624)

A. Lateral and cephalad to the upper pole ureter

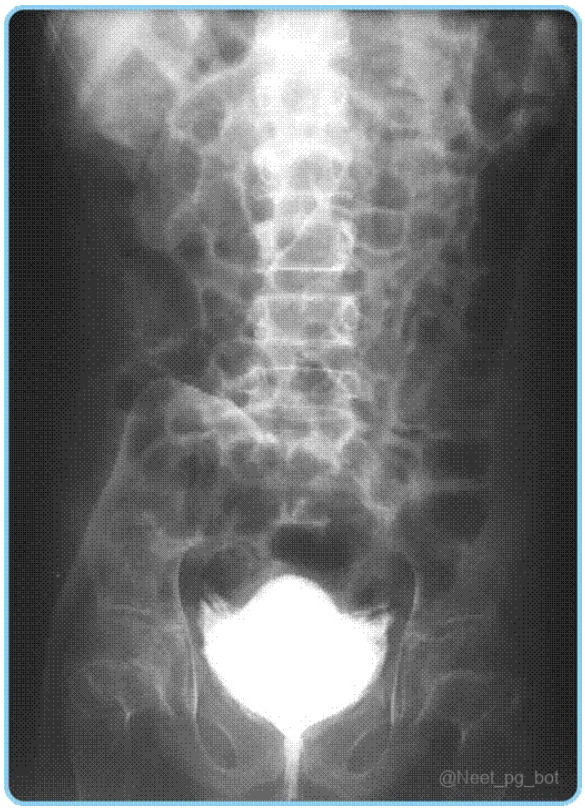
B. Lateral and caudal to the upper pole ureter

C. Medial and cephalad to the upper pole ureter

D. Medial and caudal to the upper pole ureter

See Answer in Part B → Q79

@Neet_pg_bot



Q80: A 35-year-old male presents to the emergency department after a motor vehicle accident with a pelvic fracture and gross hematuria. The CT cystogram showed the following characteristic findings. Which of the following statements regarding the diagnosis of this patient is incorrect? (Q859625)

A. Retrograde cystography demonstrates extravasation of contrast limited to the perivesical space.

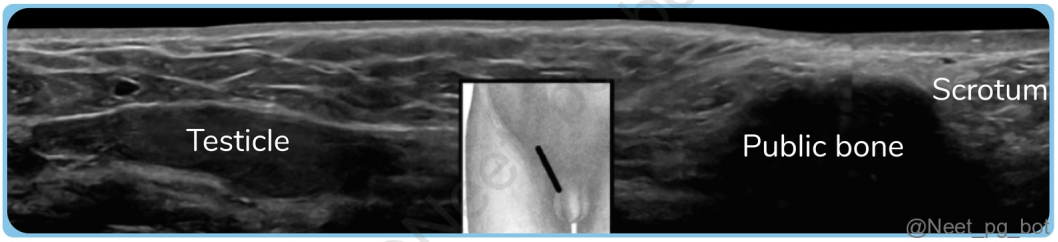
B. Catheter drainage for 10-14 days is the treatment of choice for uncomplicated cases.

C. Immediate surgical repair in cases of bladder neck injury.

D. Both urethral and suprapubic catheters are recommended in all cases.

See Answer in Part B → Q80

@Neet_pg_bot



Q81: An 11-month-old boy had a recent urinary tract infection that was resolved with antibiotics. Vital signs are within normal limits. Physical examination revealed an empty scrotum on the right side with normal left testis. However, a mass was palpable on the right inguinal canal. The USG revealed the right testicle under the subcutaneous fat near the right inguinal canal, as shown in the image below. What is the next best step in management? (Q859626)

A. Observation

B. Hormonal therapy with hCG

C. Orchidopexy

D. Diagnostic laparoscopy

See Answer in Part B → Q81

@Neet_pg_bot

Q82: A 65-year-old male presents with a low backache and weight loss. He has progressive difficulty in urination and had an episode of urinary retention two days back, which was relieved by catheterisation. PSA was done, which was 5.2 ng/ml, and an x-ray of the LS spine showed osteoblastic changes. What is the clinical diagnosis? (Q859832)

A. Benign prostatic hypertrophy

B. Carcinoma bladder

C. Prostate cancer

D. Renal cell cancer

See Answer in Part B → Q82

@Neet_pg_bot

Q83: What should be the initial course of action for a patient who has presented with a pelvic fracture and a rupture in the membranous urethra? (Q859840)

A. A suprapubic catheter should be inserted as soon as possible

B. IVP should be done

C. Immediate urethroplasty

D. MCU should be done

See Answer in Part B → Q83

@Neet_pg_bot

Q84: What is the cause of the following appearance in IVP? (Q859841)

A. Horseshoe kidney

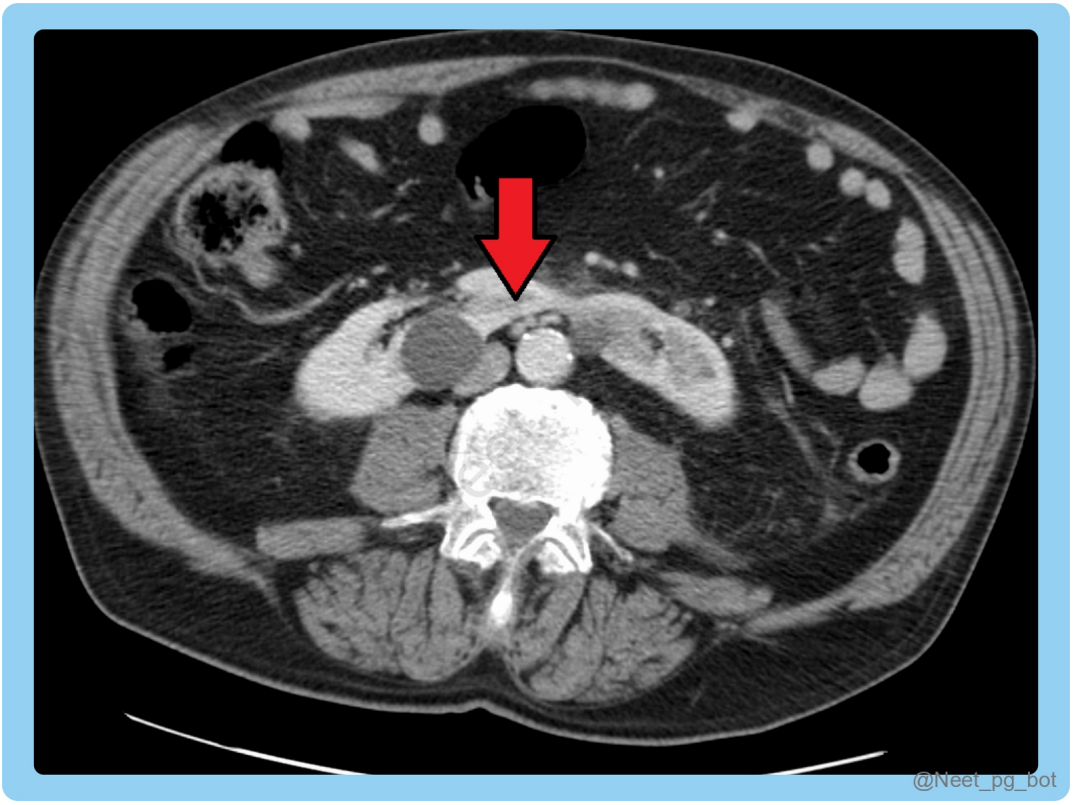
B. Ureterocoele

C. Bladder tumour

D. Posterior urethral valve

See Answer in Part B → Q84

@Neet_pg_bot



Q85: A 30-year-old man developed abdominal pain for which he was being evaluated. You notice the following in his CECT. What is the likely condition indicated by the arrow in the image? (Q859842)

A. Appendicitis

B. Horseshoe kidney

C. Wilms tumor

D. Abdominal aortic aneurysm

See Answer in Part B → Q85

@Neet_pg_bot

Q86: What is the likely diagnosis for a patient who visited the outpatient department (OPD) experiencing intense pain during erection and a deviated penis for the past half-year? (Q859845)

A. Peyronie’s disease

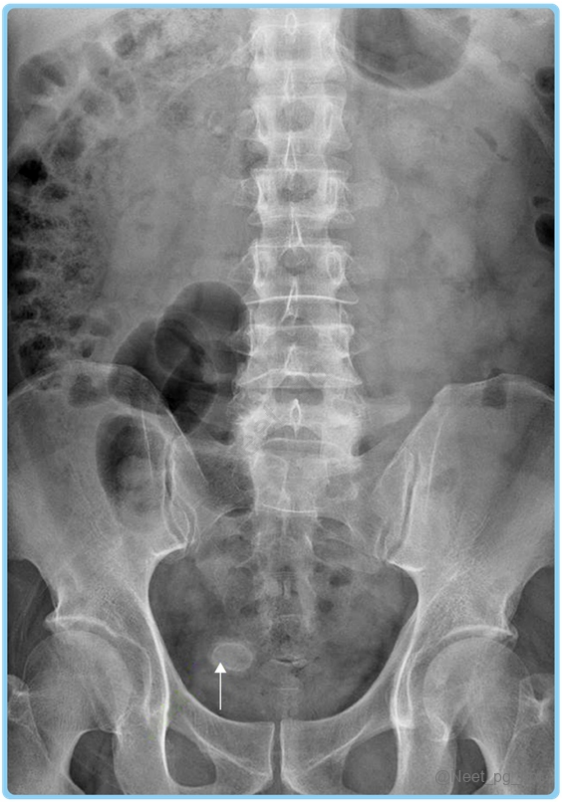
B. Priapism

C. Marion’s disease

D. Erectile dysfunction

See Answer in Part B → Q86

@Neet_pg_bot



Q87: What is the diagnosis based on the X-ray given below? {{caption_text}} (Q859858)

A. Renal calculi

B. Bladder calculi

C. Schistosomiasis

D. Ureteric calculi

See Answer in Part B → Q87

@Neet_pg_bot

Q88: A 60-year-old patient undergoes TURP, and after 3 days, the patient develops altered sensitiveness and drowsiness. The most probable diagnosis is: (Q859864)

A. Hypernatremia

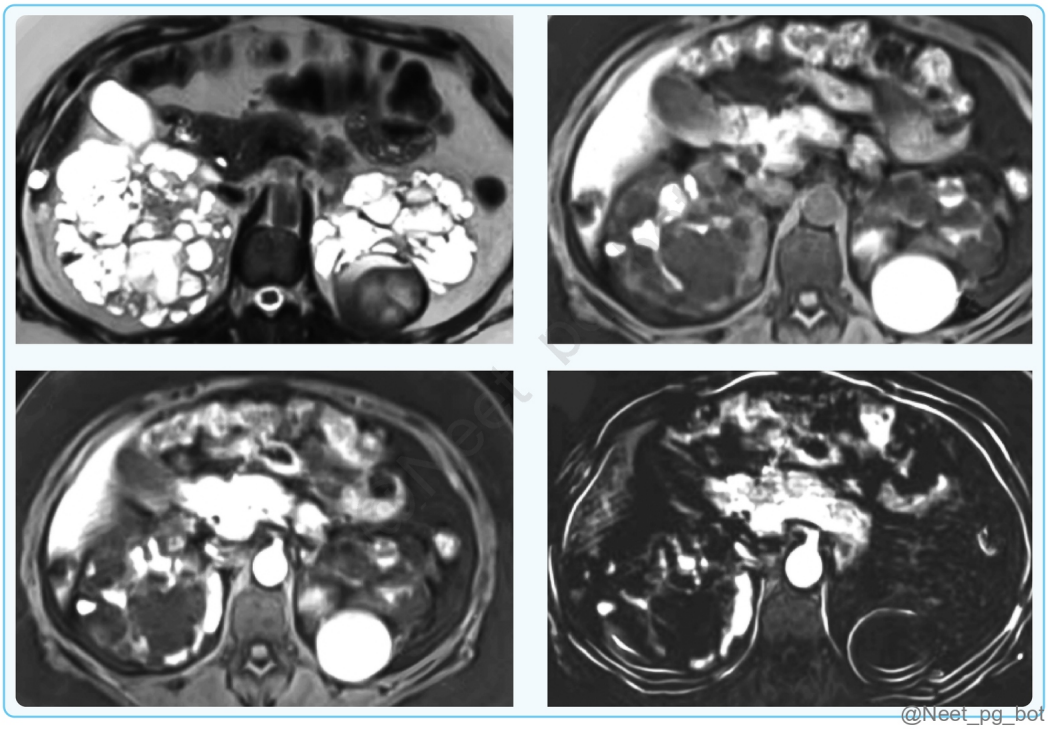
B. Hyponatremia

C. Stroke

D. Meningitis due to spinal anaesthesia

See Answer in Part B → Q88

@Neet_pg_bot



Q89: A 40-year-old man with a known case of hypertension presented with multiple episodes of hematuria and loin pain. His elder brother passed away due to a stroke at the age of 40. The CT abdomen is shown below. What is the probable diagnosis? (Q855565)

A. Renal cell carcinoma

B. Autosomal dominant polycystic kidney disease

C. Tuberculosis of the kidney

D. Autosomal recessive polycystic kidney disease

See Answer in Part B → Q89

@Neet_pg_bot

Q90: What is the probable diagnosis for an elderly male patient who experienced scrotal pain and discharge, as indicated in the provided image? (Q855763)

A. Torsion of testis

B. Acute epididymo-orchitis

C. Scrotal carcinoma

D. Fournier’s gangrene

See Answer in Part B → Q90

@Neet_pg_bot

Q91: A patient presents with prostate carcinoma, which has now spread to the vertebra. What is the route of spread to the lumbar vertebra? (Q855766)

A. Batson's plexus

B. Transcoelomic spread

C. Inferior vesical vein

D. Internal iliac vein

See Answer in Part B → Q91

@Neet_pg_bot

Q92: A 6-year-old boy came with a history of recurrent urinary tract infections. Imaging was done and is shown below. What is the diagnosis? (Q855781)

A. Vesicoureteric reflux

B. Urinary bladder diverticulum

C. Urinary bladder hernia

D. Vesicocolic fistula

See Answer in Part B → Q92

@Neet_pg_bot

Q93: A young male patient with a history of a motor vehicle accident cannot pass urine. Blood is seen at the meatus. What is the most likely site of urethral injury? (Q855797)

A. Bulbar urethra

B. Spongy urethra

C. Membranous urethra

D. Penile urethra

See Answer in Part B → Q93

@Neet_pg_bot

Q94: A delayed intravenous urogram of a patient is given below. What is the likely diagnosis? (Q855803)

A. Pelviureteric junction obstruction

B. Putty kidney

C. Staghorn calculus

D. Cystic kidney

See Answer in Part B → Q94

@Neet_pg_bot

Q95: What is the initial management approach for urinary symptoms in a patient with benign prostatic hyperplasia (BPH) ? (Q794786)

A. TURP: Transurethral resection of prostate

B. Tamsulosin

C. Finasteride

D. Observation

See Answer in Part B → Q95

@Neet_pg_bot

Q96: A 50-year-old male patient came to the outpatient department with complaints of hematuria . A 2x2 cm bladder mass is seen which is low grade transitional cell carcinoma . Which among the following is the ideal management? (Q802848)

A. Transurethral resection of the tumor

B. Resection with ileal conduit

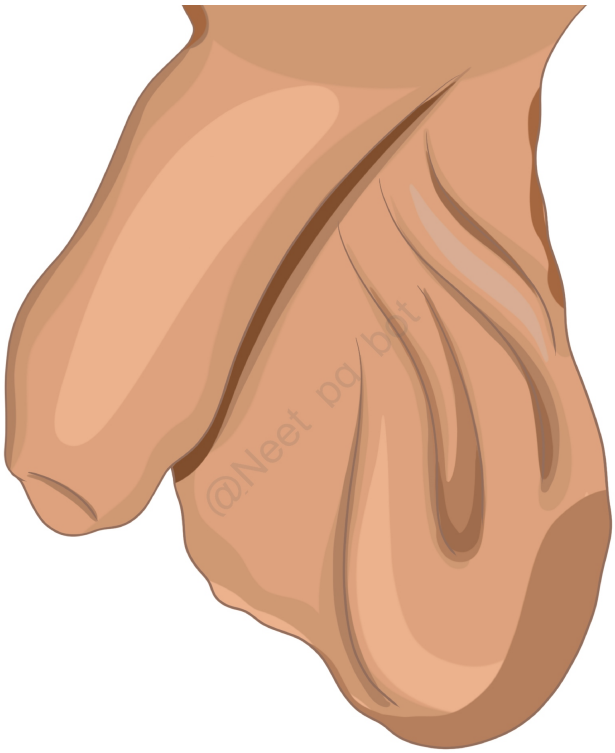
C. Partial cystectomy with bladder reconstruction

D. Neoadjuvant chemotherapy

@Neet_pg_bot

See Answer in Part B → Q96

@Neet_pg_bot



Q97: A 33-year-old man was referred to the surgery OPD from the infertility clinic . On inspection, the scrotum appeared as in the image. On palpation, a bag of worm sensation was felt . What is the most likely diagnosis? (Q793368)

A. Hydrocele

B. Varicocele

C. Testicular torsion

D. Epididymo Orchitis

See Answer in Part B → Q97

@Neet_pg_bot

Q98: Which of the following are s torage symptoms of benign prostatic hyperplasia ? 1. Urgency 2. Enuresis 3. Hesitancy 4. Frequency 5. Dribbling (Q793417)

A. 1, 3, 4

B. 2 and 5

C. 1, 2, 4, 5

D. 1, 2, 4

See Answer in Part B → Q98

@Neet_pg_bot

Q99: What diagnosis would you suggest for a 10-month-old male baby who presented with an empty scrotum , wherein ultrasonography showed the right testis located in the right inguinal canal and the left testis located in the perineum? (Q793435)

A. Bilateral undescended testis

B. Bilateral ectopic testis

C. Right side undescended testis and left sided ectopic testis

D. Right side ectopic testis and left side undescended testis

See Answer in Part B → Q99

@Neet_pg_bot

Q100: Identify the investigation and the lesion depicted in the image given below. (Q793492)

A. Retrograde cystourethrogram with membranous urethra stricture

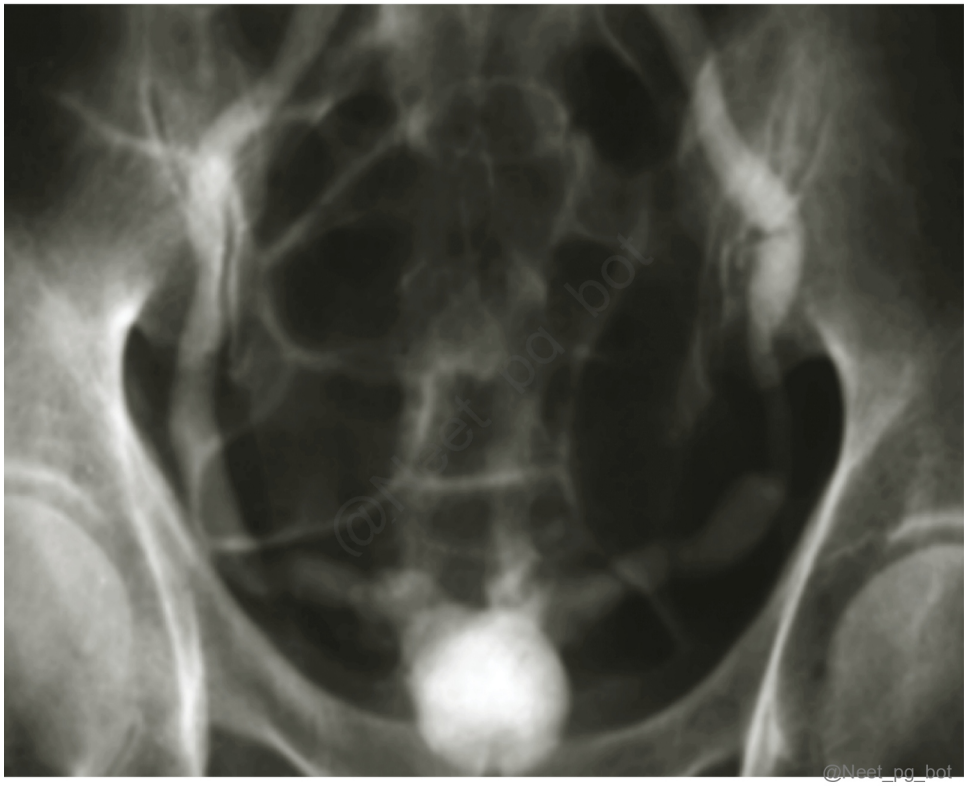
B. Retrograde cystourethrogram with penile urethral stricture

C. Micturating cystourethrography with bulbar stricture

D. Micturating cystourethrography with psoriatic urethra stricture

See Answer in Part B → Q100

@Neet_pg_bot



Q101: A patient presented to the hospital with a history of increased frequency of micturition . On cystoscopy, a pale ureteric orifice was seen. The patient's KUB x-ray is given below. What is the most probable diagnosis? (Q793507)

A. Bladder carcinoma

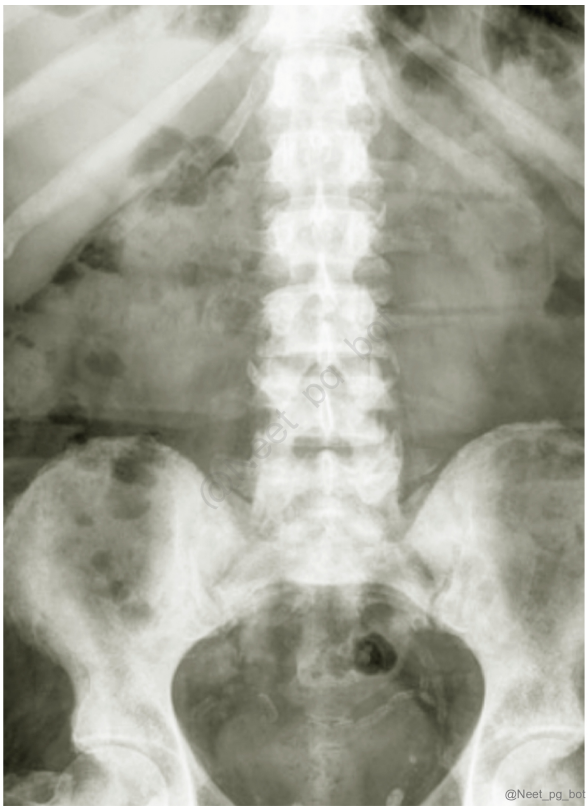
B. Schistosomiasis

C. Bladder tuberculosis

D. Papilloma of urinary bladder

See Answer in Part B → Q101

@Neet_pg_bot



Q102: A 77-year-old man presented with worsening hip and back pain . He also reports weight loss and loss of appetite . His PSA levels are elevated. What is the most likely diagnosis here? (Q793512)

A. Ankylosing spondylitis

B. Osteosarcoma

C. Osteoclastoma

D. Prostate cancer

See Answer in Part B → Q102

@Neet_pg_bot

Q103: A 50-year-old male patient presents with palpitations, episodic headaches , and sweating episodes . Workup shows a small left-sided suprarenal mass . Which of the following would be done for confirmation? (Q793850)

A. Urinary vanillyl mandelic acid levels

B. Blood 5-HIAA levels

C. Urine myoglobin

D. Stool trypsin levels

See Answer in Part B → Q103

@Neet_pg_bot

Q104: If radiotherapy is administered along with chemotherapy for bladder cancer, which drug's dosage should be decreased? (Q793872)

A. Cisplatin

B. Gemcitabine

C. Paclitaxel

D. Ifosfamide

See Answer in Part B → Q104

@Neet_pg_bot

Q105: Which of the following is used for prostate cancer ? (Q793878)

A. Gleason score

B. Bethesda score

C. Alvarado score

D. Nottingham score

See Answer in Part B → Q105

Q1: A 45-year-old woman has a painless, firm breast lump and enlarged lymph nodes in the armpit. Which imaging technique is most sensitive for detecting cancer, especially in dense breast tissue? (Q880445)

A. 2D mammography

B. Digital mammography

C. Tomosynthesis with conventional mammography

D. Full-field digital mammography

See Answer in Part B → Q1

@Neet_pg_bot

Q2: During the luteal phase of the menstrual cycle, which hormone is mainly responsible for promoting lobular and alveolar development of the mammary glands? (Q880421)

A. Estrogen

B. Progesterone

C. Both A and B

D. Prolactin

See Answer in Part B → Q2

@Neet_pg_bot

Q3: During a routine third-trimester checkup, a pregnant woman is found to have additional nipples along the embryonic milk line. What is the proper medical term for this condition? (Q880423)

A. Polymastia

B. Polythelia

C. Accessory mammary tissue

D. Mammary hypertrophy

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 28-year-old woman is noted to have extra glandular tissue in her axilla that becomes tender during her menstrual cycle. Regarding accessory breast tissue, which of the following statements is incorrect? (Q880425)

A. It can respond to hormonal changes such as menstruation or pregnancy

B. It is synonymous with supernumerary nipples

C. It can rarely be found along the chest wall or abdomen

D. Surgical removal may be considered for cosmetic or symptomatic reasons

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Congenital absence of the breast (amazia) is most commonly associated with which syndrome? (Q880427)

A. Turner syndrome

B. Poland’s syndrome

C. Klinefelter syndrome

D. Marfan syndrome

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is a typical clinical feature of Poland syndrome? (Q880430)

A. Absence of the sternal portion of pectoralis major

B. Short, webbed fingers (symbrachydactyly)

C. Unilateral breast hypoplasia or aplasia

D. All of the above

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 41-year-old woman presents with a painful, cord-like structure on the anterior chest wall extending over her breast. She denies trauma, infection, or fever. On examination, a tender, subcutaneous cord is palpable, fixed to the overlying skin. When she raises her arm, a narrow groove alongside the cord becomes visible. What is the most likely diagnosis? (Q880431)

A. Mastitis

B. Mondor’s disease

C. Inflammatory breast carcinoma

D. Lymphangitis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 48-year-old woman with mammary duct ectasia presents with persistent periareolar swelling, recurrent nipple discharge, and discomfort despite conservative management and antibiotics. Which surgical procedure is most appropriate in this scenario? (Q880432)

A. Microdochectomy

B. Hadfield's procedure

C. Axillary lymph node dissection

D. Excision of breast tissue related to the affected duct

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 42-year-old woman presents with a single-duct, bloody nipple discharge from her right breast. She has no palpable lumps, and her mammogram and ultrasound are normal. She is concerned about the possibility of cancer. Which of the following is the most appropriate next step in management? (Q880433)

A. Simple reassurance and annual imaging follow-up

B. Microdochectomy of the affected duct

C. Hadfield’s major mammary duct excision

D. Start empirical antibiotics and observe

See Answer in Part B → Q9

@Neet_pg_bot

Q10: At what age is routine screening mammography generally recommended for asymptomatic women without high-risk factors? (Q880441)

A. After 30 years

B. After 35 years

C. After 40 years

D. After 50 years

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following is correct regarding screening mammography? (Q880442)

A. Performed in symptomatic women and requires only a single view of each breast

B. Two standard views, mediolateral oblique and craniocaudal, are obtained for each breast in asymptomatic women

C. Not performed in women older than 40 years

D. Diagnostic mammography and screening mammography are identical in technique and timing

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 65-year-old patient undergoes a screening mammogram. The radiologist identifies a cluster of calcifications and a discrete mass. Which of the following radiological descriptors in the mammography report would be the least concerning for malignancy? (Q880443)

A. Irregular mass

B. Wide halo

C. Macrocalcification

D. Spiculated margins

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Match the following findings with the associated condition: Type of calcification Disease A. Popcorn calcification i) Fibrocystic disease B. Lead-pipe calcification ii) Duct ectasia C. Broken needle calcification iii) Traumatic fat necrosis D. Tea cup calcification iv) Fibroadenoma (Q880444)

A. A-iii, B-ii, C-i, D-iv

B. A-iv, B-iii, C-ii, D-i

C. A-i, B-iii, C-ii, D-iv

D. A-ii, B-iv, C-iii, D-i

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following describes the basal type of breast malignancy? (Q848861)

A. ER +, PR -, and HER2 +

B. ER -, PR -, and HER2 -

C. ER +, PR +, and HER2 +

D. ER -, PR -, and HER2 +

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 45-year-old woman diagnosed with early-stage breast cancer opts for surgery that involves the removal of the entire breast, including the nipple and areola, but not the axillary lymph nodes. Which type of mastectomy is she likely undergoing? (Q848864)

A. Total (Simple) Mastectomy

B. Modified Radical Mastectomy

C. Radical Mastectomy

D. Extended Mastectomy

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following conditions is not an absolute contraindication for breast-conserving surgery (BCS)? (Q848863)

A. Prior radiation therapy to the chest wall or breast

B. Diffuse malignant microcalcifications

C. Stage IIB breast cancer

D. Pregnancy

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following are components of the Van Nuys Prognostic Index (VNPI) for DCIS? Tumor size Margin status Histological grade Patient age (Q848862)

A. 1 & 2

B. 1 & 3

C. 1, 2 & 3

D. 1, 2, 3 & 4

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Arrange the following in decreasing order of frequency of metastasis in breast cancer (Q848853)

A. Lumbar vertebrae> femur> thoracic vertebrae> ribs> skull

B. Lumbar vertebrae> thoracic vertebrae> ribs> skull> femur

C. Thoracic vertebrae>lumbar vertebrae> ribs> skull> femur

D. Thoracic vertebrae> femur> lumbar vertebrae> ribs> skull

See Answer in Part B → Q18

@Neet_pg_bot

Q19: What is the primary arterial supply to the superior part of the breast? (Q848845)

A. Internal thoracic artery

B. Lateral thoracic artery

C. Thoracoacromial artery

D. Intercostal artery

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following is the most common cause of bloody nipple discharge? (Q848846)

A. Breast cancer

B. Fibroadenoma

C. Intraductal papilloma

D. Duct Ectasia

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following statements about breast cancer risk factors is true? (Q848847)

A. The median age of breast cancer presentation is 60 years in India

B. The relative risk of Papillomatosis is 8-10

C. Relative Risk for breast cancer in 1st-degree relative is 3

D. Early onset of menstruation increases breast cancer risk.

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following is the most common model used for breast cancer risk assessment? (Q848848)

A. Gail Model

B. Framingham Risk Score

C. ASCVD Risk Estimator

D. QRISK3

See Answer in Part B → Q22

@Neet_pg_bot

Q23: All of the following are invasive carcinomas except: (Q848849)

A. Ductal carcinoma

B. Lobular carcinoma

C. Tubular carcinoma

D. Fibroadenoma

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 52-year-old woman undergoes a routine mammogram, which reveals clustered calcifications in her left breast. Further investigation confirms the diagnosis of ductal carcinoma in situ (DCIS). The lesion is small, low-grade, and has clear margins. The patient expresses a strong desire to preserve her breast if possible. What is the most appropriate initial treatment approach? (Q848850)

A. Hormonal therapy alone

B. Lumpectomy with radiation therapy

C. Lumpectomy alone

D. Systemic chemotherapy

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 38-year-old premenopausal woman is diagnosed with Lobular Carcinoma In Situ (LCIS) after a breast biopsy. She opts for chemoprevention as her management strategy. Her doctor discusses various medication options with her. Which of the following statements about chemoprevention for LCIS is correct? (Q848851)

A. Chemoprevention eliminates the risk of developing breast cancer

B. Tamoxifen reduces breast cancer risk by 25% over 5 years

C. Chemoprevention is only effective for the ipsilateral breast

D. Tamoxifen reduces breast cancer risk by 56% over 5 years

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 55-year-old woman is diagnosed with breast cancer. The pathology report shows a 2.5 cm tumor with positive lymph nodes. The tumor is ER-positive, PR-positive, and HER2-negative. Which of the following statements is most accurate

regarding her prognosis and treatment? (Q848852)

A. The tumor size and lymph node status suggest a favorable prognosis

B. The hormone receptor status indicates the tumor will not respond to endocrine therapy

C. The absence of HER2 overexpression means targeted therapies are the primary treatment option

D. The ER-positive status suggests a better prognosis and responsiveness to endocrine therapy

See Answer in Part B → Q26

@Neet_pg_bot

Q27: Which of the following statements about lymphatic drainage of the breast is true? (Q848844)

A. Level III lymph nodes are located lateral to the pectoralis minor muscle.

B. Lymphatic drainage from the breast is directed to the subclavian lymph nodes.

C. Level I lymph nodes are also known as Rotter’s nodes.

D. Level II lymph nodes are located posterior to the pectoralis major

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 52-year-old female presents with a two-month history of persistent itching, redness, and scaling of the right nipple, unresponsive to moisturizing creams. Physical examination reveals erythema and crusting of the nipple and areola without palpable breast lumps. The image of her right breast is given below. What is the most probable diagnosis? {{caption_text}} (Q848854)

A. Paget disease of the nipple

B. Scirrhous tumor

C. Ductal papilloma

D. Inflammatory carcinoma

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 45-year-old female presents with a painless lump in her right breast, noticed during a self-examination two weeks ago. Which of the following tests has the maximum accuracy? (Q848855)

A. FNAC

B. Core biopsy

C. Mammography

D. Triple assessment

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A lesion was found in a routine mammogram of a 52-year-old asymptomatic woman. Which of the following statements regarding mammogram findings is false? (Q848856)

A. If the density of the lesion is high, it is mostly malignant

B. Architectural distortion is usually present in benign lesions

C. Calcification in benign lesions is diffuse

D. Margins are well-circumscribed in benign lesions

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A 48-year-old female underwent a lumpectomy for a 2 cm invasive ductal carcinoma in her right breast. Post-surgery pathology revealed positive margins, indicating residual cancerous tissue. Which of the following investigations is most suitable to check for residual cancer tissues? (Q848857)

A. MRI

B. USG

C. Mammography

D. Repeat the biopsy

See Answer in Part B → Q31

@Neet_pg_bot

Q32: Match the following: Biopsy Feature 1. FNAC a. Evaluation of cellular fibroadenoma 2. Core-needle biopsy b. Assessment of suspicious lymph nodes 3. Excisional biopsy c. Sampling solid masses, calcifications, and densities identified on imaging (Q848858)

A. 1-b,2-c,3-a

B. 1-a,2-b,3-c

C. 1-c,2-b,3-a

D. 1-b,2-a,3-c

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A 45-year-old woman presents for her routine mammogram. She has no family history of breast cancer and no previous history of breast issues. A mammogram reveals a well-circumscribed, homogeneous lesion with characteristic benign features, such as a simple cyst with no suspicious calcifications or architectural distortions. Based on these findings, What is the appropriate BI-RADS category for this lesion? (Q848859)

A. BI-RADS 1

B. BI-RADS 2

C. BI-RADS 3

D. BI-RADS 4

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A 55-year-old woman presents with a palpable breast lump. After imaging studies and a biopsy, the results show a tumor measuring 3.5 cm in the breast. The patient also has involvement of ipsilateral internal mammary lymph nodes, but no distant metastases are detected. Based on the TNM staging system, what is the appropriate stage for this breast cancer? (Q848860)

A. T1 N2

B. T2 N1

C. T2 N2

D. T3 N1

See Answer in Part B → Q34

Q1: What is the approximate risk of malignancy associated with a lesion classified as BI-RADS 4A? (Q880446)

A. 2–10%

B. 10–50%

C. 50–95%

D. ≥95%

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 38-year-old woman presents with localized, non-cyclical medial breast pain. Examination and imaging are normal. Pain is maximal at a specific point, and musculoskeletal causes have been excluded. Which of the following is the most appropriate management? (Q880439)

A. Reassurance only

B. Oral NSAIDs for 1 week

C. Local injection of corticosteroid plus lidocaine

D. Empirical antibiotics

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following are indications for adjuvant chemotherapy in breast cancer? Post-surgery eradication of microscopic residual disease in high-risk patients Inflammatory breast cancer. HER2-positive breast cancer in combination with HER2-targeted therapy Triple-negative breast cancer Enabling breast-conserving surgery by reducing tumor size. (Q848826)

A. 1, 3, and 5 are correct

B. 2, 3, and 5 are correct

C. 2, 4, and 5 are correct

D. 1, 3, and 4 are correct

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Physiological gynecomastia is not typically seen in which of the following age groups? (Q880438)

A. Neonates

B. Pubertal boys

C. Men over 50 years

D. Men aged 30–40 years

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following statements regarding phyllodes tumours is true? (Q880437)

A. Most commonly seen in women aged 15–25 years

B. True mixed neoplasms comprising both epithelial and mesenchymal elements

C. Rarely require wide local excision due to low recurrence risk

D. Frequently infiltrate the skin early in their course

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 16-year-old girl presents with a rapidly enlarging breast lump. On examination, the lump is firm, well-circumscribed, and measures more than 5 cm in diameter. Which of the following terms best describes this fibroadenoma? (Q880436)

A. Simple fibroadenoma

B. Giant fibroadenoma

C. Complex fibroadenoma

D. Phyllodes tumor

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Regarding breast carcinoma, which of the following statements is incorrect? (Q880435)

A. Inflammatory carcinoma produces cutaneous oedema due to obstruction of subdermal lymphatics by tumour cells

B. Mucinous carcinomas are typically hormone receptor–negative

C. Ductal carcinoma in situ often shows associated calcifications

D. Lobular carcinoma in situ tends to be multicentric and bilateral

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 22-year-old woman presents with a firm, mobile, well-circumscribed breast lump measuring 2.5 cm. Ultrasound confirms a typical fibroadenoma. She has no family history of breast cancer. Which of the following best describes the underlying pathological process in fibroadenoma? (Q880434)

A. Hyperplasia of a breast lobule

B. Malignant transformation of ductal epithelium

C. Cystic degeneration of breast stroma

D. Inflammatory infiltration of breast tissue

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 28-year-old lactating mother presents with fever, breast pain, swelling, and a tender, erythematous area on her left breast. Ultrasonography confirms the presence of a pus-filled cavity. What would be the initial treatment in this scenario? (Q848841)

A. Close Observation

B. Antibiotics and breast emptying

C. Hormonal therapy

D. Surgical excision

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 55-year-old menopausal woman presents with a unilateral, scaly, and erythematous lesion on her nipple, initially resembling eczema but without itching. She was diagnosed with Paget's disease of the nipple. Which of the following cancers is most commonly associated with Paget's disease? {{caption_text}} (Q848836)

A. Invasive ductal carcinoma

B. Invasive lobular carcinoma

C. Ductal carcinoma in situ

D. Lobular carcinoma in situ

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 45-year-old woman with a family history of breast cancer undergoes genetic testing and is found to have a BRCA1 mutation. What are the implications of this mutation regarding the cancer risks and potential associated cancers? (Q848843)

A. Increased risk of breast cancer with well-differentiated hormone receptor-positive tumors.

B. Increased risk of breast cancer, typically high-grade and triple-negative, along with higher risks of colon and ovarian cancers.

C. Increased risk of breast cancer and higher risk of endometrial cancer.

D. Increased risk of ovarian cancer with no significant increase in breast cancer risk.

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 35-year-old woman presents with cyclical breast pain and palpable lumps in her breasts. She reports that the pain increases just before her menstrual period. Physical examination reveals dense breast tissue without any nipple discharge or skin involvement. What is the most likely diagnosis? (Q848842)

A. Mucinous carcinoma

B. Fibrocystic Changes

C. Medullary Carcinoma

D. Ductal carcinoma

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 35-year-old woman presents with a tender, thrombosed subcutaneous cord on her right breast, which becomes more pronounced when she raises her arm. She reports no recent trauma or infections. What is the most likely diagnosis? (Q848839)

A. Ductal carcinoma in situ

B. Mondor's Disease

C. Mastitis

D. Fibrocystic Changes

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 20-year-old woman presents with a painless, firm, mobile lump in her breast. On physical examination, the lump is approximately 1 cm in diameter, firm,

well-circumscribed, and freely mobile. Ultrasound confirms a well-defined, solid, homogeneous mass with smooth margins and no signs of calcifications. What is the most likely diagnosis and management plan? (Q848838)

A. Cyst; surgical excision.

B. Fibroadenoma; conservative management with regular monitoring.

C. Giant fibroadenoma; immediate surgical removal.

D. Inflammatory carcinoma; urgent biopsy and treatment.

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following statements regarding phyllodes tumor are correct? Statements: Tumors of mixed connective tissue and epithelium Classified as benign, intermediate, and malignant Discrete structure with cystic spaces in USG Excisional biopsy is the definitive diagnostic method (Q848837)

A. 1,3

B. 4

C. 3,4

D. 1,2,3,4

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 45-year-old woman presents with a palpable mass in her left breast. On examination, the mass is 3 cm in diameter, and there is no evidence of skin or chest wall involvement. An ultrasound reveals a single enlarged axillary lymph node. Biopsy confirms invasive ductal carcinoma, ER/PR positive, HER2 negative, shows no distant metastasis. What is the most appropriate management approach? (Q848823)

A. Total mastectomy with sentinel lymph node biopsy (SLNB)

B. Breast-conserving surgery (BCS) with SLNB followed by radiotherapy (RT)

C. Neoadjuvant chemotherapy followed by mastectomy

D. BCS with axillary lymph node dissection (ALND) without radiotherapy

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 65-year-old man presents with a hard, unilateral breast lump and nipple retraction. Clinical examination reveals skin dimpling and axillary lymphadenopathy. A biopsy confirms breast cancer. Which of the following is wrong about his diagnosis? (Q848835)

A. Associated with BRCA2 mutation

B. Most common in 4th decade of life

C. Poorer prognosis compared to carcinoma breast in females

D. Infiltrating duct carcinoma is the most common type

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 25-year-old was diagnosed with invasive ductal carcinoma in her 5th week of gestation. Her axillary lymph node biopsy has come back positive. What is the most appropriate management along with modified radical mastectomy? (Q848834)

A. Termination of pregnancy

B. Chemotherapy

C. Radiation therapy

D. Termination of pregnancy and chemotherapy

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 35-year-old lactating woman presents with a rapidly progressing, painful, and warm swelling involving her entire left breast. She was diagnosed with inflammatory breast cancer. Which of the following statements are correct regarding her condition? {{caption_text}} (Q848833)

A. The prognosis is bad

B. Stage III B carcinoma (T4d)

C. Can be mistaken for acute mastitis

D. All are true

See Answer in Part B → Q19

@Neet_pg_bot

Q20: What is the primary purpose of a sentinel lymph node biopsy in the management of cancer, and how does it help guide treatment decisions? (Q848832)

A. To determine the exact stage of the cancer by identifying all affected lymph nodes.

B. To assess whether cancer has spread to the lymph nodes.

C. To completely remove all lymph nodes to prevent cancer recurrence.

D. To evaluate the effectiveness of chemotherapy before surgery.

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following components is not evaluated in the Bloom-Richardson grading system? (Q848831)

A. Tubule formation

B. Nuclear pleomorphism

C. Mitotic count

D. Tumor size

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which of the following statements about the TRAM flap is true? (Q848830)

A. The TRAM flap uses only skin and fat from the abdomen, preserving the abdominal muscle.

B. The TRAM flap relies on tissue from the back, including skin and muscle, for reconstruction.

C. The TRAM flap involves using tissue from the abdomen, including both skin and muscle, for breast reconstruction.

D. The TRAM flap uses tissue from the thigh, including skin and fat, to reconstruct the breast.

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A patient develops a painful, swollen area in the axillary region two weeks after mastectomy. What is the most likely diagnosis? (Q848829)

A. Seroma

B. Lymphedema

C. Hematoma

D. Axillary lymphadenopathy

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Match the following hormonal therapy drugs with their primary use: 1.Tamoxifen a. Pre-menopausal hormone receptor-positive breast cancer 2.Anastrozole b. Post-menopausal hormone receptor-positive breast cancer 3.Fulvestrant c. HER2-positive breast cancer 4.Trastuzumab d. Hormone receptor-positive metastatic breast cancer (Q848828)

A. 1-a, 2-b, 3-d, 4-c

B. 1-b, 2-c, 3-d, 4-a

C. 1-a, 2,d, 3-b, 4-c

D. 1-c, 2-a, 3-b, 4-d

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following types of breast carcinoma is most likely to respond best to radiation therapy? (Q848827)

A. Invasive ductal carcinoma

B. Inflammatory breast cancer

C. Ductal carcinoma in situ (DCIS)

D. Triple-negative breast cancer

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 55-year-old woman with Stage IV HER2-positive metastatic breast cancer presents with fungation of the breast, multiple metastases to the liver and bones. Which of the following treatment strategies is most appropriate for her condition? (Q848825)

A. Trastuzumab + Chemotherapy + Palliative mastectomy

B. Tamoxifen + Radiation Therapy + Bone-targeted therapy

C. Hormonal Therapy alone

D. Surgical Resection of Metastases + Radiotherapy

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 52-year-old woman presents with Stage III B breast cancer. Her diagnostic workup includes imaging studies and biopsy, revealing a locally advanced tumor with involvement of regional lymph nodes. The tumor is hormone receptor-positive and HER2-positive. What would be the most appropriate management approach for this patient? (Q848824)

A. Neoadjuvant chemotherapy followed by modified radical mastectomy and adjuvant radiotherapy

B. Immediate modified radical mastectomy followed by adjuvant chemotherapy and endocrine therapy

C. Primary endocrine therapy followed by adjuvant chemotherapy and radiotherapy

D. Neoadjuvant chemotherapy followed by lumpectomy and adjuvant radiotherapy

See Answer in Part B → Q27

Q1: A 12-year-old child presents with congenital sensorineural hearing loss, recurrent episodes of vertigo, and a palpable thyroid gland. The child's mother has a similar history. What is the most likely diagnosis? (Q848948)

A. Alport syndrome

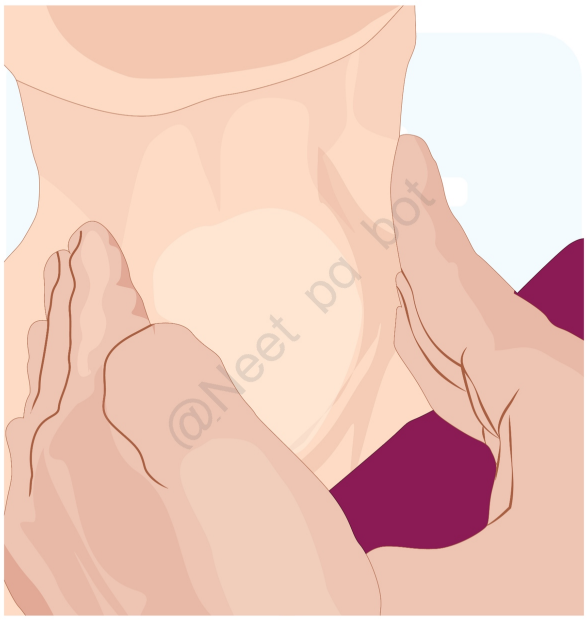
B. Pendred syndrome

C. Usher syndrome

D. Perrault syndrome

See Answer in Part B → Q1

@Neet_pg_bot



Q2: Identify the below technique used during the examination of the thyroid gland. (Q848947)

A. Kocher's method

B. Lahey’s method

C. Crile’s method

D. Pizillo’s method

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 44-year-old woman presents with a solitary thyroid swelling. On examination, a 3 cm non-tender thyroid nodule is noted, and her thyroid function tests are normal. What is the next step in the investigation of this thyroid swelling? (Q848935)

A. Fine Needle Aspiration Cytology

B. USG of thyroid

C. Core biopsy

D. CT neck

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following conditions is a contraindication for radioactive iodine therapy? (Q848945)

A. Medullary thyroid carcinoma

B. Papillary thyroid carcinoma

C. Hurthle cell carcinoma

D. Tumor size > 2cm + distant metastasis

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 27-year-old female presents with symptoms of weight loss, palpitations and eye protrusion. Lab tests reveal ■ TSH and ■ T3, T4 values. What is the most likely diagnosis and the primary target of this condition? (Q848938)

A. Toxic multinodular goiter,TSH receptor

B. Graves disease, TSH receptor

C. Hashimoto's Thyroiditis, TPO

D. Subacute Thyroiditis, Thyroglobulin

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 50-year-old woman with Graves disease has been receiving medical management for 6 months but continues to have significant symptoms and persistent ophthalmopathy. The goitre remains large. Considering her ongoing symptoms, what is the most appropriate next step in her treatment? (Q848940)

A. Thyroidectomy

B. Radioactive iodine ablation

C. Antithyroid medications and beta-blockers.

D. External beam radiotherapy

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 45-year-old man presents with neck pain, fever, and fatigue. His physical examination shows a tender, swollen thyroid gland. Lab reports revealed elevated inflammatory markers and low radioactive iodine uptake, and he is HLA B35 positive. What is the most appropriate initial treatment step for this patient? (Q848942)

A. NSAIDs

B. Start Levothyroxine and continue throughout

C. Start antithyroid drugs

D. Thyroidectomy

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 40-year-old woman with a known history of Graves' disease presents with signs of thyroid storm i.e., fever, delirium, tachycardia, and restlessness. In addition to beta-blockers and antithyroid drugs, she is started on glucocorticoids. What is the primary rationale for administering glucocorticoids in the management of thyroid storm? (Q848950)

A. To block the conversion of T4 to T3

B. To suppress the synthesis of thyroid hormones

C. To reduce the effects of catecholamines

D. To block the release of T4 and T3

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 20-year-old male presents with a painless midline neck swelling that has been present since childhood and has gradually increased in size. The swelling moves upward on protrusion of the tongue. Ultrasound shows a cystic midline lesion .Which of the following is the correct statement regarding this condition? (Q848929)

A. High risk of developing squamous cell carcinoma

B. Removal of the cyst along with the tract and part of the hyoid bone is done

C. Most commonly seen in the suprahyoid region

D. Incision and Drainage are the preferred management

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 64-year-old man with multinodular goitre is being treated with a large dose of iodine. Subsequently, his thyroid function tests show significantly elevated TSH and low free T4 levels, but he is asymptomatic. What is the most likely finding? (Q848949)

A. Jod- Basedow effect

B. Wolff-Chaikoff effect

C. Amiodarone- induced thyrotoxicosis

D. Thyroid storm

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 31-year-old female with Graves' disease who underwent total thyroidectomy now presents with hoarseness of voice and stridor due to recurrent laryngeal nerve injury. What is the most common site of injury to the recurrent laryngeal nerve? (Q848946)

A. Through the carotid sheath

B. At the level of the zuckerkandl tubercle

C. At the level of the cricothyroid muscle

D. Near the inferior thyroid artery

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 60-year-old man presents with worsening shortness of breath and difficulty swallowing. On physical examination, a large, firm, and non-tender neck swelling is noted. The lower limit of the swelling cannot be palpated, and raising his arms above his head results in the finding shown in the image. Given these clinical findings, which of the following is the Investigation of choice? (Q848944)

A. Ultrasound of the Neck

B. CT Scan of the Neck and Chest

C. MRI of the Neck

D. Radioactive Iodine Uptake Test

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 60-year-old woman with a large multinodular goitre is scheduled for a total thyroidectomy. To prepare her for the surgery and reduce the risk of complications, her endocrinologist prescribed Lugol's iodine. Which of the following statements are true regarding Lugol's iodine? It is used to reduce thyroid vascularity before thyroid surgery It works by inhibiting the synthesis of thyroid hormones in the thyroid gland It increases the uptake of radioactive iodine It is not commonly indicated in the management of toxic multinodular goiter It is not indicated in case of a thyroid storm (Q848943)

A. 1,2,5

B. 2,3,4

C. 3,4,5

D. 1,2,4

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 55-year-old woman presents with an enlarging, hard, and fixed thyroid mass, neck discomfort, and difficulty swallowing. On examination, the thyroid gland feels rock-hard with no tenderness. Ultrasound of the thyroid shows extensive fibrosis. What is the most likely diagnosis? (Q848941)

A. Riedel's Thyroiditis

B. Hashimoto's Thyroiditis

C. De Quervain's Thyroiditis

D. Silent Thyroiditis

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 30-year-old pregnant woman in her first trimester is diagnosed with Graves disease. What is the most appropriate first-line treatment for her condition? (Q848939)

A. Propylthiouracil

B. Methimazole

C. Levothyroxine

D. Propranolol

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 23-year-old female visited the clinician with a solitary thyroid nodule and was advised for thyroid function tests where Tsh level is 27.3mU/L, T3 is 1.24 ng/ml, and T4 is 4.87 microgram/ml. Which of the following manifestations is true regarding the condition? (Q848937)

A. Heat intolerance

B. Tachycardia

C. Diarrhea

D. Weight gain

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 36-year-old woman presents with a solid, hypoechoic thyroid nodule. She undergoes Fine Needle Aspiration Cytology (FNAC), which confirms the nodule is benign. What is the most appropriate Bethesda classification and its management for this benign thyroid nodule? (Q848936)

A. Bethesda I; Repeat FNA

B. Bethesda II; Clinical and sonographic follow-up

C. Bethesda III; Near total thyroidectomy

D. Bethesda VI; Repeat FNA, molecular testing or lobectomy

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 65-year-old woman presents with a thyroid mass and normal thyroid function tests. Fine Needle Aspiration Cytology (FNAC) is planned to evaluate the mass. Which of the following conditions is FNAC effective in diagnosing? (Q848934)

A. Follicular Neoplasm

B. Riedel’s Thyroiditis

C. Thyroid Lymphoma

D. Solitary Thyroid Nodule

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 45-year-old patient with a history of multinodular goitre is being considered for thyroid surgery. The surgical team decides to perform a procedure that removes the majority of the thyroid gland, leaving a small amount of tissue in one of the lobes and removing the isthmus. Which of the following best describes this procedure? (Q848932)

A. Total Thyroidectomy

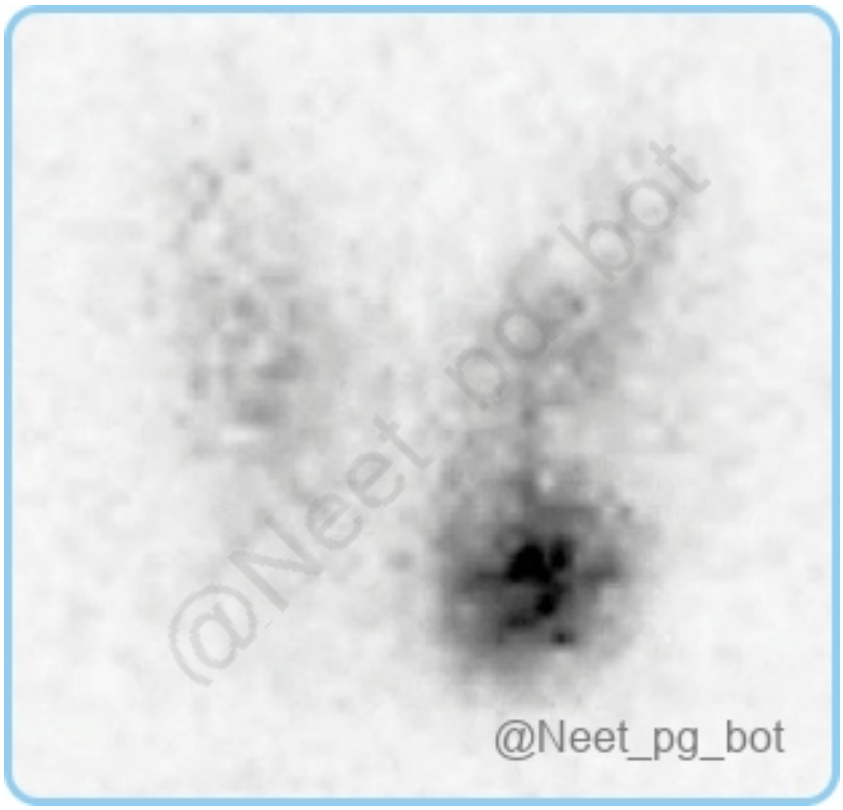
B. Lobectomy

C. Dunhill Procedure

D. Subtotal Thyroidectomy

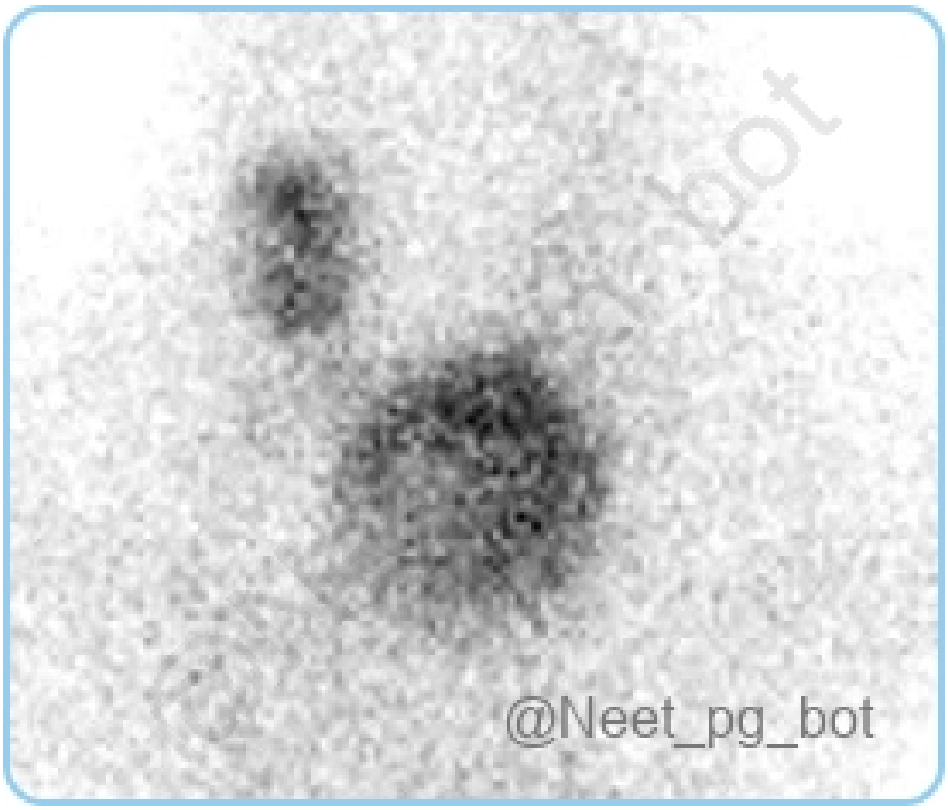
See Answer in Part B → Q19

@Neet_pg_bot

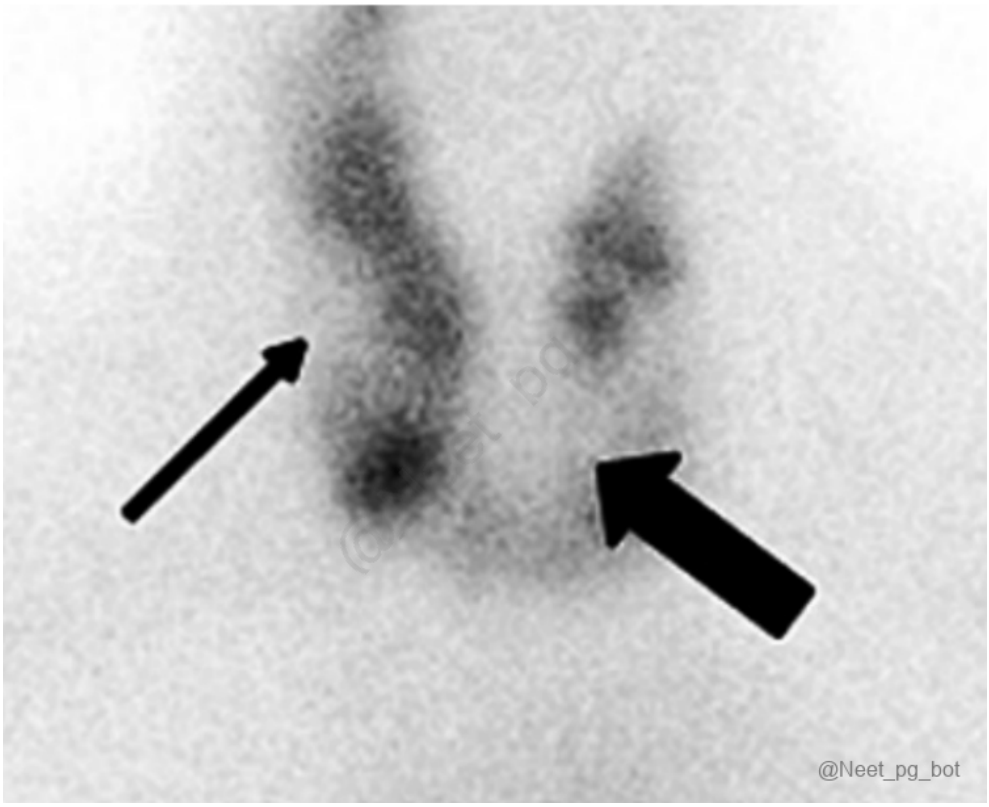


Q20: Match the following Thyroid scan images with respective conditions: 1. A. Graves Disease 2. B. Cold nodule 3. C. Hot Nodule 4. D. Toxic Multinodular Goiter (Q848931)

A. 1-C, 2-A, 3-D, 4-B



B. 1-A, 2-C, 3-B, 4-D



C. 1-B, 2-D, 3-A, 4-C

D. 1-C, 2-D, 3-A, 4-B

@Neet_pg_bot

@Neet_pg_bot

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 45-year-old woman with differentiated thyroid cancer has undergone a total thyroidectomy. To target any residual thyroid tissue or cancer cells, she is scheduled for radioactive iodine ablation therapy. Which of the following isotopes of iodine is used for this therapeutic procedure? (Q848930)

A. Iodine-123 (I-123)

B. Iodine-125 (I-125)

C. Iodine-131 (I-131)

D. Iodine-132 (I-132)

See Answer in Part B → Q21

Q1: What is the best investigation to check for extra thyroid spread of thyroid gland neoplasm ? (Q882181)

A. USG

B. MRI

C. PET scan

D. Iodine scan

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 30-year-old patient presents with hypertension, sweating, and frequent headaches. Imaging reveals a thyroid nodule, and tests show elevated serum calcitonin. The family history includes similar early-onset cases. What condition is most likely associated with these findings? (Q848961)

A. MEN 1

B. MEN 2A

C. Cowden syndrome

D. Familial medullary thyroid carcinoma

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 72-year-old male presents with a rapidly growing thyroid mass accompanied by severe pain and hoarseness of voice. Imaging shows the direct invasion of surrounding structures, including the trachea and oesophagus. The diagnosis of anaplastic thyroid carcinoma is confirmed. In managing this condition, which of the following is not typically included? (Q848972)

A. Radioactive iodine

B. Tumor debulking

C. Doxorubicin

D. Trametinib

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old female recently underwent total thyroidectomy for papillary thyroid carcinoma. Which of the following is not part of her post-surgical management? (Q848970)

A. Immediately start high-dose thyroxine (T4) to prevent hypothyroidism.

B. Stop thyroxine (T4) for 6 weeks before a whole-body scan.

C. Administer recombinant TSH if stopping thyroxine (T4) is intolerable.

D. PET scan if thyroglobulin rises despite normal neck USG and chest X-ray.

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 45-year-old patient undergoes a total thyroidectomy for a large multinodular goitre. Postoperatively, the patient is monitored for complications. Which of the following is least likely to occur? (Q848969)

A. Tension Hematoma

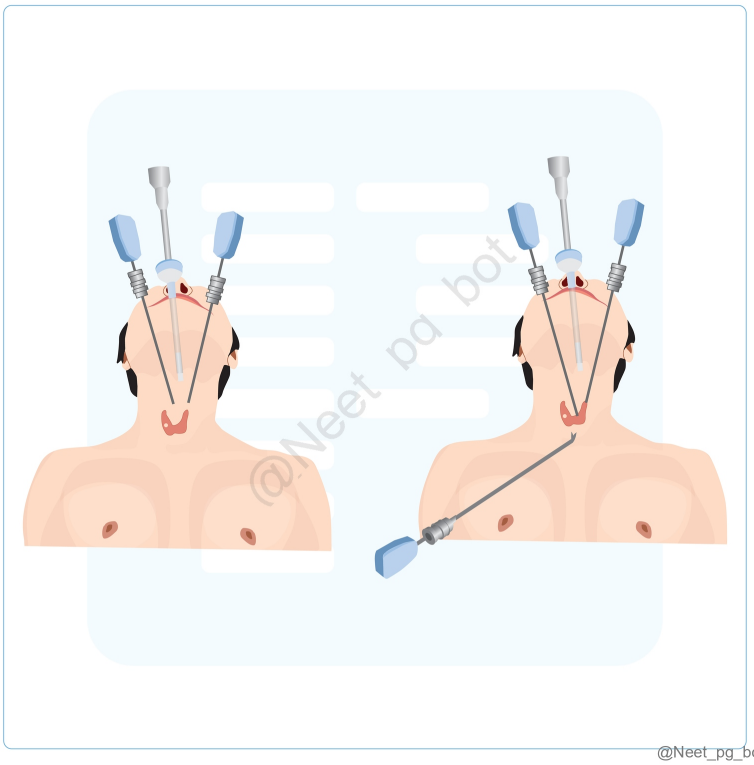
B. Horner's syndrome

C. RLN Palsy

D. Hypercalcemia

See Answer in Part B → Q5

@Neet_pg_bot



Q6: A 45-year-old woman with a thyroid pathology is being considered for the procedure shown in the image. Which of the following conditions is a contraindication for this procedure? (Q848983)

A. Hashimoto's thyroiditis

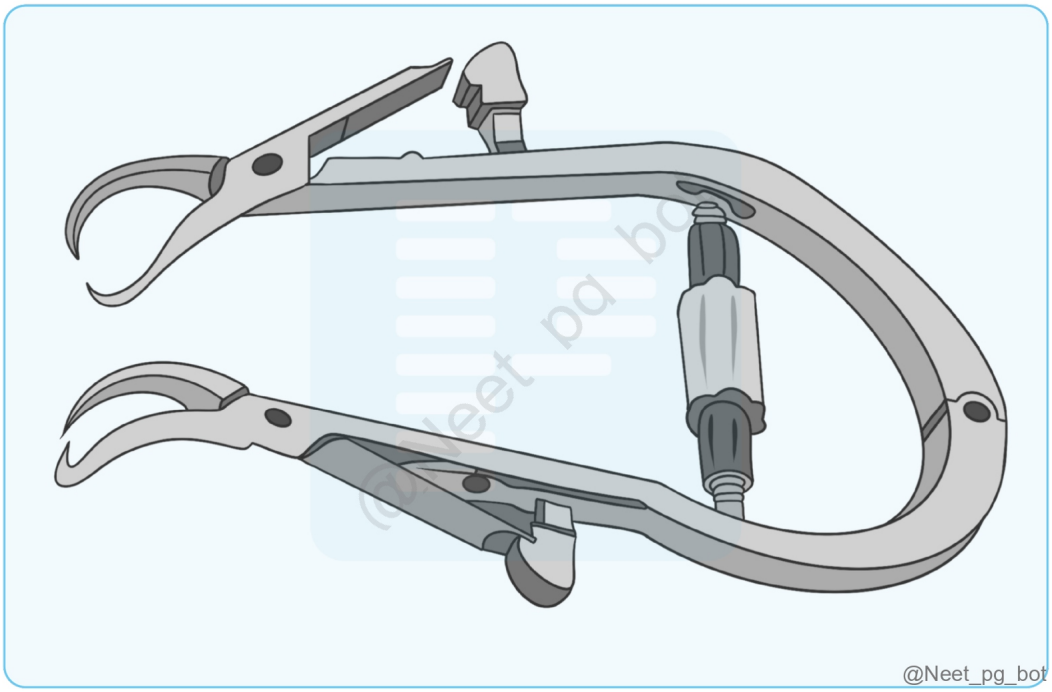
B. Benign thyroid nodule 2 cm

C. T1 Papillary carcinoma

D. Thyroid adenoma 2.5 cm

See Answer in Part B → Q6

@Neet_pg_bot



Q7: A 55-year-old patient is undergoing a thyroidectomy, and the surgical team uses a specialized retractor to improve exposure and facilitate the operation. Identify the retractor. (Q848981)

A. Deaver’s retractor

B. Joll’s retractor

C. Richardson retractor

D. Volkmann retractor

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 60-year-old woman presents with symptoms of hyperthyroidism, including weight loss, palpitations, and tremors. A large thyroid nodule is noted on examination, and laboratory tests reveal elevated thyroid hormones with suppressed thyroid-stimulating hormone (TSH) levels. An ultrasound shows multiple nodules in the thyroid gland. Which of the following management strategies is most appropriate for this patient? (Q848980)

A. Antithyroid drugs followed by total thyroidectomy

B. Radioactive iodine therapy

C. Thyroid hormone replacement therapy

D. Treat with lugol iodine followed by surgery

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 72-year-old woman with a history of Hashimoto's thyroiditis presents with a rapidly growing thyroid mass, dysphagia, dyspnea, and hoarseness. Biopsy confirms diffuse large B-cell lymphoma. Which of the following is most appropriate for treating this patient? (Q848979)

A. Surgical resection alone

B. External beam radiotherapy combined with chemotherapy

C. Expectant management with hormone replacement

D. Chemotherapy followed by thyroidectomy

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 62-year-old woman has recently undergone surgery for papillary thyroid carcinoma (PTC). Postoperative pathology reports indicate: Tumour Size: 3.8 cm Extrathyroidal Invasion: Present No lymph node involvement No distant metastases Complete surgical resection Which of the following scoring systems is specifically used to assess the prognosis in the postoperative setting? (Q848977)

A. AGES Scoring System

B. AMES Scoring System

C. MACIS Scoring System

D. TNM Staging System

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 40-year-old patient presents with midline neck swelling, persistent diarrhoea, and elevated serum calcitonin. Imaging shows the tumour confined to the thyroid without lymph node involvement. Histopathology reveals amyloid stroma. Which of the following is most appropriate for managing this condition? (Q848975)

A. Radioactive iodine therapy

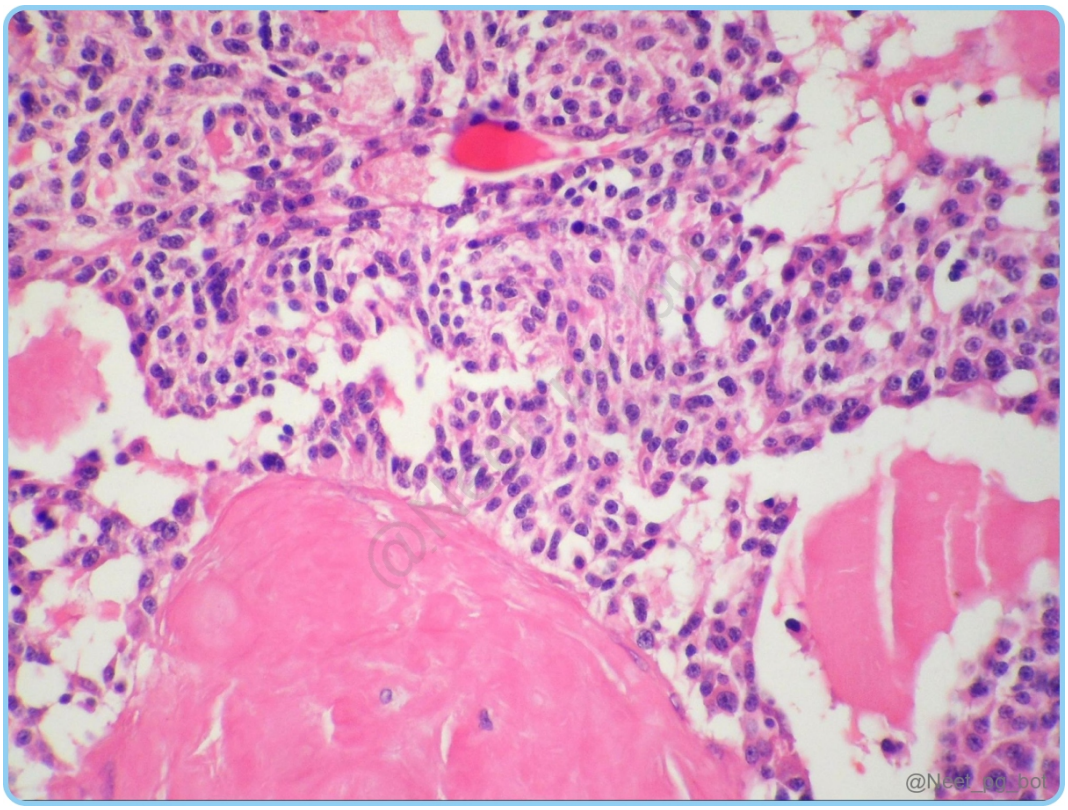
B. Total thyroidectomy with modified radical neck dissection

C. Tyrosine kinase inhibitors and radiotherapy

D. Total thyroidectomy with central neck dissection

See Answer in Part B → Q11

@Neet_pg_bot



Q12: A 45-year-old with midline neck swelling and persistent diarrhoea has an enlarged thyroid gland. The family history includes pheochromocytoma and hyperparathyroidism. The image shows a histopathological examination of the thyroid. Which marker is most valuable for monitoring this condition? (Q848973)

A. Serum TSH

B. Serum Calcitonin

C. Serum Thyroglobulin

D. Serum PTH

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 48-year-old female presents with a midline neck swelling which moves upwards when she swallows. On examination, the swelling is suspected to be related to the thyroid gland. What is the most likely anatomical structure responsible for this movement, and what is the clinical significance of this feature? (Q848954)

A. Prevertebral fascia - distinguishing thyroid masses from parathyroid masses

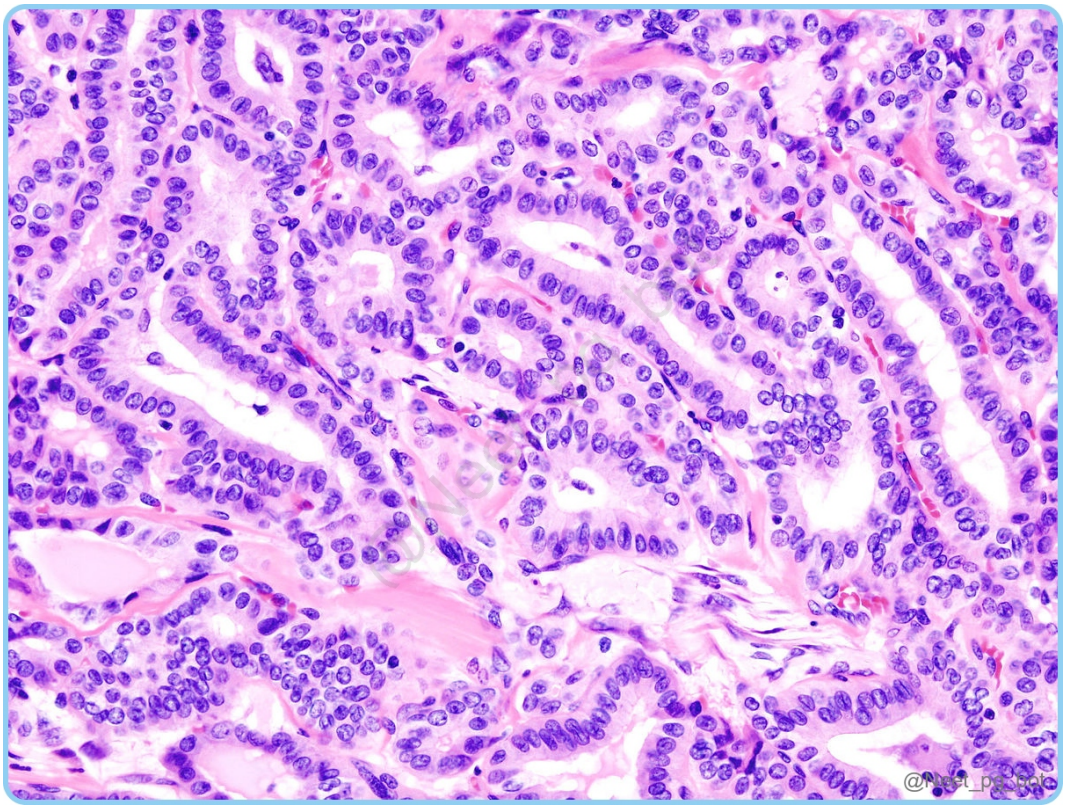
B. Pretracheal fascia - causes thyroid masses to move with swallowing

C. Investing layer of the deep cervical fascia - encloses both the thyroid and trachea

D. Superficial fascia - supports the thyroid gland’s position in the neck

See Answer in Part B → Q13

@Neet_pg_bot



Q14: A 32 year old female patient presented with complaints of midline swelling in neck without any palpable lymph nodes. FNAC and biopsy revealed the image below. Which of the following should be the management of this condition ? (Q848968)

A. Thyroidectomy + Removal of enlarged lymph nodes

B. Thyroidectomy + Removal of enlarged lymph nodes + MRND

C. MRND

D. Thyroidectomy

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which type of incision is typically used for thyroidectomy? (Q848966)

A. Killian's incision

B. Gridiron incision

C. Lanz crease incision

D. Kocher’s collar incision

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 56-year-old female patient with a history of long-standing goiter, presented with complaints of sudden, painless increase in the size of swelling of the neck. Biopsy revealed the presence of follicles suggestive of carcinoma. What is the most common site and route of metastasis in this condition? (Q848964)

A. Lungs, lymphatic

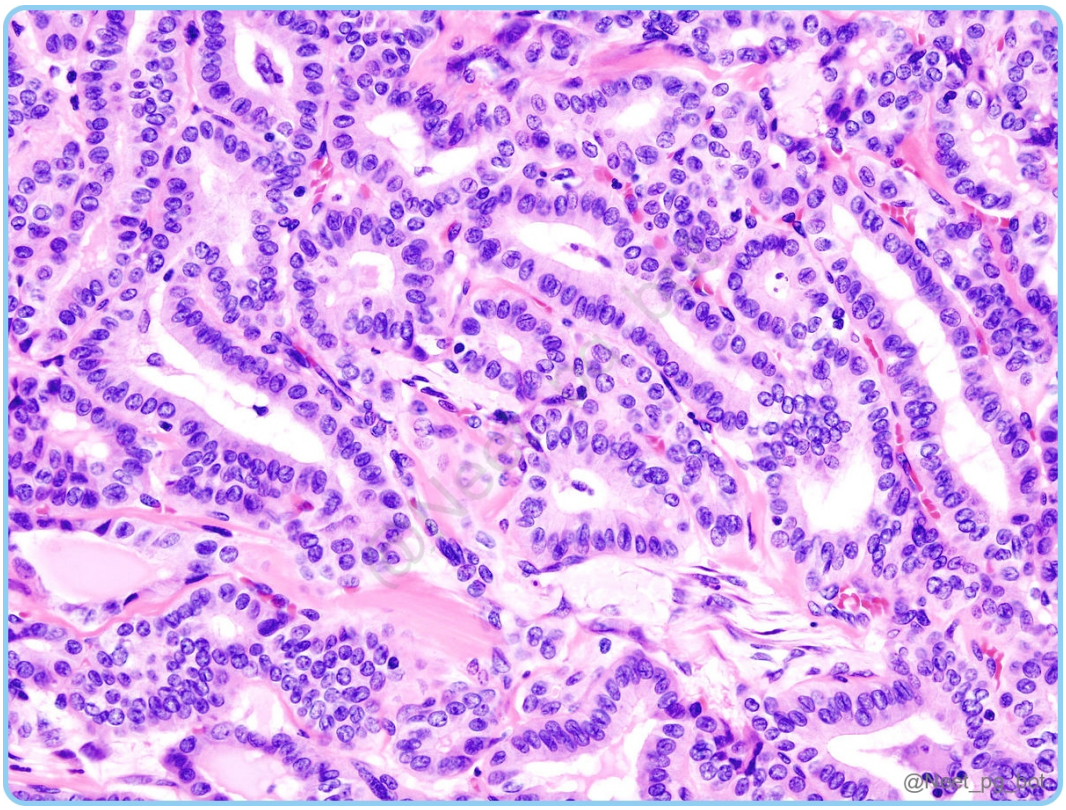
B. Liver, lymphatic

C. Bones, hematogenous

D. Liver, hematogenous

See Answer in Part B → Q16

@Neet_pg_bot



Q17: A 34-year-old female presents with neck swelling and a history of childhood neck irradiation for Hodgkin’s lymphoma. On examination, a hard mass is found in the neck. FNAC confirms thyroid carcinoma with HPE image given below, what is the most likely diagnosis? (Q848963)

A. Follicular thyroid carcinoma

B. Medullary thyroid carcinoma

C. Anaplastic thyroid carcinoma

D. Papillary thyroid carcinoma

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 58-year-old woman has a 5 cm thyroid tumour with extrathyroidal extension, cervical lymphadenopathy, and no distant metastasis. Based on the TNM staging system, what is the most accurate classification for this patient? (Q848959)

A. T3b N1 M0

B. T4 N1 M1

C. T4 N1 M0

D. T2 N0 M0

See Answer in Part B → Q18

@Neet_pg_bot

Q19: All the following forms the boundaries of Beahrs' triangle except? (Q848958)

A. Common Carotid Artery

B. Inferior Thyroid Artery

C. Recurrent Laryngeal Nerve

D. Superior Thyroid Artery

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 60-year-old male undergoes a total thyroidectomy for a large multinodular goitre. Postoperatively, he experiences hoarseness and difficulty speaking. Which anatomical site is most commonly associated with this nerve injury during thyroidectomy? (Q848957)

A. Right subclavian artery

B. Arch of the aorta

C. Berry’s ligament

D. Tubercle of Zuckerkandl

See Answer in Part B → Q20

@Neet_pg_bot

Q21: During thyroid surgery on a patient, significant bleeding occurs near the superior pole of the thyroid gland. Which vessel branches from the artery supplying this region? (Q848955)

A. Common carotid artery

B. Subclavian artery

C. External carotid artery

D. Brachiocephalic trunk

See Answer in Part B → Q21

Q1: A 45-year-old woman presents with a large adrenal mass discovered incidentally on imaging. The tumor measures 12 cm and shows irregular borders with central necrosis. She exhibits symptoms of Cushing syndrome. What is the most likely diagnosis for this adrenal mass? (Q848874)

A. Benign Cortical Adenoma

B. Adrenal Myelolipoma

C. Adrenocortical Carcinoma

D. Aldosterone-Producing Adenoma

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is not an indication for surgery in an asymptomatic patient with primary hyperparathyroidism? (Q848886)

A. Serum calcium level 0.25 mmol/L above the upper limit of normal

B. DEXA T score of -2.5 at the lumbar spine

C. Creatinine clearance <60 mL/min

D. Age >60 years

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following statements is TRUE regarding olfactory neuroblastoma? (Q848885)

A. Benign tumor arising from the squamous epithelium of the nasal cavity.

B. Presents as a bilateral mass in the lower nasal cavity.

C. Causes anosmia and nasal obstruction due to a unilateral polypoidal mass.

D. Treated with chemotherapy alone, with no surgical excision.

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A mother brought her 2-year-old child as she noticed he is unable to completely open his eyes and that there is a limp in his walk. On examination, there is a mass in the abdomen and miosis and anhidrosis in the eyes. A biopsy confirms neuroblastoma. What would be the laboratory findings in this case? (Q848884)

A. Raised 24 hr urinary catecholamines

B. Low serum LDH

C. Low neuron specific enolase

D. Thrombocytopenia

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A child of 2 years is brought to the hospital with an abdominal mass that has grown from the right to the center of the abdomen for a few months. The child has urinary symptoms and bluish-purple discoloration around the eyes. What is the most probable diagnosis? (Q848883)

A. Pheochromocytoma

B. Adrenocortical carcinoma

C. Paraganglioma

D. Neuroblastoma

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 55-year-old patient is diagnosed with malignant pheochromocytoma after presenting with persistent hypertension and elevated plasma metanephrines. Imaging reveals metastasis to various sites. Which of the following is not a common site for metastasis? (Q848881)

A. Liver

B. Brain

C. Lungs

D. Kidney

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 30-year-old woman in her 24th week of pregnancy presents with severe headaches, palpitations, and paroxysmal hypertension. Laboratory investigations reveal elevated plasma metanephrines, and imaging confirms the presence of a pheochromocytoma. Which of the following is the most appropriate management strategy for this patient? (Q848880)

A. Use phenoxybenzamine and plan laparoscopic adrenalectomy in the second trimester.

B. Wait until the third trimester, use Labetalol to control BP, and perform a C-section followed by adrenalectomy.

C. Use calcium channel blockers and plan for surgical resection postpartum.

D. Perform immediate open adrenalectomy.

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 33-year-old man presents with a history of paroxysmal hypertension, palpitations, headaches, and sweating. Initial plasma-free metanephrine testing returns positive results. What is the most appropriate next step in the investigation of this patient's condition to confirm the diagnosis? (Q848878)

A. Performing an MIBG (metaiodobenzylguanidine) scan

B. Performing a 24-hour urine collection for metanephrines

C. Conducting a clonidine suppression test

D. Ordering a CT/MRI scan of the abdomen

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 35-year-old woman presents with episodes of severe headaches, palpitations, and sweating. Imaging reveals a large adrenal mass and biochemical tests confirm elevated plasma metanephrines. Further genetic testing shows a mutation in the SDHB gene. Which of the following genetic syndromes is most likely associated with her condition? (Q848877)

A. MEN 2 Syndrome

B. Hereditary Paraganglioma-Pheochromocytoma Syndrome (HPPS)

C. Von Hippel–Lindau Disease (VHL)

D. Neurofibromatosis Type 1 (NF1)

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 52-year-old patient presents with intermittent episodes of hypertension, headache, and sweating. After conducting a series of tests, the diagnosis points toward an extra-adrenal pheochromocytoma. What is the most common site for an extra-adrenal pheochromocytoma? (Q848876)

A. Adrenal medulla

B. Organ of Zuckerkandl

C. Parotid gland

D. Pancreas

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 48-year-old man presents with episodic symptoms of severe headache, palpitations, and profuse sweating. His laboratory tests reveal elevated plasma metanephrines, and a CT scan identifies a vascular adrenal mass. Which of the following statements accurately describes the nature of this adrenal mass? (Q848875)

A. Primarily secretes ACTH, causing continuous hypertension.

B. It intermittently releases catecholamines, leading to episodes of headache, palpitations, and sweating.

C. Presents with chronic, steady symptoms without significant paroxysms.

D. Usually non-vascular and causes minimal clinical symptoms.

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old patient with h/o chronic kidney disease is found to have elevated serum calcium levels. Which of the following actions of parathyroid hormone (PTH) is most directly responsible for increasing serum calcium levels? (Q848840)

A. Inhibition of calcium reabsorption in the kidneys.

B. Stimulation of 1,25-dihydroxyvitamin D production.

C. Decreased intestinal calcium absorption.

D. Promotion of bone mineralization.

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 55-year-old woman undergoes a routine abdominal CT scan for an unrelated issue. The scan reveals a 2.5 cm mass in the left adrenal gland. The patient has no history of adrenal disorders but reports occasional episodes of sweating and palpitations. Her blood pressure is elevated. Based on these findings, what condition should be primarily ruled out in the diagnostic workup? (Q848873)

A. Subclinical Cushing syndrome

B. Adrenocortical carcinoma

C. Pheochromocytoma

D. Aldosteronoma

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 50-year-old patient presents with elevated serum calcium levels and a neck mass. After further evaluation, the diagnosis of parathyroid carcinoma is confirmed. The patient is scheduled for surgery. What is the standard surgical treatment for this case to minimize the risk of local recurrence? (Q848872)

A. Total thyroidectomy

B. En bloc resection

C. Lymph node dissection

D. Total parathyroidectomy

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 45-year-old woman undergoes a total thyroidectomy for the treatment of Graves' disease. Two days postoperatively, she presents with numbness and tingling around her mouth and in her fingers. She also complains of muscle cramps and mild weakness. Laboratory tests reveal decreased serum calcium levels. What is the most likely cause of her symptoms following the surgery? (Q848871)

A. Postoperative hypophosphatemia

B. Hypocalcemia due to damage to the parathyroid glands

C. Infection at the surgical site

D. Postoperative bleeding leading to hypovolemia

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 62-year-old woman with a history of tertiary hyperparathyroidism undergoes total parathyroidectomy. Three days later, she presents with carpopedal spasms and numbness around her mouth. Her serum calcium level is 6.9 mg/dL. What is the most likely diagnosis? (Q848870)

A. Pseudohypoparathyroidism

B. Hungry bone syndrome

C. Persistent hyperparathyroidism

D. Recurrent hyperparathyroidism

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 57-year-old patient with chronic renal failure is found to have elevated parathyroid hormone levels, but his serum calcium level is in the normal range. What is the diagnosis? (Q848869)

A. Primary hyperparathyroidism

B. Tertiary hyperparathyroidism

C. Secondary hyperparathyroidism

D. Calciphylaxis

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 40-year-old lady comes to the emergency department with muscle weakness, fatigue, and abdominal pain, and on evaluation, has some memory loss. Her lab reports show elevated serum calcium levels (13mg%), and she is diagnosed with primary hyperparathyroidism. Which of the following is the preferred treatment in this scenario? (Q848868)

A. Selective estrogen receptor modulators

B. Bisphosphonates

C. Parathyroidectomy

D. Calcimimetic drugs

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following is the most accurate investigation to localize the lesion in a case of primary hyperparathyroidism? (Q848867)

A. Ultrasonography

B. Sestamibi scan

C. 4D computed tomography

D. MRI

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 55-year-old postmenopausal woman presents with a fracture of the radius. She is found to have some mild memory impairment on questioning and her X-ray shows osteoporosis. On further evaluation, her serum calcium levels are elevated. Which of the following is not a common manifestation of this condition? (Q848866)

A. Nephrolithiasis

B. Salt and pepper skull

C. Neck mass

D. Brown tumors

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 45-year-old woman presents with recurrent kidney stones. Lab tests showed elevated calcium and parathyroid hormone levels. Imaging reveals pituitary adenoma and pancreatic neuroendocrine tumors. Her father had similar issues. What is the most likely diagnosis? (Q848865)

A. Wermer syndrome

B. Werner syndrome

C. MEN 4

D. Sipple syndrome

See Answer in Part B → Q21

Q1: A 30-year-old lactating mother presents with pain in her left breast and a fever. On examination of the affected side, there is localized erythema, warmth, and point tenderness, the fluctuation test is positive. There is mild axillary lymphadenopathy on the affected side and the contralateral breast is normal. Repeated aspirations under antibiotic cover were unsuccessful. A USG done showed fluid collection. What is the management plan for this patient? (Q857135)

A. Incision and drainage

B. Broad spectrum antibiotics only

C. Breast conservation surgery

D. Punch biopsy

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Fluorescence in-situ hybridization (FISH) is required in which of the following interpretations of HER2/NEU? (Q856565)

A. 1+

B. 2+

C. 3+

D. All of the above

See Answer in Part B → Q2

@Neet_pg_bot

Q3: What would be the appropriate next step in the management of a 55-year-old female patient who has a 4x3 cm lump in the right upper outer quadrant, with no involvement of axillary lymph nodes, and a BIRADS 4b staging on mammography? The patient underwent breast conservation surgery, and the final histopathology examination (HPE) report indicated high nuclear-grade ductal carcinoma in situ (DCIS) with necrosis and a 10mm margin clearance. (Q856541)

A. Adjuvant radiotherapy

B. Adjuvant chemotherapy

C. Follow up 6 monthly for 2 years and then yearly follow up

D. Trastuzumab therapy

See Answer in Part B → Q3

@Neet_pg_bot

Q4: In the surgical procedure for breast carcinoma, a frozen section was performed. This technique has benefits for all individuals, with the exception of: (Q858358)

A. To assess sentinel lymph node

B. To know margin positivity

C. To know metastasis

D. To confirm definitive diagnosis immediately in all cases

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which patient has better prognosis in breast cancer? (Q857556)

A. Her2+

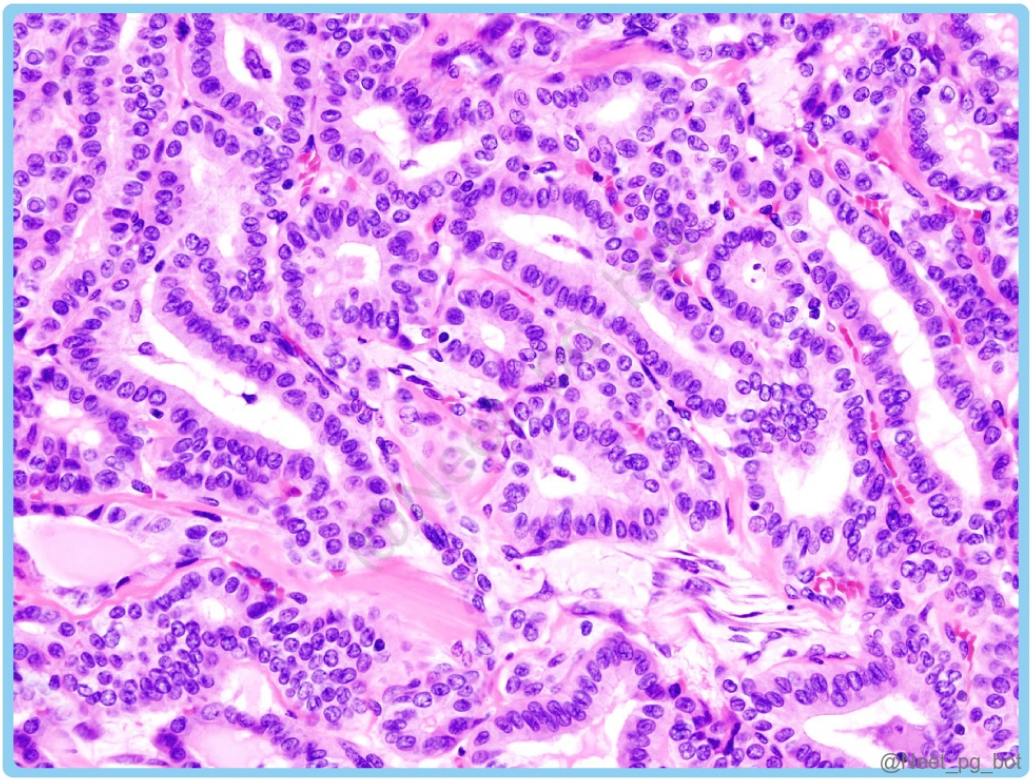
B. Triple negative

C. Luminal B

D. Luminal A

See Answer in Part B → Q5

@Neet_pg_bot



Q6: A 45-year-old lady presented with a swelling in her neck. She had an exposure to radiation in the past. Identify the type of disease, image of FNAC is given below: (Q857495)

A. Papillary carcinoma

B. Follicular carcinoma

C. Medullary carcinoma

D. Anaplastic carcinoma

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 30-year-old lactating mother presents with pain in her left breast and a fever. On examination of the affected side, there is localised erythema, warmth, and point tenderness, and the fluctuation test is positive. Mild axillary lymphadenopathy is on the affected side, and the contralateral breast is normal. What is the most likely diagnosis for this patient? (Q857494)

A. Lactational mastitis

B. Breast carcinoma

C. Breast abscess

D. Fibroadenoma

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Best prognosis among the following breast cancer subtypes is for: (Q857269)

A. Luminal A

B. Luminal B

C. ER negative

D. Basal like

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 23-year-old woman presents to the surgery out-patient with a left-sided breast lump, which she noticed on a self-breast examination 3 weeks ago. She has no other complaints. On palpation, the lump seems to be mobile and firm. FNAC is characterized by stromal and epithelial elements with no signs of malignancy. What is the best next step in management? (Q857141)

A. Mammography

B. Reassurance and follow-up

C. Surgical excision

D. Start Tamoxifen

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following statements are true? 1. Due to increasing mammography there occurs over diagnosis of breast carcinoma 2. Colon cancer screening is done by digital rectal examination 3. Oral cancer screening is done by visual inspection 4. Cervix cancer screening is done by a pap smear (Q856570)

A. 2, 3, 4

B. 1, 2, 3, 4

C. 4 only

D. 1, 3, 4

See Answer in Part B → Q10

@Neet_pg_bot

Q11: For a patient presenting with a new breast lump, which of the following investigations is the LEAST appropriate for the initial diagnosis? (Q855288)

A. Radiological investigations

B. PET scan

C. Clinical examination

D. Histology and cytology

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 25-year-old woman presents with a breast lump, no skin changes, and no indurations. In histology, fibroadenoma appeared. Which of the following categories does it fall under? (Q855202)

A. BI-RADS 1

B. BI-RADS 2

C. BI-RADS 3

D. BI-RADS 4

See Answer in Part B → Q12

@Neet_pg_bot

Q13: What is the appropriate next step in managing a 37-year-old unmarried woman who has never given birth, is sexually active, and is currently taking oral contraceptive pills, considering that her mother was diagnosed with breast cancer at the age of 60 and her older sister was diagnosed with ovarian cancer at 40? (Q855690)

A. Genetic counseling and screening for BRCA

B. Routine mammography

C. Stop taking oral and contraceptive pills

D. Prophylactic surgery

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following is not a relative contraindication for breast conservative surgery? (Q855688)

A. Tumor size <4 cm

B. Li-Fraumeni Syndrome

C. Prior radiation to the chest

D. Genetic Predisposition to Breast Cancer

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 49-year-old female presents with a breast lump. Which of the following findings is in accordance with basal cell type breast cancer? (Q855676)

A. ER +ve, PR +ve, HER2 -ve

B. ER +ve, PR -ve, HER2 -ve

C. ER -ve, PR -ve, HER2 -ve

D. ER -ve, PR -ve, HER2 +ve

See Answer in Part B → Q15

@Neet_pg_bot

Q16: What preoperative intervention can be administered to minimise intraoperative bleeding in a 32-year-old female patient diagnosed with Grave's disease, presenting with eye symptoms and an enlarged thyroid, who is scheduled to undergo a total thyroidectomy? (Q855665)

A. Potassium iodide

B. Propranolol

C. Propylthiouracil

D. Betamethasone

See Answer in Part B → Q16

@Neet_pg_bot

Q17: What is the probable diagnosis for a 30-year-old woman who complains of a painless mass in her left breast that can be felt? The mass is highly movable, measures 3 x 3 cm, and has a rubbery texture. (Q793449)

A. Breast abscess

B. Phyllodes tumor

C. Fibroadenoma

D. Invasive ductal carcinoma

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following carries the lowest risk of developing invasive ductal carcinoma? (Q793425)

A. Florid epithelial hyperplasia

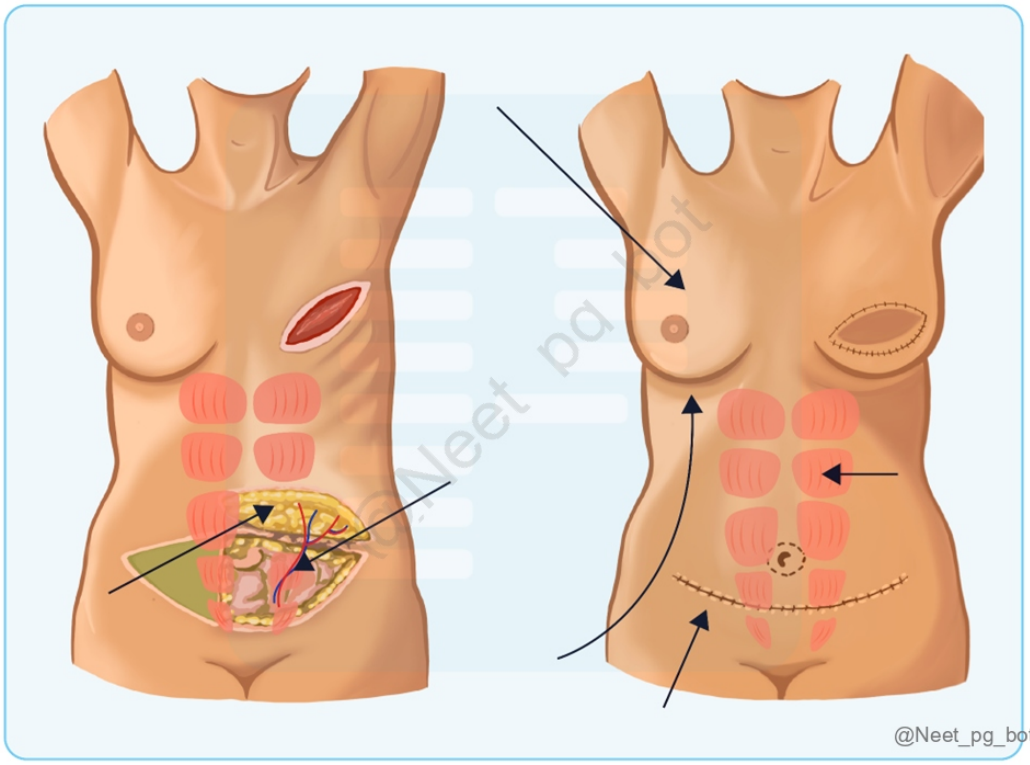
B. Papilloma with fibrovascular core

C. Atypical hyperplasia

D. Squamous metaplasia

See Answer in Part B → Q18

@Neet_pg_bot



Q19: Which of the following is true about the flap given in the image? (Q858485)

A. Pedicled TRAM based on superior epigastric artery

B. Free TRAM based on superior and inferior epigastric artery

C. DIEP based on deep inferior epigastric artery

D. Lower abdominal fat-based inferior epigastric vessels

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A woman presented with the following findings in the left breast for 3 months and pain for 2 months. What is the management plan for the following? (Q879127)

A. Simple mastectomy followed by management of complications

B. Neoadjuvant chemotherapy followed by radical mastectomy

C. Radical mastectomy with Axillary Lymph node dissection

D. Neoadjuvant chemotherapy followed by MRM and RT

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Identify the wrong statement about late dumping syndrome from the following? (Q879109)

A. Symptoms start after 2 hours of food intake

B. Symptoms worsen with physical activity

C. Symptoms are relieved on lying down

D. Clinical features include tremors, dizziness and palpitations

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 59-year-old lady presents with a progressive, painless lump in the breast. What is the cause for the following skin change? (Q855834)

A. Infiltration of subdermal lymphatics

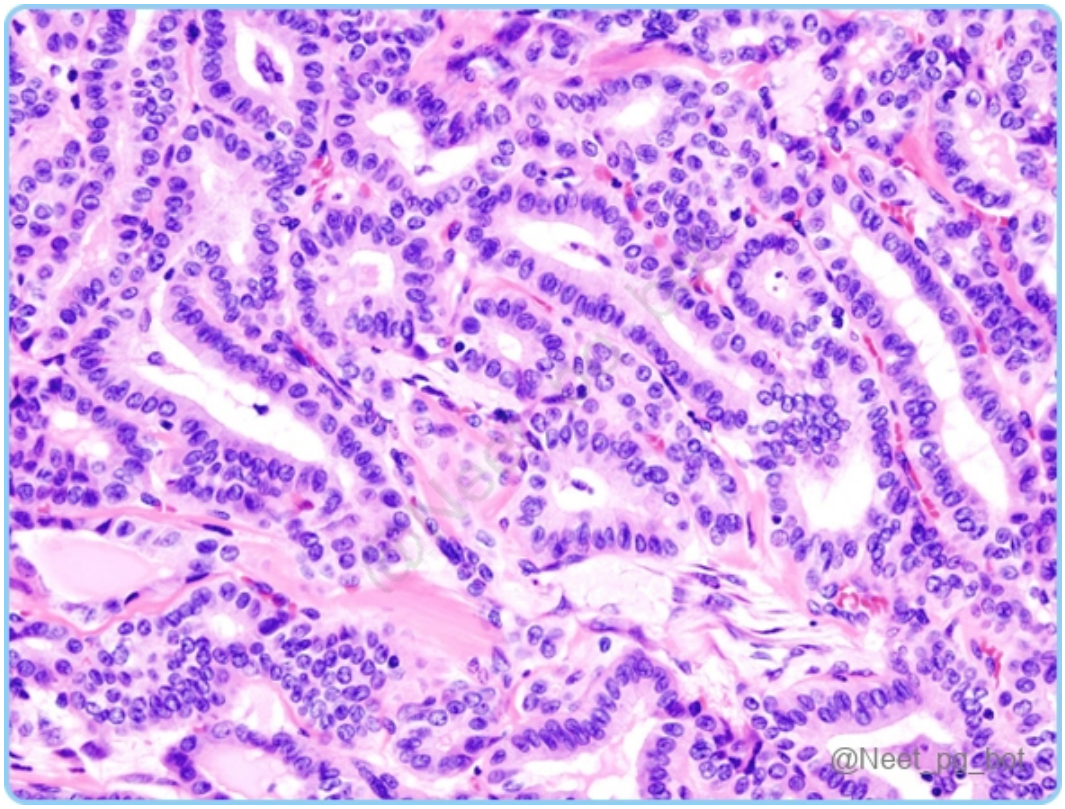
B. Infiltration of the lactiferous duct

C. Involvement of Cooper’s ligament

D. Spread of the tumour to the anterior chest wall

See Answer in Part B → Q22

@Neet_pg_bot



Q23: A male patient presented with midline neck swelling. He later developed cervical node enlargement. The histopathology of the lesion is shown below. Which of the following statements is false about this condition? (Q855784)

A. Excellent prognosis is associated with this condition

B. It spreads quickly via lymphatics

C. Nuclear characteristics are used for the identification

D. Fine needle aspiration cytology (FNAC) is not diagnostic

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Grey-Turner's sign is seen in: (Q859891)

A. Acute appendicitis

B. Acute pancreatitis

C. Acute cholecystitis

D. Acute hepatitis

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Best way to localise extra-adrenal pheochromocytoma: (Q859889)

A. X-ray

B. Nucleotide scan

C. VMA excretion

D. Clinical examination

See Answer in Part B → Q25

@Neet_pg_bot

Q26: What kind of thyroid cancer is frequently linked to prior radiation exposure, elevated RET/PTC rearrangements, and BRAF mutations? (Q859619)

A. Follicular carcinoma

B. Papillary carcinoma

C. Anaplastic carcinoma

D. Medullary carcinoma

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 15-year-old boy undergoes bilateral adrenalectomy for phaeochromocytoma. On the third postoperative day, the boy feels lethargic and tired. Blood pressure is 80/60 mm Hg; there is no sign of bleeding. What could be the cause of this? (Q858492)

A. Addisonian crisis

B. SIADH

C. Diabetes insipidus

D. Cerebral salt wasting disease

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 28-year-old lactating mother presents with pain in her left breast. Which of the following is the most likely cause of acute mastitis? (Q857792)

A. Breast engorgement

B. Hormonal influence

C. Absence of lactation

D. Crack in the nipple

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Which of the following nerves is least injured during thyroid surgery? (Q856287)

A. Recurrent laryngeal nerve

B. Cervical sympathetic trunk

C. External laryngeal nerve

D. Marginal mandibular nerve

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 40-year-old woman presents with complaints of swelling of the right breast over the past 15 days. On examination, there was a local rise in temperature, and the lump was mobile over the chest wall. What is the likely diagnosis? (Q856239)

A. Inflammatory carcinoma

B. Giant fibroadenoma

C. Phyllodes tumour

D. Galactocele

See Answer in Part B → Q30

@Neet_pg_bot

Q31: What will be the most likely associated condition with increased TSH and low T4 levels? (Q856211)

A. Hypoparathyroidism

B. Pituitary Adenoma

C. Grave's disease

D. Hashimoto's thyroiditis

See Answer in Part B → Q31

@Neet_pg_bot

Q32: What risks are associated with the initiation of tamoxifen in a patient diagnosed with unilateral breast cancer? (Q856774)

A. Ovarian cancer

B. Endometrial cancer

C. Breast cancer, on the other side

D. Cervical cancer

See Answer in Part B → Q32

@Neet_pg_bot

Q33: Which of the following statements is correct regarding adequate thyroid FNAC sampling? (Q856768)

A. 6 follicular clusters each with 10 cells each

B. 3 follicular clusters with 10-15 cells each

C. 10 follicular cell clusters with 6-8 cells each

D. 12 follicular cell clusters with 10-12 cells each

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A 50-year-old female presents with a 4 x 3 cm irregular mass in the upper outer quadrant of the right breast, which is not fixed to the skin or the chest wall. A 2 cm lymph node is palpated in the right axilla. No mass is noted in the opposite breast. Which of the following investigations would you perform in this patient? Bilateral Mammography PET Scan Biopsy of the breast mass USG guided biopsy of the lymph node (Q856729)

A. 1, 2, 3 & 4

B. 1, 2 & 3

C. 1, 3 & 4

D. 1 & 3

See Answer in Part B → Q34

@Neet_pg_bot

Q35: A patient underwent surgery for breast carcinoma. She now presents with painless swelling involving the arm, as shown in the image below. What is the most likely diagnosis? (Q856226)

A. Lymphedema

B. Lymphangiosarcoma

C. Venous thrombosis

D. Cellulitis

See Answer in Part B → Q35

@Neet_pg_bot

Q36: Which of the following is the most common cause of bloody nipple discharge? (Q852700)

A. Breast cancer

B. Fibroadenoma

C. Intraductal papilloma

D. Duct Ectasia

See Answer in Part B → Q36

@Neet_pg_bot

Q37: A patient presents with polyuria, polydipsia, lethargy, and abdominal pain. She also has a history of mood disorders and recurrent kidney stones. Which of the following investigations would not be useful in arriving at the diagnosis? (Q860481)

A. Nuclear sestamibi scan

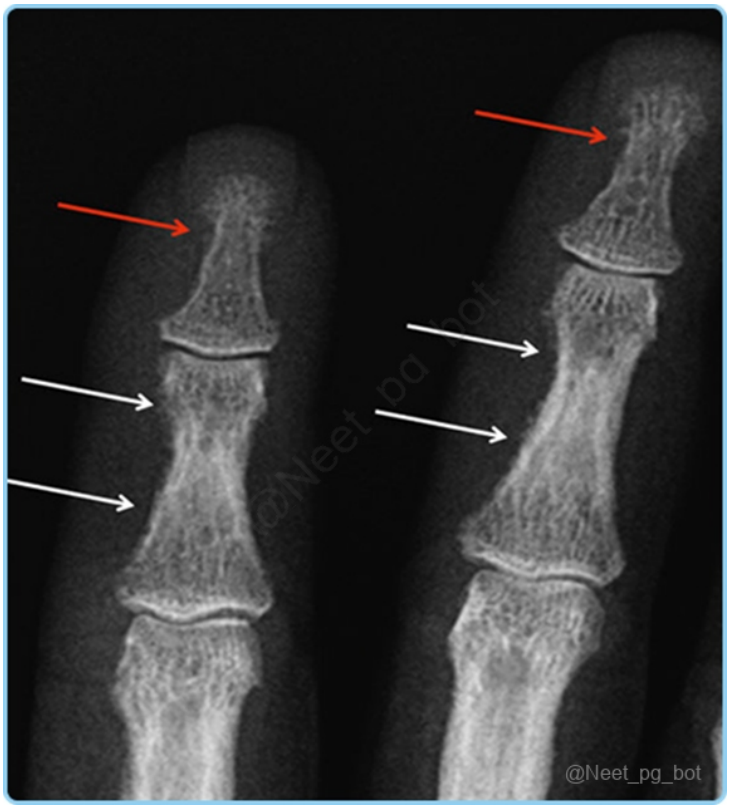
B. USG neck

C. Dual-energy radiographic absorptiometry (DEXA)

D. Angiography of renal arteries

See Answer in Part B → Q37

@Neet_pg_bot



Q38: A middle-aged man with a history of renal calculi presents with bone pain and abdominal cramps. X-ray shows subperiosteal resorption of the 2nd and 3rd metacarpals and phalanges. Serum calcium and PTH are raised, and phosphate levels are decreased. Which of the following investigations will help localise the pathology? (Q860470)

A. 99Tc radiolabelled sestamibi scan

B. MRI scan

C. USG

D. CT scan

See Answer in Part B → Q38

@Neet_pg_bot

Q39: Which of the following is not an indication for parathyroidectomy in a patient with primary hyperparathyroidism? (Q860451)

A. Serum calcium > 1 mg/dL above the upper limit of normal

B. 24-hour urine calcium > 400 mg/d

C. Age < 50 years

D. Creatinine clearance < 90 mL/min

See Answer in Part B → Q39

@Neet_pg_bot

Q40: A patient presents with a swelling in the thyroid region that moves with deglutination and protrusion of the tongue. The swelling has ruptured, resulting in pus discharge. What is the preferred treatment? (Q860404)

A. Sistrunk procedure

B. Antibiotics

C. Incision and drainage

D. None of the above

See Answer in Part B → Q40

@Neet_pg_bot

Q41: A female presented with 1x 1 cm thyroid swelling. What is next best step in management? (Q844302)

A. I 131

B. TSH

C. TSH and T4

D. T3 and T4

See Answer in Part B → Q41

@Neet_pg_bot

Q42: A patient presents to the outpatient department with an ulcerated breast tumor and liver metastasis. What is the appropriate management? (Q844324)

A. Simple mastectomy

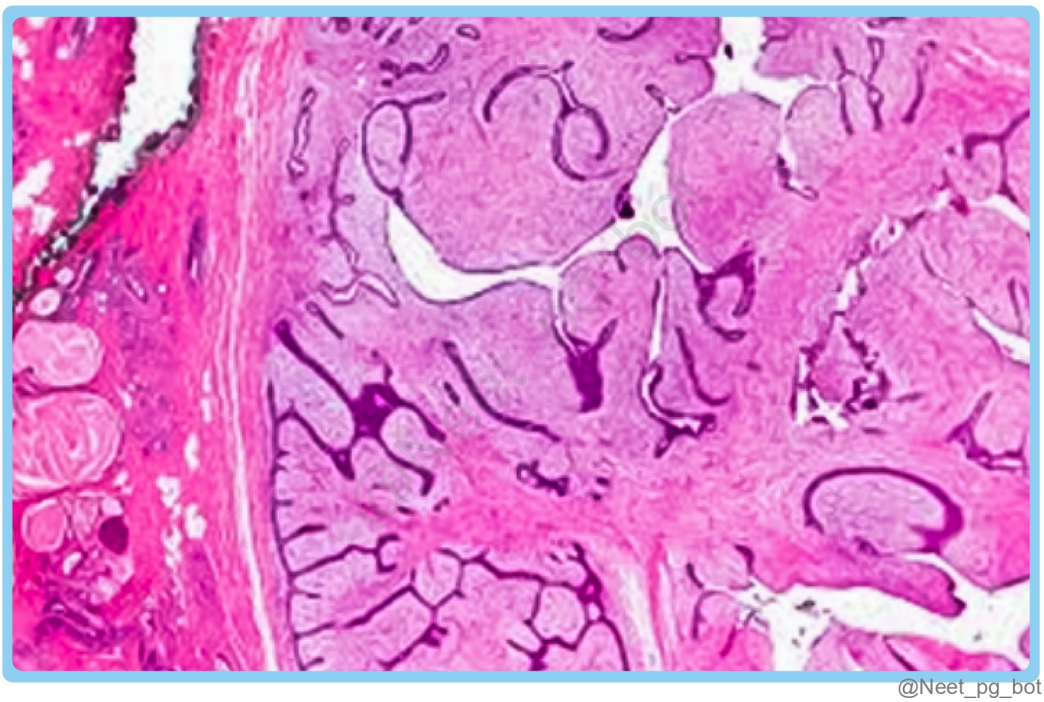
B. Modified Radical Mastectomy (MRM)

C. Radical mastectomy

D. Neoadjuvant chemotherapy followed by surgery

See Answer in Part B → Q42

@Neet_pg_bot



Q43: A 40-year-old female presents with an irregular 5 x 6 cm mass in the right breast. Histopathological examination reveals findings consistent with which of the following diagnoses? (Q844306)

A. Phyllodes tumor

B. Fibroadenoma

C. Mastitis

D. Grade 2 breast tumor

See Answer in Part B → Q43

@Neet_pg_bot

Q44: A 23-year-old female visited the clinician with a solitary thyroid nodule and was advised for thyroid function tests where Tsh level is 27.3mU/L, T3 is 1.24 ng/ml, and T4 is 4.87 microgram/ml. Which of the following manifestations is true regarding the condition? (Q852701)

A. Heat intolerance

B. Tachycardia

C. Diarrhea

D. Weight gain

See Answer in Part B → Q44

@Neet_pg_bot

Q45: What is the preferred treatment for a benign tumour of the superficial parathyroid gland? (Q860494)

A. Enucleation

B. Surgical resection

C. Chemotherapy

D. Radiation therapy

See Answer in Part B → Q45

@Neet_pg_bot

Q46: Which is the most lethal nerve injury during thyroid surgery? (Q853037)

A. U/L RLN (partial)

B. B/L RLN (partial)

C. U/L RLN (complete)

D. B/L RLN (complete)

See Answer in Part B → Q46

@Neet_pg_bot

Q47: A 20-year-old male presents with occasional palpitations, high blood pressure, and headache. He is diagnosed with pheochromocytoma. What is the preferred initial investigation? (Q853036)

A. USG-abdomen

B. MRI - abdomen

C. MIBG

D. 24 hours urine metanephrines

See Answer in Part B → Q47

@Neet_pg_bot

Q48: Which of the following is not a component of MEN2B syndrome? (Q853035)

A. Medullary thyroid carcinoma

B. Mucosal ganglioneuromatosis

C. Marfanoid habitus

D. Parathyroid hyperplasia

See Answer in Part B → Q48

@Neet_pg_bot

Q49: A 40-year-old patient with a history of Hodgkin's lymphoma and prior radiation therapy presents with a right-sided thyroid swelling. Fine needle aspiration cytology (FNAC) confirms papillary carcinoma with no evidence of lymph node involvement. What is the next step in management? (Q853034)

A. Hemi-thyroidectomy with modified radical neck dissection

B. Total thyroidectomy

C. Total thyroidectomy with modified radical neck dissection

D. Hemi-thyroidectomy

See Answer in Part B → Q49

@Neet_pg_bot

Q50: A 34-year-old male presents with a serum calcium level of 12.8 mg/dL (normal range: 8.5–10.25 mg/dL) along with elevated parathyroid hormone (PTH) levels. Ultrasound imaging reveals a 1.5 x 1.5 cm mass in the right lower lobe of the thyroid gland. Which of the following statements is correct regarding this condition? (Q853033)

A. MIBI followed by focussed parathyroidectomy to be done

B. Normal DEXA scan rules out the need for surgery

C. Only observation, no need for surgery

D. Creatinine clearance > 80 ml/min mandates the surgery

See Answer in Part B → Q50

@Neet_pg_bot

Q51: A neonate is diagnosed with congenital hypothyroidism. Thyroid ultrasound shows normal gland in-situ, but radioiodine uptake scan shows no uptake. What is the diagnosis? (Q866458)

A. Absent thyroid gland

B. Thyroid dyshormogenesis

C. lodine deficiency

D. Defective thyroid uptake

See Answer in Part B → Q51

@Neet_pg_bot

Q52: A 43 year old female present to OPD due changes in breast changes in breast and a lump in breast as given below, what is the diagnosis? (Q866420)

A. T4d

B. T4a

C. T1c

D. T3

See Answer in Part B → Q52

@Neet_pg_bot

Q53: A 45-year-old woman with a history of multinodular goitre undergoes a CT angiogram with iodinated contrast for suspected pulmonary embolism. Two weeks later, she presents with palpitations, heat intolerance, and weight loss. Her thyroid function tests show suppressed TSH and elevated T3 and T4. Which of the following best explains this patient's current condition? (Q865430)

A. Wolff-Chaikoff effect

B. Jod-Basedow effect

C. Thyroid storm

D. Hashitoxicosis

See Answer in Part B → Q53

@Neet_pg_bot

Q54: A 52-year-old female patient presents with HER-2-positive breast cancer that has become resistant to trastuzumab treatment. The oncologist is considering the next

line of treatment. Which of the following options would be the most appropriate choice? (Q854756)

A. Lapatinib

B. Sorafenib

C. Vemurafenib

D. Erlotinib

See Answer in Part B → Q54

@Neet_pg_bot

Q55: A 50-year-old woman after thyroidectomy comes to you for a 2 nd opinion for further treatment of papillary thyroid cancer. What would you recommend for this patient? (Q857779)

A. Radiotherapy

B. Chemotherapy

C. Radioiodine scan

D. Wait and watch

See Answer in Part B → Q55

@Neet_pg_bot

Q56: Genetic testing for BRCA 1/BRCA 2 is indicated for all of the following except: (Q857771)

A. Breast cancer diagnosed in a postmenopausal female >50 years of age

B. Male breast cancer

C. Two breast cancer primaries

D. TNBC diagnosed age 60 years

See Answer in Part B → Q56

@Neet_pg_bot

Q57: A 51-year-old woman is evaluated for a right breast mass. Physical examination reveals a 6 cm firm tumor. Palpable, mobile lymph nodes are also noted in the right axilla. A core biopsy confirms invasive ductal carcinoma, and a subsequent workup for distant disease is negative. According to the AJCC TNM staging system, what is the clinical stage of her cancer? (Q857767)

A. cT3N1M0

B. cT4N0M0

C. cT4N1M0

D. cT3N0M0

See Answer in Part B → Q57

@Neet_pg_bot

Q58: A woman presents with a BIRADS-5 breast lesion. Which of the following is a good prognostic factor for this lesion? (Q855191)

A. BRCA-1 positive

B. p53 positive

C. ER positive

D. High Ki-67

See Answer in Part B → Q58

@Neet_pg_bot

Q59: What is the primary prognostic factor that significantly influences the outcome of breast cancer? (Q854789)

A. Lymph node

B. Distant metastasis

C. Size

D. Hormone receptors

See Answer in Part B → Q59

@Neet_pg_bot

Q60: A 55-year-old female presents with a breast lump and is seeking medical evaluation. On examination, a palpable mass is detected in the breast. Which of the following conditions is not associated with the development of breast cancer? (Q854764)

A. Alcohol intake

B. Late menopause

C. Hormone replacement therapy

D. Multiparity

See Answer in Part B → Q60

@Neet_pg_bot

Q61: Which of the following are typically done in breast conservation therapy? Wide local excision Axillary node dissection Frozen section during surgery Optional: Post-operative radiotherapy (Q854762)

A. 1, 2, 3

B. 1, 3, 4

C. 1, 2

D. 2, 3

See Answer in Part B → Q61

@Neet_pg_bot

Q62: A 50-year-old woman presents with a slowly enlarging, painless thyroid nodule. She has no history of radiation exposure. On examination, the nodule is firm and mobile. Thyroid function tests are within normal limits. Ultrasound shows a solitary, solid lesion in the right lobe of the thyroid. Fine-needle aspiration cytology (FNAC) is performed, but is inconclusive. A hemithyroidectomy is done, and histopathology reveals capsular and vascular invasion. What is the most likely diagnosis? (Q865363)

A. Papillary thyroid carcinoma

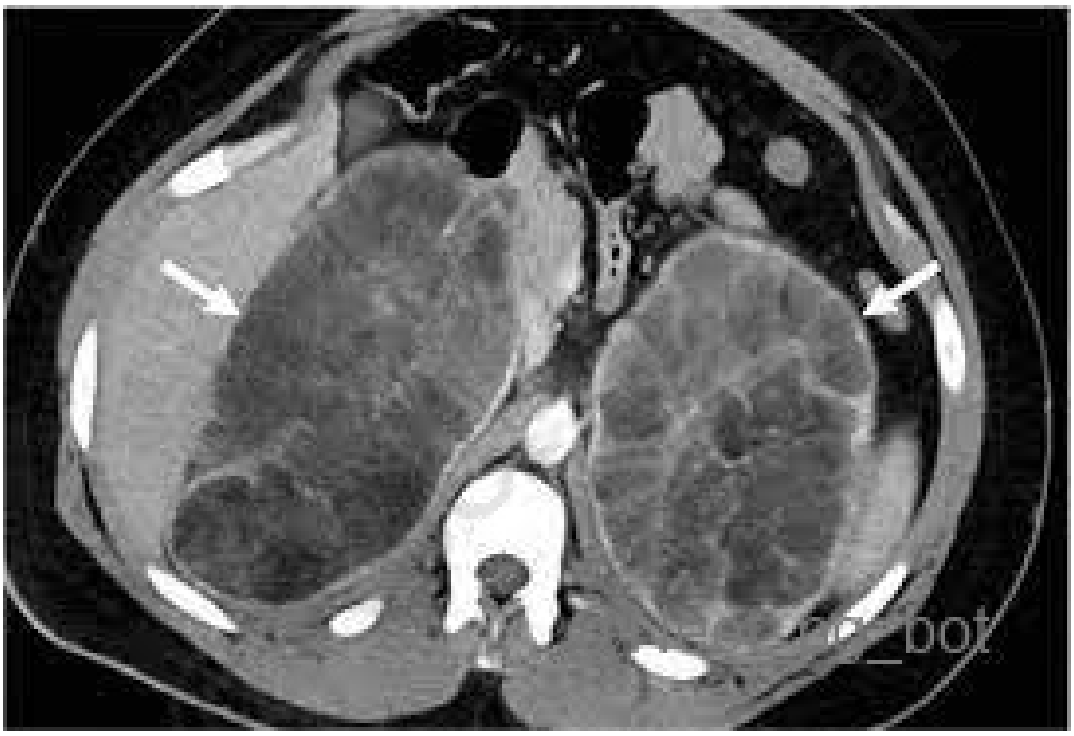
B. Follicular adenoma

C. Follicular thyroid carcinoma

D. Medullary thyroid carcinoma

See Answer in Part B → Q62

@Neet_pg_bot



Q63: Which of the following condition is depicted in the given CT image ? (Q820159)

A. Cirrhosis

B. HCC

C. Congenital Adrenal Hyperplasia

D. Hepatitis

See Answer in Part B → Q63

@Neet_pg_bot

Q64: A patient with a known history of rheumatoid arthritis is brought to the ER due to dizziness. Her blood pressure is 90/60 mmHg. She stopped taking a medication prescribed by her local doctor. Her blood sugar is low, and serum potassium is 6 mEq/L. Which of the following drugs should be given to her next? (Q857303)

A. IV Saline

B. Hydrocortisone

C. Dopamine infusion

D. Sodium bicarbonate

See Answer in Part B → Q64

@Neet_pg_bot

Q65: Which of the following is the best method to conclusively localize a parathyroid adenoma? (Q857302)

A. SPECT Sestamibi

B. Tc99 Sestamibi Scan

C. USG Neck

D. MRI

See Answer in Part B → Q65

@Neet_pg_bot

Q66: Which of the following drugs are not used for thyrotoxic crisis management? (Q857301)

A. Acetaminophen

B. Aspirin

C. Lugol's iodine

D. Propranolol

See Answer in Part B → Q66

@Neet_pg_bot

Q67: Identify the most common pancreatic islet tumor associated with MEN-1 syndrome. (Q860303)

A. VIPoma

B. Gastrinoma

C. Insulinoma

D. Lipoma

See Answer in Part B → Q67

@Neet_pg_bot

Q68: Which of the following will not result in hoarseness of voice after a thyroid surgery? (Q840046)

A. Dissecting/retracting strap muscles

B. Exploring Beahrs triangle

C. Tubercle of zuckerkandl dissection

D. Ligating inferior thyroid vessels

See Answer in Part B → Q68

@Neet_pg_bot

Q69: A 52-year-old woman is diagnosed with invasive ductal carcinoma of the left breast. On examination, there is skin ulceration overlying the tumor, localized edema and redness, but no diffuse inflammatory changes. Nipple retraction is present. No axillary lymphadenopathy is noted, and imaging shows no distant metastasis. What is the T-stage of this tumor? (Q840029)

A. T2

B. T3

C. T4a

D. T4b

See Answer in Part B → Q69

@Neet_pg_bot

Q70: ER positivity is used as which of the following in the context of breast carcinoma? (Q840015)

A. Diagnostic marker

B. Prognostic marker

C. Surrogate molecular marker

D. Treatment

See Answer in Part B → Q70

@Neet_pg_bot

Q71: What is the term used to describe the signs and symptoms caused by hormones released from tumor tissue, which cannot be explained by the tumor's anatomical distribution? (Q793543)

A. Pretumor syndrome

B. Paraneoplastic syndrome

C. Paratumour syndrome

D. Autocrine phenomenon

See Answer in Part B → Q71

Q19 (p. 785)	*Q20 (p. 785)*				

Q1: A 35 year old industrial worker presents to the ED with severe pain and burns on his right hand after exposure to hydrofluoric acid. The burns are superficial, with erythema and blistering. What is the most appropriate initial management step? (Q849515)

A. Immediate surgical debridement

B. Topical application of calcium gluconate gel

C. Intravenous calcium gluconate

D. Bier's block with calcium gluconate 10%

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 40-year-old man suffered burns from a wildfire affecting his entire right upper limb and the front of his torso. What is the total percentage of body surface area that has been burned? (Q849512)

A. 27%

B. 18%

C. 36%

D. 32%

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 29-year-old woman sustained severe burns following a spillage of boiling water in the kitchen by accident. She requires colloid resuscitation after the first 24 hours of crystalloid resuscitation. Which of the following can be used to calculate colloid fluid volume? (Q849510)

A. Parkland formula

B. Muir and Barclay regime

C. Evan's formula

D. Galveston regime

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 24-year-old boy sustained burns in an accident. He has 20% burns and is of 60 kg. What is the total fluid requirement for a day according to the Parkland regime? (Q849508)

A. 4800 mL

B. 5000 mL

C. 4000 mL

D. 3800 mL

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 25-year-old female is brought to the emergency department after being found unconscious during a thunderstorm. On examination, she has fern-like marks on his neck (as shown in the image below). After regaining consciousness, she complains of weakness and numbness in her lower limbs. What is the most likely diagnosis of her

condition? (Q849517)

A. Compartment syndrome

B. Keraunoparalysis

C. Hypokalemic periodic paralysis

D. Transient ischemic attack

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 35-year-old electrician is brought to the emergency department after sustaining an electrical injury while working on a faulty high-voltage switchboard. On examination, he is noted to have an entry wound on his left hand and an exit wound on his right foot and dark urine in the Foley catheter bag. Laboratory tests show the following results: Serum creatinine: 2.5 mg/dL Potassium: 5.8 mEq/L Creatine kinase (CK): 25,000 U/L What is the most appropriate next step in the management of this patient? (Q849516)

A. Initiate intravenous fluid resuscitation and monitor urine output

B. Immediate surgical debridement of the entry and exit wounds

C. Administer calcium gluconate for hyperkalemia

D. Start hemodialysis immediately

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 32 year old male arrives at the emergency department with severe facial burns after being involved in a car accident. The patient's facial burns are extensive, covering the entire face and neck region, and have caused significant swelling. He is conscious and in pain, but his airway is patent. Which method of dressing should be chosen for this patient's facial burns, and why? (Q849514)

A. Exposure Method – To allow continuous monitoring of the facial burns and prevent airway compromise.

B. Closed Method – To reduce the risk of infection by providing a protective barrier over the burned area.

C. Exposure Method – To facilitate a moist environment that promotes healing in the facial area.

D. Closed Method – To minimize fluid loss from the burned area and aid in preventing dehydration.

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 36 year old male is admitted to the hospital with severe second and third-degree burns. On the fourth day, the patient develops a fever, increased pain in the burned area, and a malodorous discharge from the wound. The burn wound appears to have significant eschar formation. Wound cultures reveal heavy growth of Pseudomonas aeruginosa. Which of the following topical agents would be most appropriate for this patient? (Q849513)

A. Silver sulfadiazine (1%)

B. Sulfamylon (Mafenide acetate) (5%/11%)

C. Silver nitrate (0.5%)

D. Povidone iodine (5%)

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 24-year-old burns patient is receiving fluid resuscitation and is being closely monitored. What should his ideal urine output be? (Q849511)

A. 1 mL/kg/hr

B. 3 mL/kg/hr

C. 5 mL/kg/hr

D. 2 mL/kg/hr

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 10-year-old boy contracted burns and is in need of fluid resuscitation. Which of the following formulas can be used to measure the fluid volume? (Q849509)

A. Parkland formula

B. Modified Brooke formula

C. Evan’s formula

D. Galveston formula

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 70-year-old woman presents to the emergency department after a house fire. She has burns involving parts of her face, neck, and both hands. The total body surface area (TBSA) affected is approximately 12%. After emergency management using ATLS guidelines, What is the most appropriate next step in management? (Q849498)

A. Discharge with outpatient follow-up for wound care and pain management

B. Admit to the general medical floor for observation and supportive care

C. Refer to a burn center for specialized treatment

D. Manage in the emergency department with fluids and dressings, then discharge

See Answer in Part B → Q11

@Neet_pg_bot

Q12: What is the most commonly used fluid for initial resuscitation in burn patients? (Q849507)

A. Hypertonic saline

B. Ringer lactate

C. 5% Dextrose

D. Albumin

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following complications in a patient with an airway burn most at risk? (Q849506)

A. Chronic bronchitis

B. Pulmonary embolism

C. Acute airway obstruction

D. Pleural effusion

See Answer in Part B → Q13

@Neet_pg_bot

Q14: What is the most common cause of death in the first 24 hours after sustaining severe burns? (Q849505)

A. Septicemia

B. Hypovolemic shock

C. Acute respiratory distress syndrome (ARDS)

D. Renal failure

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 35-year-old male presents to the emergency department with complaints of extensive burns on his back, chest, and legs. On examination, the affected areas are dry, leathery, and charred black with no blister formation.What is the most likely type of burn? (Q849504)

A. Second-degree burn

B. First-degree burn

C. Third-degree burn

D. Fourth-degree burn

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Match the type of burn with its corresponding characteristic: Type of Burn Characteristics 1. First-degree burn A. Blistering, partial-thickness damage 2.

Second-degree burn B. Charring, full-thickness skin damage 3. Third-degree burn C. Redness, Epidermal burn 4. Fourth-degree burn D. Involvement of muscles and bones (Q849503)

A. 1-C, 2-A, 3-B, 4-D

B. 1-A, 2-B, 3-D, 4-C

C. 1-C, 2-B, 3-A, 4-D

D. 1-D, 2-C, 3-A, 4-B

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following best differentiates deep partial-thickness burns from superficial partial-thickness burns? (Q849502)

A. Involvement of the epidermis and papillary dermis with visible capillary refill.

B. Blistering and loss of epidermis with pink and moist dermis.

C. Healing within 2 weeks without scarring.

D. Reduced sensation, fixed capillary staining and no blanching with pressure.

See Answer in Part B → Q17

@Neet_pg_bot

Q18: In burn injuries, which zone is characterized by necrotic tissue and irreversible cell damage at the time of injury? (Q849501)

A. Zone of Hyperemia

B. Zone of Stasis

C. Zone of Coagulation

D. Zone of Inflammation

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 55-year-old male with a history of a recent traumatic brain injury presents with sudden epigastric pain, vomiting of blood, and black stools. He is diagnosed with a Cushing ulcer. Despite initial management with IV fluids and proton pump inhibitors (PPIs), the patient continues to bleed. What is the most appropriate next step in management? (Q849500)

A. Increase the dose of IV PPIs and observe for improvement.

B. Perform an urgent endoscopy to control the bleeding.

C. Schedule the patient for a planned surgical vagotomy and pyloroplasty.

D. Refer the patient for immediate angiography with embolization.

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which among the following statements about the body responses to severe burns are true? A) Hypermetabolism after a burn increases oxygen consumption and leads to muscle wasting. B) The zone of coagulation is a reversible area of tissue damage in burns. C) Cardiopulmonary effects in severe burns can result in reduced cardiac output. D) Immune suppression following a burn increases the risk of infection. E) Inflammation and edema in burn injuries cause increased vascular permeability and fluid loss. (Q849499)

A. All except A and C

B. All except A and B

C. All except B

D. All are correct

See Answer in Part B → Q20

Q1: The following are good prognostic factors for melanoma except (Q849574)

A. No or very few mitoses (<1 per mm sq)

B. Lack of ulceration

C. Absence of Regression

D. Thinner tumor growth

See Answer in Part B → Q1

@Neet_pg_bot

Q2: After a skin graft procedure in a burn patient, regeneration of the epidermis occurs from resident stem cells in the basal layer. These regenerative cells belong to which category of stem cell potency? (Q882386)

A. Multipotent

B. Pluripotent

C. Totipotent

D. Unipotent

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is true regarding basal cell carcinoma? (Q849639)

A. Superficial BCC typically appears with a thin pearly border

B. Nodular is the least common type of BCC

C. Morpheaform variant is the most common type of BCC

D. The prognosis is very poor for all cases

See Answer in Part B → Q3

@Neet_pg_bot

Q4: All of these are used for flap monitoring except: (Q849638)

A. Clinical assessment

B. Color Doppler sonography

C. Microdialysis

D. None of the above

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following types do osteomyocutaneous flaps belong to? (Q849637)

A. Conjoined flaps

B. Chimeric flaps

C. Composite flaps

D. None of the above

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following is an example of a free flap? (Q849636)

A. Z-Plasty

B. Pectoralis major myocutaneous flap

C. Radial artery forearm flap

D. Deltopectoral flap

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 45-year-old man presents with a large soft tissue defect on his lower leg following a motorcycle accident. The wound measures 10 cm x 15 cm and involves exposure of the tibia. The plastic surgeon is considering an axial flap for reconstruction. Which of the following statements is incorrect regarding the usage of an axial flap? (Q849635)

A. Axial pattern flaps derive their blood supply directly from a fasciocutaneous artery that runs beneath the flap's longitudinal axis.

B. It allows for a larger flap design compared to random pattern flaps and delivers better cosmetic results

C. Deltopectoral flap is a type of axial flap

D. Due to larger size, axial flaps require a high complexity, multi-step method for reconstruction of defects

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Regarding the use of random flaps in grafting, which of the following statements is incorrect? (Q849634)

A. V-Y Plasty is a random flap used for fingertips and extremities

B. Random flaps rely on perfusion from the subdermal vascular plexus which is a low-pressure system

C. Z-Plasty is used for lengthening of tissue and scars.

D. Due to the tenuous blood supply, a minimum length-width ratio of 3:1 is required

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 48-year-old man presents with a progressively enlarging, painless mass in his groin. A biopsy confirms a diagnosis of soft tissue sarcoma. Which of the following characteristics would most likely increase the probability of lymph node involvement in this patient? (Q849633)

A. Tumor Size >5 cm

B. High-grade histology

C. Rhabdomyosarcoma histotype

D. Deep location relative to fascia

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 35-year-old woman with a family history of multiple cancers presents with a soft tissue mass. Genetic testing reveals a TP53 mutation. Which of the following is the most likely clinical course associated with her condition? (Q849632)

A. Development of multiple benign lipomas

B. Increased risk of developing gastrointestinal stromal tumors (GIST)

C. High likelihood of developing soft tissue sarcomas, breast cancer, and brain tumors

D. Predominantly risk of osteosarcoma and leukemia

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 5-year-old boy is brought to the OPD by his mother with complaints of swelling on her nape. On examination, a hard, freely mobile, and slow-growing mass is seen. A photograph of the lesion is shown below. Which of the following is the most appropriate clinical diagnosis for this patient? (Q849631)

A. Cock's Peculiar Tumor

B. Pott's Puffy Tumor

C. Pilomatrixoma

D. Cylindroma

See Answer in Part B → Q11

@Neet_pg_bot

Q12: All of the following conditions resolve spontaneously in an infant except (Q849578)

A. Port wine stain

B. Strawberry angioma

C. Salmon patch

D. Cock’s peculiar tumor

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 28-year-old female patient came to OPD complaining of swelling on the side of her face. On examination, the swelling was painless, smooth, soft, and non-tender. A CT scan was done to rule out dural attachment and a diagnosis of angular dermoid was made. How will you manage the case? (Q849577)

A. Surgical excision

B. Wait and watch

C. Wide local excision with a 2 cm margin

D. Laser ablation

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 64-year-old male patient came to the OPD with complaints of swelling on the back of the neck. O/E the swelling is soft and doughy to the touch and non-tender. A diagnosis of lipoma is made. What is the definitive management of this condition? (Q849576)

A. Surgical excision

B. Wide local excision with sentinel node biopsy

C. Excision of the cyst with the wall

D. Incision and drainage followed by excision

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A patient came with complaints of a painful swelling present on the trunk. On examination, tenderness and pus discharge present with a black-colored punctum seen. A provisional diagnosis of an infected sebaceous cyst is made. Identify the incorrect statement about this condition. (Q849575)

A. It contains sebum.

B. It is a type of retention cyst

C. Black colored punctum is present on the cyst

D. There is the proliferation of epidermal cells

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A patient with a skin graft is experiencing mild swelling and oozing at the graft site 24 hours after surgery. Which phase of graft take is most likely occurring? (Q849551)

A. Imbibition

B. Inflammation

C. Revascularization

D. Maturation

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following Clark levels indicates that malignant melanoma has invaded the subcutaneous tissue? (Q849573)

A. Level II

B. Level III

C. Level IV

D. Level V

See Answer in Part B → Q17

@Neet_pg_bot

Q18: Which of the following statements is true about malignant melanoma? (Q849572)

A. CK-20 is a positive marker for malignant melanoma

B. Lentigo Maligna is the most malignant type of malignant melanoma

C. Lymphatic spread is the common route of metastasis

D. Most common site of metastasis is the Lymph Node

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 70-year-old male presents with a large, aggressive squamous cell carcinoma on his lower lip. After initial treatment attempts, the tumor remains persistent. Which of the following treatment options is most appropriate to ensure complete removal of the tumor while minimizing damage to surrounding healthy tissue? (Q849571)

A. Cryotherapy

B. Electrodesiccation and Curettage

C. Wide Local Excision

D. Mohs Micrographic Surgery

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 65-year-old farmer presents with a persistent, scaly lesion on his ear. The lesion has irregular, everted edges and has been gradually growing as shown below. Which of the following is the most common causative factor for his condition? (Q849567)

A. Tobacco Use

B. Arsenic Exposure

C. Sunlight Exposure

D. Radiation Exposure

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 62-year-old male presents with a slow-growing, pearly nodule on his nose. The lesion shows telangiectatic vessels on its surface and has a central depression. Which of the following is the most appropriate diagnostic method to confirm the diagnosis of this skin lesion? (Q849566)

A. Punch Biopsy

B. Wedge Biopsy

C. Excisional Biopsy

D. None of the above

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 65-year-old man presents with a non-healing ulcer on the popliteal surface of his leg that has been present for several months. The ulcer developed at the site of a burn scar he sustained 30 years ago. On examination, the ulcer is painless, slow-growing, and has irregular borders as shown in the image? What is the most appropriate initial management for this patient? (Q849560)

A. Cryotherapy and regular dressing changes

B. Wide local excision followed by flap cover

C. Wide local excision followed by flap cover and radiotherapy

D. Observation and follow-up in 6 months

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 55-year-old man with a history of diabetes presents with a chronic wound on his lower leg. On examination, you observe a well-defined lesion with the following characteristics: The deepest part of the lesion shows exposed muscle tissue. The exposed surface appears red and moist with some granulation tissue. There is a distinct boundary between healthy skin and the wound. A narrow area surrounds the wound where the skin appears different from both the healthy skin and the wound itself. Based on this clinical scenario, which of the following correctly matches the described features with the parts of an ulcer? (Q849558)

A. Exposed muscle - Floor; Red, moist surface with granulation - Base; Boundary of healthy skin - Edge; Narrow surrounding area - Margin

B. Exposed muscle - Base; Red, moist surface with granulation - Floor; Boundary of healthy skin - Margin; Narrow surrounding area - Edge

C. Exposed muscle - Floor; Red, moist surface with granulation - Base; Boundary of healthy skin - Margin; Narrow surrounding area - Edge

D. Exposed muscle - Base; Red, moist surface with granulation - Edge; Boundary of healthy skin - Floor; Narrow surrounding area - Margin

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following is not a type of fasciocutaneous flap? (Q849557)

A. Radial forearm flap

B. Groin flap

C. Tensor fascia lata flap

D. Scapular flap

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following is not an absolute indication for flap surgery? (Q849556)

A. Post-burn contractures

B. Exposed bony prominences in the joint area

C. Radiated vessel

D. Stage III bedsores

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 30-year-old patient with extensive third-degree burns requires skin grafting. The surgical team opts for a meshed split-thickness skin graft (STSG). Which of the following is a key benefit of using a meshed skin graft in this scenario? (Q849555)

A. Enhanced cosmetic appearance

B. Coverage of a large area with minimal donor skin

C. Reduced risk of secondary contraction

D. Decreased need for vascularization

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 45-year-old male undergoes a split-thickness skin graft for a large wound on his leg. Three days postoperatively, the graft appears swollen with fluid accumulating underneath it. Which of the following complications is most likely? (Q849554)

A. Graft failure

B. Hematoma or seroma formation

C. Infection

D. Poor cosmetic outcome

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A patient needs a graft to cover a small, non-weight-bearing area that is prone to contraction. Which type of graft would be most appropriate to minimize the risk of contraction? (Q849553)

A. Thiersch graft, due to its minimal contraction

B. Wolfe graft, due to its full-thickness nature

C. Split-thickness graft, because it can cover larger areas

D. Composite graft, because it includes skin and underlying tissue

See Answer in Part B → Q28

@Neet_pg_bot

Q29: During a skin grafting procedure, the surgeon opts for a tool that can precisely control the thickness of the graft to ensure uniformity. Which of the following instruments is most appropriate for this task? (Q849552)

A. Surgical scissors

B. Dermabrader

C. Ferris-Smith forceps

D. Electric dermatome

See Answer in Part B → Q29

@Neet_pg_bot

Q30: Match the following types of ulcers with their characteristic edge appearance: Conditions Edges 1. Healing Ulcer a. Punched-out edges 2. Ischaemic Ulcer b. Undermined edges 3. Tubercular Ulcer c. Sloping edges 4. Basal Cell Carcinoma d. Everted edges 5. Squamous Cell Carcinoma e. Rolled or Pearly white edges (Q849559)

A. 1-c, 2-a, 3-b, 4-d, 5-e

B. 1-b, 2-c, 3-a, 4-d, 5-e

C. 1-c, 2-a, 3-b, 4-e, 5-d

D. 1-b, 2-c, 3-a, 4-e, 5-d

See Answer in Part B → Q30

Q13 (p. 809)

Q1: A 75-year-old bedridden patient is admitted to the hospital with pneumonia. During routine care, the nurse notices an area of redness and tissue breakdown over the patient's sacrum. The patient has been immobile for several days due to weakness. Which of the following statements is incorrect regarding pressure sores? (Q849533)

A. Pressure sores occur when external pressure exceeds capillary occlusive pressure of 30 mm Hg

B. Malnutrition and neurological deficits are contributing factors to pressure sore development

C. The most common site for pressure sores is the greater trochanter

D. In case of pressure sores on Malleolus, lateral is more commonly affected than medial

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 75-year-old bedridden patient in a long-term care facility is found to have a pressure sore on his sacral area during a routine skin assessment. Upon examination, the nurse notices a deep, crater-like wound extending through the dermis into the subcutaneous tissue. The base of the wound appears red, and there is no visible bone, tendon, or muscle. Based on the staging system for pressure sores, how would this be classified? (Q849536)

A. Stage IV

B. Stage II

C. Stage III

D. Stage I

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 25-year-old woman presents with a raised, firm, reddish-purple lesion extending beyond the margins of a surgical scar on her chest. The scar is from a surgery performed 8 months ago. The lesion is pruritic and occasionally painful. Which of the following is the most likely diagnosis? (Q849542)

A. Hypertrophic scar

B. Keloid

C. Dermatofibroma

D. Malignant transformation of the scar

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following best describes the proliferative phase of wound healing? (Q849523)

A. Vasoconstriction and thrombus formation

B. Fibroblast activity and collagen production

C. Maturation of collagen

D. Recruitment of neutrophils and macrophages

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following factors is most likely to adversely affect wound healing? (Q849524)

A. Proper oxygenation

B. Vitamin A supplementation

C. Ionizing radiation

D. Normal body temperature

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 50-year-old woman undergoes an elective cholecystectomy. How would you classify this surgical wound? (Q849525)

A. Class I

B. Class II

C. Class III

D. Class IV

See Answer in Part B → Q6

@Neet_pg_bot

Q7: All of the following measures help prevent surgical site infections except: (Q849526)

A. Minimizing postoperative hospital stay

B. Proper hand hygiene and surgical scrubbing

C. Prolonged use of postoperative drains

D. Administering pre-operative antibiotics at induction

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A patient presents with a large, open wound on the lower leg that has been left to heal naturally without surgical closure. This type of healing is best described as: (Q849527)

A. Healing by primary intention

B. Healing by secondary intention

C. Healing by tertiary intention

D. Delayed primary closure

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 68-year-old diabetic patient presents with a non-healing ulcer on their heel that has persisted for 4 months despite regular dressing changes and offloading. The image showing the wound is given below. Based on this clinical scenario, which of the following statements is incorrect? (Q849530)

A. Chronic wound is a wound that persists beyond 4-12 weeks from its first appearance

B. Delay in healing most commonly occurs due to prolonged inflammatory phase

C. Pain is initially severe, but disappears with time due to nociceptor damage

D. Examples of chronic wounds include vascular ulcers, diabetic ulcers, and pressure sores

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 35-year-old factory worker presents to the emergency department with a severe injury to his right forearm after it was caught in a machine, as shown in the picture below. Which of the following statements is incorrect with respect to the injury? (Q849531)

A. It occurs due to shearing force between tissue planes, usually between subcutaneous tissue and deep fascia or between muscle and bone.

B. Skin viability is assessed using Fluorescein injection under anesthesia

C. Characteristic Morel-Lavallée lesion can be seen due to edema of surrounding viable tissue around the wound

D. Treatment primarily involves a multidisciplinary approach which may require amputation

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 25-year-old man is brought to the emergency department following a motorcycle accident. He has a closed fracture of the right tibia and complains of severe pain in his right lower leg. On examination, there is pain on passive stretching of the affected limb and distal sensory disturbances are noted. The emergency physician suspects compartment syndrome. Which of the following is the most applicable next step in an ideal clinical setting in the management of the patient? (Q849532)

A. Immediate fasciotomy without further investigation

B. Measurement of compartment pressure

C. Application of a compression bandage to reduce swelling

D. Administration of intravenous antibiotics

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 65-year-old bedridden patient presents with a stage III pressure sore on the sacrum. Which of the following is the most appropriate initial management approach? (Q849537)

A. Immediate surgical debridement

B. Application of hydrocolloid dressing

C. Negative pressure wound therapy

D. Flap reconstruction

See Answer in Part B → Q12

@Neet_pg_bot

Q13: What is the maximum tensile strength that a mature scar can achieve compared to normal skin? (Q849540)

A. 20-30%

B. 40-50%

C. 70-80%

D. 90-100%

See Answer in Part B → Q13

Q1: A 7-year-old boy is brought to the emergency department 6 hours after sustaining burns involving 22% of total body surface area (TBSA). On examination, he has cool extremities, blood pressure 92/50 mmHg, pulse rate 56/min, and urine output <0.5 mL/kg/hour since the burn. What is the most appropriate next step in management? (Q866923)

A. Administer a crystalloid bolus of 10–20 mL/kg (Ringer’s lactate)

B. Start colloid infusion for volume expansion

C. Proceed with surgical intervention for burn wound management

D. Initiate fluid resuscitation at 30 mL/kg/hour

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A patient presented with a 0.3 cm nodule on the left nasolabial fold. It was excised, and a pathological examination was done. What is the diagnosis? (Q855808)

A. Basal cell carcinoma

B. Melanoma

C. Squamous cell carcinoma

D. Nevus

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 4-year-old child presents with burn injuries after accidental contact with a hot metal surface. Examination shows burns involving the entire posterior trunk, the upper half of the anterior trunk, and the anterior and posterior surfaces of both arms. Using the pediatric Lund and Browder chart, estimate the total body surface area (TBSA) burned. (Q855773)

A. 15-20%

B. 25-30%

C. 35-40%

D. 10-15%

See Answer in Part B → Q3

@Neet_pg_bot

Q4: The image below shows a pressure sore. Which stage does this belong to? (Q855758)

A. Stage 1

B. Stage 2

C. Stage 3

D. Stage 4

See Answer in Part B → Q4

@Neet_pg_bot

Q5: What is the preferred management of the condition in the image below? (Q859868)

A. Surgical excision

B. Radiotherapy

C. Antibiotics

D. Intralesional steroids

See Answer in Part B → Q5

@Neet_pg_bot

Q6: What is the probable diagnosis for the lesion developed by a patient after 6 months of undergoing a surgery, as depicted below? (Q859844)

A. Hypertrophic scar

B. Atrophic scar

C. Keloid scar

D. Contracture

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 23-year-old man presented with a burn injury. He is covered with burns on his head & neck, both upper limbs, front and back of the chest. Calculate the percentage of burns. (Q856257)

A. 27%

B. 36%

C. 45%

D. 18%

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following statements regarding Marjolin's ulcer is not true? (Q857471)

A. It is seen in sites of chronic wounds or scars

B. It rapidly progresses to malignancy

C. It can progress to squamous cell carcinoma

D. It is radioresistant due to avascularity

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 65-year-old man who has the following lesion over the face. He complains of bleeding while itching. The most likely diagnosis is (Q857457)

A. Dermatofibrosarcoma

B. Marjolin’s ulcer

C. Basal cell carcinoma

D. Naevus

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Pressure greater than __ mm of Hg causes pressure sores.: (Q857264)

A. 33

B. 45

C. 54

D. 67

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A patient who underwent surgery for a lipoma 5 weeks ago now presents with a scar at the incision site that is limited to the original wound boundaries. What is the most likely diagnosis? (Q857170)

A. Keloid

B. Exuberant granulation

C. Hypertrophic scar

D. Granulation tissue

See Answer in Part B → Q11

@Neet_pg_bot

Q12: What is the preferred management of angular dermoid cyst? (Q857146)

A. Surgical excision

B. Wait and watch

C. Wide local excision with a 2 cm margin

D. Laser ablation

See Answer in Part B → Q12

@Neet_pg_bot

Q13: In the case of a woman who has suffered third and fourth degree burns on her back, what would be the appropriate sequence of steps in her treatment? (Q793406)

A. Resuscitation – reconstruction – debridement

B. Resuscitation – debridement – allograft or autograft

C. Debridement – resuscitation – autograft

D. Debridement – reconstruction – resuscitation

See Answer in Part B → Q13

@Neet_pg_bot

Q14: What type of graft is used when a patient undergoes skin grafting following a road traffic accident in which the graft is harvested from the patient's own body? (Q857870)

A. Autograft

B. Xenograft

C. Allograft

D. Isograft

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 56-year-old female was treated for a burn wound in the lower limb 5 years ago. Now she has developed an ulcer in the burn scar as shown in the image below. What is the most probable diagnosis ? (Q820097)

A. Marjolin’s ulcer

B. Venous ulcer

C. Arterial ulcer

D. Cellulitis

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Estimate the extent of injury for a patient with burns involving front of the chest & abdomen, right upper limb, and right thigh(Anterior). (Q857246)

A. 45%

B. 27%

C. 36%

D. 31.5%

See Answer in Part B → Q16

@Neet_pg_bot

Q17: How does the graft get nutrition on day 3? (Q844293)

A. Imbibition

B. Inosculation

C. Neovascularization

D. None

See Answer in Part B → Q17

@Neet_pg_bot

Q18: What type of dressing is used to cover this post burn wound? (Q844314)

A. Split thickness skin graft

B. Full thickness skin graft

C. VAC dressing

D. Normal sumag dressing

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 30 year old female was brought to EMR after fire on examination of lower limb full-thickness burns and deep partial-thickness burns were present involving it Circumferentially, procedure was performed as given below, identify the procedure? (Q866414)

A. Escharotomy

B. Debridement

C. Excised to healthy tissue fat/fascia

D. Early skin grafting

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following is correct regarding nerve grafts: Nerve graft is used for peripheral nerves It is used for surgical repair of facial nerve palsy Most common nerve grafts are saphenous nerve and anterior interosseous nerve Nerve graft can be reconstructed only with fibrin glue (Q865378)

A. 2, 3

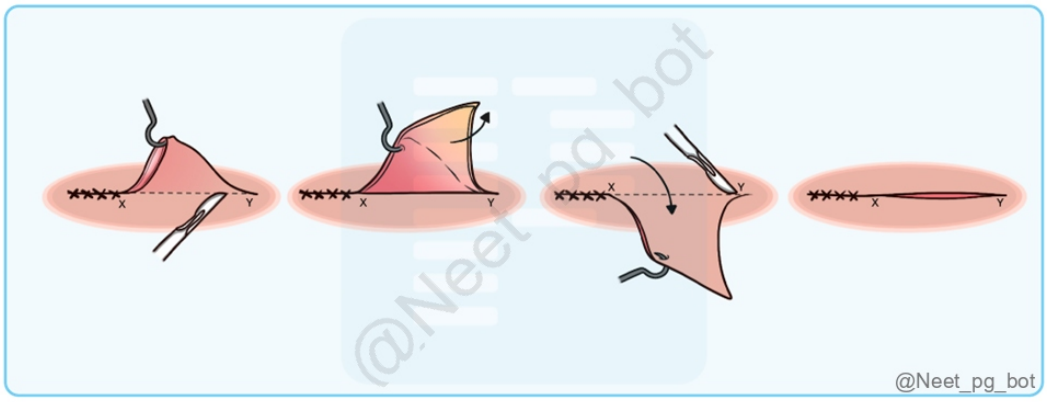
B. 1, 3, 4

C. 1, 2

D. 1, 2, 3

See Answer in Part B → Q20

@Neet_pg_bot



Q21: The following approach is used in: (Q865375)

A. Keloid excision

B. Abscess Drainage

C. Correcting Dog ear

D. Split thickness skin graft

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Identify the procedure given below in the image? (Q865299)

A. Transposition flap is used for scar revision

B. Split-thickness skin grafting

C. Repositioning flap without transposition

D. Tissue transplantation

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A patient underwent split-thickness skin grafting for a burn injury on the arm. On post-operative day 6, he develops stiffness of the arm during physiotherapy. What is the most appropriate next step in management? (Q866899)

A. Surgical excision of contracture

B. Passive extension of the joint under direct visualization of the graft

C. Continue physiotherapy without intervention

D. Remove the graft and regraft the area

See Answer in Part B → Q23

@Neet_pg_bot

Q24: What does the inclusion of a split-thickness skin graft in wound closure on the thigh entail? (Q793440)

A. Epidermis and full dermis

B. Epidermis and variable part of the dermis

C. Epidermis, dermis and fat

D. Epidermis only

See Answer in Part B → Q24

Q1: Which of the following is the most common type of soft tissue sarcoma in adults? (Q849395)

A. Leiomyosarcoma

B. Liposarcoma

C. Rhabdomyosarcoma

D. Angiosarcoma

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 60-year-old male presents with a rapidly enlarging mass in the retroperitoneal area. Imaging reveals a large, heterogeneous mass with areas of necrosis. A biopsy confirms the diagnosis of dedifferentiated liposarcoma . What is the most common cause of death in patients with this condition? (Q849396)

A. Hemorrhage due to tumour rupture

B. Metastasis to lungs

C. Infection secondary to immunosuppression

D. Local recurrence leading to organ failure

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following malignant tumours is known for spreading through both hematogenous and lymphatic routes? (Q849397)

A. Liposarcoma

B. Leiomyosarcoma

C. Angiosarcoma

D. Rhabdomyosarcoma

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old male presents with a rapidly enlarging, painless mass in his right thigh, which has been growing over a few months. The mass is firm, deep-seated, and non-tender on examination. Which of the following is the most appropriate next step to establish a definitive diagnosis? (Q849398)

A. Contrast-Enhanced CT (CECT)

B. MRI

C. Tru-cut biopsy

D. PET-CT

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 60-year-old male presents with a rapidly growing, painless mass in the upper arm. Imaging shows that the mass is located deep in the fascia, and biopsy results indicate poorly differentiated pleomorphic cells with high mitotic activity. What is the most important prognostic factor for this patient's soft tissue sarcoma? (Q849400)

A. Tumor Size

B. Presence of Necrosis

C. Depth of Tumor

D. Histological Grade

See Answer in Part B → Q5

@Neet_pg_bot

Q6: In the surgical management of soft tissue sarcoma, which of the following criteria is most appropriate for achieving optimal outcomes? (Q849402)

A. Wide local excision with a 1 cm margin

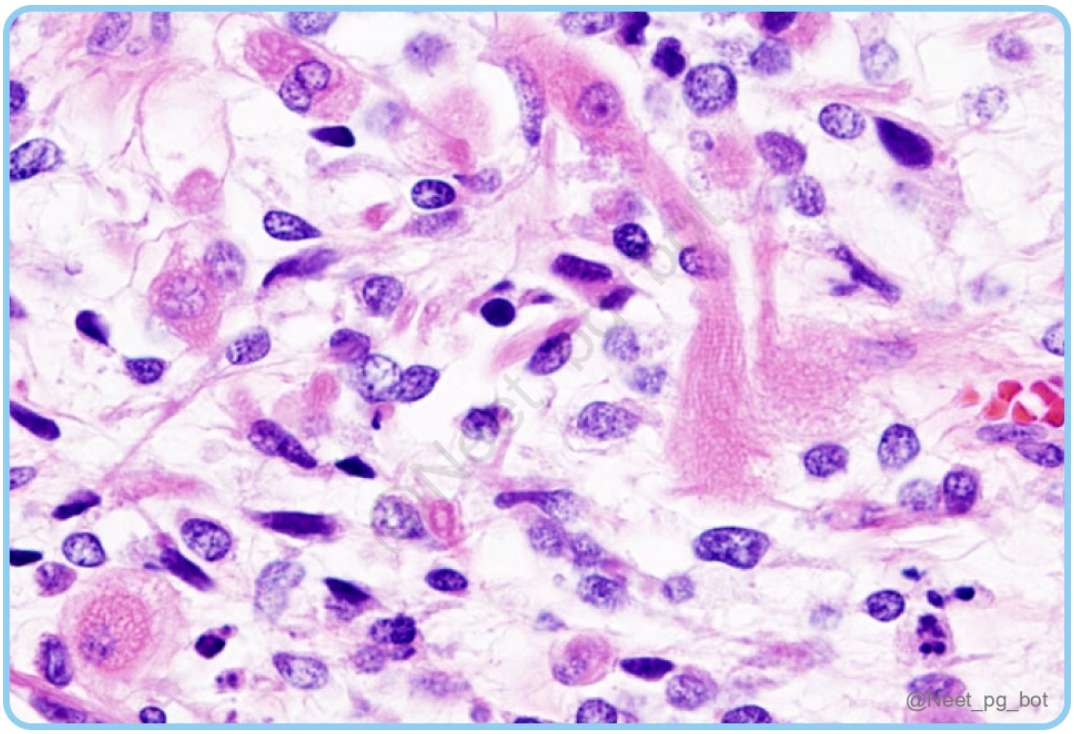
B. Radical excision with removal of adjacent muscle groups

C. Wide local excision with a 2 cm margin

D. Radical excision with lymph node removal

See Answer in Part B → Q6

@Neet_pg_bot



Q7: A 6-year-old boy has a rapidly growing 3 cm mass in his right cheek. Biopsy shows small round blue cells, alveolar patterns, eosinophilic cytoplasm with cross-striations, and positive immunochemistry for desmin and myogenin. What is the most likely diagnosis? (Q849403)

A. Ewing sarcoma

B. Neuroblastoma

C. Rhabdomyosarcoma

D. Lymphoma

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 58-year-old woman is diagnosed with a high-grade retroperitoneal liposarcoma. After treatment, her oncologist monitors for metastases. What's the most common site of metastasis for retroperitoneal sarcomas? (Q849414)

A. Lungs

B. Liver

C. Bone

D. Brain

See Answer in Part B → Q8

@Neet_pg_bot

Q9: In unresectable or metastatic Dermatofibrosarcoma Protuberans (DFSP), which targeted therapy is considered the drug of choice? (Q849416)

A. Vemurafenib

B. Imatinib

C. Pembrolizumab

D. Dabrafenib

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following is NOT a critical metabolic derangement typically observed in tumour lysis syndrome? (Q849417)

A. Hyperkalemia

B. Hyperuricemia

C. Hypercalcemia

D. Hyperphosphatemia

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 50-year-old male who has been taking chemotherapy for chronic leukaemia for 2 years was having shortness of breath, dizziness, and flank pain for 3 days. His investigations revealed elevated serum uric acid, phosphate and potassium levels and decreased calcium levels. Which of the following is not the management of this condition? (Q849419)

A. Aggressive hydration

B. Allopurinol

C. Bisphosphonates

D. Hemodialysis

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 48-year-old male with small cell carcinoma of the lung presents with cyanosis of the neck and face, epistaxis, headache, dizziness and swelling over the face, neck and upper chest. He is irregular regarding chemotherapy sessions. Chest x-ray revealed a widening of the superior mediastinum. What is the investigation of choice in this condition? (Q849420)

A. Chest x-ray

B. MRI

C. Ultrasound

D. CT scan

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements regarding desmoid tumours is NOT true? (Q849421)

A. It is often associated with FAP (familial adenomatous polyposis)

B. It arises in musculoaponeurotic structures

C. It is more common in females than males

D. Estrogen inhibits its growth

See Answer in Part B → Q13

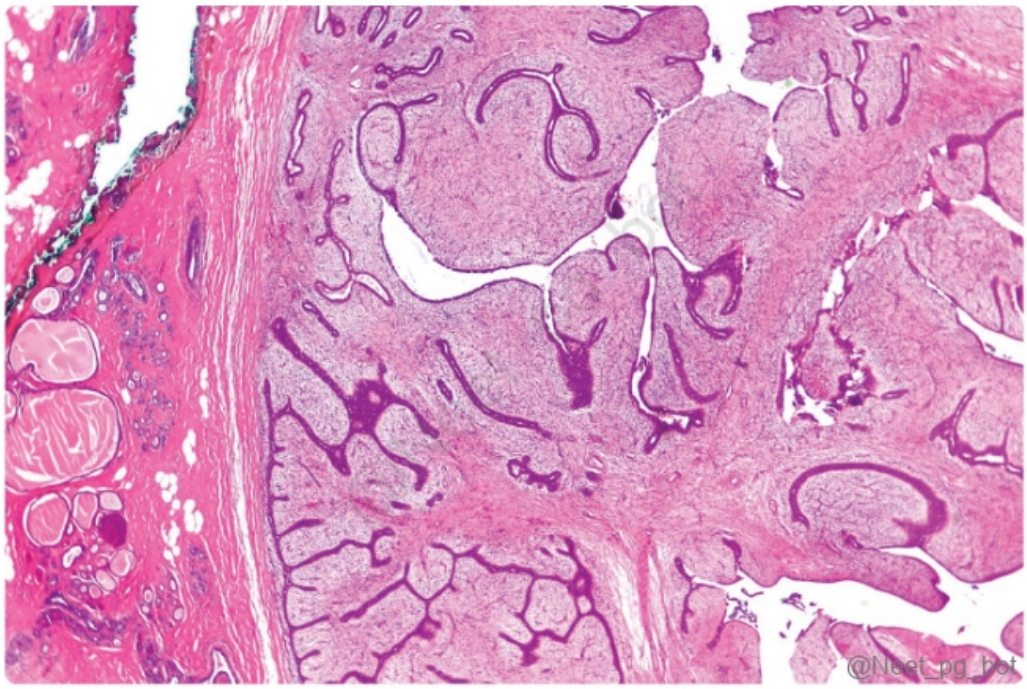
Q13 (p. 837)	*Q14 (p. 838)*	*Q15 (p. 838)*	*Q16 (p. 838)*	*Q17 (p. 839)*	



Q1: A 30-year-old female presents to the OPD with a 3 cm breast lump in the upper medial quadrant . The lump has an uneven, bosselated surface , and the overlying skin is mildly ulcerated . Microscopic examination reveals the given findings. What is the most likely diagnosis? (Q852716)

A. Phyllodes tumor

B. Galactocele

C. Fibroadenoma

D. Paget's disease

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A patient present with abdominal pain on evaluation patient has raised mucin and CEA levels and normal amylase what might be the diagnosis? (Q879136)

A. Serous cystadenoma of pancreas

B. Pseudocyst of pancreas

C. Mucinous cystic neoplasm of pancreas

D. Intraductal papilloma of pancreas

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 40-year-old man presents with a lesion over his left ear. It slowly grew in size over the past 3 months, and he is a chronic smoker with 20 pack years. Vitals are within normal limits, and his physical examination is otherwise unremarkable. The histopathologic evaluation shows keratin pearls. What is the most likely diagnosis for this patient? (Q859628)

A. Nodular melanoma

B. Basal cell carcinoma

C. Squamous cell carcinoma

D. Malignant melanom

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 50-year-old lady presented with a 1.5 cm pigmented lesion on her face that was growing rapidly in size and associated with itching. The lesion is shown below. Which of the following is likely the diagnosis? (Q859627)

A. Dysplastic nevus

B. Congenital melanocytic nevus

C. Acquired melanocytic nevus

D. Malignant melanoma

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Most common primary source of metastasis to the brain is: (Q859618)

A. Thyroid

B. Lung

C. Liver

D. Breast

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A factory worker working in a plastic pipe factory presented to the OPD with weight loss and right upper quadrant abdominal pain for 6 months duration. He had hepatomegaly. Further investigation revealed that most of the liver was replaced by a

hemorrhagic tumour with extensive necrosis. What can be the likely diagnosis in this case? (Q859608)

A. Cavernous hemangioma

B. Metastatic carcinoma of the liver

C. Angiosarcoma of the liver

D. Primary hepatocellular carcinoma

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following is the most commonly seen tumour in the retroperitoneal space? (Q856278)

A. Liposarcoma

B. Rhabdomyosarcoma

C. Synovial sarcoma

D. Neurofibroma

See Answer in Part B → Q7

@Neet_pg_bot

Q8: What is the most likely primary site of origin for metastatic liver adenocarcinoma with CK 7 (-), CK 20 (+), and CDX-1 (+) IHC markers? (Q856231)

A. Colon carcinoma

B. Breast carcinoma

C. Pancreatic carcinoma

D. Ovarian carcinoma

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Match the following: A. Marjolin ulcer over the dorsum of foot measuring 3cm x 2cm 1. Excision biopsy B. 1.5 cm cervical lymph node in the neck 2. Core needle biopsy C. Soft tissue sarcoma over mid-thigh 3. USG guided FNAC D. Solitary thyroid nodule 4. Wedge biopsy (Q855301)

A. A-1, B-2, C-3, D-4

B. A-4, B-1, C-2, D-3

C. A-3, B-2, C-1, D-4

D. A-4, B-3, C-2, D-1

See Answer in Part B → Q9

@Neet_pg_bot

Q10: What is the meaning of neoadjuvant chemotherapy in the context of a 54-year-old woman diagnosed with stage 2A cervical cancer? (Q855282)

A. Chemotherapy is given along with radiation.

B. Chemotherapy is given during surgery.

C. Chemotherapy is given before radical surgery to reduce the bulk of the tumour.

D. Chemotherapy is given after radical surgery for micrometastases.

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A patient with a known case of HTN came in with complaints of headaches for five days. All classical signs, increased metanephrine levels, and other investigations indicate pheochromocytoma. What is the best imaging modality for this patient? (Q820147)

A. CECT Chest and Abdomen

B. Sestamibi scan

C. MIBG

D. USG

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 45-year-old female presents with redness and a Peau d'orange appearance involving more than 2/3 of her breast, without any palpable lump in the breast. On further evaluation, it is found that the skin involvement extends to the chest wall and is suggestive of inflammatory carcinoma . What is the appropriate TNM staging for this patient? (Q820110)

A. T4a

B. T4b

C. T3

D. T4d

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A female presents with a non-palpable lump in the breast. The biopsy and IHC results reveal Luminal A. What characteristics are included under Luminal A? (Q857277)

A. ER positive, PR positive, Her2 neu positive

B. ER positive, PR positive, Her2 neu negative with low proliferation

C. ER positive, PR positive, Her2 neu negative with high proliferation

D. Triple-negative

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Spread of prostate cancer to lumbar vertebra is via? (Q852720)

A. Arterial spread

B. Local spread

C. Lymphatic spread

D. Venous spread

See Answer in Part B → Q14

@Neet_pg_bot

Q15: In a follow-up case of prostate cancer, what do we need to check? (Q852724)

A. Alkaline phosphatase

B. PSA

C. Testosterone

D. Acid phosphatase

See Answer in Part B → Q15

@Neet_pg_bot

Q16: What is the T stage for this tumour in the oral cavity? (Q853071)

A. T3

B. ■■■T4a

C. T2

D. ■■■T4b

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the following drugs is preferred for lowering uric acid to prevent renal damage in tumor lysis syndrome ? (Q793897)

A. Furosemide

B. Rasburicase

C. Corticosteroids

D. Febuxostat

See Answer in Part B → Q17

Q1: Match the following 1. Urine Bag 2. Nasogastric Tube 3. Underwater seal bag 4. Suction cannula (Q856303)

A. 1-D, 2-C, 3-A, 4-B

B. 1-C, 2-A, 3-B, 4-D

C. 1-D, 2-A, 3-C, 4-B

D. 1-B, 2-A, 3-C, 4-D

See Answer in Part B → Q1

@Neet_pg_bot

Q2: What steps should be taken to manage the case of a 24-year-old male who was hit by a motorbike while crossing the road, leading to abdominal injuries and bruising, with a blood pressure of 88/60 and IV fluids already administered, along with a positive FAST examination? (Q857115)

A. Abdominal CT scan

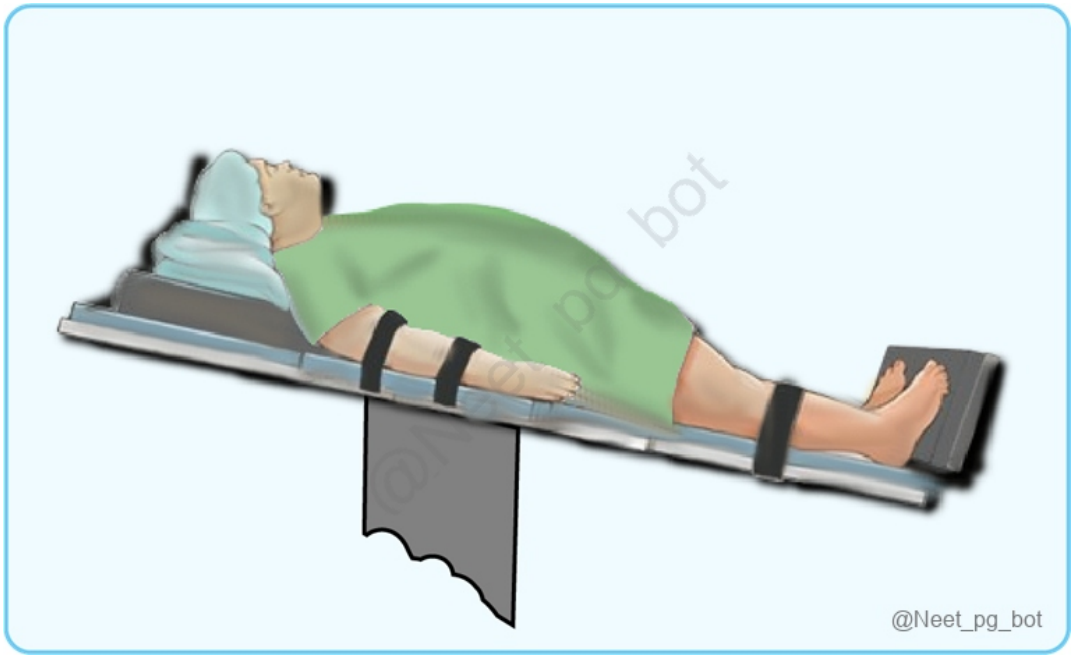
B. Abdominal MRI scan

C. Exploratory laparotomy

D. Diagnostic peritoneal lavage

See Answer in Part B → Q2

@Neet_pg_bot



Q3: The position of the patient in the image shown below is known as: (Q856730)

A. Lloyd Davis position

B. Jack knife position

C. Trendelenburg position

D. Reverse Trendelenburg position

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following methods is accurate for measuring the nasogastric tube? (Q856572)

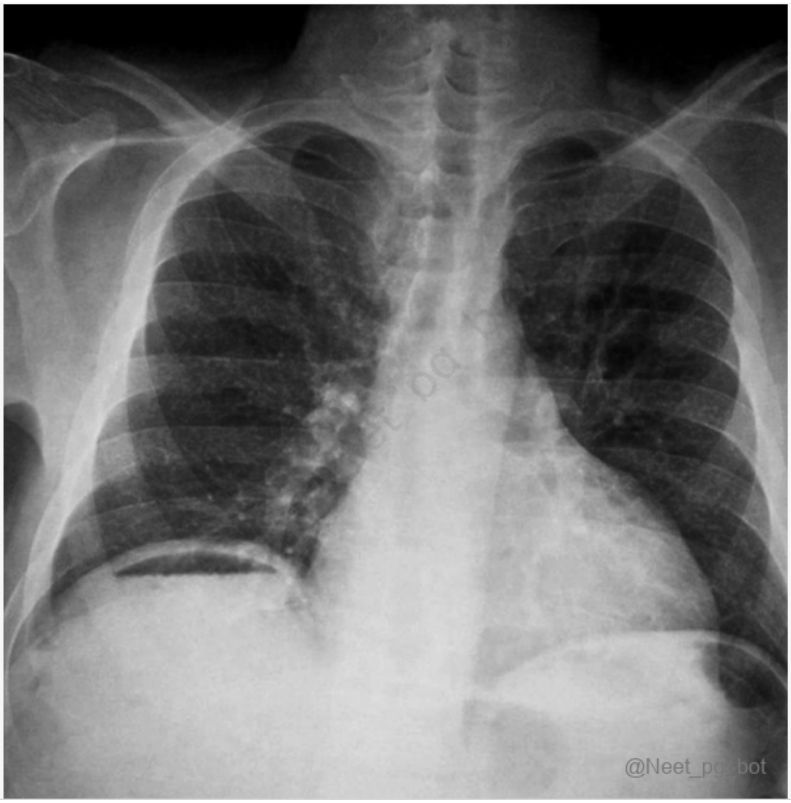
A. Tip of nose to ear lobule to xiphisternum

B. Angle of mouth to tragus to xiphisternum

C. Ala of nose to angle of mandible to xiphisternum

D. Angle of mouth to ear lobule to umbilicus

See Answer in Part B → Q4



Q5: What might you suspect as the diagnosis for a 26-year-old male patient who arrives at the emergency department complaining of abdominal pain and constipation persisting for the last three days? The patient recalls being struck in the abdomen by a bull three days ago. Could yo u examine the provided X-ray to aid in your assessment? (Q856561)

A. Hemothorax

B. Hollow viscus perforation

C. Pneumothorax

D. Intestinal obstruction

See Answer in Part B → Q5

Q6: What is the needle placement angle when using the interrupted suturing technique to suture a laceration in the ER? (Q856559)

A. 60 degrees

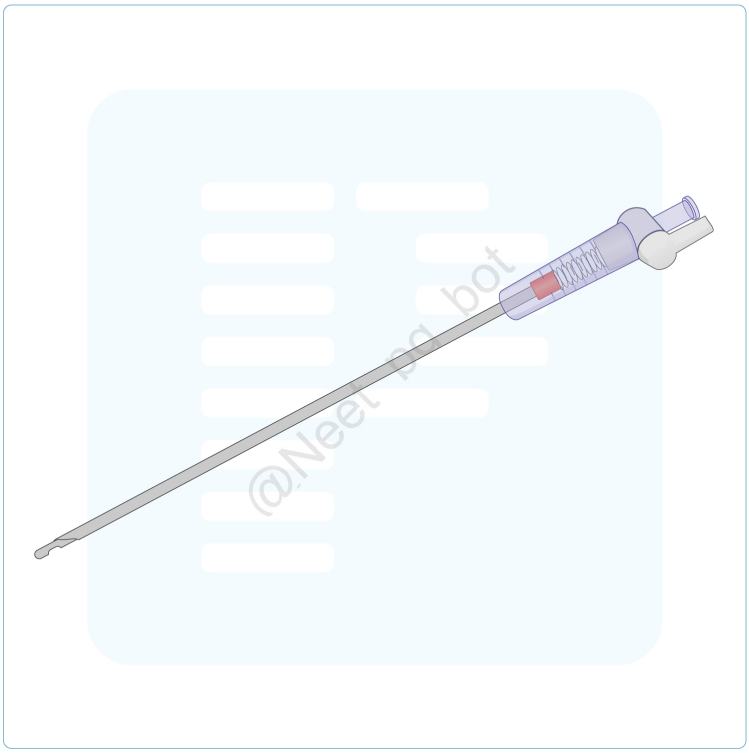
B. 70 degrees

C. 80 degrees

D. 90 degrees

See Answer in Part B → Q6

@Neet_pg_bot



Q7: What is the name of the instrument depicted below, which is utilized for the creation of a pneumoperitoneum? (Q856535)

A. Veress needle

B. Morris' needle

C. Yankauer suction tip

D. Von Graefe needle

@Neet_pg_bot

See Answer in Part B → Q7

@Neet_pg_bot

Q8: What is triage for? (Q856526)

A. To prepare for a disaster

B. To assess the impact of a disaster

C. To classify the priority of treatment

D. To rehabilitate following a disaster

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Match the correct answer related to the nerve injuries in various surgeries: A. Breast surgery 1. External Laryngeal nerve B. Thyroid surgery 2. Hypoglossal nerve

C. Submandibular excision 3. Phrenic nerve D. Thymectomy 4. Long Thoracic Nerve (Q856314)

A. A-1, B-2, C-3, D-4

B. A-2, B-3, C-4, D-1

C. A-3, B-4, C-1, D-2

D. A-4, B-1, C-2, D-3

See Answer in Part B → Q9

@Neet_pg_bot

Q10: The components of qSOFA scoring include: A. Mental status B. Blood pressure C. Respiratory rate D. Heart rate (Q856309)

A. A & B

B. C & D

C. A, B & C

D. A, B, C & D

See Answer in Part B → Q10

@Neet_pg_bot

Q11: In a patient with liver cirrhosis, what is the primary cause of mortality when esophageal varices are present? (Q857119)

A. Hypovolemic shock

B. Cardiogenic shock

C. Obstructive shock

D. Distributive shock

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 32-year-old woman has been declared brain dead, and her family has chosen to donate her organs. Who would be the most suitable recipient of her organs? (Q856294)

A. 14-year-old child with multi-organ dysfunction syndrome

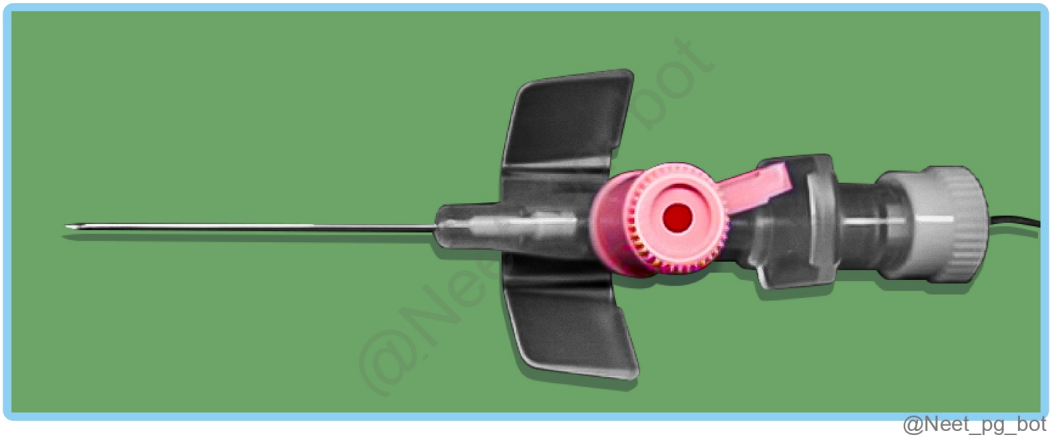
B. 50-year alcoholic man with liver cirrhosis with 1 month abstinence

C. 70-year-old woman with end-stage renal disease

D. 32-year-old woman with renal failure

See Answer in Part B → Q12

@Neet_pg_bot



Q13: What is the size of the cannula shown in the below image? (Q856292)

A. 16 G

B. 18 G

C. 20 G

D. 22 G

See Answer in Part B → Q13

@Neet_pg_bot

Q14: FAST stands for (Q856255)

A. First assessment with sonography in trauma

B. Focussed assessment with sonography in trauma

C. First abdominal sonography in trauma

D. Focussed abdominal sonography in trauma

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A patient, after a road traffic accident, presented with pain in the abdomen. The resident examined the child and found that vitals were stable, and tenderness was present in the left lumbar region. Which is the best investigation of choice? (Q856254)

A. Contrast-enhanced CT scan

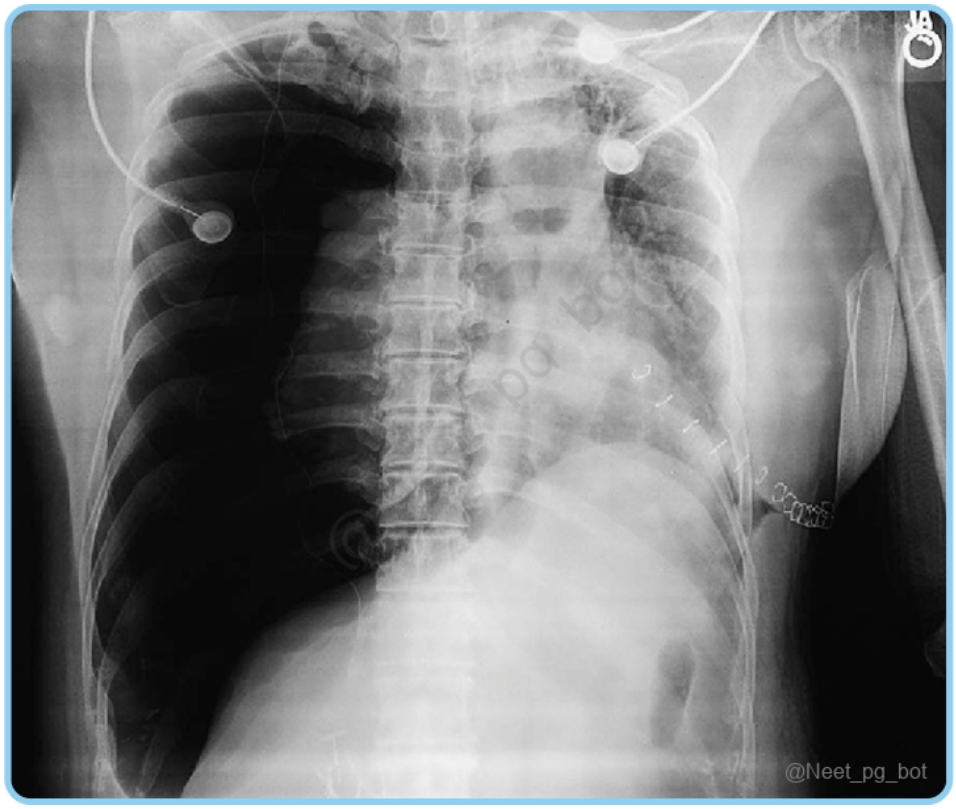
B. Retrograde urethrogram

C. Wait and watch

D. Emergency laparotomy

See Answer in Part B → Q15

@Neet_pg_bot



Q16: A patient following a road traffic accident presented with subcutaneous emphysema. On auscultation, there was no air entry on the right side. Vitals were unstable. What will be your immediate management? (Q856246)

A. Insertion of wide bore needle in the 2nd intercostal space

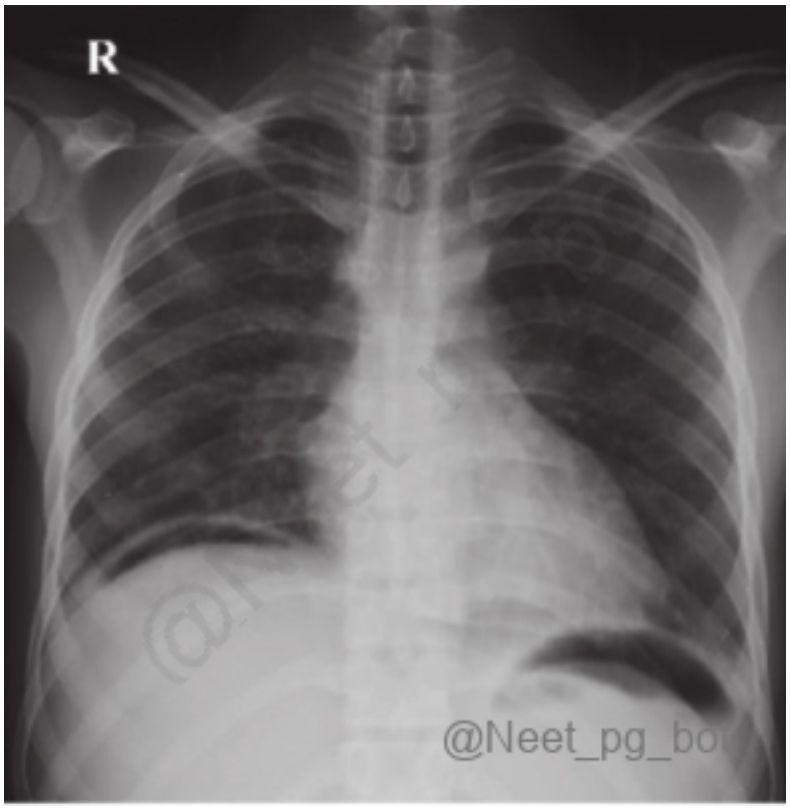
B. Wide bore needle decompression and IV fluids

C. Intubation and positive pressure ventilation

D. e-FAST

See Answer in Part B → Q16

@Neet_pg_bot



Q17: What is the most probable diagnosis for a 25-year-old patient who has been experiencing abdominal pain and fever for the past three days, based on the provided chest X-ray taken in an upright position? (Q856206)

A. Hollow viscus perforation

B. Gastric volvulus

C. Liver abscess

D. Empyema thoracis

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A patient presented with blunt trauma to the abdomen. On evaluation, liver injury was noted, for which primary repair was done. Coagulation function was monitored intraoperatively using the method shown below. What is the method used? (Q855836)

A. Thromboelastography

B. Plethysmography

C. Sonography

D. Elastography

@Neet_pg_bot

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A patient with an incident of being stabbed in the front part of the abdomen is brought to the emergency. The patient's vital signs are stable. What will be the next step in managing this case? (Q855832)

A. Emergency laparotomy

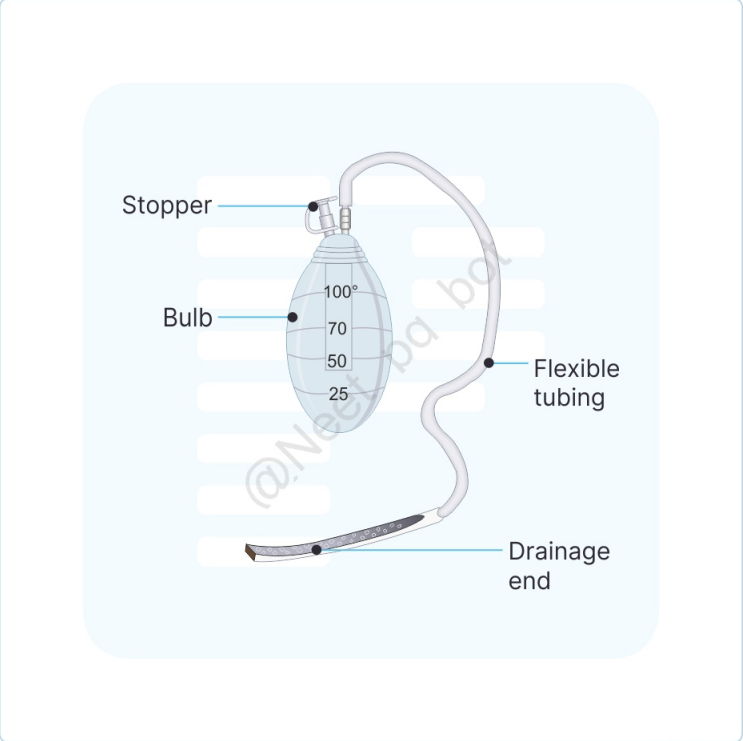
B. Observation

C. Intravenous hydration

D. Further investigation

See Answer in Part B → Q19

@Neet_pg_bot



Q20: A 45-year-old patient undergoes a mastectomy for breast cancer. Post-operatively, the surgeon decides to use a closed suction drain. Which of the following drain types is shown in the image below? (Q858365)

A. Penrose drain

B. Jackson Pratt drain

C. Romovac suction drain

D. Hemovac drain

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which among the following are incorrect about tension pneumothorax? Occurs due to improper dressing of open wound Blunt trauma with simple pneumothorax can never convert to tension pneumothorax Most common cause is due to positive pressure in mechanical ventilation Can be caused due to spinal injury (Q865398)

A. 1, 4

B. 2,3,4

C. 1,2,4

D. 2,3

See Answer in Part B → Q21

@Neet_pg_bot

Q22: All of the following is a contraindication to Breast Conservation surgery except ? (Q865393)

A. Previous history of radiation to the chest

B. Tumor involving single quadrant

C. Scleroderma

D. Persistent positive margins even after resection

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 40-year-old male presents to the emergency department with severe respiratory distress, BP: 70/59 mmHg, tracheal deviation to the right, distended neck veins, and absent breath sounds on the left side. These findings are suggestive of a tension pneumothorax. What is the most appropriate immediate next step in management? (Q865354)

A. Perform needle thoracostomy immediately

B. CT Chest

C. Airway, breathing, and circulation (ABC) assessment

D. Chest tube insertion

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 65-year-old patient is on mechanical ventilation for acute respiratory distress syndrome (ARDS). Suddenly, the patient becomes hypotensive, tachycardic, and shows absent breath sounds on the left side with tracheal deviation to the right. What is the most common cause of this in patients receiving mechanical ventilation? (Q865348)

A. High tidal volume

B. Barotrauma due to high airway pressure

C. Endotracheal tube malposition

D. Oxygen toxicity

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A patient presents with a breast lump, and imaging (X-ray mammography) along with histopathology confirms a diagnosis of breast cancer. She has a family history of breast cancer involving two relatives and has a 29-year-old daughter. Which gene should be tested to assess hereditary breast cancer risk in this patient? (Q865316)

A. BRCA1

B. TP53

C. BRCA2

D. STK11

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Which of the following is not a component of TNM stage T4b breast cancer? (Q865312)

A. Ulceration

B. Peau d’orange

C. Inflammatory carcinoma

D. Ipsilateral macroscopic satellite nodules

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 38-year-old man was brought to the emergency department after sustaining an RTA and injury to the lower chest. On presentation, the patient is stable, and vitals are normal. Chest radiography showed clear lung fields. What is the next step in management? (Q858483)

A. eFAST

B. Tube thoracostomy

C. CECT chest

D. CECT abdomen

See Answer in Part B → Q27

@Neet_pg_bot

Q28: What could be the most likely reason for a patient presenting with chronic non-pitting edema in the lower extremities? (Q858480)

A. Lymphedema

B. Arterial Disorders

C. Venous Disorders

D. Coronary heart disease

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Identify the fluid shown below on the basis of composition: Sodium (Na+) 131 millimoles per liter Chloride (Cl-) 111 millimoles per liter Lactate 29 millimoles per liter Potassium (K+) 5 millimoles per liter Calcium (Ca2+) 2 millimoles per liter Total osmolarity 279 millimoles per liter (Q855761)

A. Haemaccel

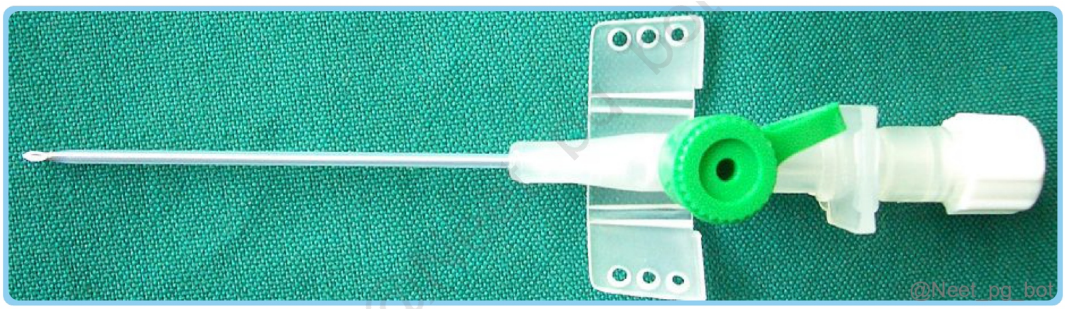
B. Ringer lactate

C. Isolyte

D. Isolyte M

See Answer in Part B → Q29

@Neet_pg_bot



Q30: A patient was received in the casualty following a road traffic accident. His BP was 90/60 mmHg and his pulse rate was 120/min. The emergency room physician asked you to replace the fluid loss in this patient. What is the flow rate of fluid with the IV cannula given in the image? (Q858350)

A. 86ml/min

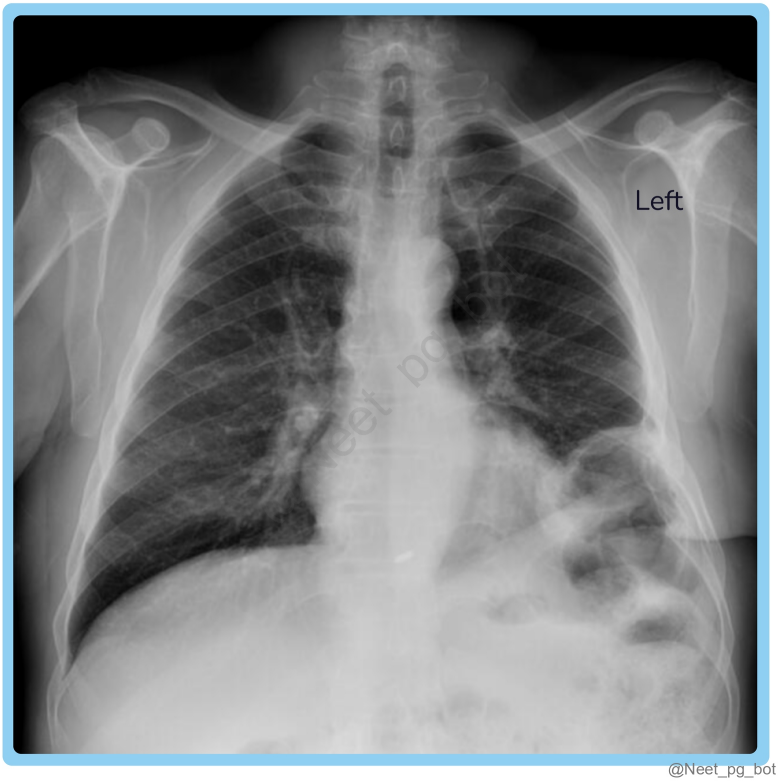
B. 96ml/min

C. 90 ml/min

D. 63ml/min

See Answer in Part B → Q30

@Neet_pg_bot



Q31: A 24-year-old male patient was brought to the emergency department following a road traffic accident. His heart rate was 100/min, respiratory rate was 24/min, and his chest X ray is given below. Which of the following is contraindicated in him? (Q858348)

A. Nasogastric tube insertion

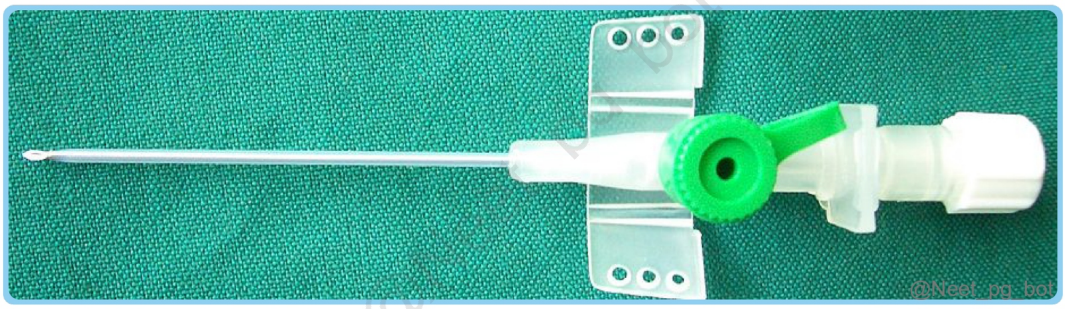
B. Chest tube insertion

C. Log roll

D. Epidural anaesthesia

See Answer in Part B → Q31

@Neet_pg_bot



Q32: What is the size of the cannula gauge used in this picture? (Q858341)

A. 14

B. 16

C. 18

D. 20

See Answer in Part B → Q32

@Neet_pg_bot

Q33: In all types of shock, which of the following is observed? (Q857889)

A. Reduced tissue perfusion

B. Increased peripheral resistance

C. Decreased respiratory rate

D. Cold clammy skin

See Answer in Part B → Q33

@Neet_pg_bot

Q34: Among the options provided, which pairing correctly matches the trauma patients brought to the casualty? (Q857835)

A. Extradural hemorrhage (EDH) - Pin point pupil

B. Penetrating injury to eustachian tube - CSF otorrhea

C. Penetrating injury to eye - Battle sign

D. Gaze palsy - Mid brain lesion

See Answer in Part B → Q34

@Neet_pg_bot

Q35: Which of the following is not included in the qSOFA score components? (Q857805)

A. Respiratory rate >22

B. Lactate dehydrogenase

C. Altered mental status

D. Systolic blood pressure <100 mmHg

See Answer in Part B → Q35

@Neet_pg_bot

Q36: A 38-year-old man was brought to the emergency department after sustaining an RTA and injury to the lower chest. On presentation, the patient is stable, and vitals are normal. Chest radiography showed clear lung fields. What is the next step in management? (Q857798)

A. eFAST

B. Tube thoracostomy

C. CECT chest

D. CECT abdomen

See Answer in Part B → Q36

@Neet_pg_bot

Q37: Which class of hypovolemic shock, according to Advanced Trauma Life Support (ATLS) guidelines, is characterised by the absence of urine output? (Q857765)

A. Class I

B. Class II

C. Class III

D. Class IV

See Answer in Part B → Q37

@Neet_pg_bot

Q38: Among the options provided, which one is NOT acknowledged as a potential complication resulting from a significant blood transfusion? (Q854760)

A. Hypocalcemia

B. Hypokalemia

C. Hypothermia

D. Hypernatremia

See Answer in Part B → Q38

@Neet_pg_bot

Q39: A patient arrives at the emergency department after being involved in a car accident. The patient is experiencing difficulty breathing and their neck veins appear dilated. The x-ray reveals a significant amount of air on the left side. What is the most appropriate course of action for treatment? (Q793363)

A. Wide bore needle insertion in the 5th intercostal space

B. Endotracheal intubation

C. Tracheostomy

D. Pericardiocentesis

See Answer in Part B → Q39

@Neet_pg_bot

Q40: A patient sustained a crush injury on their right arm. He was taken to the hospital and on examination, his arm was pulseless, swollen, and dark red. What would be the best way to manage this case? (Q793385)

A. Intraosseous administration of fluids

B. Acidification of urine

C. Fasciotomy

D. Hemodialysis

See Answer in Part B → Q40

@Neet_pg_bot

Q41: During a complicated delivery, a mother died. Which of the following is the most common Direct cause of maternal death? (Q820108)

A. Embolism

B. Heart Disease

C. Hemorrhage

D. Anemia

See Answer in Part B → Q41

@Neet_pg_bot

Q42: Which fluid is administered most commonly during intraoperative blood loss? (Q820149)

A. Isolyte P

B. Crystalloids

C. Blood

D. Colloids

See Answer in Part B → Q42

@Neet_pg_bot

Q43: A 39-year-old female presented in the OPD with bloody discharge from the nipple . On examination, it was found to be from a single lactiferous duct . What is the treatment for bloody nipple discharge with single duct involvement? (Q820183)

A. Microdochectomy

B. Hadfield’s procedure

C. Microdiscectomy

D. IV antibiotics + Incision

See Answer in Part B → Q43

@Neet_pg_bot

Q44: Which of the following is not correct for the device depicted below: (Q820185)

A. Based on infrared emitted from RBCs

B. Localizes calcified plaque

C. Checks blood flow

D. Checks thickness of artery and vein

@Neet_pg_bot

See Answer in Part B → Q44

@Neet_pg_bot

Q45: A 35-year-old male sustained a head injury following a motorcycle accident. He experienced a brief loss of consciousness at the scene. Upon regaining consciousness, he developed a severe headache and began to feel drowsy. A CT scan of the head is

performed. Which of the following should be the management for this patient? (Q840033)

A. Anticoagulants

B. Immediate surgical decompression

C. Observation in ICU

D. Mannitol administration

See Answer in Part B → Q45

@Neet_pg_bot

Q46: Which of the following is not done in the primary survey of trauma? (Q840042)

A. NCCT head

B. CXR

C. Intubation

D. ICD drainage

See Answer in Part B → Q46

@Neet_pg_bot

Q47: Mount fuji sign on CT is seen in which of the following? (Q840051)

A. Pneumocephalus

B. Pneumoperitoneum

C. Pneumomediastinum

D. Pneumothorax

See Answer in Part B → Q47

@Neet_pg_bot

Q48: Which of the following is a complication usually associated with the procedure shown in the image below? (Q854753)

A. Aspiration

B. Torticollis

C. Pneumothorax

D. Recurrent laryngeal nerve paralysis

See Answer in Part B → Q48

@Neet_pg_bot

Q49: For the purpose of preventing surgical site infection, what is the recommended technique and optimal timing for hair removal prior to surgery? (Q793358)

A. On the OT table with electric hair clippers

B. With a razor 24 hours before surgery

C. With a hair removal cream on the previous day

D. On the OT table with a razor

See Answer in Part B → Q49

@Neet_pg_bot

Q50: What is the minimum platelet count necessary for most surgical procedures? (Q854782)

A. 20,000 (10^9/L)

B. 30,000 (10^9/L)

C. 40,000 (10^9/L)

D. 50,000 (10^9/L)

See Answer in Part B → Q50

@Neet_pg_bot

Q51: Which one of the following is excluded from the primary survey? (Q854940)

A. Measuring blood pressure

B. Removing clothes to inspect for wounds

C. Taking CT scan of the patient

D. Checking airway patency

See Answer in Part B → Q51

@Neet_pg_bot

Q52: Which of the following is not taken into consideration in ASEPSIS wound scoring? (Q854951)

A. Wound swab from the site

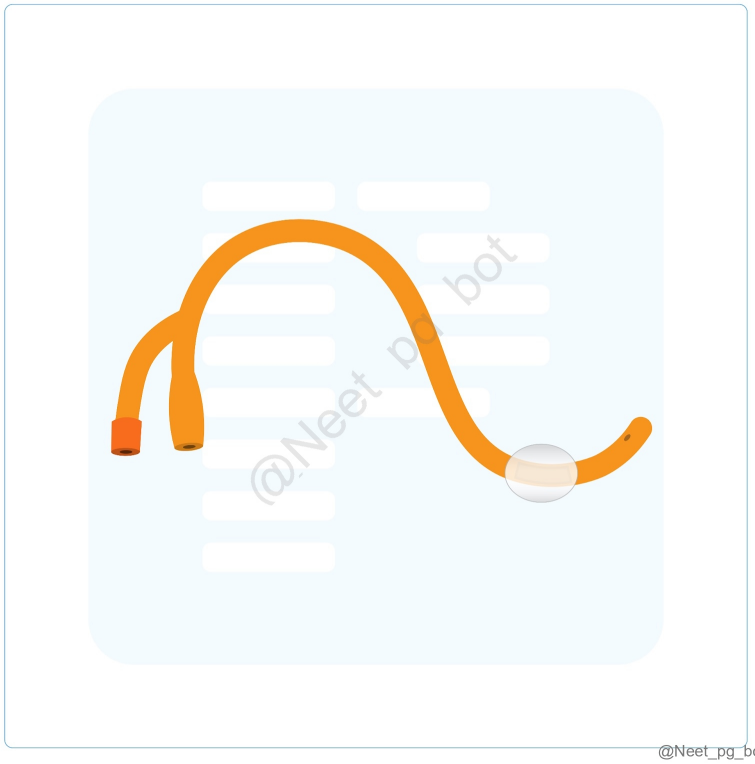
B. Serous discharge

C. Erythema

D. Induration

See Answer in Part B → Q52

@Neet_pg_bot



Q53: What does the number (14Fr) marked on the Foley catheter correspond to? (Q855673)

A. Inner lumen diameter

B. Length of the tube

C. Outer tube diameter

D. Bulb size

See Answer in Part B → Q53

@Neet_pg_bot

Q54: Which of the following statements are true regarding central venous access and peripheral venous access? Phlebitis is the most common complication in peripheral venous access. Isotonic saline and heparin are flushed to retain patency If an arteriovenous fistula is present in a limb, avoid peripheral venous access in the same limb. Vasopressors for septic shock are given in the central line to avoid limb ischemia. (Q855686)

A. 1, 3, 4

B. 2, 3, 4

C. 1, 2, 3, 4

D. 1, 2, 3

See Answer in Part B → Q54

@Neet_pg_bot

Q55: Which of the following statements is accurate concerning split-thickness and full-thickness skin grafts? Primary contractures are more in split skin grafts Secondary contractures are more in split skin grafts Primary contractures are more in full-thickness grafts Secondary contractures are more in full-thickness grafts (Q855680)

A. 2 and 3

B. 2 and 4

C. 1 and 3

D. 1 and 4

See Answer in Part B → Q55

@Neet_pg_bot

Q56: Which of the following options does not represent one of the boundaries of the triangle of safety for the insertion of an ICD in a patient with a chest x-ray showing pneumothorax? (Q855678)

A. Lateral edge of the pectoralis major

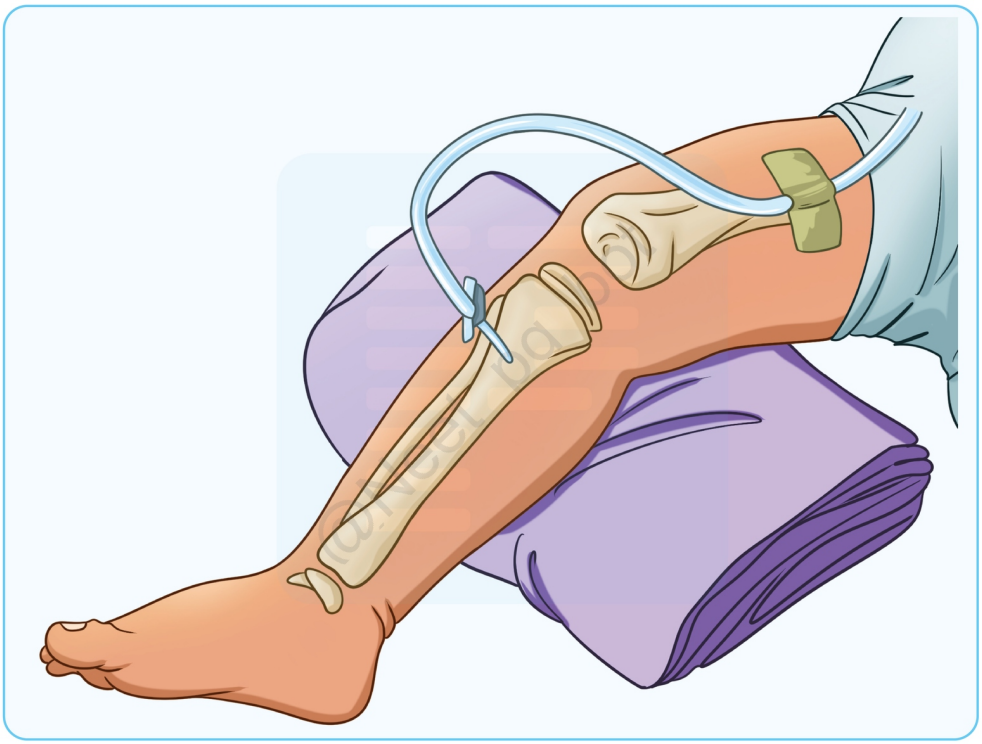
B. Mid-clavicular line

C. 5th intercostal space

D. Lateral border of latissimus dorsi

See Answer in Part B → Q56

@Neet_pg_bot



Q57: Identify the procedure being performed in the image given below. (Q855166)

A. Intraosseous cannula for pain relief

B. Bone marrow aspiration

C. Intraosseous route access for giving IV fluids

D. Bone marrow biopsy

@Neet_pg_bot

See Answer in Part B → Q57

@Neet_pg_bot

Q58: In the case of a patient arriving at the emergency department with a road traffic accident (RTA), what is the appropriate order of steps in their management? Cervial spine stabilisation Intubation IV cannulation CECT (Q855671)

A. 1, 3, 2, 4

B. 1, 2, 3, 4

C. 2, 1, 3, 4

D. 2, 1, 4, 3

See Answer in Part B → Q58

@Neet_pg_bot

Q59: Hand rub can be utilised in accordance with the standard hand hygiene protocol in all locations listed below, with the exception of: (Q855667)

A. If the hands are visibly soiled

B. While moving from a contaminated site to a clean site during patient care

C. After removing sterile gloves

D. During direct patient contact

See Answer in Part B → Q59

@Neet_pg_bot

Q60: Which of these is the most life-threatening injury that can be identified by assessing the breathing component of the patient? (Q855661)

A. Cervical spine injury

B. Tension pneumothorax

C. Blunt cardiac injury

D. Laryngotracheal injury

See Answer in Part B → Q60

@Neet_pg_bot

Q61: According to triage, which of the following categories of patients comes under green? (Q855552)

A. Ambulatory patients

B. Moderate priority

C. High Priority

D. Dead patients

See Answer in Part B → Q61

@Neet_pg_bot

Q62: A patient presents with multiple stab injuries to the chest. On examination, there is reduced chest movement on the right side and tracheal deviation to the left side. Additionally, the neck veins are distended. What is the next best step in the management of this patient? (Q855325)

A. Resuscitative thoracotomy

B. ICD placement

C. Needle thoracocentesis

D. Finger thoracotomy

See Answer in Part B → Q62

@Neet_pg_bot

Q63: Which of the following is true regarding shock? (Q855318)

A. Anaerobic respiration produces carbon dioxide

B. Hypovolaemic shock—most common type

C. Stage of compensatory shock is also called stage 2 of shock

D. Anaphylactic shock—is due to a Type 2 hypersensitivity reaction

See Answer in Part B → Q63

@Neet_pg_bot

Q64: Which one of the options listed below does not belong to the category of damage control surgery? (Q855279)

A. Control of hemorrhage

B. Resuscitation

C. Decontamination

D. Vascular anastomosis

See Answer in Part B → Q64

@Neet_pg_bot

Q65: A young patient presents with a 5-day fever history and signs of hypotension, tachycardia, tachypnea, and altered mental status. Lab results show elevated white blood cell count, neutrophil proportion, and serum creatinine. The intern doctor plans to assess the quick Sequential Organ Failure Assessment (qSOFA) score for prognosis prediction and hospitalisation duration. Which elements are part of the qSOFA score? (Q855275)

A. BP, RR, and CBC

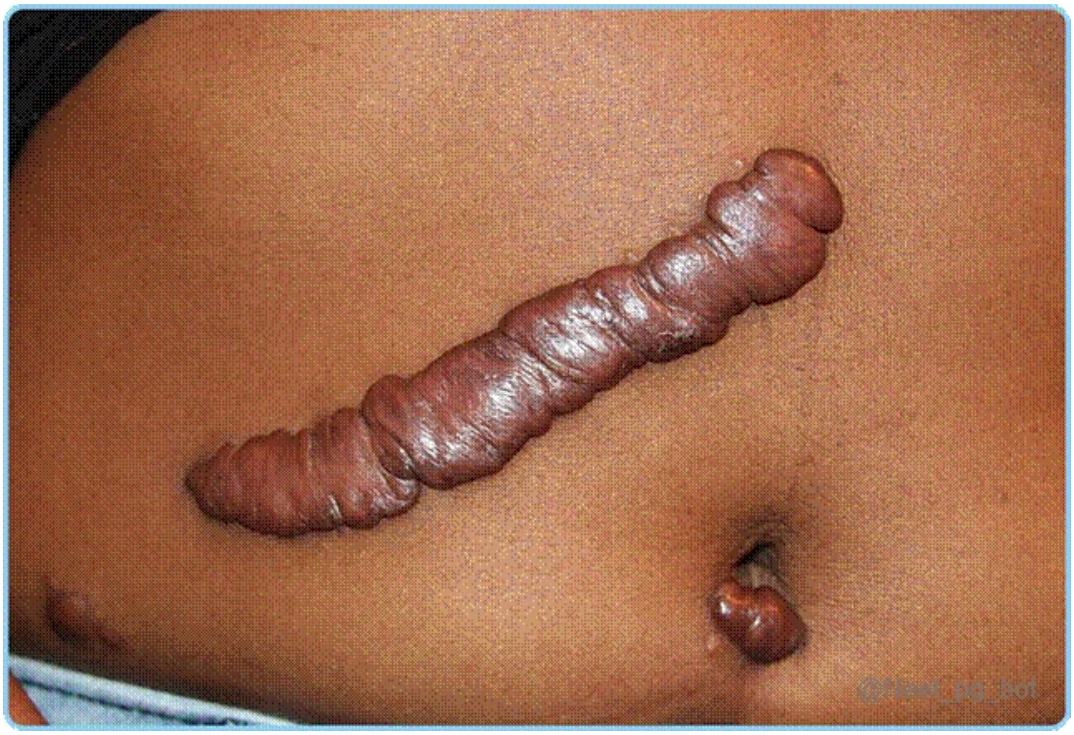
B. Creatinine, PR, and BP

C. RR, Body temperature, and PR

D. SBP, RR, and GCS score

See Answer in Part B → Q65

@Neet_pg_bot



Q66: A patient presents to the clinic with a lesion as shown in the image. He had a traumatic injury to the chest one year ago, and the scar has grown beyond the boundary of the initial injury. What is the most likely diagnosis? (Q855177)

A. Hemangioma

B. Hypertrophic scar

C. Keloid

D. Neurofibroma

See Answer in Part B → Q66

@Neet_pg_bot

Q67: A 38-year-old man was brought to the emergency department after sustaining an RTA and injury to the lower chest. On presentation, the patient is stable, and vitals are normal . Chest radiography showed clear lung fields. What is the next step in management? (Q801160)

A. eFAST

B. Tube thoracostomy

C. CECT chest

D. CECT abdomen

See Answer in Part B → Q67

@Neet_pg_bot

Q68: Which of the following tests is not conducted before a blood transfusion for a person with RTA, when a family member is volunteering for blood donation? (Q793932)

A. Hepatitis A

B. Hepatitis B

C. Hepatitis C

D. HIV 1 & 2

See Answer in Part B → Q68

@Neet_pg_bot

Q69: What guidance would you provide to the female patient prior to undergoing laparoscopic surgery? (Q793926)

A. Eat full before surgery.

B. Drink plenty of water before surgery.

C. Enema on the night before surgery

D. NPO for specific hours before surgery

See Answer in Part B → Q69

@Neet_pg_bot

Q70: Which of the following is not included in the AAST grading system for splenic trauma? (Q793921)

A. Parenchymal destruction

B. Vascular involvement

C. Adjacent organ involvement

D. Hematoma

See Answer in Part B → Q70

@Neet_pg_bot

Q71: What is the likely reason behind the occurrence of surgical emphysema in the patient following an emergency tracheostomy performed outside of the hospital? (Q793917)

A. Puncture of posterior wall

B. High tracheostomy

C. Blockage of the tube

D. Tight suture

See Answer in Part B → Q71

@Neet_pg_bot

Q72: What would be the subsequent course of action for this injury depicted in the image after a three-day period following a Road Traffic Accident (RTA)? (Q793911)

A. Debridement of necrotic tissue with primary closure

B. Debridement of necrotic tissue and hyperbaric oxygen

C. Amputation

D. Clean and close with rotation flap

See Answer in Part B → Q72

@Neet_pg_bot

Q73: Which of the following CT findings is not an indication to perform angiography in a splenic trauma patient under conservative management? (Q793370)

A. Subcapsular hematoma covering 40% surface area.

B. Significant hemoperitoneum

C. Presence of pseudoaneurysm

D. Contrast extravasation

See Answer in Part B → Q73

Q1: Identify the type of ulcer shown in the image below: (Q860399)

A. Venous ulcer

B. Malignant ulcer

C. Arterial ulcer

D. Trophic ulcer

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 35-year-old woman, 10 years after mastectomy, notices gradual swelling and heaviness in her right upper limb without pain. On examination, bluish nodules on the skin with no infections are noted. What is the most likely cause of her symptoms? (Q860167)

A. Lymphangiosarcoma

B. Thoracic outlet syndrome

C. Chronic venous insufficiency

D. Recurrent breast cancer

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A patient presents to the emergency room after a road traffic accident with shock and hypotension. The extended focused assessment with sonography for trauma (eFAST) is negative, the X-ray is normal, and the ECG shows bradycardia. The patient's SpO2 is 93%, blood pressure is 80/60 mmHg, and pulse rate is 40/min. Based on this information, what type of shock is most likely? (Q860219)

A. Septic shock

B. Hemorrhagic shock

C. Cardiogenic shock

D. Neurogenic shock

See Answer in Part B → Q3

@Neet_pg_bot

Q4: In patients at risk of refeeding syndrome, which of the following electrolyte imbalances is typically not associated with this condition? (Q860221)

A. Hypokalemia

B. Hyperkalemia

C. Hypocalcemia

D. Hypophosphatemia

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Identify the edges of the lesion given in the image: (Q860254)

A. Everted

B. Rolled out

C. Sloping

D. Punched out

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A patient following a road traffic accident (RTA) with a crush injury presents with crepitus and a reddish-brown wound within 3 days after amputation. What is the most likely condition? (Q860260)

A. Gas gangrene

B. Impetigo

C. Tetanus

D. Cellulitis

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Arrange the stages of wound healing in the correct sequence: (Q860267)

A. Proliferation, hemostasis, inflammation, remodeling

B. Inflammation, remodeling, hemostasis, proliferation

C. Hemostasis, inflammation, proliferation, remodeling

D. Remodeling, proliferation, hemostasis, inflammation

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Which of the following is considered a “sure sign” of abdominal wound dehiscence in a post-operative hypotensive patient? (Q860272)

A. Increased bowel sounds

B. Persistent abdominal pain

C. Serosanguinous drainage from the wound

D. Widening of the abdominal scar with palpable edges

See Answer in Part B → Q8

@Neet_pg_bot

Q9: An elderly chronic smoker male is diagnosed with squamous cell carcinoma of the lower lip with no lymph node involvement. What is the treatment of choice? (Q860276)

A. Radiotherapy

B. Combined chemoradiotherapy

C. Wide local excision with negative borders

D. Wide local excision with frozen section

See Answer in Part B → Q9

@Neet_pg_bot

Q10: In a triage setting, which of the following categories requires the highest priority intervention? (Q860294)

A. Red

B. Yellow

C. Green

D. Black

See Answer in Part B → Q10

@Neet_pg_bot

Q11: What type of skin graft is used in the image shown? (Q860305)

A. Split thickness

B. Full thickness

C. Wolfe graft

D. Local flap

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A female patient presents to the outpatient department 10 days postpartum with complaints of a fluctuant breast mass with tenderness, high-grade fever, and cracked nipples. What is the most probable diagnosis? (Q860324)

A. Breast engorgement

B. Breast abscess

C. Acute mastitis

D. Fibroadenoma

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following is characteristic of hypovolemic shock? (Q860374)

A. Increase in cardiac output

B. High vascular resistance

C. Increase in venous pressure

D. Increased mixed venous saturation

See Answer in Part B → Q13

@Neet_pg_bot

Q14: What is the diagnosis based on the image below? (Q859893)

A. Botryomycosis

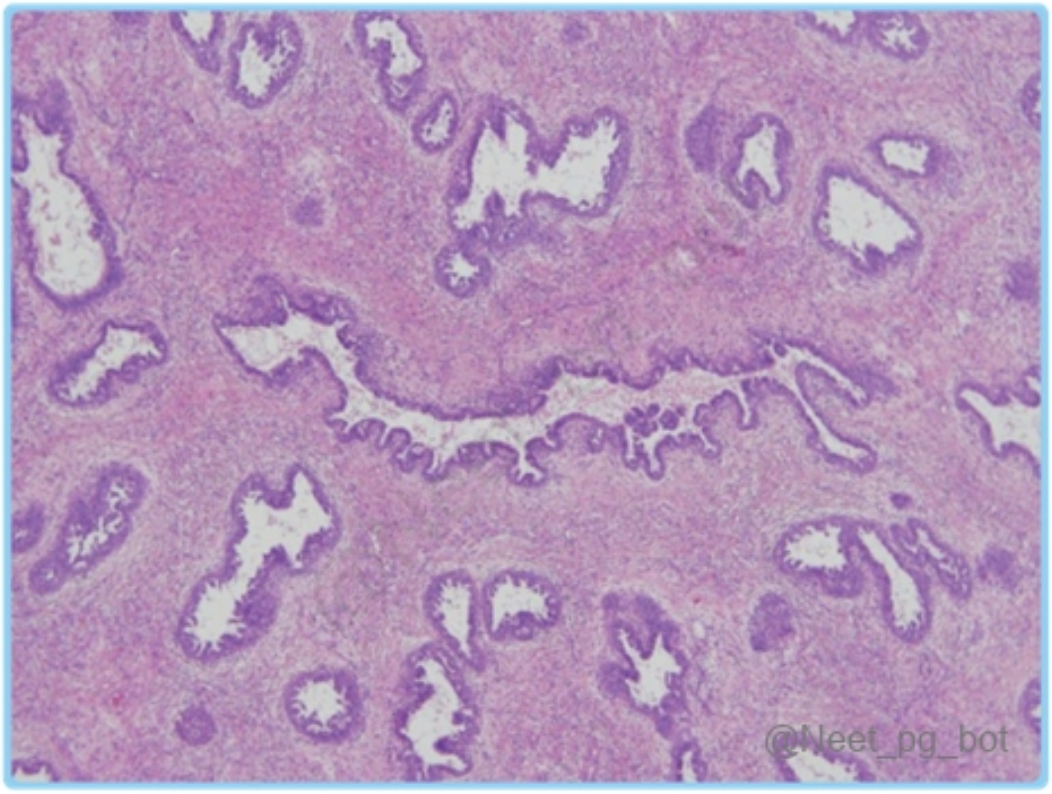
B. Erysipelas

C. Ecthyma

D. Carbuncle

See Answer in Part B → Q14

@Neet_pg_bot



Q15: A 30-year-old female who is receiving cyclosporine A following renal transplantation develops multiple and bilateral breast lumps that regress after cessation of the treatment. Biopsy image is given below. What is the most likely diagnosis? (Q860452)

A. Fat necrosis

B. Phyllodes tumour

C. Fibroadenoma

D. Carcinoma breast

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 65-year-old male presents to the outpatient department with a swelling in the back of his neck that has been present for almost a year. The swelling has not increased in size. On examination, it is non-pulsatile, and the slip sign is positive, with the swelling measuring 3x3 cm. Which of the following statements is most likely true? (Q860457)

A. High chances of malignant transformation

B. FNAC necessary for diagnosis

C. PET scan necessary for staging

D. Excision can be done if the patient requests it

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 47-year-old man presents with a chronic non-healing painless ulcer over his scalp for 8 years. He has a history of electric burns to the scalp 8 years ago. The examination findings are shown below. Which of the following statements is true? (Q860461)

A. Radiotherapy is useful

B. It can progress to squamous cell carcinoma

C. No lymphatic spread

D. Long-duration antibiotics will improve the condition.

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 25-year-old woman presents with severe pain and swelling in her right hand, which is increasing in size and severity. She had a prick injury in the garden 5 days ago. On examination, she cries out in pain when her hand is extended and when the palmar aspect is palpated passively. Which of the following statements is true about the condition? (Q860463)

A. More common in the dorsal aspect of the hand

B. X-ray imaging will aid in the location of the foreign body in all patients

C. It requires incision and drainage

D. Oral analgesics are the mainstay of treatment

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A patient fell from a train onto the railway track and injured both his legs severely. He was urgently taken to the hospital, and the following procedure was performed (image shown below). What is the rationale for performing this procedure? (Q860466)

A. Better fit for prosthesis

B. Life-saving procedure

C. Reduces risk of cancer

D. Good cosmetic outcomes

See Answer in Part B → Q19

@Neet_pg_bot

Q20: In solid organ transplantation, which of the following organs is associated with a higher incidence of rejection? (Q860491)

A. Lungs

B. Intestine

C. Kidney

D. Liver

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 55-year-old female patient with chronic pancreatitis undergoes a Puestow procedure. What is the most preferred route for supplementary nutrition in this patient? (Q860504)

A. TPN (Total Parenteral Nutrition)

B. Oral feeding

C. Feeding gastrostomy

D. Feeding jejunostomy

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 30-year-old female presents to the emergency department with burn injuries sustained from a stove explosion. She has burns involving the face with singeing of eyelashes, both upper limbs entirely, and the anterior chest. The burns are partial-thickness, involving the epidermis and part of the dermis. Based on the rule of Nines, what is the approximate total body surface area (TBSA) affected by burns? (Q865330)

A. 33-36%

B. 40-45%

C. 25-28%

D. 50-55%

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following is incorrect regarding the following dressing? (Q865340)

A. Redressing is done after 4 - 7 days

B. Negative pressure 10-20 mmHg

C. Increase proliferation and protein matrix synthesis

D. Can be continuous & intermittent

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following cancers is NOT related to obesity? (Q865421)

A. Meningioma

B. Gastric carcinoma

C. Pancreatic carcinoma

D. Multiple myeloma

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 30-year-old lactating mother presents with pain in her left breast and a fever. On examination, the left breast appears as shown in the image below. There is mild axillary lymphadenopathy on the affected side and the contralateral breast is normal.

Repeated aspirations under antibiotic cover were unsuccessful. A USG done showed fluid collection. What is the next best step in the management of this patient? (Q865425)

A. Incision and drainage

B. Broad-spectrum antibiotics only

C. Breast conservation surgery

D. Punch biopsy

See Answer in Part B → Q25

@Neet_pg_bot

Q26: An 84-year-old man who had a stroke 2 years ago and has been on extended bed rest, develops a pressure ulcer with partial skin thickness loss and a clean base. What is the grade of his pressure sore? (Q853066)

A. 1

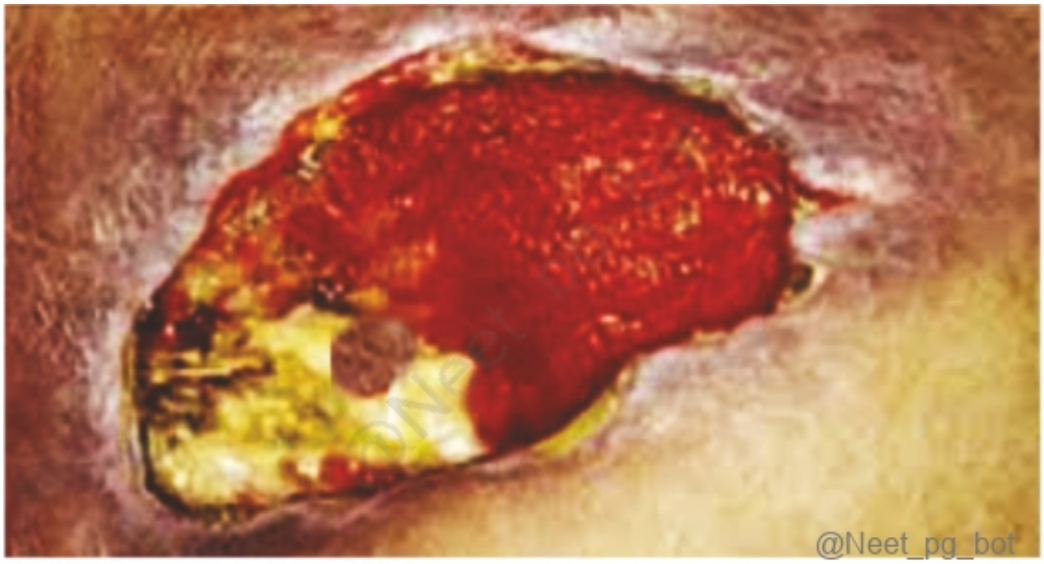
B. 2

C. 3

D. 4

See Answer in Part B → Q26

@Neet_pg_bot



Q27: Identify the grade of the condition given in the image below ? (Q844279)

A. Grade 1

B. Grade 2

C. Grade 3

D. Grade 4

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 20-year-old chronic alcoholic presents with severe hematemesis. An ultrasound (USG) shows distention of the portal vein, and the liver appears hyperechoic. Pantoprazole has been administered. What is the next appropriate step

in management? (Q844303)

A. Initiate a course of broad-spectrum antibiotics

B. Order a liver biopsy to assess for fibrosis

C. Administer intravenous fluids and electrolyte replacement

D. Perform an endoscopy to look for varices

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Which of the following is a complication of Total Parenteral Nutrition (TPN) in a sepsis patient in the ICU? (Q844304)

A. Hyperlipidemia

B. Hyperglycemia

C. Hyperglyceridemia

D. Hypoglycemia

See Answer in Part B → Q29

@Neet_pg_bot

Q30: What is the ideal pressure setting for vacuum-assisted closure (VAC) therapy? (Q844308)

A. -125 mm Hg

B. 60 to 80 mm Hg

C. 130 mm Hg

D. 80 to 100 mm Hg

See Answer in Part B → Q30

@Neet_pg_bot

Q31: During laparoscopic port placement, injury to which abdominal wall vessels must be avoided while inserting the trocar?During laparoscopic surgery, where shouldn't the trocar be inserted? (Q852687)

A. Superior epigastric artery

B. Inferior epigastric artery

C. Abdominal aorta

D. Both A and B

See Answer in Part B → Q31

@Neet_pg_bot

Q32: A 45-year-old male patient was brought to the emergency department following a road traffic accident.O/E, he had multiple injuries all over his body and was found to be in class III hemorrhagic shock. The percentage of blood loss would be between: (Q852705)

A. 5-15%

B. 30-40%

C. >40%

D. 15-30%

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A 45-year-old man is found unconscious after a fall from a ladder. In the emergency department, his eyes do not open even in response to pain; he is making incomprehensible sounds, and he exhibits abnormal flexion in response to painful stimuli. What is his Glasgow Coma Scale (GCS) score? (Q852706)

A. 5

B. 6

C. 7

D. 8

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A 20-year-old male presents to the outpatient department with a swelling on his wrist. He reports fluctuation in size , mild numbness in the hand , and occasional pain . What is the most likely diagnosis? (Q852713)

A. Lipoma

B. Ganglion cyst

C. Dermoid cyst

D. Hematoma

See Answer in Part B → Q34

@Neet_pg_bot

Q35: A woman, a few weeks after delivery, complains of bloody discharge from nipple and fever. On examination, diffuse lump under areola. What is the diagnosis? (Q852719)

A. Galactocele

B. Lactational mastitis

C. Mondor disease

D. Fibrocystic disease

See Answer in Part B → Q35

@Neet_pg_bot

Q36: A patient with dilated tortuous veins of the leg presented to the OPD and is diagnosed with varicose vein of grade C4a. What is the best preferred treatment? (Q852721)

A. Compression

B. Endothermal ablation

C. Non endothermal non tumescent ablation

D. Open surgery

See Answer in Part B → Q36

@Neet_pg_bot

Q37: The ureter is safe in which type of hysterectomy? (Q852722)

A. Open laparotomy

B. Laparoscopy

C. Robotic

D. Vaginal

See Answer in Part B → Q37

@Neet_pg_bot

Q38: A 25-year-old male with a history of a road traffic accident presents to the emergency department. His GCS is 8/15, oxygen saturation is 85%, blood pressure is 100/60 mmHg and heart rate is 60 beats per minute. On examination, breath sounds are absent on the right side. What is the next step in management? (Q853038)

A. Start IV fluids, give atropine and secure airway

B. Secure airway, give oxygen, insert ICD, secure IV line

C. Evaluate for head injury and do CT-head

D. ■■■Administer IV dextrose followed by NCCT head

See Answer in Part B → Q38

@Neet_pg_bot

Q39: What should be the next course of action in the management of a 30-year-old breastfeeding mother who is experiencing pain and fever in her left breast? The left breast appears abnormal as depicted in the provided image. There is slight swelling of the lymph nodes in the armpit on the affected side, while the opposite breast appears normal. Despite multiple attempts at draining the fluid with the use of antibiotics, it was unsuccessful. An ultrasound examination revealed the presence of fluid collection. (Q793402)

A. Incision an drainage

B. Broad spectrum antibiotics only

C. Breast conservation surgery

D. Punch biopsy

See Answer in Part B → Q39

@Neet_pg_bot

Q40: A 35-year-old male had surgery for an ileal perforation. Due to significant contamination, only the sheath was sutured, leaving the wound open. Daily wound irrigation was carried out, and the wound was closed on postoperative day 5. What type of wound-healing mechanism is occurring in this scenario? (Q853067)

A. Primary intention

B. Secondary intention

C. Tertiary intention

D. Quaternary intention

See Answer in Part B → Q40

@Neet_pg_bot

Q41: A friend of yours is teaching you about enhanced recovery after surgery. Which of the following statements he makes is inaccurate? (Q853068)

A. ■■■Prolonged fasting is necessary

B. Epidural anaesthesia recommended in laparoscopic surgery for pain control

C. Reduction of hospital stay by 2-3 weeks

D. Beta-blockers are given after major surgery done under general anaesthesia to improve the outcome

See Answer in Part B → Q41

@Neet_pg_bot

Q42: What kind of wound is an open cardiac massage? (Q857262)

A. Clean

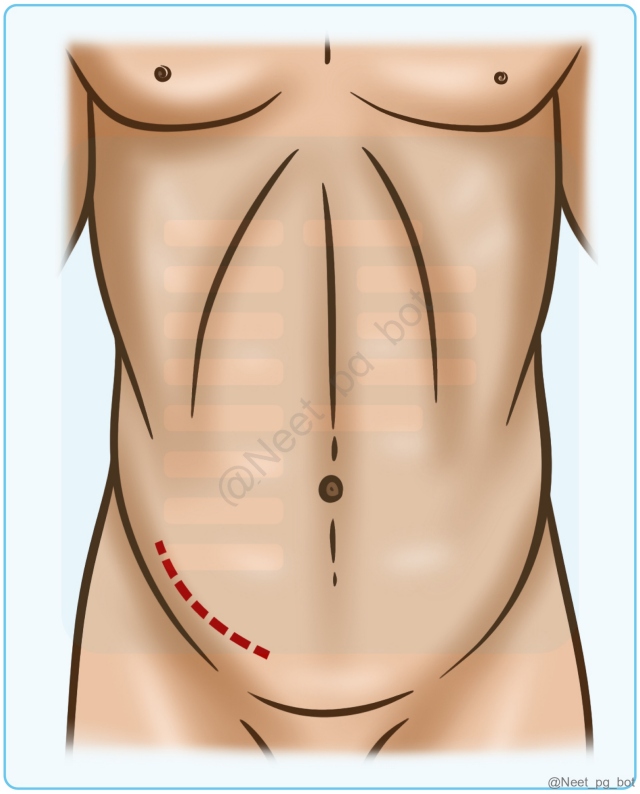
B. Contaminated

C. Dirty

D. Clean Contaminated

See Answer in Part B → Q42

@Neet_pg_bot



Q43: Identify the incision made and marked in the image. (Q857292)

A. Robson

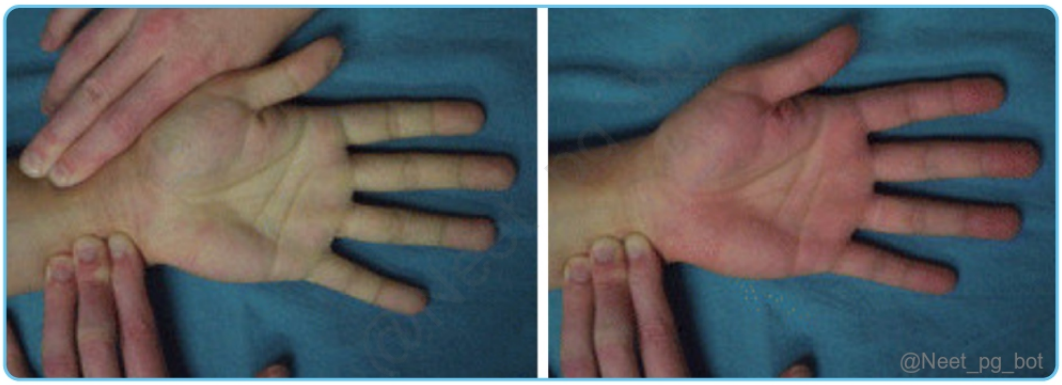
B. Maylard

C. Gibson Abernathy

D. Kocher's

See Answer in Part B → Q43

@Neet_pg_bot



Q44: Identify the test provided in the image below. (Q857294)

A. Allen’s test

B. Adson’s test

C. Elevated arm stress test

D. Nicoladoni’s test

See Answer in Part B → Q44

@Neet_pg_bot

Q45: Smoking increases the risk of which of the following diseases? Duct ectasia Fibroadenoma Mondor disease Breast carcinoma (Q857295)

A. 2, 3

B. 1, 4

C. 2, 3, 4

D. 1, 3, 4

See Answer in Part B → Q45

@Neet_pg_bot

Q46: A 25-year-old male patient is brought to the casualty after a road traffic accident (RTA) with suspected pelvic fractures. On examination, he is found to be in hypovolemic shock. What is the earliest treatment for control of haemorrhage in this case? (Q857297)

A. Immediate internal fixation

B. Multiple blood transfusions

C. Use bedsheets to compress the pelvis

D. Emergency external fixation

See Answer in Part B → Q46

@Neet_pg_bot

Q47: A soldier arrives at a referral hospital 24 hours after experiencing a shrapnel injury to his right thigh caused by a high-speed projectile. He expresses significant discomfort at the site of the wound. Upon examination, there is evidence of crepitus. Which of the following microorganisms is the probable culprit behind his current state? (Q857804)

A. Clostridium septicum

B. Clostridium difficile

C. Clostridium novyi

D. Clostridium perfringens

See Answer in Part B → Q47

@Neet_pg_bot

Q48: A 32-year-old female undergoes emergency laparotomy for perforation peritonitis. Which of the following is the surest sign of wound dehiscence? (Q857853)

A. Copious sero-sanguinous discharge

B. Rebound tenderness

C. Hemorrhage

D. Hypotension

See Answer in Part B → Q48

@Neet_pg_bot

Q49: A barber aged 42 years presented with a healed ulcer as below, over the lower medial aspect of the right leg. On examination, he has varicose veins on both his legs.

What is the most likely type of ulcer he had? (Q859836)

A. Neuropathic ulcer

B. Arterial ulcer

C. Venous ulcer

D. Tubercular ulcer

See Answer in Part B → Q49

@Neet_pg_bot

Q50: False regarding deep second-degree burns: (Q859883)

A. Heal by scar deposition

B. No blanching

C. Damage to the deeper dermis

D. Completely painless

See Answer in Part B → Q50

@Neet_pg_bot

Q1: A 35-year-old male arrives in the emergency department after a motor vehicle collision with unstable vitals and multiple injuries. Which trauma severity score is most appropriate for predicting his likelihood of survival? (Q849616)

A. Injury Severity Score (ISS)

B. Revised Trauma Score (RTS)

C. Trauma and Injury Severity Score (TRISS)

D. Mangled Extremity Severity Score (MESS)

See Answer in Part B → Q1

@Neet_pg_bot

Q2: In the context of severely injured trauma patients, which of the following is not classically included in the “lethal triad” that worsens outcomes? (Q880420)

A. Hypothermia

B. Shock

C. Acidosis

D. Coagulopathy

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following best describes the principle of balanced resuscitation in trauma patients? (Q880418)

A. Maintaining airway, breathing, and circulation

B. Allowing permissive hypotension

C. Maintaining pH by correcting acid–base balance

D. Fluid resuscitation with both colloids and crystalloids

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 28-year-old man with head trauma is on mechanical ventilation. On examination, he opens his eyes spontaneously and shows purposeful movements in all four limbs. What is his GCS? (Q880417)

A. Eyes – 4, Verbal – 1, Motor – 5

B. Eyes – 4, Verbal – NT, Motor – 5

C. Eyes – 4, Verbal – 1, Motor – 6

D. Eyes – 4, Verbal – NT, Motor – 6

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 40-year-old comatose patient on ventilatory support is being assessed for brainstem death. Which of the following findings may falsely suggest preserved brainstem activity, and therefore should not be taken as evidence of brainstem function? 1. Babinski reflex 2. Decorticate/decerebrate posturing 3. Tachycardia 4. Normal systolic BP >100 mmHg 5. Presence of oculocephalic reflex (Q880416)

A. 2, 4, and 5

B. 1, 2, and 3

C. 2, 3 and 5

D. 1, 3 and 4

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A young male presents with a severely mangled lower limb following a road traffic accident. The surgeon plans to calculate the Mangled Extremity Severity Score (MESS) to guide the decision on amputation versus salvage. Which one of the following factors is not a component of the MESS scoring system? (Q880410)

A. Age of the patient

B. Ischemia

C. Neurogenic injury

D. Energy of injury

See Answer in Part B → Q6

@Neet_pg_bot

Q7: Which of the following parameters are included in calculating the Revised Trauma Score (RTS)? 1. Glasgow Coma Scale 2. Respiratory rate 3. Pulse rate 4. Systolic blood pressure 5. Mechanism of injury (Q880409)

A. 2, 4, and 5

B. 1, 3, and 5

C. 2, 3, and 4

D. 1, 2, and 4

See Answer in Part B → Q7

@Neet_pg_bot

Q8: In a disaster scenario, assign the appropriate triage color code to the following patients: Patient Triage Color Code 1. An unconscious patient with massive head trauma and no spontaneous respiration A. Black 2. A patient with an open femur fracture and active bleeding B. Red 3. A patient with stable vitals but multiple rib fractures C. Yellow 4. A patient with a sprained ankle is walking around D. Green (Q880405)

A. 1-A, 2-B, 3-C, 4-D

B. 1-B, 2-A, 3-D, 4-C

C. 1-C, 2-A, 3-D, 4-B

D. 1-D, 2-C, 3-B, 4-A

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following does not typically rise as part of the acute neuroendocrine response to surgical stress or trauma? (Q880404)

A. ACTH

B. TNF-α

C. Growth hormone

D. Insulin

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 60-year-old man taking medication to prevent blood clots suddenly suffers severe bleeding after an accident. Which treatment option is most effective for quickly reversing the blood-thinning effects and controlling the bleeding? (Q880268)

A. Cryoprecipitate

B. Prothrombin complex concentrate

C. Fresh-frozen plasma

D. Platelets

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A person experiencing significant internal bleeding needs to have their blood levels restored to a safe range. Experts recommend not aiming too high to avoid complications. Based on current best practices, which of the following target values is considered appropriate for restoring blood levels in such a situation? (Q880266)

A. 12 g/dL

B. 6 g/dL

C. 10 g/dL

D. 8 g/dL

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Based on the shelf life of the various blood components, which should be utilized first to minimize the risk of wastage due to expiry? (Q880256)

A. Packed RBCs

B. Fresh frozen plasma

C. Cryoprecipitate

D. Platelets

See Answer in Part B → Q12

@Neet_pg_bot

Q13: With respect to the Enhanced Recovery After Surgery (ERAS) protocol, which of the following statements is incorrect? (Q880233)

A. Early initiation of physiotherapy and mobilisation is recommended

B. ERAS protocols are applicable in colorectal surgical procedures

C. Oral feeding is delayed for one week postoperatively

D. Discharge planning begins before hospital admission

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 40-year-old male is admitted to the hospital after a major traumatic injury. On the third day post-trauma, his oxygen consumption and metabolic rate have increased significantly, and he exhibits elevated catecholamine levels. Which phase of the metabolic response is this patient most likely in? (Q849617)

A. Ebb phase

B. Flow phase

C. Anabolic phase

D. Recovery phase

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A road traffic accident has occurred, and the first response team has arrived at the scene. Which of the following is not a key priority in prehospital care? (Q849595)

A. Evaluate the scene

B. Perform an initial assessment

C. Make triage-transport decision

D. Transport immediately and delay interventions

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 30-year-old woman with mid-facial trauma from a car accident is stabilized and the secondary survey begins. Which of the following is not an appropriate step in the secondary survey? (Q849615)

A. Obtaining a detailed history

B. Digital rectal examination for spinal injury

C. Nasogastric tube in a patient with mid-facial fractures

D. Repeat FAST examination for abdominal injury

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 25-year-old male involved in a high-speed motor vehicle accident is brought to the emergency department. After completing the primary survey and stabilizing the patient, the trauma team begins the secondary survey. Which of the following steps is not a part of the secondary survey? (Q849614)

A. Identifying external hemorrhage

B. Full neurological examination

C. Thorough head-to-toe examination

D. Obtaining a detailed patient history

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 45-year-old man is found unconscious after a fall from a ladder. In the emergency department, his eyes do not open even in response to pain; he is making incomprehensible sounds, and he exhibits abnormal flexion in response to painful stimuli. What is his Glasgow Coma Scale (GCS) score? (Q849613)

A. 5

B. 6

C. 7

D. 8

See Answer in Part B → Q18

@Neet_pg_bot

Q19: During the primary survey of a trauma patient in the emergency department, which of the following injuries is not classified as life-threatening under the category of "breathing" problems? (Q849604)

A. Flail chest

B. Hemothorax

C. Bronchial rupture

D. Expanding hematoma

See Answer in Part B → Q19

@Neet_pg_bot

Q20: Which of the following statements is true regarding the CRASH-2 trial in trauma? (TXA= Tranexamic acid) (Q849603)

A. TXA is more effective when given after 3 hours of trauma.

B. TXA reduced all-cause mortality versus placebo.

C. TXA in children worsens pulmonary and neurological outcomes.

D. CRASH-2 showed TXA is ineffective in trauma.

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 35-year-old male is brought in after a fall from height and is found to be in hypovolemic shock. According to ATLS protocol, which of the following investigations is not recommended during the primary survey to identify the cause of the life-threatening bleed? (Q849602)

A. FAST scan

B. Chest X-Ray

C. Pelvic radiograph

D. CT scan

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A road accident patient, stabilized with no severe external injuries, suddenly develops tachycardia, weak pulses, hypotension, and tachypnoea. Which ATLS primary assessment component is most likely causing these symptoms? (Q849601)

A. Airway

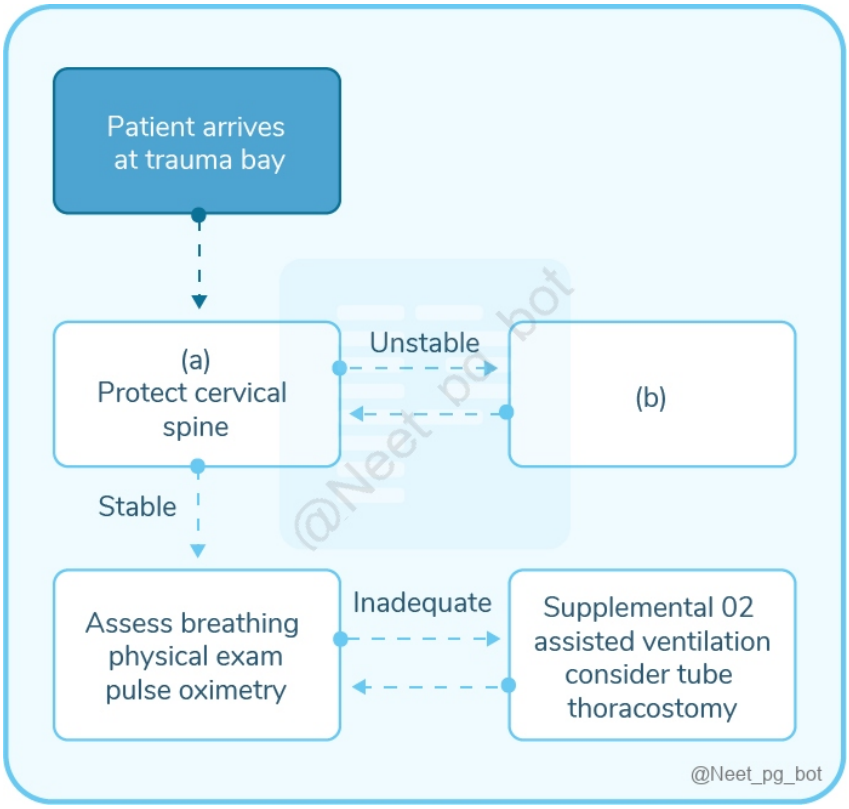
B. Circulation

C. Neurological

D. Hypothermia

See Answer in Part B → Q22

@Neet_pg_bot



Q23: A critically injured patient is brought to the emergency department. The primary assessment is started. In the following algorithm identify the missing step (a) and action (b). (Q849600)

A. a- Assess airway, b- Establish stable airway

B. a- Assess circulation, b- Prevent shock

C. a- Establish airway, b- Assess circulation

D. a- Assess airway, b- Assess circulation

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 34-year-old patient arrives at the emergency department after a motor vehicle collision. The ED physician is assessing whether to order spinal imaging. Which of the following findings does not indicate that spinal imaging is necessary? (Q849599)

A. No focal neurological deficit

B. Patient is intoxicated

C. Altered level of consciousness

D. Presence of midline spinal tenderness

See Answer in Part B → Q24

@Neet_pg_bot

Q25: In an emergency situation in the casualty, the ATLS protocol is followed after a patient who was in a road traffic accident is brought to the hospital. Which of the following is not a component in the primary evaluation of the patient? (Q849598)

A. Detailed history of the patient

B. Airway assessment

C. Rule out shock

D. Check for neurological disability

See Answer in Part B → Q25

@Neet_pg_bot

Q26: After a major earthquake, a patient presents with a compound fracture and spinal injuries. Considering the severity of these injuries and the urgency of treatment, which triage color code is most appropriate for this patient? (Q849597)

A. Black

B. Red

C. Green

D. Yellow

See Answer in Part B → Q26

@Neet_pg_bot

Q27: After a high-speed road traffic accident, a trauma team arrives to find multiple critically injured patients. According to the trimodal mortality model, which statement is correct? (Q849596)

A. Immediate deaths occur days after the injury

B. Early deaths occur within hours of reaching the hospital

C. Majority of deaths are due to cardiac causes

D. Late deaths are mostly due to internal hemorrhage

See Answer in Part B → Q27

Q1: During a laparoscopic intra-abdominal surgery, the surgeon has to insufflate the peritoneal cavity. Which of the following statements is true regarding the Veress needle technique? (Q849681)

A. It is an open technique for creating pneumoperitoneum

B. The positioning of the needle is confirmed by a laparoscopic camera

C. Veress needle is a spring-loaded needle

D. It has a sharp inner stylet that deploys in the peritoneal cavity

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A patient who has undergone gastric banding is being advised on postoperative nutritional guidelines. Which of the following supplements is specifically recommended for this patient to prevent deficiency? (Q849695)

A. Selenium

B. Folic acid

C. Zinc

D. Vitamin D

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old patient undergoes bariatric surgery and is at risk for postoperative complications. What is the most common cause of 30-day mortality following bariatric surgery? (Q849694)

A. Cardiac failure

B. Pulmonary embolism

C. Anastomotic leak

D. Respiratory failure

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A 45-year-old patient with a BMI of 38 kg/m² is considering weight loss surgery. The surgeon suggests a procedure that involves placing a band around the stomach just below the cardia to create a small gastric pouch. Which procedure is being recommended? (Q849693)

A. Sleeve gastrectomy

B. Roux-en-Y gastric bypass

C. Intragastric balloon placement

D. Laparoscopic adjustable gastric banding

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 38-year-old woman with a BMI of 40 kg/m² undergoes sleeve gastrectomy. Post-surgery, she asks how the procedure helps her lose weight. What is the primary mechanism by which sleeve gastrectomy leads to weight loss? (Q849692)

A. Reduced stomach size and hormonal changes.

B. Complete removal of the stomach.

C. Reduced appetite with no hormonal impact.

D. Nutrient malabsorption due to intestinal bypass.

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 52-year-old woman is recovering from a recent Roux-en-Y gastric bypass surgery. She has been informed about the possible complications that can arise post-surgery. Which of the following is least likely to be a complication of her bypass surgery? (Q849691)

A. Anastomotic leak

B. Internal hernia

C. Pancreatitis

D. Deep vein thrombosis

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 40-year-old obese male visits the surgical OPD. He is advised to undergo a biliopancreatic diversion and duodenal switch (BPD-DS) surgery. What would not be a possible indication for BPD-DS? (Q849690)

A. Higher BMIs

B. Failed another operation for weight loss

C. Failed surgery for metabolic control

D. Preexisting iron deficiency

See Answer in Part B → Q7

@Neet_pg_bot

Q8: In the preoperative assessment for obesity surgery, which of the following factors does NOT contribute to the obesity surgery mortality risk score? (Q849689)

A. BMI >50 kg/m²

B. Female gender

C. Age >45 years

D. Hypertension

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A patient is evaluated for obesity in the hospital for bariatric surgery. Which of the following would not be an indication for the surgery? (Q849688)

A. BMI ≥ 40kg/m2 with no comorbidities

B. BMI ≥ 35kg/m2 with no comorbidities

C. Failure of previous nonsurgical attempts

D. BMI ≥ 37.5kg/m2 in Asian population with/without comorbidities

See Answer in Part B → Q9

@Neet_pg_bot

Q10: In which of the following situations is robotic surgery not suitable? (Q849687)

A. Limited space/visualization

B. Surgeon suffers from tremors in hands

C. Gynecological operations

D. Low-budget surgical setup

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following statements about per-oral endoscopic myotomy is false? (Q849686)

A. It is a modification of NOTES surgery

B. A flexible endoscope is used to create a submucosal tunnel

C. It is a good surgical technique for achalasia cardia

D. The procedure involves the division of longitudinal muscles

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 20-year-old female comes to the OPD for an elective abdominal surgery. She is worried about developing a scar and enquires about a scarless procedure. Which among the following surgical procedures gives a scarless result? (Q849685)

A. Laparoscopic abdominal surgery

B. Laparotomy

C. Natural orifice transluminal endoscopic surgery

D. Hand-assisted laparoscopic surgery

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 25-year-old female who underwent a simple mastectomy was admitted in the hospital and discharged on the same day after the procedure. What type of surgery is this? (Q849684)

A. Daycare surgery

B. Fast track surgery

C. Overnight stay surgery

D. Short stay surgery

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A laparoscopic surgery was done on a patient for cholecystitis, and he later complained of shoulder pain. What would be the most possible cause for this? (Q849683)

A. Intrabdominal abscess

B. Mesenteric bleeding

C. Perforation of esophagus

D. Splenic trauma

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 45-year-old patient is about to undergo a cholecystectomy. He has no other comorbidities and wants a minimally invasive surgery; hence, the surgeon suggests a laparoscopic cholecystectomy. Which of the following gases is most widely used for creating a pneumoperitoneum? (Q849682)

A. Room air

B. O2 (oxygen)

C. CO2 (carbon dioxide)

D. He (helium)

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A diabetic patient with severe sepsis develops a persistent urinary tract infection (UTI) despite antibiotic treatment. The infection control team suspects a multidrug-resistant pathogen. Which of the following is true about nosocomial infections? (Q849664)

A. Staphylococcus aureus is the most common cause of hospital-acquired respiratory infections.

B. Klebsiella is a frequent cause of drug-resistant hospital-acquired UTIs.

C. Nosocomial infections are not typically transmitted between patients.

D. Patients with artificial prostheses are less prone to nosocomial infections than those with indwelling devices.

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 55-year-old woman, 4 days post-abdominal surgery, reports a sudden feeling of popping at her surgical site followed by the drainage of pinkish fluid. On examination, there is partial wound dehiscence with no visible bowel protrusion. What is the next best step in management? (Q849680)

A. Prompt reclosure of the fascia

B. Apply a wound vacuum system and monitor

C. Prescribe oral antibiotics and discharge

D. Place an abdominal binder and observe

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 68-year-old man develops a fever of 101.5°F on postoperative day 5 after total hip replacement. He also has localized pain and swelling in his left calf. The chest X-ray is normal, and there are no respiratory symptoms. What is the most likely cause of his fever? (Q849679)

A. Pulmonary embolism

B. Thrombophlebitis

C. Deep infections

D. Gas gangrene of wound

See Answer in Part B → Q18

@Neet_pg_bot

Q19: In the operating room, the surgical team is completing the WHO Surgical Safety Checklist. They are focused on final checks before closing the incision. Which of the following is not a standard checklist item at this stage? (Q849678)

A. Confirm patient identity.

B. Verify surgical team roles.

C. Reviewing anesthesia concerns.

D. Checking the patient's COVID-19 status.

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 50-year-old man develops sudden respiratory distress, altered consciousness and hypotension during a craniotomy surgery. The anesthesiologist hears a mill-wheel murmur and suspects an air embolism. What is the most appropriate immediate action? (Q849677)

A. Administer a diuretic.

B. Perform CPR.

C. Place in Trendelenburg position.

D. Administer epinephrine.

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 55-year-old female patient is scheduled for lateral thoracotomy. The surgical team prepares to position her on the operating table. Which position should the patient be placed in for optimal access to the thorax? (Q849676)

A. Jackknife Position

B. Lateral Decubitus Position

C. Lithotomy Position

D. Trendelenburg Position

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A patient's wound, evaluated on postoperative day 7, shows signs of erythema, pain and swelling with no discharge and deep tissue involvement. What is the likely Southampton wound grading? (Q849675)

A. Grade I

B. Grade II

C. Grade III

D. Grade IV

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following correctly matches the zone in an OT (Operating Theatre) complex with its primary function? (Q849673)

A. Protective zone: Includes the sterile operation rooms.

B. Clean zone: Primarily contains the change rooms for medical and paramedical staff.

C. Aseptic zone: Contains the sterile operating rooms.

D. Disposal zone: Connected directly to the aseptic zone and contains the patient transfer bay.

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following strategies is most effective in preventing surgical site infections (SSIs) during an operation? (Q849672)

A. Administering prophylactic antibiotics before the first incision and maintaining positive pressure in the operating room (OR).

B. Using concentric circles for antisepsis application and maintaining the OR temperature at 18 ± 3°C.

C. Administering antibiotics after the operation and maintaining a negative pressure differential in the OR.

D. Avoiding alcohol-based antiseptic solutions and using antibiotics with a short tissue half-life.

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 62-year-old man with hypovolemic shock requires rapid fluid resuscitation. Which of the following IV catheters would be most appropriate for this situation? (Q849671)

A. 22G yellow catheter

B. 18G green catheter

C. 14G orange catheter

D. 24G blue catheter

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 28-year-old man from a resource-poor area presents with a 3-week history of fever, abdominal pain, and altered bowel habits. Abdominal examination reveals a doughy feel and a mass in the right iliac fossa. Which finding would most likely distinguish intestinal tuberculosis from typhoid fever in this patient? (Q849670)

A. Evening rise in temperature

B. Positive blood culture for Salmonella Typhi

C. Multiple longitudinal ulcers in the terminal ileum

D. Caseating granulomas on intestinal biopsy

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 48-year-old male immigrant presents with a painless, fluctuating mass in the neck that has been gradually enlarging over 2 months, along with an evening rise in temperature and weight loss. On examination, there is a 3 cm soft, non-tender swelling in the left posterior triangle of the neck without signs of inflammation. Which of the following is the most appropriate next step in management? (Q849669)

A. Incision and drainage

B. Fine needle aspiration cytology

C. Excisional biopsy

D. Empiric antitubercular therapy

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 56-year-old diabetic male presents with severe leg pain, swelling, dusky discoloration, and bullae, 24 hours after a minor cut. The leg is edematous with crepitus, and the patient is febrile and tachycardic, showing signs of septic shock. What is the most appropriate next step? (Q849668)

A. Monitor and observe

B. Immediate surgical debridement

C. IV fluids and pain management

D. Oral antibiotics

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 45-year-old man presents with severe muscle pain and swelling in his leg following a gunshot wound. The wound has a foul-smelling, brown discharge and shows signs of crepitus. X-rays reveal gas in the soft tissues. What is the most likely diagnosis? (Q849667)

A. Hidradenitis Suppurativa

B. Fournier’s Gangrene

C. Gas Gangrene

D. Cellulitis

See Answer in Part B → Q29

@Neet_pg_bot

Q30: A 55-year-old diabetic male presents with a 2-day history of increasing redness, warmth, and swelling in his left leg and also has fever and chills. The erythema is rapidly expanding, with no clear demarcation. What is the most likely diagnosis? (Q849666)

A. Carbuncle

B. Cellulitis

C. Erysipelas

D. Necrotizing fasciitis

See Answer in Part B → Q30

@Neet_pg_bot

Q1: A 45 y/o male is brought to the emergency room after a car accident with a penetrating injury to the left chest. An eFAST reveals fluid accumulation in the pericardial sac. Which of the following is not a component of Beck's triad, a classic finding in pericardial tamponade? (Q849790)

A. Hypotension

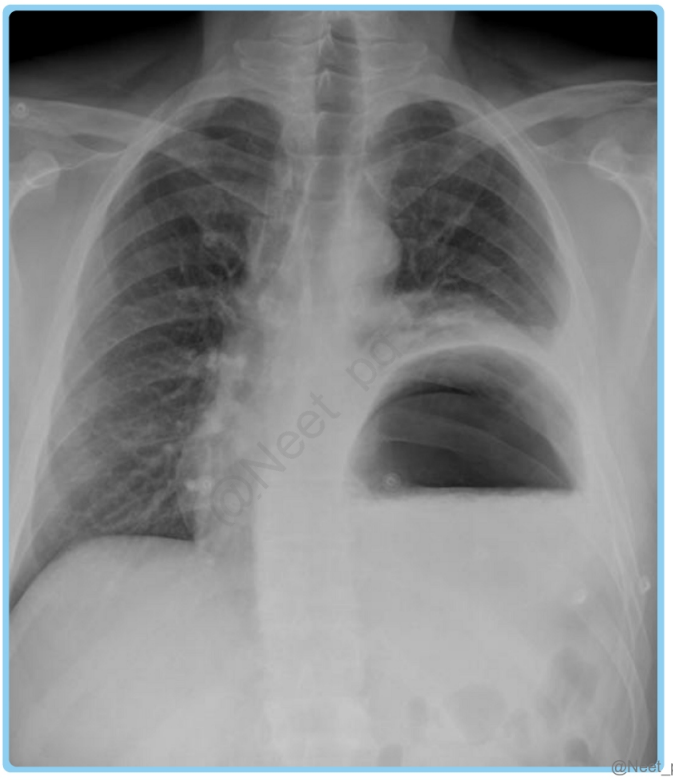
B. Jugular venous distension

C. Bradycardia

D. Muffled heart sounds

See Answer in Part B → Q1

@Neet_pg_bot



Q2: An elderly lady presents to the trauma care center following a motor vehicle collision. She complains of chest pain and abdominal pain. On examination, breath sounds are decreased on the left side. X-ray chest shows loops of bowel in the left hemithorax. Which of the following statements is false regarding the management of this patient's likely condition? (Q880429)

A. The most accurate evaluation of the condition in stable patients may be achieved by a CT scan

B. Operative repair is indicated in all symptomatic or diagnosed cases to prevent delayed complications

C. In the setting of an acute penetrating injury, repair can often be achieved via a thoracic incision

D. The defect is typically closed with non-absorbable sutures, such as polypropylene, placed in an interrupted fashion

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 35-year-old man presents to the casualty after being stabbed in the precordial region. He is in shock, with elevated jugular venous pressure and muffled heart sounds. Which of the following statements is incorrect? (Q880389)

A. Cardiac tamponade is the most likely diagnosis

B. If an open pneumothorax is suspected, the chest wound should be sealed completely on all four sides with an occlusive dressing

C. eFAST can identify fluid around the heart

D. Needle pericardiocentesis is not routinely recommended

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A patient with blunt chest trauma undergoes tube thoracostomy. Which of the following best confirms that the intercostal drain is functioning properly? (Q880388)

A. Continuous air bubbles in the underwater seal

B. Oscillation of the water column in the tube

C. Chest X-ray

D. Auscultation

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 10-year-old child is brought to the emergency department after a road traffic accident. He is in severe respiratory distress with hypotension, tracheal deviation to the left, and absent breath sounds on the right side. What is the first-line management? (Q880387)

A. Insert a wide-bore needle in the 5th ICS anterior to the mid-axillary line

B. Insert a wide-bore needle in the 5th ICS in the mid-clavicular line

C. Insert a wide-bore needle in the 2nd ICS in the mid-axillary line

D. Insert a wide-bore needle in the 2nd ICS in the mid-clavicular line

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 28-year-old man presents with pain and tenderness over the right upper chest after a fall from a motorcycle. Chest X-ray reveals a fracture of the right 3rd rib. Which of the following is not recommended in the management of an isolated rib fracture? (Q880386)

A. Provide opioid analgesia

B. Advise deep breathing

C. Advise frequent coughing

D. Strapping over the affected rib

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 35-year-old man suffers severe blunt chest trauma in a high-speed motorcycle accident. On arrival, he is tachycardic and hypotensive with unequal blood pressures in both upper limbs. Chest X-ray demonstrates mediastinal widening without evidence of lung injury. Which investigation is the most appropriate to confirm the diagnosis? (Q880383)

A. Transoesophageal echocardiography

B. CT angiography

C. MR angiography

D. Transthoracic echocardiography

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 38-year-old man arrives in the emergency department after sustaining a stab injury to the lower chest. He is bradycardic and hypotensive, not improving with IV fluids. Chest X-ray shows clear lung fields. What is the most appropriate next step in management? (Q880382)

A. eFAST

B. Tube thoracostomy

C. CECT chest

D. CECT abdomen

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 32-year-old male arrives at the trauma bay with multiple penetrating injuries to the anterior and lateral neck following an assault. Which of the following would not warrant immediate surgical exploration? (Q880378)

A. Pulsatile bleeding

B. Respiratory distress

C. Fluid-responsive hemorrhagic shock

D. Air bubbling from penetrating injury

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following regarding acute spinal cord injury is incorrect? (Q880376)

A. Hypotension occurs due to loss of parasympathetic tone

B. Immediate respiratory compromise may result from phrenic nerve involvement

C. The Canadian C-Spine rule and NEXUS are used to assess the need for cervical spine imaging

D. Patients with neurological deficits should be shifted off the backboard as early as possible

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 30-year-old man is rescued after a road traffic accident with suspected cervical spine injury. The team decides to log roll him for safe transfer. According to ATLS guidelines, what is the minimum number of people required for this maneuver? (Q880375)

A. 3

B. 4

C. 5

D. 6

See Answer in Part B → Q11

@Neet_pg_bot

Q12: While transferring a conscious patient with multiple injuries following a road accident, which of the following methods of transport is inappropriate? (Q880371)

A. Securing the thorax, abdomen, and lower limbs with straps on a stretcher

B. Positioning the patient prone to reduce aspiration risk

C. Shifting the patient in the lateral position for immediate transfer

D. Rolling the patient carefully onto a rigid spine board

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 45-year-old male with a large right-sided pneumothorax and decreased breath sounds requires an intercostal chest drain (ICD). What is the most appropriate insertion site for the ICD? (Q849794)

A. 5th intercostal space, midclavicular line

B. 2nd intercostal space, midaxillary line

C. 5th intercostal space, anterior axillary line

D. 2nd intercostal space, posterior axillary line

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 25 y/o male is brought to the ED after an explosion at a construction site. He was close to the blast and submerged in water. He has severe abdominal pain, difficulty hearing, shortness of breath, unstable vitals, and ruptured tympanic membranes on examination. Which organ is most severely damaged in this scenario? (Q849793)

A. Lungs

B. Limbs

C. Gastrointestinal tract

D. Brain

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 32 y/o male presents after a car accident with severe chest and abdominal pain. O/E there are decreased breath sounds on the left side and abdominal tenderness. Chest X-ray reveals bowel gas patterns in the left thoracic cavity. A nasogastric tube is placed, and its tip is seen in the thoracic cavity. What is the most appropriate next step in management? (Q849792)

A. Initiate conservative management and observe the patient.

B. Emergency laparotomy.

C. Order a CT scan of the chest and abdomen for further evaluation.

D. Schedule an elective surgery.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 45 y/o male presents to the emergency department after a motor vehicle accident. He is tachypneic, has severe chest pain, and paradoxical chest wall movement is noted on physical examination. His oxygen saturation is 85% on room

air. A chest X-ray shows multiple rib fractures on the left side. What is the most appropriate initial management for this patient? (Q849791)

A. Tracheostomy

B. Intercostal tube drainage

C. Positive pressure ventilation

D. Thoracotomy

See Answer in Part B → Q16

@Neet_pg_bot

Q17: In a patient with raised intracranial pressure (ICP) that remains elevated despite initial management, which of the following strategies is considered a second-tier therapy for refractory cases? (Q849783)

A. Elevate the head end of the bed to 30°.

B. Administer mannitol to maintain serum osmolality < 320 mOsm/kg.

C. Perform a decompressive craniectomy.

D. Start therapeutic hyperventilation.

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 35 y/o man with a head injury, scalp laceration, headache, skull depression, and CT showing an intracranial hematoma and frontal sinus involvement presents to the emergency department. What is the most appropriate management? (Q849775)

A. Monitor and allow spontaneous healing with no immediate intervention.

B. Order a follow-up CT scan in 24 hours to reassess the extent of the injuries.

C. Perform operative debridement and repair the scalp, and consider craniotomy

D. Administer antibiotics and provide supportive care without any surgical intervention.

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 25 y/o male presents to the emergency department after being struck on the head by a small, high-velocity object. He is conscious but reports a severe headache. A CT scan reveals a depressed skull fracture with evidence of intracranial air. Which of the following is the most appropriate next step in management? (Q849776)

A. Conservative management with observation.

B. Surgical exploration and elevation of the depressed fracture.

C. Intravenous antibiotics without surgery.

D. Application of a pressure dressing to the fracture site.

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 32 y/o male presents to the emergency department after a high-impact motor vehicle accident. He complains of a severe headache, difficulty smelling, and clear fluid dripping from his nose. O/E, there is no external evidence of trauma, but the patient has a subconjunctival haemorrhage in the right eye. What is the most likely location of his skull fracture? (Q849777)

A. Anterior cranial fossa

B. Middle cranial fossa

C. Posterior cranial fossa

D. Occipital bone

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 68 y/o male on warfarin therapy presents to the emergency department after a fall from a ladder. He is fully conscious with a Glasgow Coma Scale (GCS) score of 15. He reports no loss of consciousness but is unable to recall events that happened before the fall. According to NICE guidelines, what is the most appropriate timing for a CT head scan in this patient? (Q849778)

A. Immediate CT scan within 1 hour

B. CT scan within 8 hours

C. CT scan within 24 hours

D. No need for a CT scan; observation only

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 20 y/o male footballer sustains a blow to the head during a match. He did not lose consciousness but appeared confused and had difficulty recalling events before the impact. O/E, he is slow to respond and exhibits slight incoordination while walking. It is determined that he has suffered a concussion. Which of the following statements is most appropriate regarding his management? (Q849779)

A. He should be allowed to return to play if he feels better after 15 minutes.

B. An immediate CT scan is required to rule out a cerebral contusion.

C. He should be monitored for second-impact syndrome if he returns to play prematurely.

D. A diagnosis of concussion is unlikely since there was no loss of consciousness.

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 45 y/o male presents to the ED after a head injury sustained in a motor vehicle accident. He briefly lost consciousness at the scene but was alert and oriented upon arrival. A few hours later, he becomes progressively drowsy, and his right pupil is dilated. A CT scan shows the following findings. What is the most likely diagnosis?

(Q849780)

A. Subdural Hematoma (SDH)

B. Epidural Hematoma (EDH)

C. Intracerebral Haemorrhage (ICH)

D. Cerebral Contusion

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 60 y/o male suddenly experiences an intense headache, described as the worst headache of his life, followed by vomiting and photophobia. O/E he has neck stiffness and a dilated pupil on the right side. A CT scan reveals bleeding in the subarachnoid space. Which of the following is the most common cause of this condition? (Q849781)

A. Hypertension

B. Intracranial aneurysm

C. Arteriovenous malformation (AVM)

D. Brain tumour

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 35-year-old male in a high-speed crash presents with sudden loss of consciousness and remains comatose with neurological deficits, despite normal CT findings. What is the most likely diagnosis? (Q849782)

A. Contusion

B. Subdural hematoma

C. Diffuse axonal injury (DAI)

D. Epidural hematoma

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Match each description with the correct layer of the scalp: 1. Pericranium a) Richly vascularized 2. Aponeurosis b) Periosteum 3. Skin c) Danger zone 4. Connective Tissue d) Connects scalp muscles 5. Loose Areolar Connective Tissue e) Sebaceous glands (Q849665)

A. 1-d, 2-e, 3-c, 4-b, 5-a

B. 1-c, 2-d, 3-b, 4-d, 5-a

C. 1-e, 2-b, 3-a, 4-d, 5-c

D. 1-b, 2-d, 3-e, 4-a, 5-c

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 30 y/o woman sustains a stab wound in the neck that is located just above the cricoid cartilage but below the angle of the mandible. The injury is causing severe bleeding, and there is concern about the potential involvement of vital neck structures. Which neck zone is most relevant for assessing potential injury to major blood vessels and the trachea in this patient? (Q849784)

A. Zone I

B. Zone II

C. Zone III

D. Zone IV

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 67 y/o man collapses and requires cardiopulmonary resuscitation (CPR) in the emergency department. After successful resuscitation, imaging reveals a rib fracture. Which rib is most commonly fractured during CPR? (Q849785)

A. 1st rib

B. 2nd rib

C. 5th rib

D. 11th rib

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 55 y/o female was involved in a motor vehicle collision and now complains of severe anterior chest pain. O/E, she has point tenderness over the sternum and visible ecchymosis. What is the most likely associated injury that should be evaluated in a patient with a sternal fracture? (Q849786)

A. Rib fractures

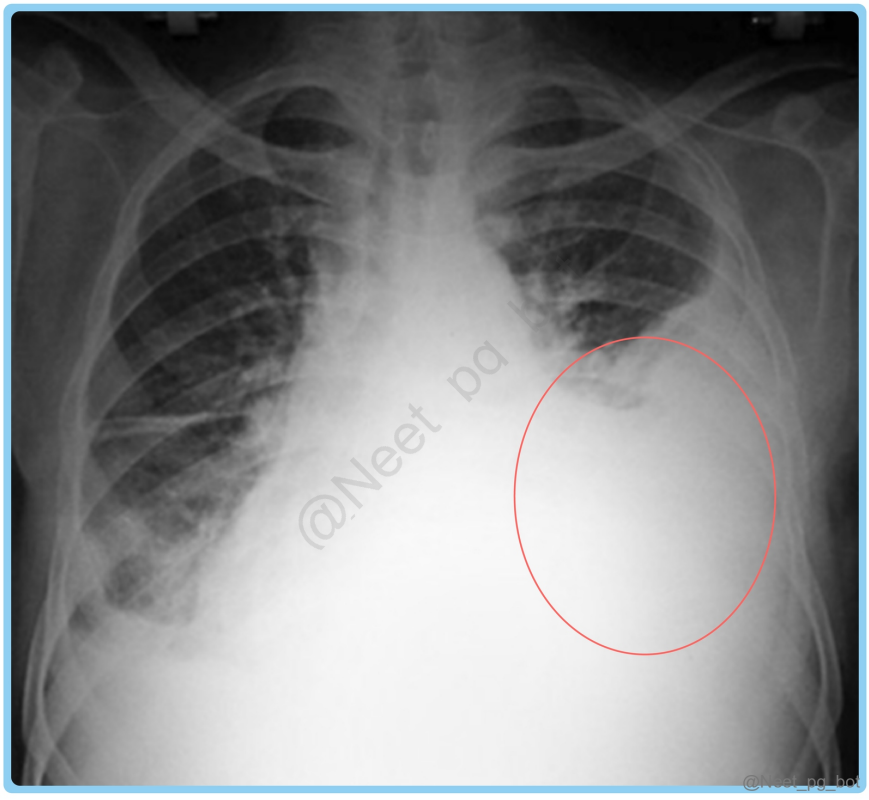
B. Pulmonary contusion

C. Myocardial contusion

D. Pneumothorax

See Answer in Part B → Q29

@Neet_pg_bot



Q30: A 34 y/o male presents to the ER after a high-speed car collision. He complains of severe shortness of breath, and physical examination reveals absent breath sounds on the lower left side with a dull note on percussion. The chest X-ray is given below. Which of the following is the most appropriate next step in management? (Q849787)

A. Needle thoracostomy

B. ICD (Intercostal Drain) insertion

C. Immediate thoracotomy

D. Observation and serial chest X-rays

See Answer in Part B → Q30

@Neet_pg_bot

Q31: A 45 y/o male presents with severe chest trauma following a motor vehicle accident. After inserting a chest tube, the initial drainage is 1600 ml of blood, and he continues to drain over 200 ml/hour for the next three hours despite stabilization efforts. What is the most appropriate next step in management? (Q849788)

A. Increase the suction on the chest tube

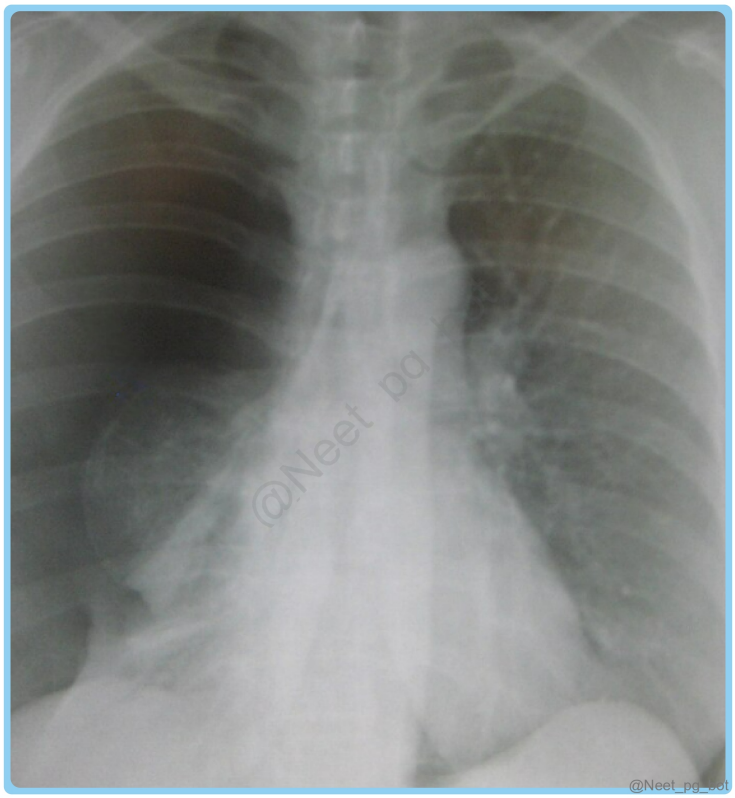
B. Administer intravenous fluids and continue observation

C. Perform an urgent thoracotomy

D. Insert a second chest tube

See Answer in Part B → Q31

@Neet_pg_bot



Q32: A 45 y/o man presents to the ED after a fall from a height. He is in severe respiratory distress, with rapid breathing. An x-ray film was taken of the chest which revealed the following. His blood pressure is rapidly dropping. Which of the following findings is least likely to be associated with this patient's condition? (Q849789)

A. Hyper-resonance on the affected side

B. Tracheal deviation towards the opposite side

C. Bilateral equal breath sounds

D. Distended neck veins

See Answer in Part B → Q32

@Neet_pg_bot

Q33: A 30-year-old male is brought in after a road traffic accident. He has quadriplegia, urinary retention, and cervical spine tenderness on examination. What is the most appropriate advice regarding radiographic evaluation in this patient? (Q880374)

A. Patient should not be moved; obtain a portable X-ray after stabilizing the neck

B. Ask the radiographer to take cervical and chest X-rays

C. Obtain AP and lateral cervical X-rays without cervical support

D. Order a cervical X-ray and allow the patient to shift himself from the trolley

See Answer in Part B → Q33

@Neet_pg_bot

Q25 (p. 958)	*Q26 (p. 958)*				

Q1: Which of the following statements about abdominal trauma is true? (Q880392)

A. The most commonly injured organ in blunt trauma is the liver

B. The spleen is the most commonly injured organ in penetrating trauma

C. In gunshot injuries, the stomach is the most commonly injured organ

D. The jejunum is the most commonly injured part of the bowel in blunt trauma

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 19-year-old male is brought to the emergency department after a high-speed car crash. He is hypotensive (SBP 65 mmHg), and a FAST scan is positive. At laparotomy, heavy bleeding is noted from the area behind the liver along with a hollow-viscus perforation. A Pringle manoeuvre does not control the bleeding. Laparotomy packs are placed, slowing the haemorrhage. Despite resuscitation, his blood pressure remains low. Arterial pH is 7.05, and core temperature is 34°C. What is the next best step in management? (Q880428)

A. Ligation of the hepatic arteries

B. Hepatectomy

C. Hepatic artery embolization

D. Shift the patient to ICU for resuscitation

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 10-year-old boy is brought to the emergency department after a bicycle handlebar injury to the abdomen. Ultrasound reveals a Grade II splenic laceration. The child is hemodynamically stable with no signs of ongoing bleeding. What is the most appropriate management in this case? (Q880426)

A. Conservative management

B. Splenectomy

C. Embolization

D. Splenorrhaphy

See Answer in Part B → Q3

@Neet_pg_bot

Q4: During an emergency laparotomy for a patient with blunt abdominal trauma, the surgeon encounters a perirenal hematoma around the left kidney. The patient remains hemodynamically unstable.What is the next best step in management? (Q880424)

A. Single-shot intravenous pyelography

B. Contrast-enhanced computed tomography

C. Ultrasonography of the abdomen

D. Direct renal exploration

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A young man sustains a renal injury following a road traffic accident and is initially managed conservatively. A few days later, he develops a flank swelling and imaging reveals a urinoma. What is the next best step in management? (Q880422)

A. Ureteral stenting

B. Surgical repair and exploration

C. Observation

D. Percutaneous drainage

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 25-year-old male presents after a high-velocity road traffic accident. He is hypotensive (BP 85/60 mmHg) and tachycardic (HR 100/min). Imaging suggests a pelvic fracture with retroperitoneal bleeding. Regarding the principles of damage control surgery (DCS), which of the following statements is correct? (Q880419)

A. Coagulopathy is corrected in Phase II of DCS

B. Definitive repair of injuries is done 12–24 hours after Phase III

C. Internal iliac artery ligation is done in Phase II

D. Hypothermia and acidosis are corrected in Phase I

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A trauma patient is undergoing diagnostic peritoneal lavage (DPL) to evaluate for intra-abdominal bleeding. Which one of the following statements regarding the interpretation of DPL results is incorrect? (Q880415)

A. More than 100,000 red blood cells per mm^3 is considered positive

B. More than 200 white blood cells per mm^3 is considered positive

C. Aspiration of 10 mL or more of gross blood is an indication for laparotomy

D. Amylase level greater than 175 units/dL is considered positive

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 12-year-old boy presents after a fall from a height with abdominal pain. He is hemodynamically stable on examination, with tenderness in the left flank region. Urinalysis reveals 50 RBC/hpf.What is the investigation of choice for this patient? (Q880400)

A. Contrast-enhanced CT scan

B. Retrograde urethrogram

C. Wait and watch

D. Emergency laparotomy

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 40-year-old man is admitted to the ICU following blunt abdominal trauma. On monitoring, his intra-abdominal pressure is measured as 24 mmHg.What is the grade of intra-abdominal hypertension in this patient? (Q880399)

A. Grade I

B. Grade II

C. Grade III

D. Grade IV

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 35-year-old woman with 35% total body surface area (TBSA) deep burns over the abdomen and lower limbs is admitted to the burns ICU. She had received 9 litres of Ringer's lactate at a peripheral hospital. On arrival, she is hypotensive (BP 86/52 mmHg), tachycardic (HR 120 bpm), and her urine output has been less than 15 mL over the past 2 hours. On examination, there are tight circumferential eschars over the abdomen. The ventilator shows peak airway pressures of 40 cm H■O. What is the most appropriate next step? (Q880396)

A. Administration of dobutamine

B. Measurement of bladder pressure

C. Diuresis with furosemide

D. Increase PEEP

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A critically ill patient on mechanical ventilation develops rising airway pressures, hypotension, and oliguria. Abdominal compartment syndrome is suspected. Which of the following statements is false regarding this condition? (Q880395)

A. Hypercarbia and respiratory acidosis

B. Hypoxia due to increased peak inspiratory pressure

C. Hypotension due to a decrease in venous return

D. Oliguria due to ureter obstruction

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 35-year-old man sustained a penetrating abdominal injury during a street altercation. At laparotomy, the cecum was found to be extensively damaged and non-salvageable. What is the most appropriate management for this patient? (Q880394)

A. Catheter tube cecostomy

B. Right hemicolectomy with ileocolostomy

C. Transverse colostomy

D. End loop sigmoid colostomy

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Regarding abdominal trauma, which of the following is correct? 1. The mesentery is the most commonly injured structure in seat belt injuries. 2. The first investigation in blunt abdominal trauma is CT scan. 3. FAST (Focused Assessment with Sonography for Trauma) is the initial investigation of choice. 4. CECT is the investigation of choice in a hemodynamically stable patient. (Q880393)

A. 1,3,4

B. 1,2,3

C. 2,3,4

D. 2,4

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following statements is true? The most commonly injured organ in blunt trauma to the abdomen is the liver. The liver is the most commonly injured organ in penetrating abdominal trauma. In gunshot injuries to the abdomen, the stomach is the most commonly injured organ. The jejunum is the most commonly injured part of the bowel in blunt trauma to the abdomen. The mesentery is the most commonly injured structure in seat belt injuries. The first investigation done on a patient with blunt abdominal trauma is a CT scan. CECT is the investigation of choice for a stable patient with blunt abdominal trauma. (Q849659)

A. 1, 2, 3, 6, 7

B. 3, 4, 5, 6

C. 2, 4, 5, 7

D. 1, 2, 5, 7

See Answer in Part B → Q14

@Neet_pg_bot

Q15: A 35 y/o male presents to the ER after a high-speed motor vehicle accident. He is hemodynamically stable but complains of left-sided abdominal pain. He has hematuria & his CECT shows a 3 cm laceration extending into the renal cortex and medulla without involvement of the collecting system. No evidence of vascular injury is noted. What is the most appropriate grade of renal trauma based on the findings? (Q849746)

A. Grade I Renal Trauma

B. Grade II Renal Trauma

C. Grade III Renal Trauma

D. Grade IV Renal Trauma

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 40 y/o male presents to the ER after being involved in a motorcycle collision. His vital signs are stable, and a CT scan reveals an expanding hematoma confined to the lateral retroperitoneum with no active bleeding. What is the most appropriate management approach for this patient? (Q849738)

A. Immediate surgical exploration

B. Extraperitoneal packing

C. Diagnostic peritoneal lavage (DPL)

D. Angioembolization

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 45 y/o male patient presents with abdominal distension, decreased urine output, and difficulty breathing following abdominal surgery. His intra-abdominal pressure (IAP) is measured at 28 cm H■O. Which of the following is the most appropriate next step in management? (Q849734)

A. Close monitoring in the ICU

B. Aggressive fluid resuscitation

C. Surgical decompression

D. Administration of diuretics

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 45 y/o male is undergoing damage control surgery after sustaining severe abdominal injuries in a construction accident. After rapid haemorrhage control, he is moved to the ICU for further resuscitation. What is the main focus during the ICU stage of damage control surgery? (Q849733)

A. Definitive Closure of the Abdomen

B. Ongoing Resuscitation and Stabilization

C. Repair of Organ Injuries

D. Selection of the Next Surgical Procedure

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 29 y/o male presents to the emergency following a high-speed car crash. He was wearing a seat belt and had a clear seat belt sign across his lower abdomen. He reports increasing abdominal pain and tenderness. Which structure is commonly injured in this scenario? (Q849732)

A. Mesentery

B. Liver

C. Spleen

D. Bladder

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 28 y/o male suffers a stab wound to the abdomen. During surgery, an injury to the head of the pancreas is discovered, with the involvement of both the main pancreatic duct and the intrapancreatic bile duct. Which surgical procedure is most appropriate for this injury? (Q849731)

A. Distal pancreatectomy

B. Whipple procedure

C. External drainage alone

D. Repair of the pancreatic duct without resection

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 40 y/o male presents to the emergency after a high-speed motorcycle collision. He is hemodynamically stable but reports severe, diffuse abdominal pain. On examination, there is significant tenderness in the upper abdomen, but no guarding or rebound tenderness is noted. Which of the following findings on the CT scan would most strongly suggest a duodenal injury? (Q849730)

A. Free air in the retroperitoneum

B. Liver laceration with intra-abdominal free fluid

C. Large splenic hematoma with peri splenic fluid collection

D. Moderate free fluid in the pelvis without solid organ injury

See Answer in Part B → Q21

@Neet_pg_bot

Q22: During liver trauma surgery, the Pringle manoeuvre is performed to control bleeding. Which of the following structures is occluded during this manoeuvre? (Q849674)

A. Hepatic artery

B. Portal vein

C. Both the hepatic artery and portal vein

D. Bile duct

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 35 y/o male presents to the emergency following a motor vehicle accident. He is hemodynamically stable with left upper quadrant tenderness. A FAST exam reveals free fluid in the abdomen. The CT scan shows a minor splenic injury. What is the most appropriate next step in management? (Q849663)

A. Immediate splenectomy

B. Non-operative management with close monitoring in ICU

C. Exploratory laparotomy

D. Angiography with embolization

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 34 y/o man presents with a gunshot wound to the abdomen. He is hemodynamically unstable with a blood pressure of 90/60 mmHg and a heart rate of 130 bpm. On examination, there is significant abdominal tenderness with guarding and rigidity. What is the best initial management step? (Q849662)

A. Perform a FAST scan

B. Start fluid resuscitation and obtain an abdominal X-ray

C. Urgent exploratory laparotomy

D. Obtain a CT scan with IV contrast

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following is the most accurate diagnostic tool for evaluating blunt abdominal trauma in a hemodynamically stable patient? (Q849661)

A. FAST (Focused Assessment with Sonography for Trauma)

B. Diagnostic Peritoneal Lavage (DPL)

C. CT scan with IV contrast

D. Plain abdominal X-ray

See Answer in Part B → Q25

@Neet_pg_bot

Q26: A 30 y/o male is admitted after a motorcycle accident with abdominal trauma. The doctor decides to perform initial imaging tests. Which statement about FAST, eFAST, and DPL is incorrect? (Q849660)

A. eFAST can detect >100 mL of free blood in the abdomen and thoracic cavities.

B. FAST is reliable for assessing retroperitoneum and detecting injuries to hollow viscus.

C. DPL is valuable in resource-limited settings and detects blood or contaminants in the abdomen.

D. FAST and eFAST do not determine the specific nature or extent of injuries.

See Answer in Part B → Q26

Q1: An elderly man with diabetes presents with progressive weight loss and poor appetite. You decide to assess his nutritional status using the Malnutrition Universal Screening Tool (MUST) . Which of the following factors are included in this assessment? 1. Body Mass Index (BMI) 2. Age 3. Recent weight loss 4. Current nutritional intake 5. Acute illness (Q880220)

A. 1,3,4,5

B. 1,2,3,4

C. 2,3,4,5

D. 1,2,3,5

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A patient with long-standing Crohn’s disease is found to have several skip lesions in the small intestine. If surgical excision includes the segment primarily responsible for bile salt absorption, the patient is most likely to develop steatorrhea. Which segment is this? (Q880219)

A. Duodenum

B. Ileum

C. Jejunum

D. Caecum

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Following an emergency laparotomy for a penetrating abdominal injury, a patient is left with less than 100 cm of jejunum and a jejunostomy is created. Which of the following statements regarding management of this condition is incorrect? (Q880218)

A. The patient behaves as a net secretor

B. Oral water intake should be restricted to less than 1 L per day

C. Resuscitation is best achieved with hypotonic intravenous fluids

D. Use of antisecretory agents is recommended

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following parameters is NOT included in the MELD (Model for End-Stage Liver Disease) score? (Q849882)

A. Bilirubin

B. Creatinine

C. International Normalized Ratio (INR)

D. Albumin

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 55 y/o male with advanced idiopathic pulmonary fibrosis (IPF) is evaluated for lung transplantation. He has significant dyspnea on minimal exertion, and his forced vital capacity (FVC) is 42% of the predicted value. His pre-transplant workup is

normal, and he is listed for a single lung transplant. Which of the following conditions is most likely to benefit from single lung transplantation? (Q849892)

A. Cystic fibrosis

B. Pulmonary arterial hypertension

C. Idiopathic pulmonary fibrosis

D. Bronchiectasis

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A 55 y/o male who underwent heart transplantation 10 years ago presents with exertional dyspnea and fatigue for a few weeks. His initial post-transplant course was uneventful, and he has been compliant with his immunosuppressive regimen. What is the most common cause of late mortality in heart transplant recipients that should be considered in this patient? (Q849891)

A. Graft rejection

B. Infection

C. Cardiac allograft vasculopathy (CAV)

D. Renal failure

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 45-year-old male with end-stage heart failure secondary to ischemic cardiomyopathy is being evaluated for orthotopic heart transplantation. After confirming the indications for transplantation, the surgical team begins the procedure. Which of the following represents the correct sequence of anastomoses typically performed? (Q849890)

A. Pulmonary artery → Left atrium → Aorta → Right atrium

B. Left atrium → Right atrium → Pulmonary artery → Aorta

C. Aorta → Pulmonary artery → Left atrium → Right atrium

D. Right atrium → Aorta → Pulmonary artery → Left atrium

See Answer in Part B → Q7

@Neet_pg_bot

Q8: In isolated intestine transplantation, the venous outflow from the allograft is typically established by anastomosis of which of the following? (Q849889)

A. Donor SMV to the recipient superior vena cava

B. Donor SMV to the recipient portal vein or inferior vena cava

C. Donor SMA to the recipient portal vein

D. Donor SMV to the recipient splenic vein

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A transplant team is evaluating potential cadaveric donors for a small bowel transplant. Criteria for donor selection include compatible blood type, size of the donor relative to the recipient, and viral serologic testing. Which of the following is NOT a criterion for donor selection in small bowel transplantation? (Q849888)

A. Blood type compatibility

B. Donor body weight 50% to 75% of the recipient’s weight

C. Maximum cold ischemia time of 10 to 12 hours

D. Donor's minimal vasopressor requirement

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 50-year-old female with a history of type 1 diabetes mellitus presents with recurrent severe hypoglycemia with decreased awareness. He is scheduled for islet cell transplantation. Which immunosuppressive regimen is most commonly used to prevent immune rejection of the transplanted islet cells? (Q849887)

A. Cyclosporine + azathioprine + prednisolone

B. Methotrexate + mycophenolate mofetil + hydrocortisone

C. Cyclophosphamide + etanercept + rituximab

D. Daclizumab + sirolimus + tacrolimus

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 45-year-old male with a history of type 1 diabetes mellitus undergoes a pancreas transplantation. On postoperative day 3, he develops sudden-onset severe abdominal pain, and doppler ultrasound reveals no blood flow to the pancreas graft. What is the most common cause of pancreatic graft failure in this scenario? (Q849886)

A. Vascular thrombosis

B. Anastomotic leak

C. Pancreatitis

D. Bleeding

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following statements is/are true regarding pancreas transplantation? Type-2 DM with clear c-peptide deficiency is not an indication for pancreas transplantation. End-to-end anastomosis is done between the internal iliac artery and splenic artery Systemic venous drainage is preferred over portal venous drainage Enteric drainage of endocrine secretion is preferred (Q849885)

A. Only 2

B. 1, 2, and 4

C. 2 and 3

D. All of the above

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following statements is NOT true regarding contraindications and complications of renal transplantation? (Q849884)

A. Renal vein thrombosis post-surgery is managed conservatively with anticoagulants

B. Active IV drug abuse is a contraindication for the transplant

C. Lymphocele can cause ureteric obstruction

D. Renal artery stenosis post-transplant is best treated by angioplasty

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 45-year-old male with end-stage renal disease due to polycystic kidney disease is scheduled for a renal transplant, with his brother serving as the donor. During the transplant procedure, where is the donor kidney typically placed, and to which vessel is its renal artery anastomosed? (Q849883)

A. Right hypochondrium and aorta

B. Left hypochondrium and external iliac artery

C. Iliac fossa and Internal iliac artery

D. Lumbar region and Inferior vena cava

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following best describes the definition of a "deceased person" according to the Transplantation of Human Organs Act? (Q849795)

A. A person who has been unconscious for more than 24 hours.

B. A person who has a permanent cessation of all evidence of life.

C. A person who has been declared clinically dead but with potential for revival.

D. A person who has undergone a major surgery with no sign of life for 6 hours.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 55-year-old patient with end-stage liver disease receives a liver from a donor with familial amyloid polyneuropathy (FAP) as part of a domino liver transplantation. Which of the following statements is incorrect? (Q849881)

A. It can use a liver from a patient with familial amyloid polyneuropathy (FAP).

B. FAP symptoms appear immediately after transplantation.

C. If the recipient later develops FAP symptoms, they can undergo a retransplantation without risk of malignancy recurrence.

D. The recipient is less likely to develop or be significantly affected by the metabolic syndrome

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 52-year-old woman, who underwent a liver transplant 2 months ago, presents with jaundice and bile leakage from the surgical site. Imaging studies suggest narrowing of the bile ducts. What is the most likely complication she is experiencing, and what could be the potential need for management? (Q849880)

A. Acute cellular rejection- Increase immunosuppressants

B. Chronic rejection- Continue monitoring

C. Ischemic-type biliary lesion (ITBL)- Consider retransplantation

D. Hepatic artery thrombosis- Start anticoagulation therapy

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 40-year-old male with end-stage liver disease due to chronic hepatitis C is being evaluated for a liver transplant. During the evaluation, it was noted that his 38-year-old sister is willing to donate a portion of her liver. Which of the following liver transplant options is most appropriate for this patient? (Q849879)

A. Deceased Donor Liver Transplantation (DDLT)

B. Domino Liver Transplantation

C. Living Donor Liver Transplantation (LDLT)

D. Split Liver Transplantation

See Answer in Part B → Q18

@Neet_pg_bot

Q19: Which of the following methods is currently considered the gold standard for preserving the pancreas before transplantation? (Q849878)

A. Hypothermic machine perfusion (HMP)

B. Normothermic machine perfusion (NMP)

C. Static cold storage (SCS) with University of Wisconsin (UW) solution

D. Normothermic regional perfusion (NRP)

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 45-year-old male is declared legally dead due to irreversible brainstem function loss following a severe head injury. He is considered for organ donation. Which of the following statements is true regarding Donation After Brainstem Death (DBD)? (Q849877)

A. In DBD complications like graft dysfunction, especially with the liver and pancreas, are expected.

B. A 5-minute "no-touch" period is observed in the case of DBD.

C. In DBD, organs are perfused with oxygenated blood at the time of procurement.

D. Warm ischemia is seen in DBD.

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 52-year-old female who received a multi-visceral transplant presents with unexplained fever, night sweats, and significant weight loss. Her laboratory results show persistent Epstein–Barr virus (EBV) viremia. Which of the following transplant recipients is at the highest risk of developing post-transplant lymphoproliferative disorder (PTLD)? (Q849803)

A. Kidney transplant recipient

B. Liver transplant recipient

C. Intestinal transplant recipient

D. Heart transplant recipient

See Answer in Part B → Q21

@Neet_pg_bot

Q22: In transplant recipients, which of the following is the most common cause of viral infection within the first 6 months post-transplant? (Q849802)

A. Herpes Simplex Virus (HSV)

B. Cytomegalovirus (CMV)

C. Epstein-Barr Virus (EBV)

D. BK Virus

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which intervention has been shown to reduce the risk of graft loss in kidney transplant recipients with BK virus nephropathy? (Q849801)

A. Increasing the dosage of calcineurin inhibitors

B. Administering antiviral therapy as a first-line treatment

C. Timely reduction of immunosuppressive therapy

D. Routine use of corticosteroids

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following is the most common malignancy in transplant recipients? (Q849800)

A. Kaposi Sarcoma

B. Post-transplant lymphoproliferative Disorder (PTLD)

C. Squamous Cell Carcinoma

D. Cytomegalovirus-Associated Tumors

See Answer in Part B → Q24

@Neet_pg_bot

Q25: Which of the following drugs works by inhibiting T-cell activation through the blockage of calcineurin, ultimately reducing IL-2 production? (Q849799)

A. Azathioprine

B. Prednisone

C. Tacrolimus

D. Sirolimus

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Which type of graft involves tissue transplantation between genetically identical individuals, such as identical twins? (Q849798)

A. Autograft

B. Allograft

C. Isograft

D. Xenograft

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 45-year-old patient requires a kidney transplant. Which statement about HLA matching is most accurate for this transplant? (Q849797)

A. Mismatches at the HLA-B locus have a more significant impact on transplant outcomes than mismatches at the HLA-DR locus.

B. HLA typing is typically performed using DNA sequencing to assess compatibility.

C. HLA Class I molecules are categorized into HLA-DP, HLA-DQ, and HLA-DR.

D. Tissue typing in transplantation includes HLA-B, HLA-C, and HLA-DP loci.

See Answer in Part B → Q27

@Neet_pg_bot

Q28: A 45-year-old male patient undergoes a kidney transplant. Shortly after the procedure, he experiences a rapid onset of graft dysfunction characterized by the destruction of the graft's vascularization. Which type of rejection does this patient most likely have? (Q849796)

A. Hyperacute Rejection

B. Acute Cellular Rejection

C. Acute Humoral Rejection

D. Chronic Rejection

See Answer in Part B → Q28

Q25 (p. 982)

Q1: Which of the following is the recommended knot for securing the final stitch in a continuous suture technique during surgery? (Q849771)

A. Reef knot

B. Aberdeen knot

C. Surgeon’s knot

D. Buried knot

See Answer in Part B → Q1

@Neet_pg_bot

Q2: In a patient suffering from acute pancreatitis, which electrolyte disturbance is most commonly observed? (Q880229)

A. Hypercalcemia

B. Hypocalcemia

C. Hypernatremia

D. Hyperkalemia

See Answer in Part B → Q2

@Neet_pg_bot

Q3: All of the following are recognised causes of hypokalemia except: (Q880228)

A. Hyperaldosteronism

B. Diarrhoea

C. High nasogastric output

D. Metabolic acidosis

See Answer in Part B → Q3

@Neet_pg_bot

Q4: In a post-surgical patient, which of the following is typically the first clinical indication of fluid overload? (Q880227)

A. Distended neck veins

B. Peripheral edema

C. Weight gain

D. Increased cardiac output

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Long-term dependence on total parenteral nutrition without adequate supplementation can most commonly lead to deficiency of which of the following? (Q880226)

A. Vitamin B12

B. Folic acid

C. Amino acids

D. Zinc

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A patient has been receiving total parenteral nutrition (TPN) through a central venous line for more than a month. Which of the following is not routinely recommended as part of monitoring during TPN therapy? (Q880225)

A. Regular assessment for new-onset glucose intolerance

B. Checking serum electrolytes every 2–3 days

C. Weekly monitoring of liver function tests and blood urea nitrogen

D. Scheduled replacement of the central venous catheter every two weeks

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A patient is started on total parenteral nutrition through a peripherally inserted central catheter. After placement, a chest radiograph is obtained to confirm the line's position. The catheter tip should ideally terminate in which vessel? (Q880223)

A. Subclavian vein

B. Internal jugular vein

C. Superior vena cava

D. Inferior vena cava

See Answer in Part B → Q7

@Neet_pg_bot

Q8: While inserting a Ryle's tube in a conscious patient, which position is considered most appropriate to facilitate the smooth passage of the tube? (Q880221)

A. Supine with neck flexion

B. Supine with neck extension

C. Sitting with neck flexion

D. Sitting with neck extension

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following contributes to the generation of endogenous water within the body? (Q880217)

A. Ingested fluids

B. Breakdown of solid food

C. Oxidation of solid foodstuffs

D. Both A and C

See Answer in Part B → Q9

@Neet_pg_bot

Q10: During morning rounds, an intern is asked how to recognise inadequate perfusion in a burns patient receiving fluid therapy. The resident explains that a fluid bolus of 10 mL/kg should be given if certain warning signs appear. Which of the following is not an indication for administering a fluid bolus?: (Q880215)

A. Tachycardia

B. Low hematocrit

C. Restlessness

D. Cool peripheries

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 60-year-old patient is undergoing ileostomy closure and the surgeon opts for a hand-sewn anastomosis technique. Which of the following accurately describes the single-layer hand-sewn anastomosis technique? (Q849774)

A. It includes an inner continuous suture layer and an outer layer of interrupted sutures.

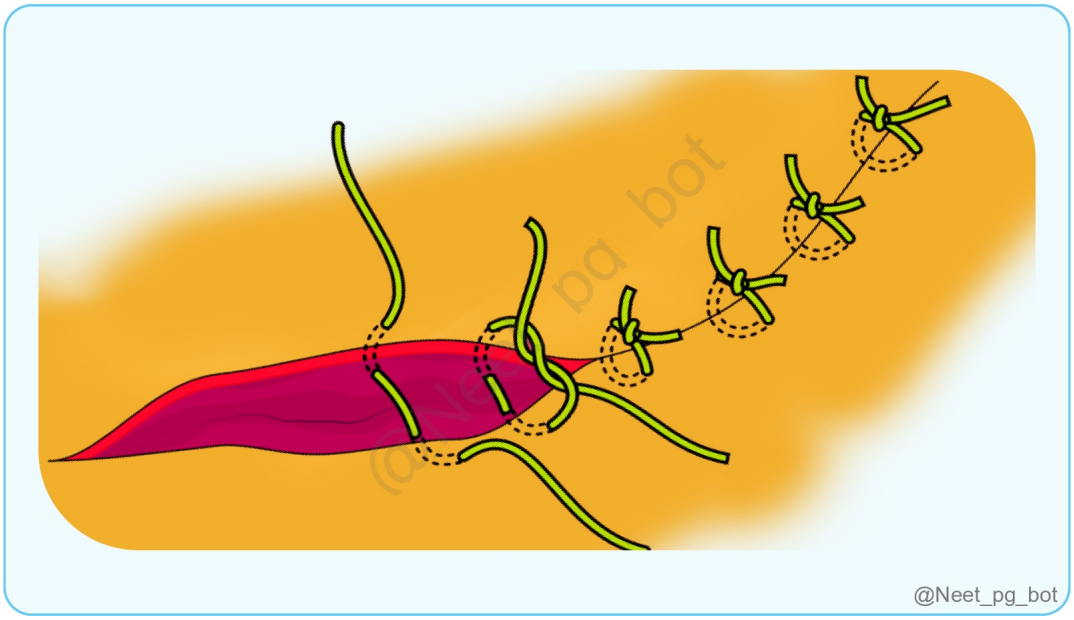
B. It uses a continuous suture line through all layers of the bowel wall, except the mucosa.

C. It uses a continuous suture line through all layers of the bowel wall.

D. It involves placing a purse-string suture on the distal stump and stapling the anastomosis.

See Answer in Part B → Q11

@Neet_pg_bot



Q12: Identify the type of suturing technique used in the image given below. (Q849773)

A. Interrupted sutures

B. Continuous sutures

C. Mattress sutures

D. Subcuticular sutures

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which of the following types of surgical needles is most appropriate for suturing tough or dense tissue such as skin and fascia? (Q849772)

A. Round-bodied needle

B. Triangular needle

C. Blunt-ended needle

D. J-shaped needle

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 45 y/o male patient is admitted to the ICU following a major road traffic accident, resulting in multiple fractures and abdominal injuries. The patient is currently unable to take oral nutrition. He is expected to require enteral feeding for more than 3 weeks. Imaging studies reveal delayed gastric emptying and significant gastric distension. What is the most appropriate route for enteral nutrition in this patient? (Q849754)

A. Nasogastric tube

B. Ryles tube

C. Feeding gastrostomy

D. Feeding jejunostomy

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following best describes Jenkins's rule in the context of abdominal wound closure? (Q849770)

A. Use of interrupted sutures with bites 2 cm apart to reduce wound tension.

B. Continuous suturing with bites 1 cm apart, avoiding suture locking to create a "spring coil" effect.

C. Continuous suturing with locking sutures, with bites placed 1 cm from the wound edge

D. Use of mattress sutures to maximize the tension across the wound during healing

See Answer in Part B → Q15

@Neet_pg_bot

Q16: A 60-year-old woman with a history of peripheral artery disease presents with critical limb ischemia. She is scheduled for a femoral-popliteal bypass surgery to restore blood flow to her lower extremity. Which suture is preferred for vascular anastomosis? (Q849769)

A. Prolene

B. Silk

C. Vicryl

D. Nylon

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A 45-year-old female undergoes an abdominal hysterectomy. The surgeon chooses to close the rectus sheath using PDS (polydioxanone) sutures due to their prolonged tensile strength. What is the expected time frame for the complete absorption of the polydioxanone sutures in this patient? (Q849763)

A. 60 - 90 days

B. 180 days

C. 90 - 120 days

D. 7 - 10 days

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 28-year-old male undergoes repair of a laceration on his forearm following a minor accident. The surgeon chooses monocryl for the subcutaneous layer and polyglycolic acid sutures for the deep dermal layer. Which of the following statements is/are true regarding these sutures in this case? Poliglecaprone is not preferred for subcuticular suturing Monocryl is a polymer of glycolide and caprolactone Polyglycolic acid exhibits highest affinity for adherence to E.coli and staph. aureus Patient is informed that monocryl will be completely absorbed in 180 days (Q849762)

A. Only 2

B. 2 and 3

C. 1, 2 and 4

D. All the statements

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 30-year-old female undergoes an elective laparoscopic cholecystectomy, during which the surgeon uses Vicryl sutures to close the internal fascial layers. Postoperatively, the patient expresses concern about how long the sutures will remain in her body before being fully absorbed. What is the expected time frame for complete absorption of the Vicryl sutures in this case? (Q849761)

A. 60 - 90 days

B. 180 days

C. 90 - 120 days

D. 7 - 10 days

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 30-year-old man undergoes an open appendectomy, and plain catgut sutures are used for closing the muscle layer. Which of the following statements regarding these sutures is most accurate? (Q849760)

A. Non-absorbable and provide long-term tensile strength

B. Made from synthetic materials and are highly resistant to enzymatic degradation

C. Primarily absorbed by enzymatic proteolysis and has variable tensile strength

D. Causes minimal tissue reaction and are preferred for patients with suture allergies

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 30-year-old male undergoes abdominal surgery, and the surgeon plans to use a non-absorbable monofilament suture for skin closure to minimize tissue reaction and ensure long-term wound support. Which of the following sutures should be selected? (Q849759)

A. Polyglactin 910 (Vicryl)

B. Polydioxanone (PDS)

C. Nylon

D. Polyglycolic acid (Dexon)

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 45 year old male severely malnourished patient with a history of chronic alcoholism and recent weight loss is admitted in the hospital. After stabilization, he is

started on a high-calorie enteral feeding regimen to address his nutritional deficiencies. Within 48 hours of initiating feeding, he begins to have muscle weakness, difficulty in breathing and is confused. Which of the following electrolyte abnormalities in the blood is least likely to be associated with his current condition? (Q849758)

A. Hypophosphatemia

B. Hypokalemia

C. Hypomagnesemia

D. Hypernatremia

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A 72-year-old male with severe pancreatitis is initiated on total parenteral nutrition (TPN) due to his inability to tolerate enteral feeding. Shortly after the central venous catheter is inserted, he complains of sudden onset shortness of breath and pleuritic chest pain. On examination, his breath sounds are decreased on the same side of the catheter insertion. What is the most likely complication that has occurred? (Q849757)

A. Catheter-related sepsis

B. Catheter related thrombosis

C. Dyselectrolytemia

D. Pneumothorax

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 45-year-old male recovering from gastrointestinal surgery is on total parenteral nutrition (TPN). Initially, he was receiving a 2-in-1 TPN formulation. Due to ongoing nutritional needs, the medical team switches him to a 3-in-1 TPN

formulation. Which component is newly included in the 3-in-1 formulation that was not in the 2-in-1? (Q849756)

A. Amino acids

B. Dextrose

C. Lipids

D. Fiber

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 38-year-old male involved in a motor vehicle accident has been in the ICU for several days with multiple injuries including head and abdominal trauma. The ICU team is considering starting enteral feeding. Which of the following findings would most likely contraindicate the initiation of enteral nutrition in this patient? (Q849755)

A. Inflammatory bowel disease

B. Distal low-output enterocutaneous fistula

C. Proximal small intestinal fistula

D. Constipation

See Answer in Part B → Q25

@Neet_pg_bot

[12_Miscellaneous] 061 Shock — Quick Jump

Q1 (p. 983)	*Q2 (p. 983)*	*Q3 (p. 984)*	*Q4 (p. 984)*	*Q5 (p. 984)*	*Q6 (p. 985)*
Q7 (p. 985)	*Q8 (p. 986)*	*Q9 (p. 986)*	*Q10 (p. 987)*	*Q11 (p. 987)*	*Q12 (p. 987)*
Q13 (p. 988)	*Q14 (p. 988)*	*Q15 (p. 989)*	*Q16 (p. 989)*		

Q1: A 56-year-old man is brought to the emergency department after a road traffic accident. He is confused, has a heart rate of 132/min, blood pressure 78/50 mmHg, cool clammy extremities, and a capillary refill time of >4 seconds. Arterial blood gas shows metabolic acidosis with elevated lactate.Which statement best explains the underlying pathophysiology in this patient's condition? (Q849579)

A. Decreased tissue perfusion leading to impaired oxygen delivery and utilization at the cellular level.

B. Low arterial pressure alone, irrespective of oxygen delivery.

C. Fluid loss without impact on cellular respiration.

D. Inflammatory cytokine release causing organ failure in all patients with trauma.

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 25-year-old male patient was brought with multiple injuries on his body following a road traffic accident. O/E patient was drowsy and confused, extremities were cold and clammy, weak thready pulse noted. On auscultation, tachypnoea and tachycardia observed. Identify the type of shock seen in this patient. (Q849580)

A. Hypovolemic shock

B. Distributive shock

C. Neurogenic shock

D. Cardiogenic shock

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old male patient was brought to the emergency department following a road traffic accident. O/E, he had multiple injuries all over his body and was found to be in class III hemorrhagic shock. The percentage of blood loss would be between: (Q849581)

A. 5-15%

B. 30-40%

C. >40%

D. 15-30%

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Following a road traffic accident, a 23-year-old man presents with multiple injuries on his body and the percentage of blood loss is <15%. Identify which class of ATLS classification it belongs to. (Q849582)

A. Class 1

B. Class 2

C. Class 3

D. Class 4

See Answer in Part B → Q4

@Neet_pg_bot

Q5: A 62-year-old male with a history of hypertension and type 2 diabetes presents with chest pain. His ECG shows ST-segment elevation in the anterior leads. Despite

initial treatment, his condition deteriorates with low blood pressure, rapid heart rate, and difficulty breathing. Examination reveals elevated jugular venous pressure (JVP) and crackles on lung auscultation. What type of shock is this patient most likely experiencing? (Q849583)

A. Cardiogenic shock

B. Obstructive shock

C. Hypovolemic shock

D. Septic shock

See Answer in Part B → Q5

@Neet_pg_bot

Q6: A patient admitted to the hospital with a urinary tract infection develops oliguria and lightheadedness on the third day of admission. His peripheries are warm, capillary refill is brisk, and his blood pressure is noted to be 86/56 mmHg despite fluid resuscitation. What type of shock is this patient likely experiencing? (Q849584)

A. Hypovolemic shock

B. Septic shock

C. Obstructive shock

D. Cardiogenic shock

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 42-year-old man is brought after a high-impact motor vehicle accident. On examination, he has a spinal cord injury at the level of T6 with flaccid paralysis of the lower extremities. His vital signs show hypotension, bradycardia, and warm, flushed skin. Which of the following is the most likely underlying pathophysiologic mechanism for his shock state? (Q849585)

A. Decreased cardiac output

B. Decreased blood volume

C. Increased vascular permeability

D. Decreased peripheral vascular resistance

See Answer in Part B → Q7

@Neet_pg_bot

Q8: A 28-year-old male presents with a sudden onset of severe fatigue, weakness, nausea, vomiting, and abdominal pain. On examination, he is hypotensive (BP 75/45 mmHg), tachycardic (HR 115 bpm), and has noticeable diffuse skin hyperpigmentation, especially in sun-exposed areas and palmar creases. Laboratory results reveal: Sodium: 128 mEq/L Potassium: 5.8 mEq/L Glucose: 58 mg/dL What is the most likely diagnosis? (Q849586)

A. Diabetic ketoacidosis

B. Septic shock

C. Addison's disease

D. Panhypopituitarism

See Answer in Part B → Q8

@Neet_pg_bot

Q9: A 55-year-old patient is brought to the emergency department with severe abdominal pain, tachycardia, and hypotension. Examination reveals pale, cool, and clammy skin with delayed capillary refill. The patient has oliguria. Which of the following hemodynamic profiles is most characteristic of this patient's condition? (Q849587)

A. SVR - ↓ ; CO - ↑ ; CVP - Normal or ↑

B. SVR - ↑ ; CO - ↓ ; CVP - ↓

C. SVR - ↓ ; CO - ↓ ; CVP - ↑

D. SVR - ↑ ; CO - ↑ ; CVP - ↑

See Answer in Part B → Q9

@Neet_pg_bot

Q10: A 65-year-old patient presents with sudden onset of shortness of breath, tachycardia, and hypotension. Examination reveals cool, clammy skin, and delayed capillary refill. The most appropriate initial management strategy for this patient's condition would be : (Q849588)

A. Fluid resuscitation with normal saline and initiation of norepinephrine

B. Fluid resuscitation with Ringer's lactate and initiation of dobutamine

C. Fluid resuscitation with normal saline and initiation of dopamine

D. Fluid resuscitation with Ringer's lactate and initiation of epinephrine

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Among the different types of shock, which one is most common? (Q880237)

A. Hypovolemic

B. Cardiogenic

C. Obstructive

D. Distributive

See Answer in Part B → Q11

@Neet_pg_bot

Q12: A 24-year-old man is brought to the emergency department after sustaining multiple injuries in a motorcycle crash. He is hypotensive and tachycardic, and

physical examination shows cool extremities and delayed capillary refill. His body initiates compensatory mechanisms to maintain perfusion to vital organs. Which of the following tissues is least likely to maintain adequate blood flow during this compensatory response? (Q880242)

A. Brain

B. Heart

C. Kidneys

D. GI tract

See Answer in Part B → Q12

@Neet_pg_bot

Q13: Which type of shock is associated with cardiac tamponade? (Q880246)

A. Hypovolemic shock

B. Cardiogenic shock

C. Obstructive shock

D. Distributive shock

See Answer in Part B → Q13

@Neet_pg_bot

Q14: Which of the following equations correctly represents the calculation of the modified shock index? (Q880252)

A. Heart Rate divided by Systolic Blood Pressure (HR/SBP)

B. Heart Rate divided by Diastolic Blood Pressure (HR/DBP)

C. Heart Rate divided by Mean Arterial Pressure (HR/MAP)

D. Pulse Rate divided by Systolic Blood Pressure (PR/SBP)

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following are included in the quick Sequential Organ Failure Assessment (qSOFA) criteria? 1. Respiratory rate ≥ 22 breaths per minute 2. Systolic blood pressure ≤ 100 mmHg 3. Altered mental status (Glasgow Coma Scale < 15) 4. Heart rate ≥ 120 beats per minute 5. Fever ≥ 38°C (Q880270)

A. 1, 2, 3

B. 2, 3, 4

C. 3, 4, 5

D. 1, 2, 4

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following are not included in the Systemic Inflammatory Response Syndrome (SIRS) criteria? 1. Body temperature > 38°C or < 36°C 2. Heart rate > 90 beats per minute 3. Respiratory rate > 20 breaths per minute or PaCO■ < 32 mmHg 4. White blood cell count > 12,000/mm³ or < 4,000/mm³ or > 10% immature forms (bands) 5. Systolic blood pressure < 90 mmHg (Q880272)

A. 1 only

B. 2 and 3

C. 5 only

D. 1 and 4

See Answer in Part B → Q16

Q1: A 45-year-old patient undergoes a mastectomy for breast cancer. Post-operatively, the surgeon decides to use a closed suction drain. Which of the following drain types is shown in the image below? (Q849748)

A. Penrose drain

B. Jackson Pratt drain

C. Romovac suction drain

D. Hemovac drain

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 6-month-old infant is admitted with severe vomiting and requires placement of a gastric tube. The nurse sets up the feeding equipment as shown in the image. Which of the following tubes is correctly depicted in the image? (Q849749)

A. Nasogastric tube

B. Infant feeding tube

C. Orogastric tube

D. Jejunal feeding tube

See Answer in Part B → Q2

@Neet_pg_bot

Q3: A 45-year-old patient undergoes a choledochotomy for the removal of common bile duct stones. The surgeon decides to use the given tube during the procedure.

Which of the following statements best describes its correct use and function in this scenario? (Q849750)

A. It is inserted to provide long-term biliary drainage and should be left in place for several months.

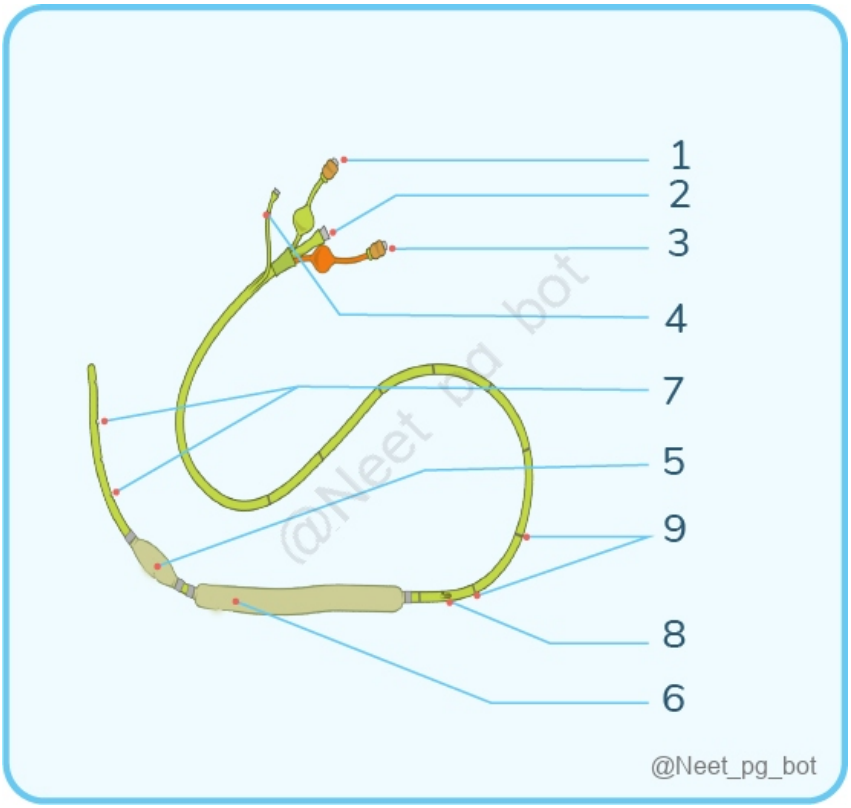
B. It acts as a stent and is retained for 4-6 weeks in the distal filling defect.

C. It is used to create a biliary-enteric anastomosis and is removed immediately after surgery.

D. It is placed to perform intraoperative cholangiography and is removed before closing the incision.

See Answer in Part B → Q3

@Neet_pg_bot



Q4: A 45-year-old patient with a history of cirrhosis presents to the emergency department with massive hematemesis. The physician uses an instrument given in the picture below. Which of the following statements is correct with respect to use of this device? (Q849751)

A. This instrument is commonly used if variceal bleeding does not stop by banding/sclerotherapy/gluing.

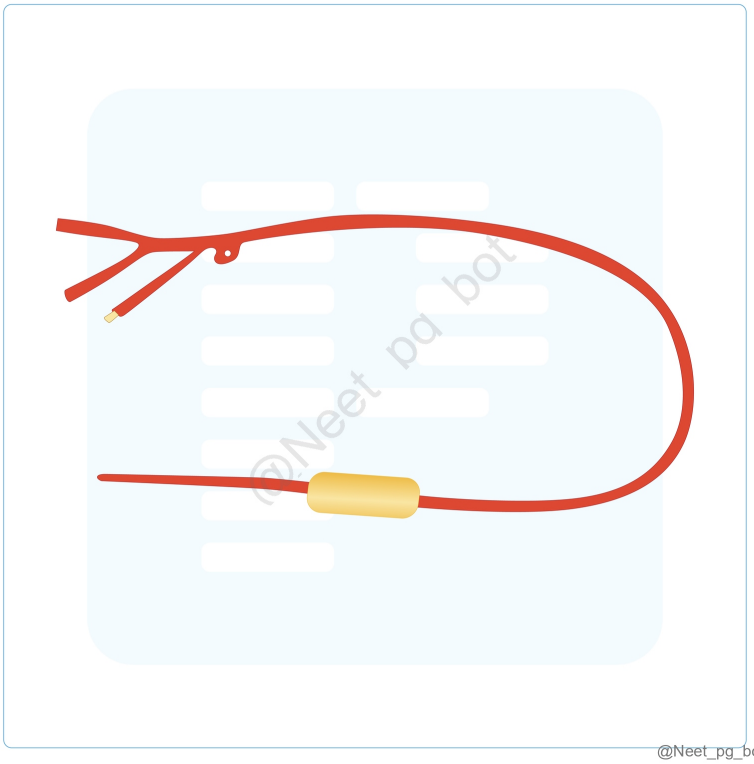
B. The esophageal balloon is inflated first with 30-40 mmHg pressure, followed by gastric balloon inflation with 400 mL of air.

C. It is a definitive treatment and does not require further procedures like banding or sclerotherapy.

D. The most common complication associated with its use is pressure necrosis of esophageal mucosa.

See Answer in Part B → Q4

@Neet_pg_bot



Q5: A 60-year-old man with a history of alcoholic cirrhosis presents to the emergency department with massive hematemesis. After initial stabilization, the decision is made to use the following device, as given in the picture below, for temporary management of suspected bleeding gastric varices. Which of the following statements about the device is INCORRECT? (Q849752)

A. The device shown in the picture is Sengstaken-Blakemore tube

B. It contains three lumens consisting of Esophageal and gastric aspiration port, and a port for balloon inflation

C. It has a single gastric balloon with capacity 500-600cc

D. It is used for temporary management of bleeding gastric varices

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following statements about the following instrument in the image is incorrect? (Q849753)

A. The catheter is coated with silicone to minimize irritation during prolonged use.

B. For self-retaining purposes, the balloon is inflated with 20-30 ml of saline.

C. It can be used for administration of intravesical chemotherapy

D. 2-way foley’s catheter can be used for bladder irrigation following TURP

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 58-year-old patient is rushed to the emergency department with symptoms of acute limb ischemia. The vascular surgeon diagnoses an arterial embolism and decides to perform an embolectomy. Which of the following catheters is specifically designed and most appropriate for this procedure? (Q849764)

A. Swan-Ganz catheter

B. Fogarty Catheter

C. De-Pezzer Catheter

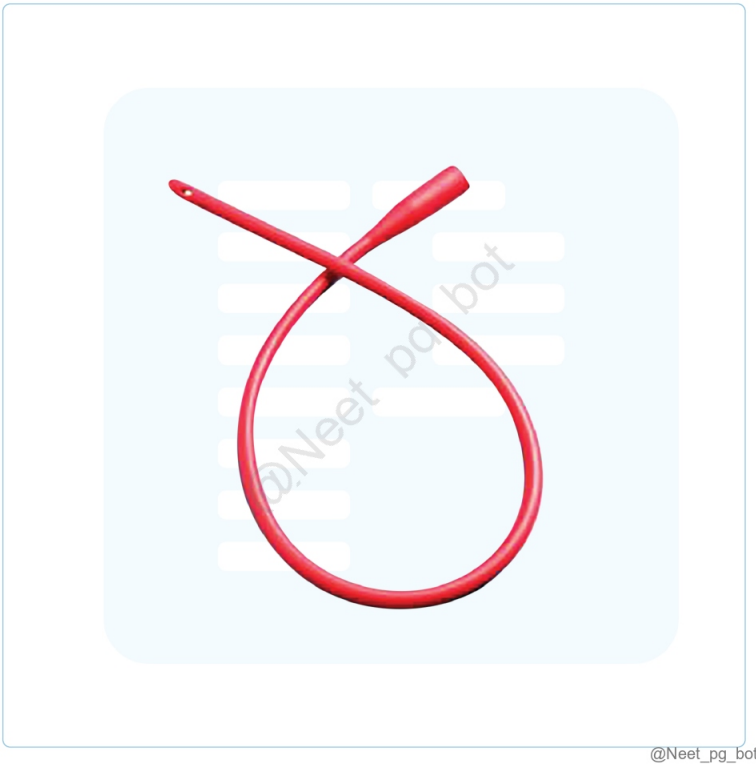
D. Malecot’s Catheter

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Match the following: a. Foley’s catheter 1. b. Nelaton’s catheter 2. c. Malecot’s catheter 3. d. Red-rubber catheter 4. (Q849765)

A. a-3, b-4, c-1,d-2



B. a-4, b-3, c-2, d-1

C. a-1, b-2, c-3, d-4

D. a-2, b-1, c-4, d-3

Q9: All of the following are true statements regarding central venous catheters except- (Q849766)

A. The tip of the catheter is situated in the inferior vena cava

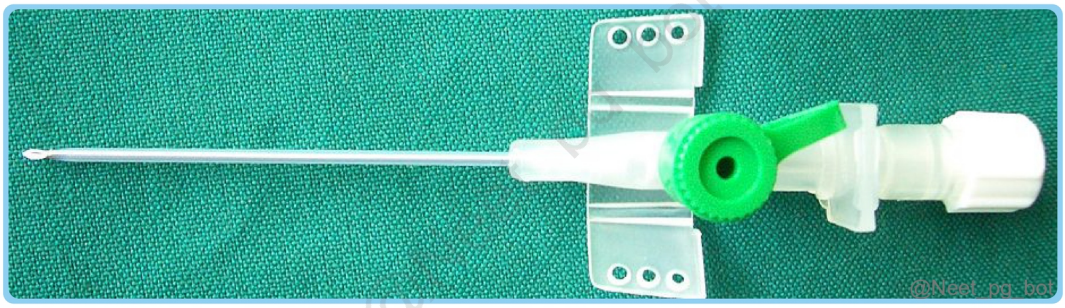
B. The most dangerous complication is pneumothorax

C. Inside OT, the Internal jugular vein is the preferred vein

D. In acutely injured, critically ill patients Femoral vein is the preferred vein

See Answer in Part B → Q9

@Neet_pg_bot



Q10: What is the size of the cannula shown in the below image? (Q849767)

A. 18G

B. 20G

C. 24G

D. 26G

See Answer in Part B → Q10

@Neet_pg_bot

Q11: All of the following about chemo-port is true, except (Q849768)

A. Retained for 5 years

B. Used for chemotherapy administration

C. The catheter is placed beneath the skin

D. The veins used are the internal jugular and subclavian veins.

See Answer in Part B → Q11

Q1: The surgical instrument displayed in the image is not typically used for which of the following purposes? (Q880283)

A. Blunt dissection of soft tissues in pelvic surgery

B. Deep tissue dissection during vagotomy

C. Cutting sutures on the skin surface

D. Dissection during laparoscopic cholecystectomy

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Which of the following is an advantage of robotic-assisted surgery over conventional laparoscopy? (Q880402)

A. Completely eliminates the need for trained surgical assistance

B. Offers fully autonomous operation without surgeon input

C. Provides motion scaling and tremor suppression for enhanced precision

D. Has lower cost compared to laparoscopic surgery

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Flexible sigmoidoscopy is a diagnostic procedure commonly used to evaluate the lower gastrointestinal tract. Up to which part of the colon can a flexible sigmoidoscope typically reach? (Q880401)

A. Ascending colon

B. Hepatic flexure

C. Splenic flexure

D. Sigmoid colon

See Answer in Part B → Q3

@Neet_pg_bot

Q4: Which of the following best explains the mechanism of action of the wound management technique shown in the image? (Q880398)

A. Application of negative pressure to promote wound healing

B. Application of positive pressure to increase tissue perfusion

C. Use of foam dressing to provide antimicrobial action

D. Use of sponge material to mechanically debride the wound

See Answer in Part B → Q4

@Neet_pg_bot

Q5: Which of the following statements about the device shown in the image is true? (Q880397)

A. The electrical current passes between two closely placed electrodes on the surgical site

B. It does not require a grounding pad since the circuit is closed within the instrument

C. Unipolar cautery has a lower risk of electrical burns compared to bipolar cautery

D. The current enters the patient through the active electrode and exits via a dispersive electrode

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Which of the following features is most characteristic of coagulation mode in electrosurgical diathermy? (Q880391)

A. Continuous low-voltage current with rapid heating and tissue vaporization

B. Energy concentrated over a small area with minimal lateral thermal spread

C. Intermittent high-voltage current causing tissue dehydration and protein denaturation

D. Generation of sparks used primarily for precise tissue dissection

See Answer in Part B → Q6

@Neet_pg_bot

Q7: What is the primary use of the instrument shown in the image below? (Q880390)

A. Measuring oral temperature

B. Measuring rectal temperature

C. Measuring tympanic temperature

D. Measuring axillary temperature

See Answer in Part B → Q7

@Neet_pg_bot

Q8: In adult males, which Foley catheter size is generally preferred to minimize urethral trauma while ensuring adequate drainage? (Q880385)

A. 8 French

B. 12 French

C. 16 French

D. 20 French

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Identify the medical device shown in the image below: (Q880384)

A. Central venous catheter

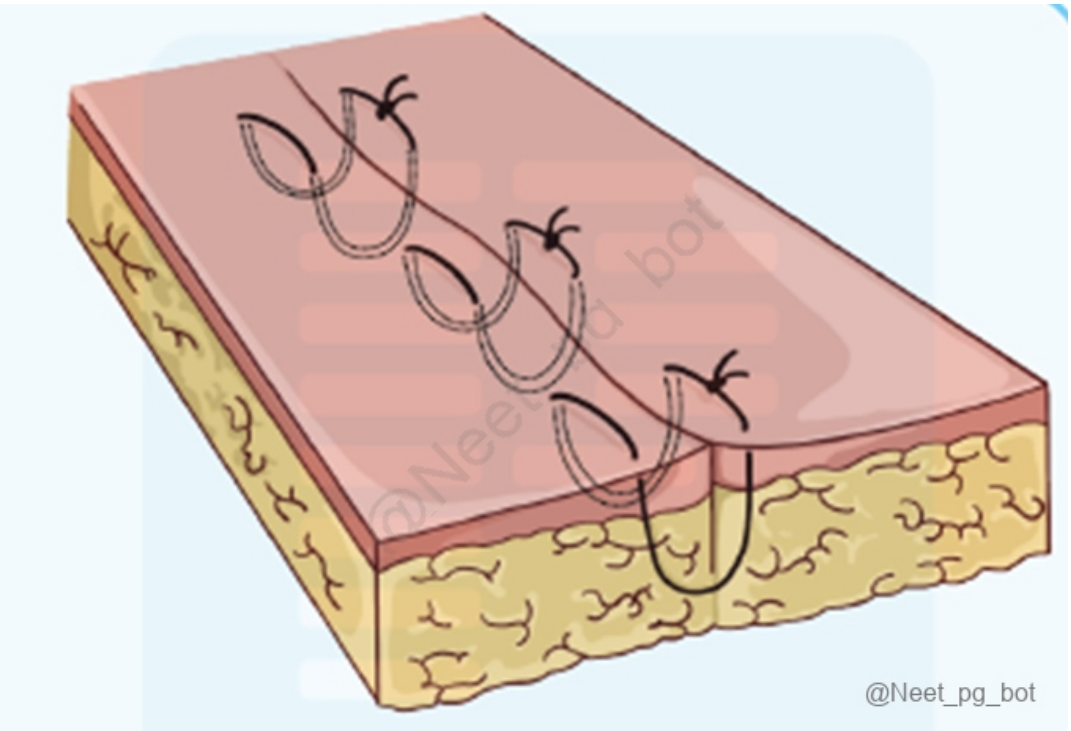
B. Pigtail catheter

C. Foley catheter

D. Nasogastric tube

See Answer in Part B → Q9

@Neet_pg_bot



Q10: Identify the suturing technique demonstrated in the accompanying image. (Q880381)

A. Interrupted sutures

B. Continuous sutures

C. Mattress sutures

D. Subcuticular sutures

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which of the following statements about surgical knots is correct? (Q880380)

A. A square knot provides more security than a granny knot due to equal tension in both throws

B. A granny knot is preferred over a square knot for ligating blood vessels because it tightens more securely

C. A surgeon's knot involves a single throw followed by multiple throws to reduce slippage in high-tension areas

D. The slip knot is used to permanently secure sutures as it does not loosen over time.

See Answer in Part B → Q11

@Neet_pg_bot

Q12: The eye present at the tip of Kocher’s thyroid dissector is used for: (Q880379)

A. Passing ligatures through it to tie the superior pedicle

B. Fixation to the thyroid capsule

C. Holding the inferior thyroid artery

D. Injecting local anesthetic

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A surgeon is performing an inguinal hernia repair and needs an instrument to retract the skin, fascia, and muscle superficially. Which retractor is most appropriate for this purpose? (Q880377)

A. Deaver retractor

B. Langenbeck retractor

C. Kocher’s intestinal clamp

D. Lahey’s thyroid tenaculum

See Answer in Part B → Q13

@Neet_pg_bot

Q14: The primary function of the instrument depicted is to, (Q880373)

A. Retracting the abdominal wall and deep viscera like liver and spleen

B. Levering tissues atraumatically to provide adequate surgical exposure

C. Clamping and holding intestinal tissue firmly during bowel surgery

D. Assisting in major abdominal surgeries such as cholecystectomy

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following statements correctly describes the Morris retractor? (Q880372)

A. Self-retaining, used in oral surgery

B. Flat curved blade with blunt ridge

C. Sharp hooks for thyroid tissue

D. Toothed clamp for intestines

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which surgical instrument is depicted in the image provided below? (Q880288)

A. Langenbeck retractor

B. Kocher’s intestinal clamp

C. Doyen’s mouth gag

D. Lahey’s thyroid tenaculum

See Answer in Part B → Q16

@Neet_pg_bot

Q17: Which of the given instrument's tip resembles the given image? (Q849835)

A. Mayo's Towel Clip

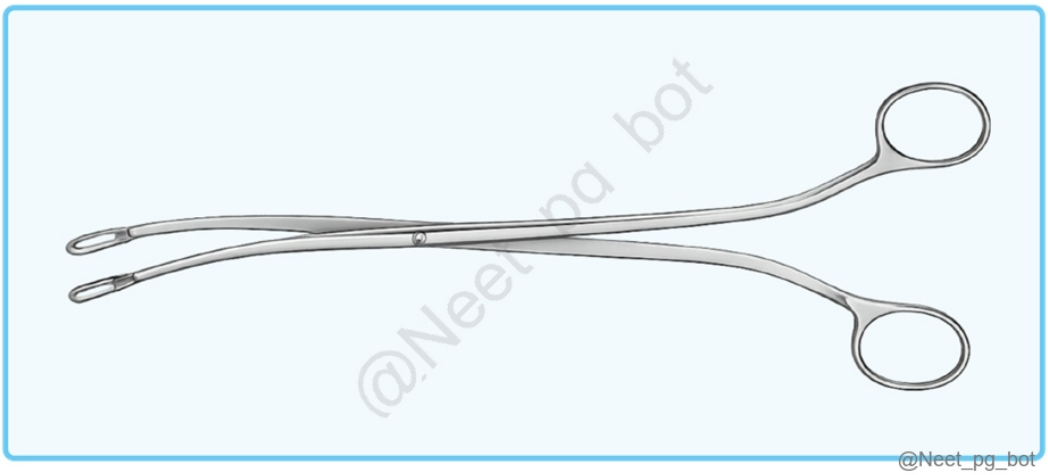
B. Rampley's Sponge Holding Forceps

C. Moynihan's Tetra-Towel Clip

D. Doyen's Towel Clip

See Answer in Part B → Q17

@Neet_pg_bot



Q18: What is the name of the instrument shown below that is used for gallstone removal? (Q880278)

A. Sponge holding forceps

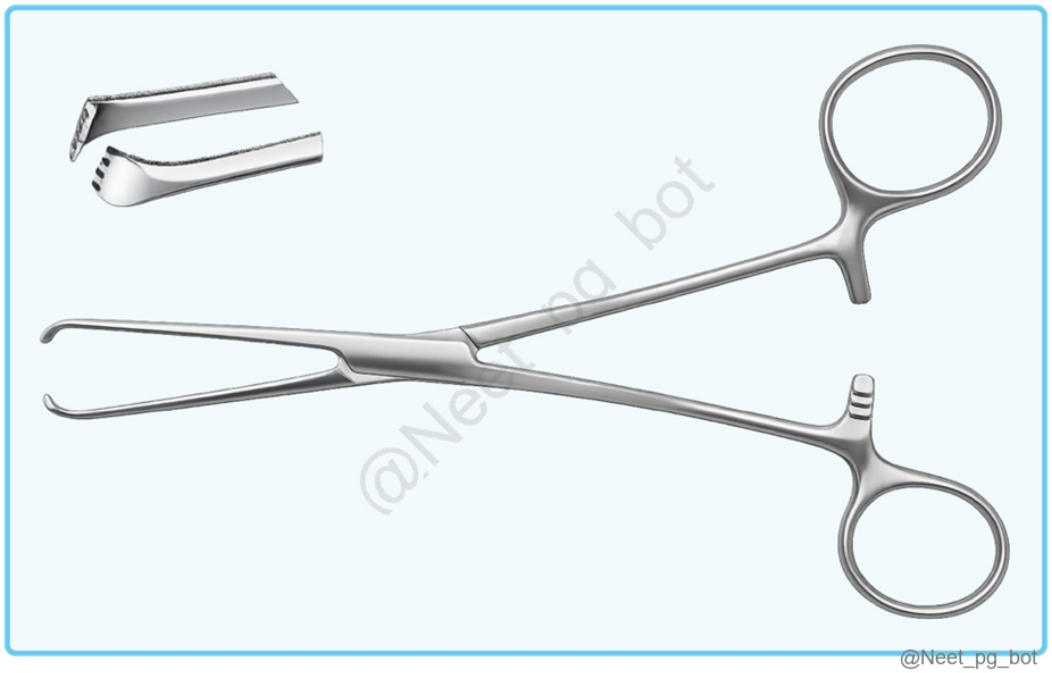
B. Desjardin’s choledocholithotomy forceps

C. Blakemore’s gallstone forceps

D. Tischler forceps

See Answer in Part B → Q18

@Neet_pg_bot



Q19: Which of the following is not a typical application of the instrument shown in the image below? (Q880275)

A. Holding the margins of vaginal flaps during a colporrhaphy operation

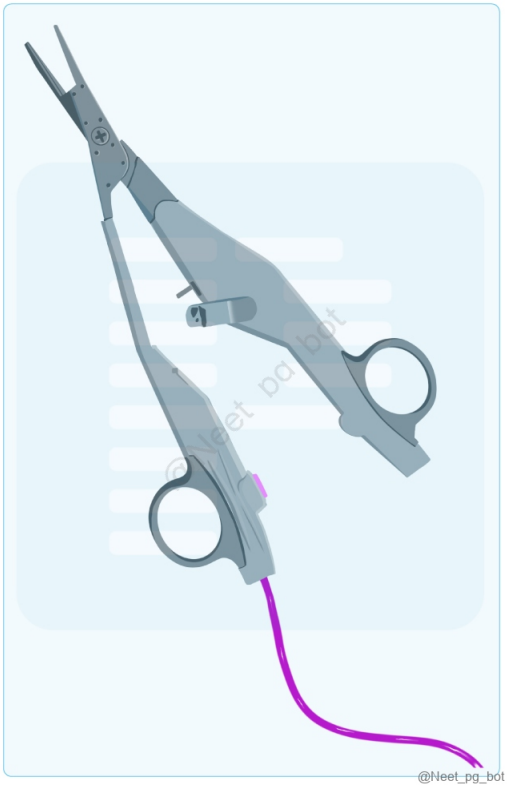
B. Grasping the rectus sheath during abdominal wall repair

C. Retracting bowel loops during a laparotomy

D. Holding the anterior lip of the cervix during a D&C procedure

See Answer in Part B → Q19

@Neet_pg_bot



Q20: Which of the following statements is false regarding the given instrument? (Q849848)

A. Uses pressure and continuous bipolar energy for vessel sealing.

B. Achieves burst pressures over three times the normal systolic blood pressure.

C. Sealing time is 8-10 seconds.

D. Denatures collagen and elastin in vessel walls, forming a solid tissue seal.

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which of the following best describes the safety protocols for electrosurgery using diathermy? (Q849847)

A. Always use the maximum current setting to ensure effectiveness and minimize burns.

B. Bipolar diathermy is preferred in patients with implants.

C. Monopolar diathermy is preferred near vital & sensitive structures.

D. There is no need to use smoke extractors as the risk of exposure to surgical smoke is minimal.

See Answer in Part B → Q21

@Neet_pg_bot

Q22: Which laparoscopic instrument is used to establish pneumoperitoneum in the closed approach? (Q849846)

A. Hasson Cannula/Trocar

B. Veress Needle

C. Laparoscopic Camera

D. Secondary Trocar

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following instruments is used to assess the patency of CBD? (Q849845)

A. Bakes Dilator

B. Tracheal Dilator

C. Urethral Dilator

D. Filiform Bougies

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Which of the following statements correctly differentiates Mayo scissors from Metzenbaum scissors? (Q849844)

A. Mayo scissors are designed for delicate dissection while Metzenbaum scissors are sturdy and suited for cutting dense tissues.

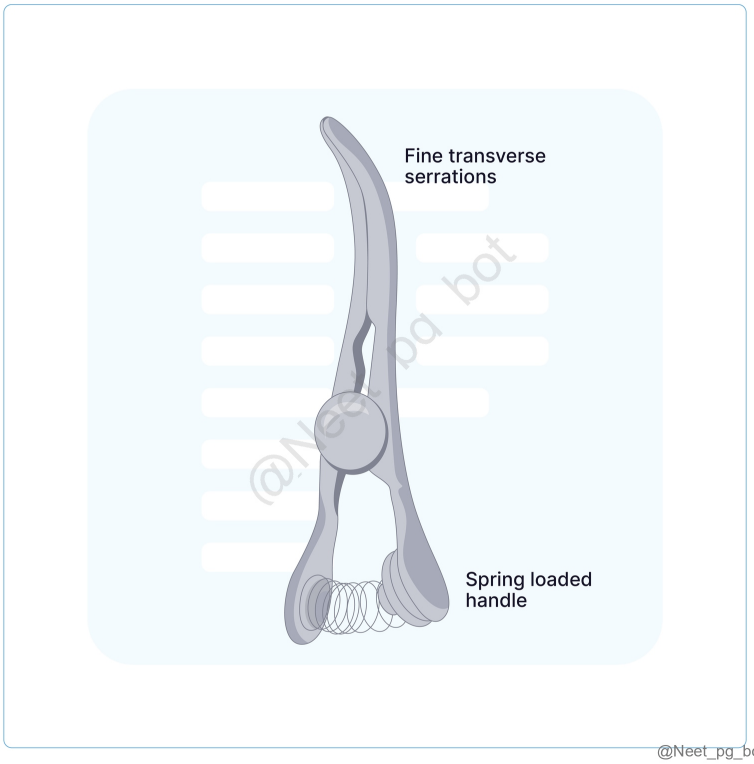
B. Mayo scissors are sturdy and suitable for cutting dense tissues, while Metzenbaum scissors are ideal for blunt dissection and fine tissue work.

C. Metzenbaum scissors are used for cutting dense tissues, while Mayo scissors are for blunt dissection in thoracic surgeries.

D. Metzenbaum scissors are suitable for cutting sutures and are sturdy, whereas Mayo scissors are delicate and used for blunt dissection

See Answer in Part B → Q24

@Neet_pg_bot



Q25: Identify the following instrument: (Q849843)

A. Payr’s gastric occlusion clamp

B. Potts bulldog clamp

C. Doyens intestinal occlusion clamp

D. Lights bulldog clamp

Q28: A 45 year old woman undergoes surgery for varicose veins involving the stripping of the long saphenous vein using a Mayo vein stripper. Post-operatively, she complains of pain and tingling along the medial aspect of her leg. Which nerve is most commonly damaged during the stripping of the long saphenous vein? (Q849840)

A. Sciatic nerve

B. Tibial nerve

C. Saphenous nerve

D. Femoral nerve

See Answer in Part B → Q28

@Neet_pg_bot

Q29: A 60 year old male presents with rectal bleeding and a history of hemorrhoids. His physician decides to perform a proctoscopy using Kelly's rectal speculum to assess the cause of the bleeding. Which of the following is NOT an indication of the use of Kelly's rectal speculum? (Q849839)

A. Diagnosing piles

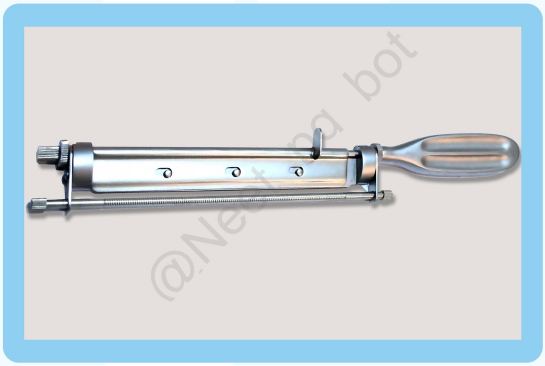
B. Treating partial rectal prolapse

C. Treating acute anal fissure

D. Assessing rectal carcinoma

See Answer in Part B → Q29

@Neet_pg_bot



Q30: Match the following instruments with their corresponding images: 1) a) Bone nibbler 2) b) Humby’s Knife 3) c) Rib Shear 4) d) Bone Cutter (Q849838)

A. 1-a. 2-d, 3-c, 4-b

B. 1-b, 2-c, 3-d, 4-a

C. 1-b, 2-a, 3-d, 4-c

D. 1-c, 2-a, 3-d, 4-b

@Neet_pg_bot

See Answer in Part B → Q30

@Neet_pg_bot

Q31: Which of the following statements is FALSE? (Q849837)

A. The needle holder is sterilized by an autoclave.

B. Toothed dissecting forceps are used to hold delicate structures like nerves and vessels.

C. Curved needle holders provide better maneuverability in deep areas like the pelvis.

D. Plain non-toothed dissecting forceps are used to hold friable structures like peritoneum and tendons.

See Answer in Part B → Q31

@Neet_pg_bot

Q32: Match the following Blade numbers with their uses given. 1. No. 11 a) Skin incisions in major surgeries 2. No. 12 b) Used in plastic surgery 3. No. 15 c) Incision and drainage of abscesses 4. No. 22 d) Used for tonsillectomy (Q849836)

A. 1-d, 2-c, 3-a, 4-b

B. 1-a, 2-b, 3-d, 4-c

C. 1-c, 2-a, 3-b, 4-d

D. 1-c, 2-d, 3-b, 4-a

See Answer in Part B → Q32

Q1: At 2 days of life, a male newborn becomes irritable and inconsolable. He is noted to have abdominal distension. He failed to pass meconium since being born. A follow-up barium enema shows microcolon and terminal ileum with meconium. What is the most probable diagnosis? (Q849737)

A. Sigmoid volvulus

B. Hirschsprung disease

C. Duodenal atresia

D. Meconium ileus

See Answer in Part B → Q1

@Neet_pg_bot

Q2: A 14-year-old boy presents with pain in the right lower abdomen and lower back. On clinical examination, there is discomfort in the right hip during passive extension, along with a palpable swelling in the right lumbar area extending towards the groin. What is the most likely diagnosis? (Q880413)

A. Pyelonephritis

B. Psoas abscess

C. Appendicitis

D. Torsion of the right undescended testis

See Answer in Part B → Q2

@Neet_pg_bot

Q3: Which of the following is the most frequently encountered extracranial solid malignancy in the pediatric age group? (Q880412)

A. Neuroblastoma

B. Nephroblastoma

C. Medulloblastoma

D. Rhabdomyosarcoma

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A pediatric surgery resident evaluates a newborn presenting with an abdominal wall malformation. Which of the following statements about this condition is incorrect? (Q880408)

A. The central abdominal wall defect can exceed 4 cm in size

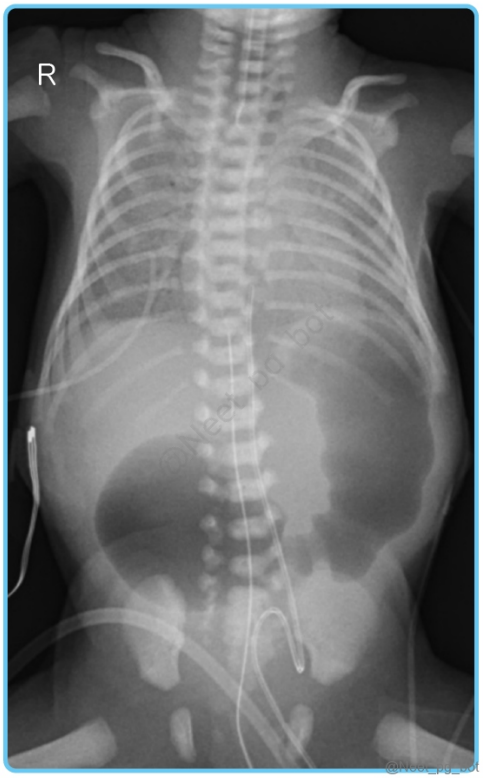
B. This malformation typically occurs without any associated congenital anomalies

C. The covering sac consists of amnion and peritoneum

D. This defect forms part of Cantrell’s pentalogy

See Answer in Part B → Q4

@Neet_pg_bot



Q5: A newborn, 3 days old, has repeated episodes of bilious vomiting. The erect abdominal X-ray is shown. What should be the immediate next step in management? (Q880407)

A. CT scan of the abdomen

B. Gastrografin follow-through

C. Abdominal ultrasound

D. Exploratory laparotomy

See Answer in Part B → Q5

@Neet_pg_bot

Q6: Among all the types of gastrointestinal atresias, which one occurs most frequently? (Q880406)

A. Duodenal atresia

B. Colonic atresia

C. Ileal atresia

D. Jejunal atresia

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A 10-day-old female baby was brought to the OPD with the following findings as shown in the image given below. On examination there is no cough impulse in the swelling. X-ray examination shows the erosion of the coccyx. The most likely clinical diagnosis would be: (Q849745)

A. Spina bifida

B. Myelomeningocele

C. Sacrococcygeal teratoma

D. Sacral agenesis

See Answer in Part B → Q7

@Neet_pg_bot

Q8: How will you manage a case of anorectal malformation with no visible fistula in a female patient with cross-table lateral X-ray showing rectum below the coccyx? (Q849744)

A. Protective colostomy followed by posterior sagittal anorectoplasty

B. Anoplasty

C. Colostomy

D. None of the above

See Answer in Part B → Q8

@Neet_pg_bot

Q9: Which of the following diagnostic methods is used to differentiate between a high and low lesion in anorectal malformation, and how does it determine the location of the rectum? (Q849743)

A. Abdominal ultrasound; identifies the rectal location by imaging the entire pelvic cavity.

B. MRI of the pelvis; differentiates based on the presence of anatomical anomalies in the pelvic floor

C. Invertogram; assesses the rectal termination by the rise of gas in relation to the pelvic floor.

D. X-ray of the pelvis; determines rectal termination based on bone structures and distance from the pelvic floor.

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Which of the following accurately describes a component and a step involved in the LADD's operation for managing intestinal malrotation? (Q849742)

A. Appendectomy; Division of LADD’s bands near the medial aspect of the duodenum

B. Reduction of volvulus; Widening of the mesenteric base by mobilizing the duodenum

C. Bowel repositioning; Resection of viable bowel wrapped in warm, moist sponges

D. Division of LADD’s bands; Placement of the duodenum and proximal jejunum on the left side of the abdomen

See Answer in Part B → Q10

@Neet_pg_bot

Q11: A 3-week-old infant presents with sudden-onset bilious vomiting and lethargy. The baby has been experiencing intermittent abdominal pain and has not been gaining

weight as expected. On examination, the infant shows signs of poor perfusion and decreased urine output. Which of the following is the most likely diagnosis, and what should be the primary investigation to confirm it? (Q849741)

A. Intestinal Malrotation with Midgut Volvulus; Upper GI Contrast Study

B. Pyloric Stenosis; Upper GI Contrast Study

C. Intestinal Malrotation with Midgut Volvulus; Barium Swallow Study

D. Pyloric Stenosis; Barium Swallow Study

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following statements is true about hyper-rotation of intestines? (Q849740)

A. The cecum is located in the left hypochondrium

B. The cecum is in the midline inferior to the pylorus

C. Arrested counter-clockwise rotation around 180°

D. The presence of Ladd's bands is noticed

See Answer in Part B → Q12

@Neet_pg_bot

Q13: A 3-day-old male baby is brought with complaints of irritable crying. Mother gave the history of not passing meconium in the first 48 hours of life. On examination, abdominal distension was seen with rebound tenderness and reduced bowel sounds. Identify the condition. (Q849739)

A. Complicated meconium ileus

B. Sigmoid volvulus

C. Duodenal atresia

D. Midgut volvulus

See Answer in Part B → Q13

@Neet_pg_bot

Q14: A 35-year-old man presents with recurrent chest infections and dyspnea. Chest CT reveals a 5 cm, well-defined, fluid-filled cystic lesion in the right paratracheal region. What is the most likely diagnosis? (Q849720)

A. Pulmonary sequestration

B. Bronchogenic cyst

C. Pericardial cyst

D. Hydatid cyst

See Answer in Part B → Q14

@Neet_pg_bot

Q15: Which of the following statements about the meconium plug are false? (Q849736)

A. Associated with hypothyroidism and cystic fibrosis

B. X-ray of the abdomen shows the corkscrew's appearance

C. Water-soluble contrast enema is used for diagnosis and therapeutic purposes.

D. It is mostly seen in preterm infants.

See Answer in Part B → Q15

@Neet_pg_bot

Q16: All of the following are true about small bowel duplication except? (Q849735)

A. These are submucosa-lined structures in continuity with the GI tract

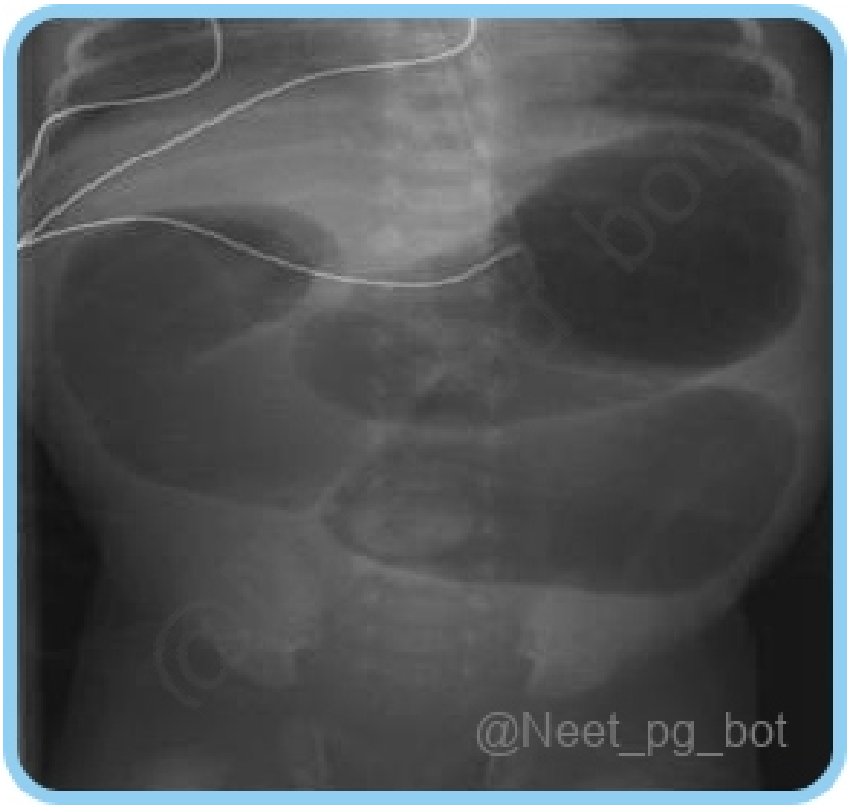
B. The most common site is the ileum

C. Cystic duplication is the most common type

D. Located along the mesenteric border

See Answer in Part B → Q16

@Neet_pg_bot



Q17: A 3-day-old neonate presents with abdominal distension and bilious vomiting. An erect X-ray of the abdomen is done, as shown below. What is the most probable diagnosis you suspect? (Q849729)

A. Jejunoileal atresia

B. Congenital diaphragmatic hernia

C. Sigmoid volvulus

D. Duodenal atresia

See Answer in Part B → Q17

@Neet_pg_bot

Q18: On observing the following finding in the X-ray of a baby with a history of Down's syndrome, what is the most likely diagnosis you would suspect? (Q849728)

A. Duodenal atresia

B. Ileal atresia

C. Jejunal atresia

D. Congenital hypertrophic pyloric stenosis

See Answer in Part B → Q18

@Neet_pg_bot

Q19: An 8-week-old infant is diagnosed with type 3 biliary atresia. The surgical team is planning the most appropriate intervention for this patient. Which of the following describes the preferred surgical approach for this patient? (Q849727)

A. Liver transplantation

B. Kasai porto-enterostomy

C. Choledochoenterostomy

D. Conservative management with ursodeoxycholic acid

See Answer in Part B → Q19

@Neet_pg_bot

Q20: A 3-week-old infant is brought to the pediatrician with persistent jaundice and pale, clay-colored stools. The parents report that the baby is not gaining weight as expected. On physical examination, the infant appears jaundiced and the liver is palpable 2 cm below the right costal margin. Which of the following diagnostic tests would be most specific for confirming the suspected diagnosis? (Q849726)

A. Abdominal ultrasound

B. CECT

C. Hepatobiliary scintigraphy

D. Intraoperative cholangiogram

See Answer in Part B → Q20

@Neet_pg_bot

Q21: A 6-week-old infant presents with persistent jaundice and acholic stools. After initial workup, a congenital hepatobiliary disorder is suspected. Intraoperative cholangiography reveals complete obliteration of the common bile duct, cystic duct, and hepatic duct up to the porta hepatis. Based on the Kasai Classification, which type of this condition does this infant have? (Q849725)

A. Type 1

B. Type 2A

C. Type 2B

D. Type 3

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A newborn is diagnosed with Type A Tracheoesophageal fistula (TEF). The surgical team is discussing treatment options based on the gap between the proximal and distal ends of the esophagus. On further investigations, the gap is considerably larger. Which of the following will be the correct management for this patient? (Q849724)

A. Tension-free Esophago-Esophagostomy

B. Feeding gastrostomy followed by tension free Esophago-Esophagostomy

C. Excision of fistula tract + Tension-free esophago-esophagostomy.

D. Excision of fistula tract + repair of the defect.

See Answer in Part B → Q22

@Neet_pg_bot

Q23: A newborn male presents with continuous drooling of saliva from the mouth and regurgitation of feeds given orally. When attempting to pass a nasogastric tube, the physician notices that it coils in the esophagus and cannot be passed into the stomach. X-ray reveals the presence of gas in the gastrointestinal tract below the diaphragm. Further evaluation reports the presence of cardiovascular abnormality. Which of the following cardiac abnormalities is most likely to be seen? (Q849723)

A. Ventricular septal defect (VSD)

B. Patent ductus arteriosus (PDA)

C. Tetralogy of Fallot (TOF)

D. Atrial septal defect (ASD)

See Answer in Part B → Q23

@Neet_pg_bot

Q24: A 45-year-old man presents with progressive dyspnea on exertion. Chest X-ray shows an elevated left hemidiaphragm. Further imaging reveals thinning and upward displacement of the left hemidiaphragm without any defect. What is the most appropriate management? (Q849722)

A. Observation and follow-up

B. Plication of the diaphragm

C. Mesh repair

D. Pneumoperitoneum induction

See Answer in Part B → Q24

@Neet_pg_bot

Q25: A 20-year-old female presents with recurrent hemoptysis. CT angiography reveals a dense lesion in the left lower lobe with arterial supply from the descending thoracic aorta. Which of the following is the most likely diagnosis? (Q849721)

A. Intralobar pulmonary sequestration

B. Extralobar pulmonary sequestration

C. Bronchogenic cyst

D. Congenital cystic adenomatoid malformation

See Answer in Part B → Q25

Q1: Identify the types of sutures? (Q866904)

A. Vertical Mattress

B. Horizontal mattress

C. Subcuticular suture

D. Simple Interrupted suture

See Answer in Part B → Q1

@Neet_pg_bot

Q2: Given below what is the correct sequence of Damage control surgery? 1. Patient selection 2. Primary exploration 3. ICU care 4. Secondary exploration (Q866908)

A. 1,2,3,4

B. 2,1,4,3

C. 3,1,2,4

D. 1,3,2,4

See Answer in Part B → Q2

@Neet_pg_bot

Q3: After an RTA patient has severe Maxillofacial trauma with SpO2 80% at room air, and the patient cannot be intubated or ventilated, what should be your immediate step for this? (Q866924)

A. Cricothyrotomy

B. Tracheostomy

C. ICD insertion

D. Do suction and again try intubation

See Answer in Part B → Q3

@Neet_pg_bot

Q4: A child comes after a train accident with stable vitals but a big laceration on the leg. Which triage category does the patient come under? (Q866932)

A. Red

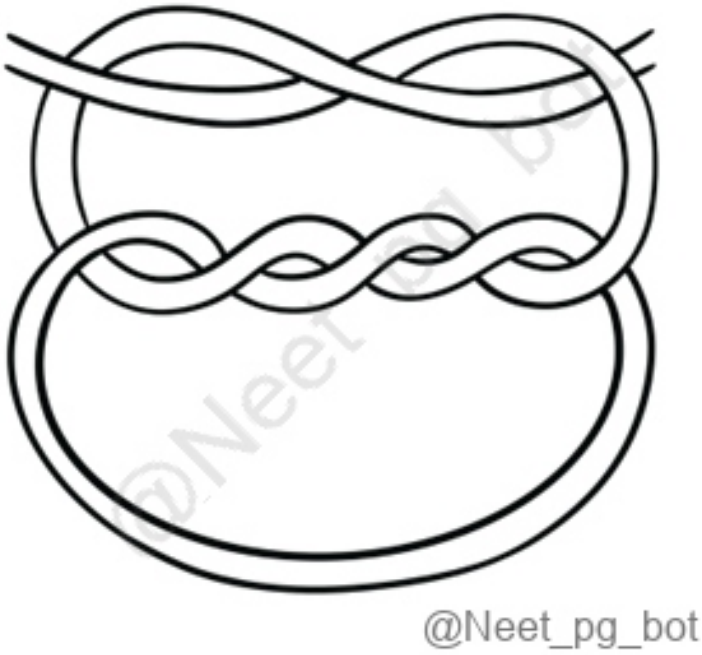
B. Yellow

C. Green

D. Black

See Answer in Part B → Q4

@Neet_pg_bot



Q5: Identify the knot? (Q866418)

A. Granny’s knot

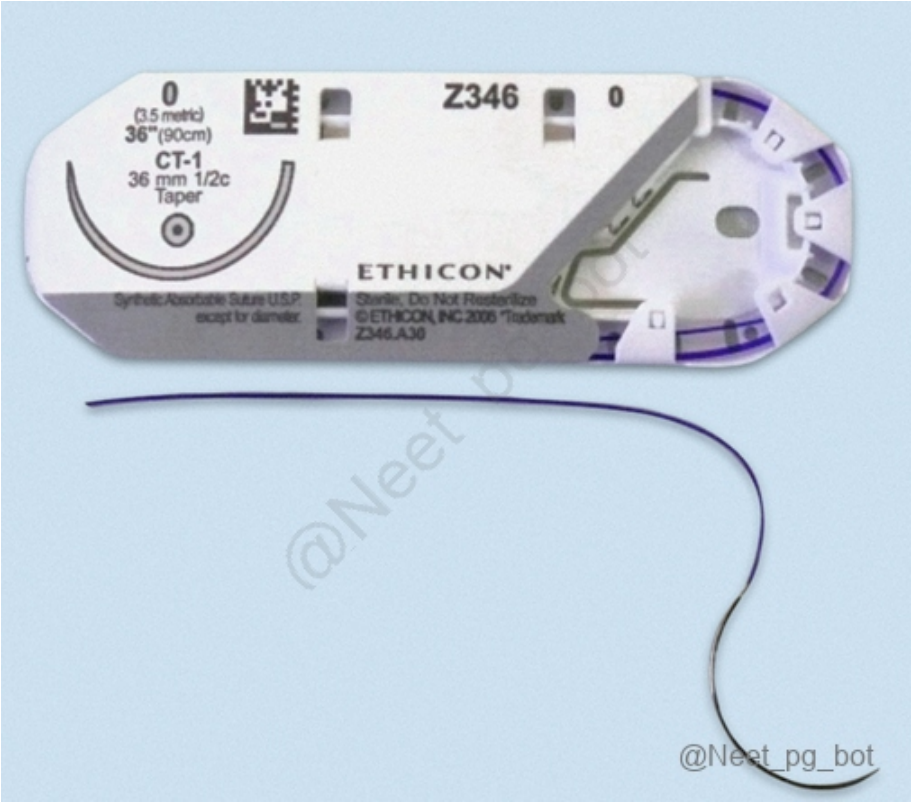
B. Reef knot

C. Double Knot

D. Surgeons knot

See Answer in Part B → Q5

@Neet_pg_bot



Q6: What is correct regarding this suture ? (Q866449)

A. Non absorbable

B. Monofilament

C. Braided multiflament

D. Collagen derived

See Answer in Part B → Q6

@Neet_pg_bot

Q7: A patient arrives at the emergency room with a penetrating injury and low blood pressure (hypotension). What is the most appropriate next step in managing this patient? (Q866481)

A. Emergency laparotomy

B. Computed Tomography (CT) scan

C. Diagnostic Peritoneal Lavage (DPL)

D. Ultrasonography (USG) of the abdomen

See Answer in Part B → Q7

@Neet_pg_bot

Q8: Apart from the abdominal cavity, which body part is included in e-FAST? (Q856756)

A. Pelvic Cavity

B. Peripheral vessels

C. Thoracic cavity

D. Dural and subdural spaces

See Answer in Part B → Q8

@Neet_pg_bot

Q9: According to GCS, a verbal score of 1 indicates: (Q859598)

A. No Verbal response

B. Inappropriate words

C. Incomprehensible sounds

D. Oriented response

See Answer in Part B → Q9

@Neet_pg_bot

Q10: Most common site of peripheral aneurysm? (Q859603)

A. Brachial artery

B. Popliteal artery

C. Radial artery

D. Femoral artery

See Answer in Part B → Q10

@Neet_pg_bot

Q11: Which one of the following is absent in cases of massive blood transfusion? (Q859604)

A. DIC

B. Febrile transfusion reaction

C. Hypercalcemia

D. Thrombocytopenia

See Answer in Part B → Q11

@Neet_pg_bot

Q12: Which of the following statements about ranula is FALSE? (Q859629)

A. Mucus extravasation cyst

B. Arises from submandibular salivary gland

C. Bluish, translucent cystic swelling on the floor of the mouth

D. Marsupialization or excision is the treatment

See Answer in Part B → Q12

@Neet_pg_bot

Q13: What is the probable diagnosis for a patient who is taking steroids for psoriasis and is experiencing a low-grade fever only at night, weight loss, and an ulcer on her neck with undermined edges, as depicted in the provided image? (Q859630)

A. Psoriasis flare-up

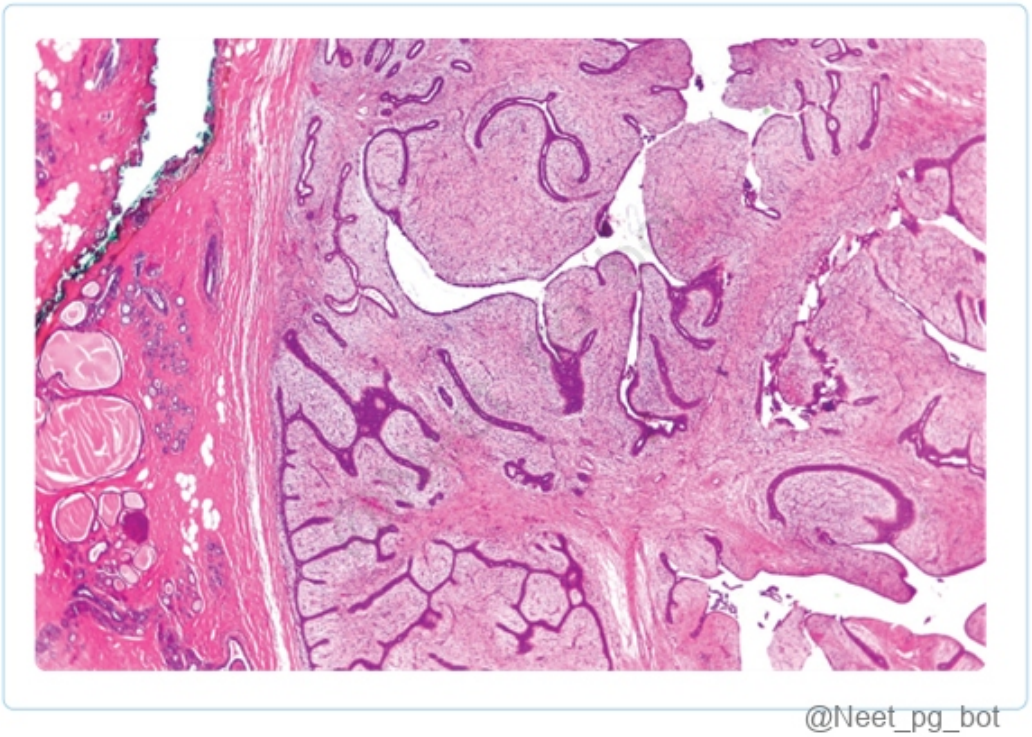
B. Tubercular lymphadenitis

C. Lymphosarcoma

D. Syphilis

See Answer in Part B → Q13

@Neet_pg_bot



Q14: A 45-year-old woman comes to the OPD with a history of a lump in the left breast. On clinical examination, the size of the lump in the left breast is 9x10 cm with the following appearance and no axillary lymphadenopathy. The histopathology of the biopsy from the lump shows increased stromal cellularity and typical leaflike architecture. What is your likely diagnosis? (Q859852)

A. Phyllodes tumour

B. Giant fibroadenoma

C. Inflammatory carcinoma

D. Ductal carcinoma

See Answer in Part B → Q14

@Neet_pg_bot

Q15: What is the diagnosis from the given abdominal x-ray? (Q859880)

A. Ureterocoele

B. Pelvic bone fracture

C. Rectal foreign body

D. Bladder stone

See Answer in Part B → Q15

@Neet_pg_bot

Q16: Which of the following is not a component of TNM stage T4b breast cancer? (Q865312)

A. Ulceration

B. Peau d’orange

C. Inflammatory carcinoma

D. Ipsilateral macroscopic satellite nodules

See Answer in Part B → Q16

@Neet_pg_bot

Q17: A patient presents with a breast lump, and imaging (X-ray mammography) along with histopathology confirms a diagnosis of breast cancer. She has a family history of breast cancer involving two relatives and has a 29-year-old daughter. Which gene should be tested to assess hereditary breast cancer risk in this patient? (Q865316)

A. BRCA1

B. TP53

C. BRCA2

D. STK11

See Answer in Part B → Q17

@Neet_pg_bot

Q18: A 65-year-old patient is on mechanical ventilation for acute respiratory distress syndrome (ARDS). Suddenly, the patient becomes hypotensive, tachycardic, and shows absent breath sounds on the left side with tracheal deviation to the right. What is the most common cause of this in patients receiving mechanical ventilation? (Q865348)

A. High tidal volume

B. Barotrauma due to high airway pressure

C. Endotracheal tube malposition

D. Oxygen toxicity

See Answer in Part B → Q18

@Neet_pg_bot

Q19: A 40-year-old male presents to the emergency department with severe respiratory distress, BP: 70/59 mmHg, tracheal deviation to the right, distended neck veins, and absent breath sounds on the left side. These findings are suggestive of a tension pneumothorax. What is the most appropriate immediate next step in management? (Q865354)

A. Perform needle thoracostomy immediately

B. CT Chest

C. Airway, breathing, and circulation (ABC) assessment

D. Chest tube insertion

See Answer in Part B → Q19

@Neet_pg_bot

Q20: All of the following is a contraindication to Breast Conservation surgery except ? (Q865393)

A. Previous history of radiation to the chest

B. Tumor involving single quadrant

C. Scleroderma

D. Persistent positive margins even after resection

See Answer in Part B → Q20

@Neet_pg_bot

Q21: Which among the following are incorrect about tension pneumothorax? Occurs due to improper dressing of open wound Blunt trauma with simple pneumothorax can never convert to tension pneumothorax Most common cause is due to positive pressure in mechanical ventilation Can be caused due to spinal injury (Q865398)

A. 1, 4

B. 2,3,4

C. 1,2,4

D. 2,3

See Answer in Part B → Q21

@Neet_pg_bot

Q22: A 35-year-old male sustained a head injury following a motorcycle accident. He experienced a brief loss of consciousness at the scene. Upon regaining consciousness, he developed a severe headache and began to feel drowsy. A CT scan of the head is performed. Which of the following should be the management for this patient? (Q840033)

A. Anticoagulants

B. Immediate surgical decompression

C. Observation in ICU

D. Mannitol administration

See Answer in Part B → Q22

@Neet_pg_bot

Q23: Which of the following is not done in the primary survey of trauma? (Q840042)

A. NCCT head

B. CXR

C. Intubation

D. ICD drainage

See Answer in Part B → Q23

@Neet_pg_bot

Q24: Mount fuji sign on CT is seen in which of the following? (Q840051)

A. Pneumocephalus

B. Pneumoperitoneum

C. Pneumomediastinum

D. Pneumothorax

See Answer in Part B → Q24

@Neet_pg_bot

Q25: During a complicated delivery, a mother died. Which of the following is the most common Direct cause of maternal death? (Q820108)

A. Embolism

B. Heart Disease

C. Hemorrhage

D. Anemia

See Answer in Part B → Q25

@Neet_pg_bot

Q26: Which fluid is administered most commonly during intraoperative blood loss? (Q820149)

A. Isolyte P

B. Crystalloids

C. Blood

D. Colloids

See Answer in Part B → Q26

@Neet_pg_bot

Q27: A 39-year-old female presented in the OPD with bloody discharge from the nipple . On examination, it was found to be from a single lactiferous duct . What is the treatment for bloody nipple discharge with single duct involvement? (Q820183)

A. Microdochectomy

B. Hadfield’s procedure

C. Microdiscectomy

D. IV antibiotics + Incision

See Answer in Part B → Q27

@Neet_pg_bot

Q28: Which of the following is not correct for the device depicted below: (Q820185)

A. Based on infrared emitted from RBCs

B. Localizes calcified plaque

C. Checks blood flow

D. Checks thickness of artery and vein

@Neet_pg_bot

See Answer in Part B → Q28

@Neet_pg_bot

Q29: Which of the following is a complication usually associated with the procedure shown in the image below? (Q854753)

A. Aspiration

B. Torticollis

C. Pneumothorax

D. Recurrent laryngeal nerve paralysis

See Answer in Part B → Q29

@Neet_pg_bot

Q30: Among the options provided, which one is NOT acknowledged as a potential complication resulting from a significant blood transfusion? (Q854760)

A. Hypocalcemia

B. Hypokalemia

C. Hypothermia

D. Hypernatremia

See Answer in Part B → Q30

@Neet_pg_bot

Q31: What is the minimum platelet count necessary for most surgical procedures? (Q854782)

A. 20,000 (10^9/L)

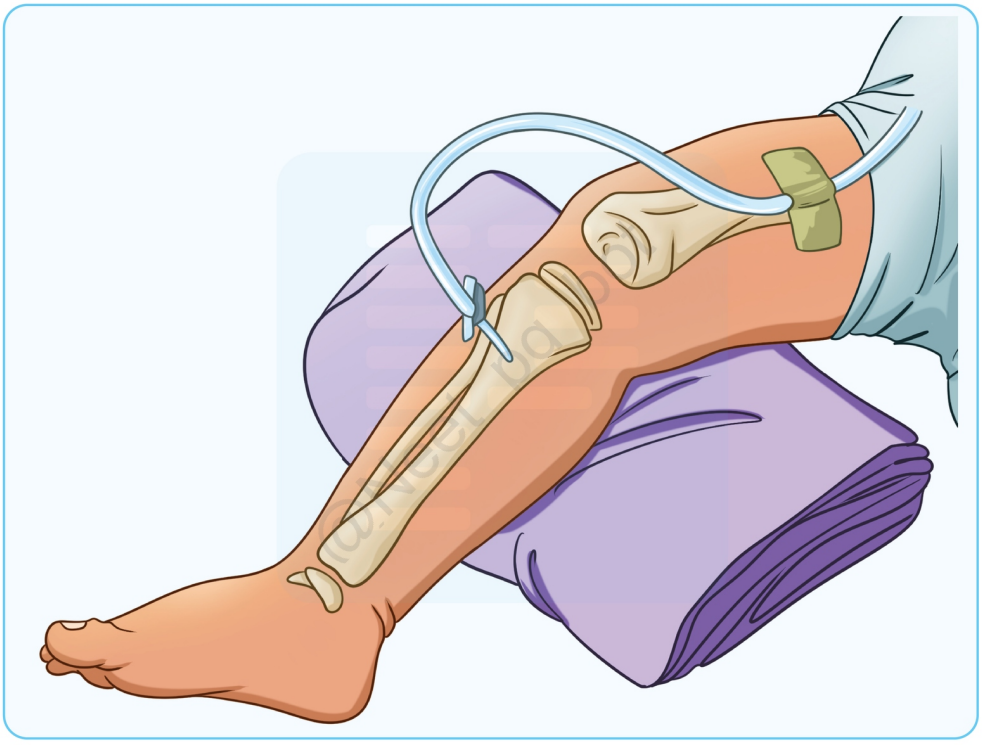
B. 30,000 (10^9/L)

C. 40,000 (10^9/L)

D. 50,000 (10^9/L)

See Answer in Part B → Q31

@Neet_pg_bot



Q32: Identify the procedure being performed in the image given below. (Q855166)

A. Intraosseous cannula for pain relief

B. Bone marrow aspiration

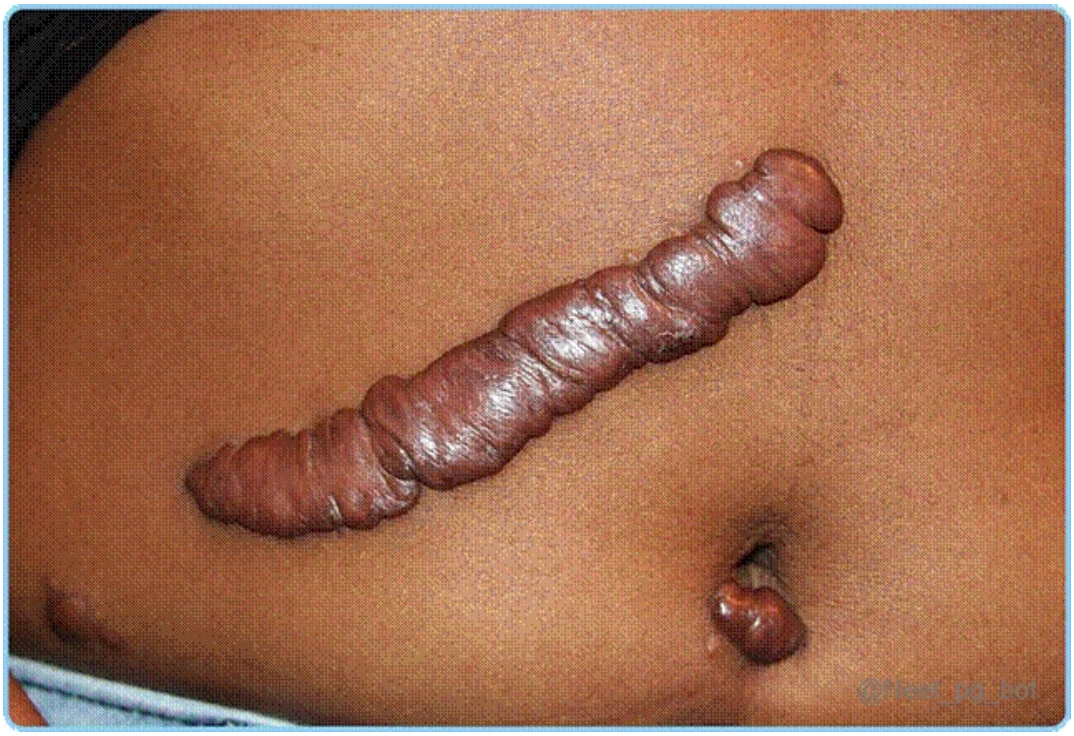
C. Intraosseous route access for giving IV fluids

D. Bone marrow biopsy

@Neet_pg_bot

See Answer in Part B → Q32

@Neet_pg_bot



Q33: A patient presents to the clinic with a lesion as shown in the image. He had a traumatic injury to the chest one year ago, and the scar has grown beyond the boundary of the initial injury. What is the most likely diagnosis? (Q855177)

A. Hemangioma

B. Hypertrophic scar

C. Keloid

D. Neurofibroma

See Answer in Part B → Q33

@Neet_pg_bot

Q34: A young patient presents with a 5-day fever history and signs of hypotension, tachycardia, tachypnea, and altered mental status. Lab results show elevated white blood cell count, neutrophil proportion, and serum creatinine. The intern doctor plans to assess the quick Sequential Organ Failure Assessment (qSOFA) score for prognosis

prediction and hospitalisation duration. Which elements are part of the qSOFA score? (Q855275)

A. BP, RR, and CBC

B. Creatinine, PR, and BP

C. RR, Body temperature, and PR

D. SBP, RR, and GCS score

See Answer in Part B → Q34

@Neet_pg_bot

Q35: Which class of hypovolemic shock, according to Advanced Trauma Life Support (ATLS) guidelines, is characterised by the absence of urine output? (Q857765)

A. Class I

B. Class II

C. Class III

D. Class IV

See Answer in Part B → Q35

@Neet_pg_bot

Q36: A 38-year-old man was brought to the emergency department after sustaining an RTA and injury to the lower chest. On presentation, the patient is stable, and vitals are normal. Chest radiography showed clear lung fields. What is the next step in management? (Q857798)

A. eFAST

B. Tube thoracostomy

C. CECT chest

D. CECT abdomen

See Answer in Part B → Q36

@Neet_pg_bot

Q37: Which of the following is not included in the qSOFA score components? (Q857805)

A. Respiratory rate >22

B. Lactate dehydrogenase

C. Altered mental status

D. Systolic blood pressure <100 mmHg

See Answer in Part B → Q37

@Neet_pg_bot

Q38: Among the options provided, which pairing correctly matches the trauma patients brought to the casualty? (Q857835)

A. Extradural hemorrhage (EDH) - Pin point pupil

B. Penetrating injury to eustachian tube - CSF otorrhea

C. Penetrating injury to eye - Battle sign

D. Gaze palsy - Mid brain lesion

See Answer in Part B → Q38

@Neet_pg_bot

Q39: In all types of shock, which of the following is observed? (Q857889)

A. Reduced tissue perfusion

B. Increased peripheral resistance

C. Decreased respiratory rate

D. Cold clammy skin

See Answer in Part B → Q39

@Neet_pg_bot

Q40: For the purpose of preventing surgical site infection, what is the recommended technique and optimal timing for hair removal prior to surgery? (Q793358)

A. On the OT table with electric hair clippers

B. With a razor 24 hours before surgery

C. With a hair removal cream on the previous day

D. On the OT table with a razor

See Answer in Part B → Q40

@Neet_pg_bot

Q41: A patient arrives at the emergency department after being involved in a car accident. The patient is experiencing difficulty breathing and their neck veins appear dilated. The x-ray reveals a significant amount of air on the left side. What is the most appropriate course of action for treatment? (Q793363)

A. Wide bore needle insertion in the 5th intercostal space

B. Endotracheal intubation

C. Tracheostomy

D. Pericardiocentesis

See Answer in Part B → Q41

@Neet_pg_bot

Q42: A patient sustained a crush injury on their right arm. He was taken to the hospital and on examination, his arm was pulseless, swollen, and dark red. What would be the best way to manage this case? (Q793385)

A. Intraosseous administration of fluids

B. Acidification of urine

C. Fasciotomy

D. Hemodialysis

See Answer in Part B → Q42

@Neet_pg_bot

Q43: Which of these is the most life-threatening injury that can be identified by assessing the breathing component of the patient? (Q855661)

A. Cervical spine injury

B. Tension pneumothorax

C. Blunt cardiac injury

D. Laryngotracheal injury

See Answer in Part B → Q43

@Neet_pg_bot

Q44: Hand rub can be utilised in accordance with the standard hand hygiene protocol in all locations listed below, with the exception of: (Q855667)

A. If the hands are visibly soiled

B. While moving from a contaminated site to a clean site during patient care

C. After removing sterile gloves

D. During direct patient contact

See Answer in Part B → Q44

@Neet_pg_bot

Q45: In the case of a patient arriving at the emergency department with a road traffic accident (RTA), what is the appropriate order of steps in their management? Cervial spine stabilisation Intubation IV cannulation CECT (Q855671)

A. 1, 3, 2, 4

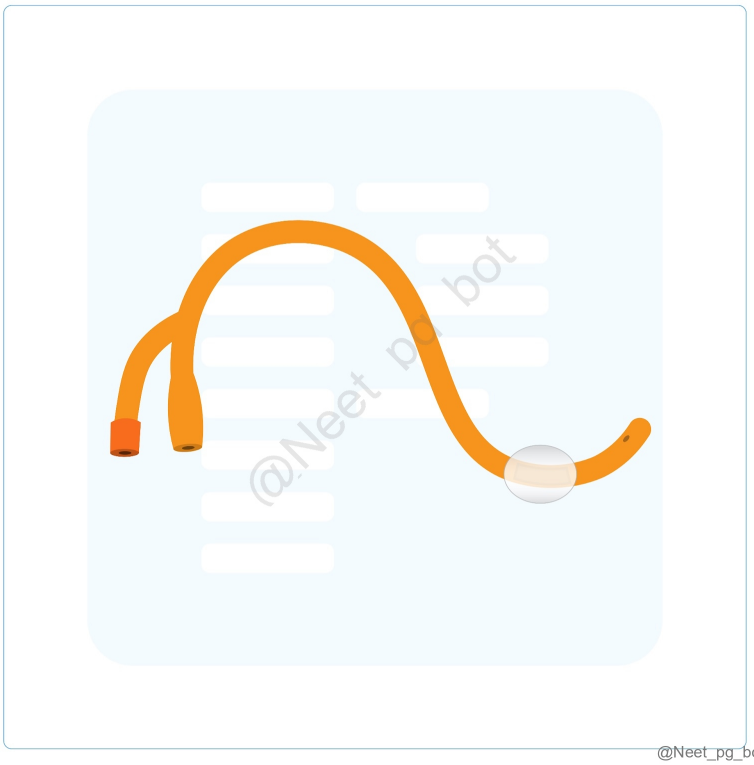
B. 1, 2, 3, 4

C. 2, 1, 3, 4

D. 2, 1, 4, 3

See Answer in Part B → Q45

@Neet_pg_bot



Q46: What does the number (14Fr) marked on the Foley catheter correspond to? (Q855673)

A. Inner lumen diameter

B. Length of the tube

C. Outer tube diameter

D. Bulb size

See Answer in Part B → Q46

@Neet_pg_bot

Q47: Which of the following options does not represent one of the boundaries of the triangle of safety for the insertion of an ICD in a patient with a chest x-ray showing

pneumothorax? (Q855678)

A. Lateral edge of the pectoralis major

B. Mid-clavicular line

C. 5th intercostal space

D. Lateral border of latissimus dorsi

See Answer in Part B → Q47

@Neet_pg_bot

Q48: Which of the following statements is accurate concerning split-thickness and full-thickness skin grafts? Primary contractures are more in split skin grafts Secondary contractures are more in split skin grafts Primary contractures are more in full-thickness grafts Secondary contractures are more in full-thickness grafts (Q855680)

A. 2 and 3

B. 2 and 4

C. 1 and 3

D. 1 and 4

See Answer in Part B → Q48

@Neet_pg_bot

Q49: Which of the following statements are true regarding central venous access and peripheral venous access? Phlebitis is the most common complication in peripheral venous access. Isotonic saline and heparin are flushed to retain patency If an arteriovenous fistula is present in a limb, avoid peripheral venous access in the same limb. Vasopressors for septic shock are given in the central line to avoid limb ischemia. (Q855686)

A. 1, 3, 4

B. 2, 3, 4

C. 1, 2, 3, 4

D. 1, 2, 3

See Answer in Part B → Q49

@Neet_pg_bot

Q50: Which one of the options listed below does not belong to the category of damage control surgery? (Q855279)

A. Control of hemorrhage

B. Resuscitation

C. Decontamination

D. Vascular anastomosis

See Answer in Part B → Q50

@Neet_pg_bot

Q51: Which of the following is true regarding shock? (Q855318)

A. Anaerobic respiration produces carbon dioxide

B. Hypovolaemic shock—most common type

C. Stage of compensatory shock is also called stage 2 of shock

D. Anaphylactic shock—is due to a Type 2 hypersensitivity reaction

See Answer in Part B → Q51

@Neet_pg_bot

Q52: A patient presents with multiple stab injuries to the chest. On examination, there is reduced chest movement on the right side and tracheal deviation to the left side.

Additionally, the neck veins are distended. What is the next best step in the management of this patient? (Q855325)

A. Resuscitative thoracotomy

B. ICD placement

C. Needle thoracocentesis

D. Finger thoracotomy

See Answer in Part B → Q52

@Neet_pg_bot

Q53: What steps should be taken to manage the case of a 24-year-old male who was hit by a motorbike while crossing the road, leading to abdominal injuries and bruising, with a blood pressure of 88/60 and IV fluids already administered, along with a positive FAST examination? (Q857115)

A. Abdominal CT scan

B. Abdominal MRI scan

C. Exploratory laparotomy

D. Diagnostic peritoneal lavage

See Answer in Part B → Q53

@Neet_pg_bot

Q54: In a patient with liver cirrhosis, what is the primary cause of mortality when esophageal varices are present? (Q857119)

A. Hypovolemic shock

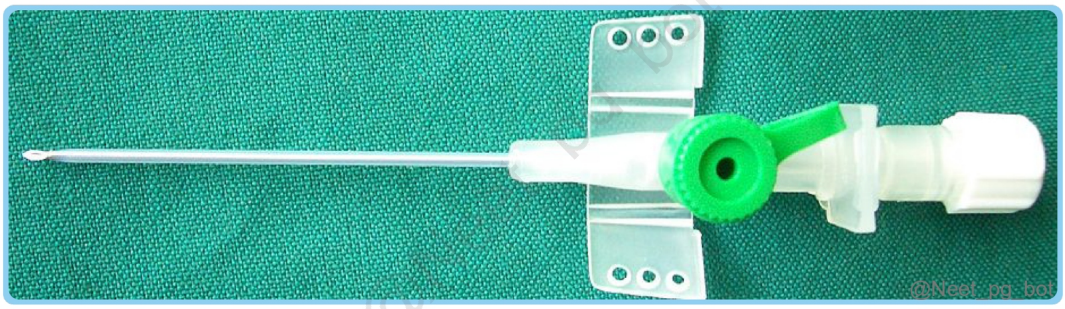
B. Cardiogenic shock

C. Obstructive shock

D. Distributive shock

See Answer in Part B → Q54

@Neet_pg_bot



Q55: What is the size of the cannula gauge used in this picture? (Q858341)

A. 14

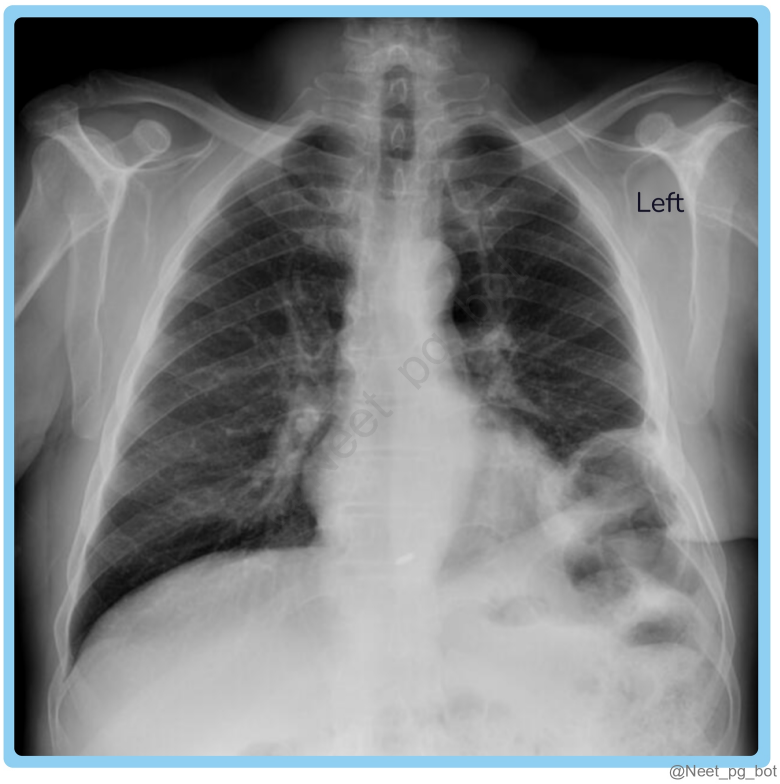
B. 16

C. 18

D. 20

See Answer in Part B → Q55

@Neet_pg_bot



Q56: A 24-year-old male patient was brought to the emergency department following a road traffic accident. His heart rate was 100/min, respiratory rate was 24/min, and his chest X ray is given below. Which of the following is contraindicated in him? (Q858348)

A. Nasogastric tube insertion

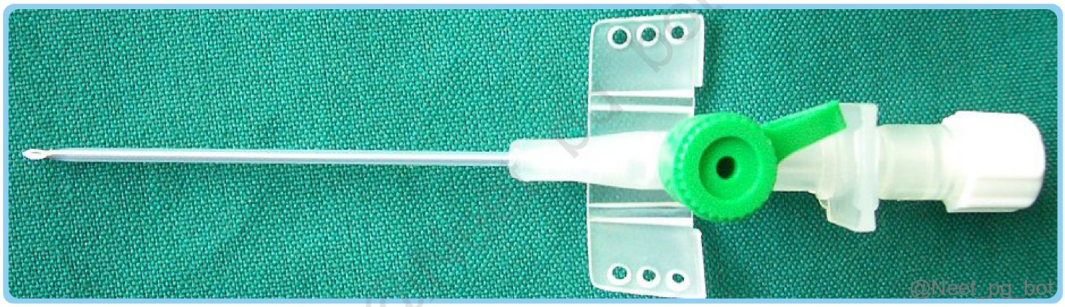
B. Chest tube insertion

C. Log roll

D. Epidural anaesthesia

See Answer in Part B → Q56

@Neet_pg_bot



Q57: A patient was received in the casualty following a road traffic accident. His BP was 90/60 mmHg and his pulse rate was 120/min. The emergency room physician asked you to replace the fluid loss in this patient. What is the flow rate of fluid with the IV cannula given in the image? (Q858350)

A. 86ml/min

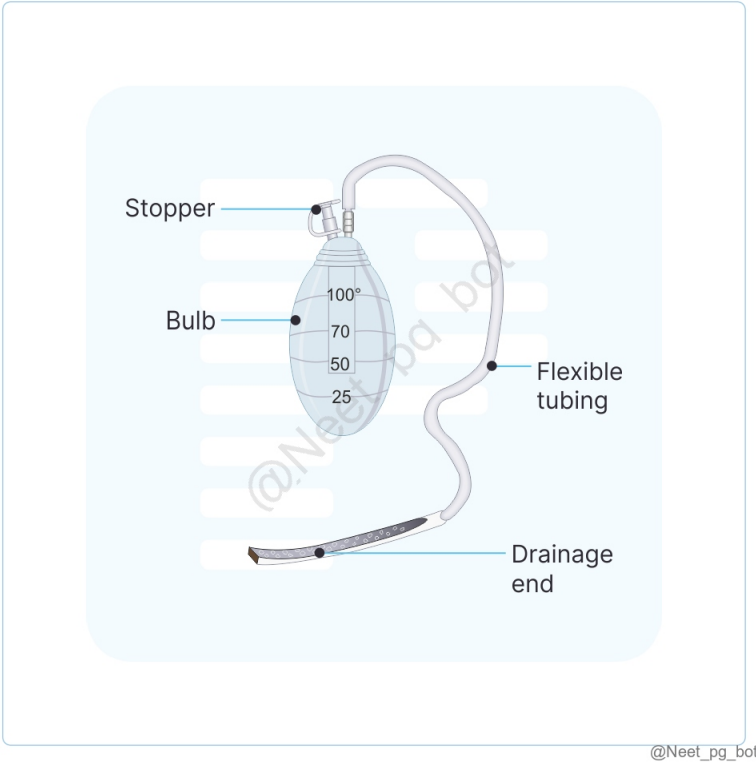
B. 96ml/min

C. 90 ml/min

D. 63ml/min

See Answer in Part B → Q57

@Neet_pg_bot



Q58: A 45-year-old patient undergoes a mastectomy for breast cancer. Post-operatively, the surgeon decides to use a closed suction drain. Which of the following drain types is shown in the image below? (Q858365)

A. Penrose drain

B. Jackson Pratt drain

C. Romovac suction drain

D. Hemovac drain

See Answer in Part B → Q58

@Neet_pg_bot

Q59: What is triage for? (Q856526)

A. To prepare for a disaster

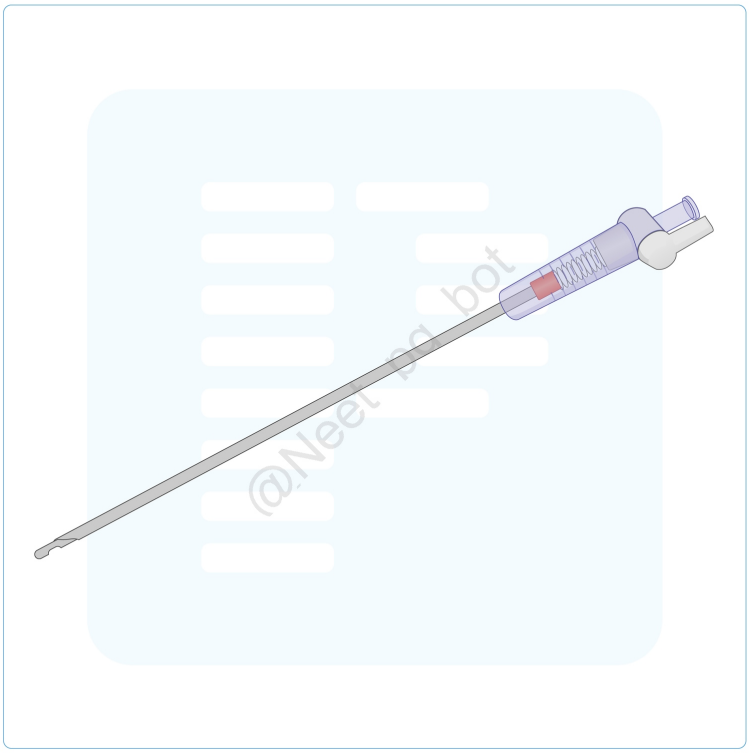
B. To assess the impact of a disaster

C. To classify the priority of treatment

D. To rehabilitate following a disaster

See Answer in Part B → Q59

@Neet_pg_bot



Q60: What is the name of the instrument depicted below, which is utilized for the creation of a pneumoperitoneum? (Q856535)

A. Veress needle

B. Morris' needle

C. Yankauer suction tip

D. Von Graefe needle

See Answer in Part B → Q60

@Neet_pg_bot

Q61: What is the needle placement angle when using the interrupted suturing technique to suture a laceration in the ER? (Q856559)

A. 60 degrees

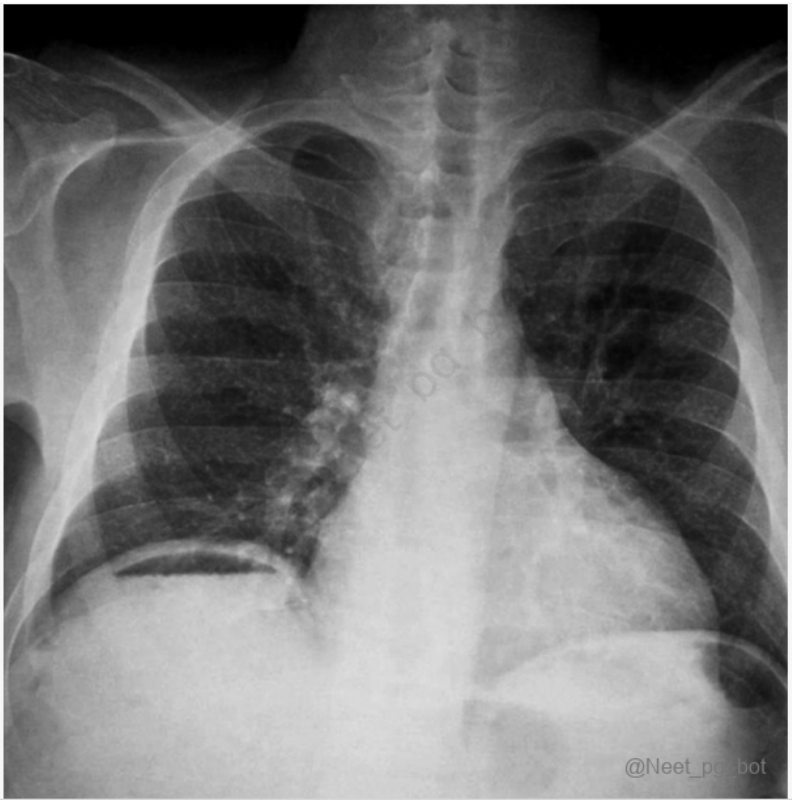
B. 70 degrees

C. 80 degrees

D. 90 degrees

See Answer in Part B → Q61

@Neet_pg_bot



Q62: What might you suspect as the diagnosis for a 26-year-old male patient who arrives at the emergency department complaining of abdominal pain and constipation persisting for the last three days? The patient recalls being struck in the abdomen by a bull three days ago. Could yo u examine the provided X-ray to aid in your assessment? (Q856561)

A. Hemothorax

B. Hollow viscus perforation

C. Pneumothorax

D. Intestinal obstruction

See Answer in Part B → Q62

@Neet_pg_bot

Q63: Which of the following methods is accurate for measuring the nasogastric tube? (Q856572)

A. Tip of nose to ear lobule to xiphisternum

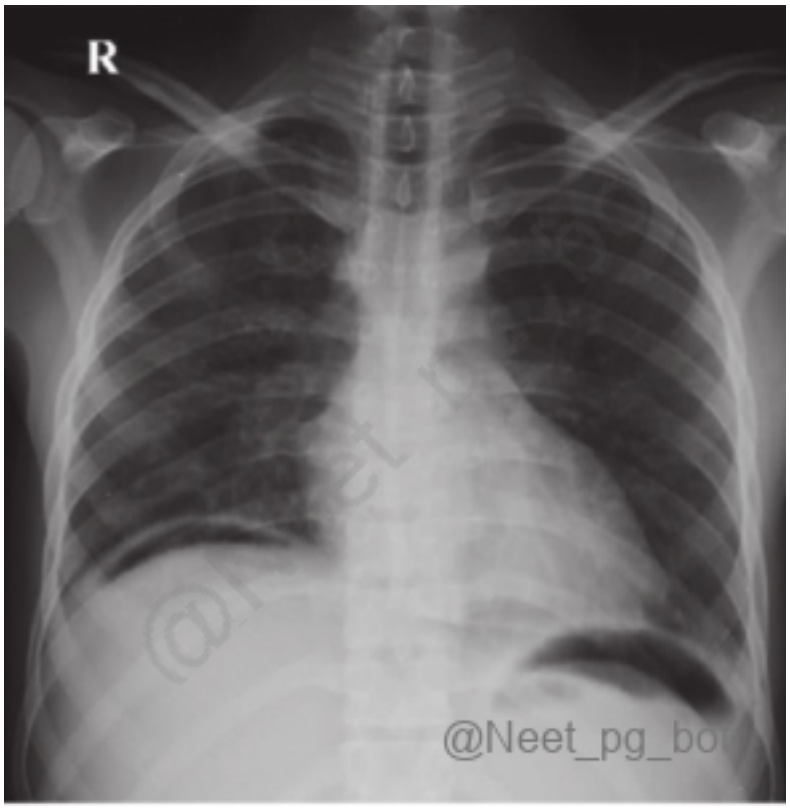
B. Angle of mouth to tragus to xiphisternum

C. Ala of nose to angle of mandible to xiphisternum

D. Angle of mouth to ear lobule to umbilicus

See Answer in Part B → Q63

@Neet_pg_bot



Q64: What is the most probable diagnosis for a 25-year-old patient who has been experiencing abdominal pain and fever for the past three days, based on the provided chest X-ray taken in an upright position? (Q856206)

A. Hollow viscus perforation

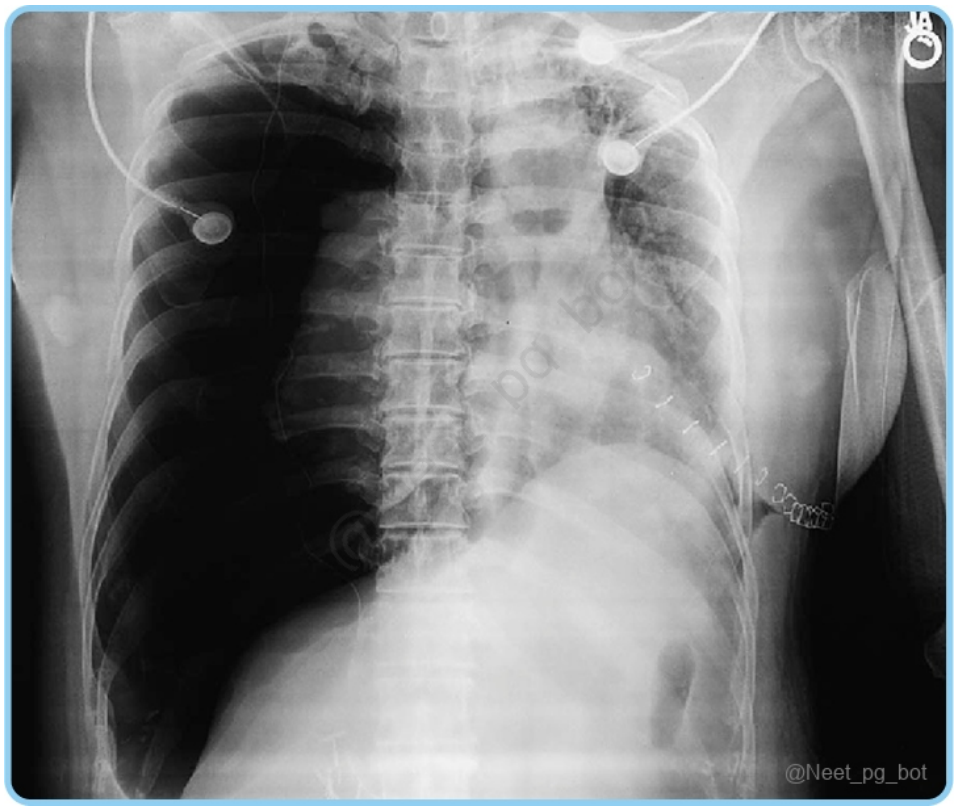
B. Gastric volvulus

C. Liver abscess

D. Empyema thoracis

See Answer in Part B → Q64

@Neet_pg_bot



Q65: A patient following a road traffic accident presented with subcutaneous emphysema. On auscultation, there was no air entry on the right side. Vitals were unstable. What will be your immediate management? (Q856246)

A. Insertion of wide bore needle in the 2nd intercostal space

B. Wide bore needle decompression and IV fluids

C. Intubation and positive pressure ventilation

D. e-FAST

See Answer in Part B → Q65

@Neet_pg_bot

Q66: A patient, after a road traffic accident, presented with pain in the abdomen. The resident examined the child and found that vitals were stable, and tenderness was present in the left lumbar region. Which is the best investigation of choice? (Q856254)

A. Contrast-enhanced CT scan

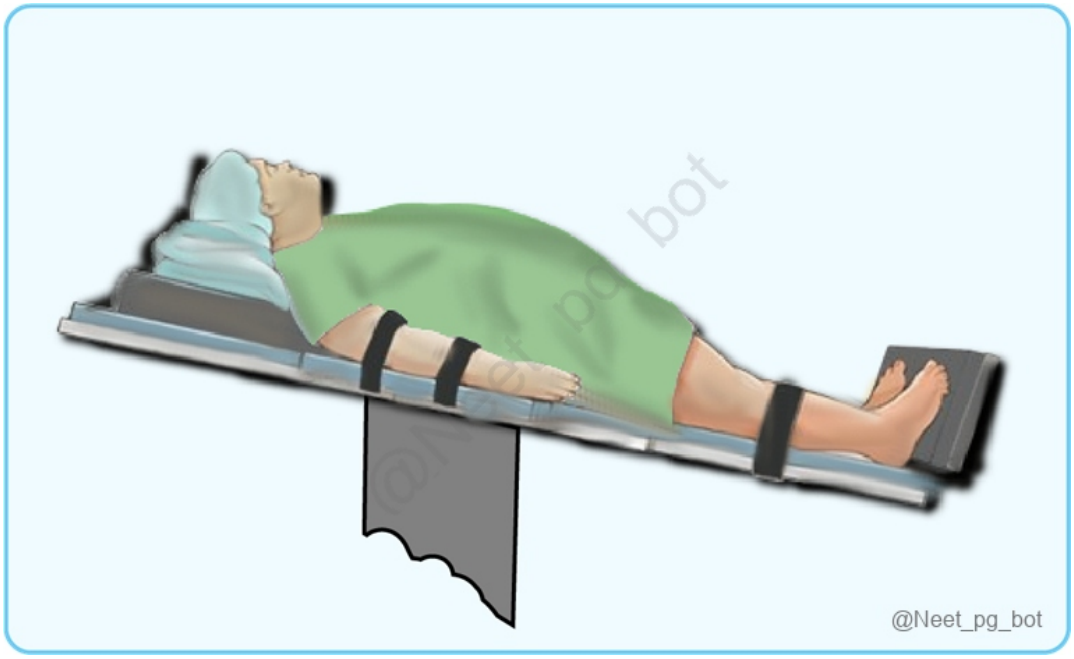
B. Retrograde urethrogram

C. Wait and watch

D. Emergency laparotomy

See Answer in Part B → Q66

@Neet_pg_bot



Q67: The position of the patient in the image shown below is known as: (Q856730)

A. Lloyd Davis position

B. Jack knife position

C. Trendelenburg position

D. Reverse Trendelenburg position

See Answer in Part B → Q67

@Neet_pg_bot

Q68: FAST stands for (Q856255)

A. First assessment with sonography in trauma

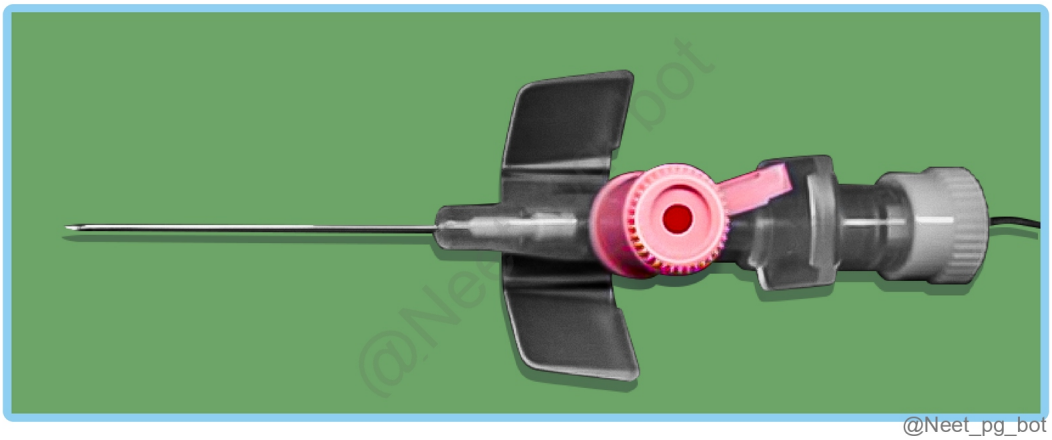
B. Focussed assessment with sonography in trauma

C. First abdominal sonography in trauma

D. Focussed abdominal sonography in trauma

See Answer in Part B → Q68

@Neet_pg_bot



Q69: What is the size of the cannula shown in the below image? (Q856292)

A. 16 G

B. 18 G

C. 20 G

D. 22 G

See Answer in Part B → Q69

@Neet_pg_bot

Q70: A 32-year-old woman has been declared brain dead, and her family has chosen to donate her organs. Who would be the most suitable recipient of her organs? (Q856294)

A. 14-year-old child with multi-organ dysfunction syndrome

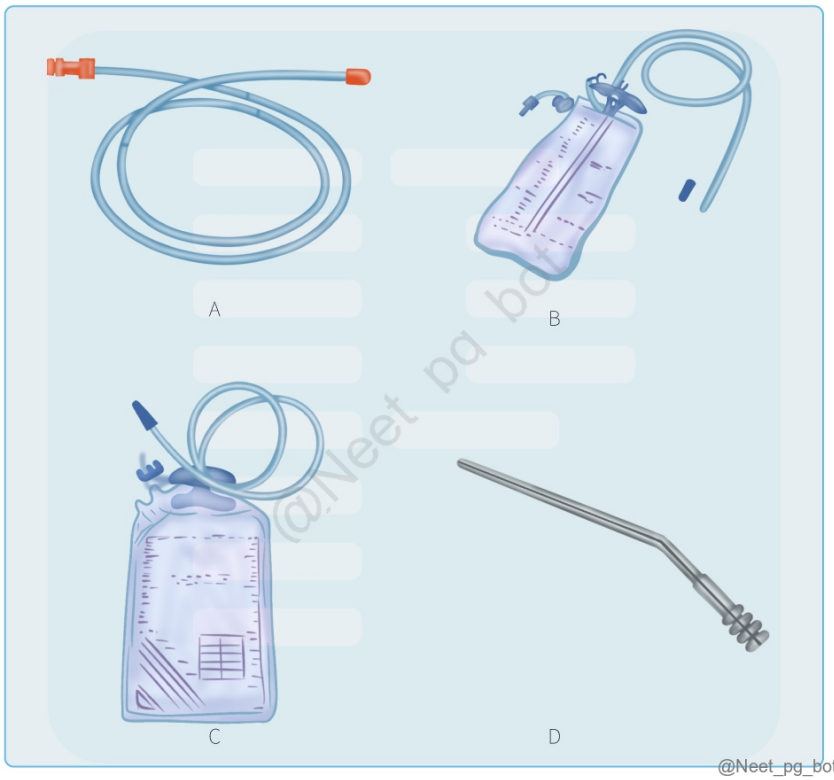
B. 50-year alcoholic man with liver cirrhosis with 1 month abstinence

C. 70-year-old woman with end-stage renal disease

D. 32-year-old woman with renal failure

See Answer in Part B → Q70

@Neet_pg_bot



Q71: Match the following 1. Urine Bag 2. Nasogastric Tube 3. Underwater seal bag 4. Suction cannula (Q856303)

A. 1-D, 2-C, 3-A, 4-B

B. 1-C, 2-A, 3-B, 4-D

C. 1-D, 2-A, 3-C, 4-B

D. 1-B, 2-A, 3-C, 4-D

See Answer in Part B → Q71

@Neet_pg_bot

Q72: The components of qSOFA scoring include: A. Mental status B. Blood pressure C. Respiratory rate D. Heart rate (Q856309)

A. A & B

B. C & D

C. A, B & C

D. A, B, C & D

See Answer in Part B → Q72

@Neet_pg_bot

Q73: Match the correct answer related to the nerve injuries in various surgeries: A. Breast surgery 1. External Laryngeal nerve B. Thyroid surgery 2. Hypoglossal nerve C. Submandibular excision 3. Phrenic nerve D. Thymectomy 4. Long Thoracic Nerve (Q856314)

A. A-1, B-2, C-3, D-4

B. A-2, B-3, C-4, D-1

C. A-3, B-4, C-1, D-2

D. A-4, B-1, C-2, D-3

@Neet_pg_bot

Q83: A patient presents with burn injuries involving the anterior and posterior torso, both upper limbs, and the perineum. The face and lower limbs are spared. According to the Rule of Nines, what is the total body surface area (TBSA) burned? (Q852680)

A. 5-10%

B. 20-30%

C. 10-15%

D. 40-50%

See Answer in Part B → Q83

@Neet_pg_bot

Q84: Identify the procedure? (Q852684)

A. Retrograde pyelogram

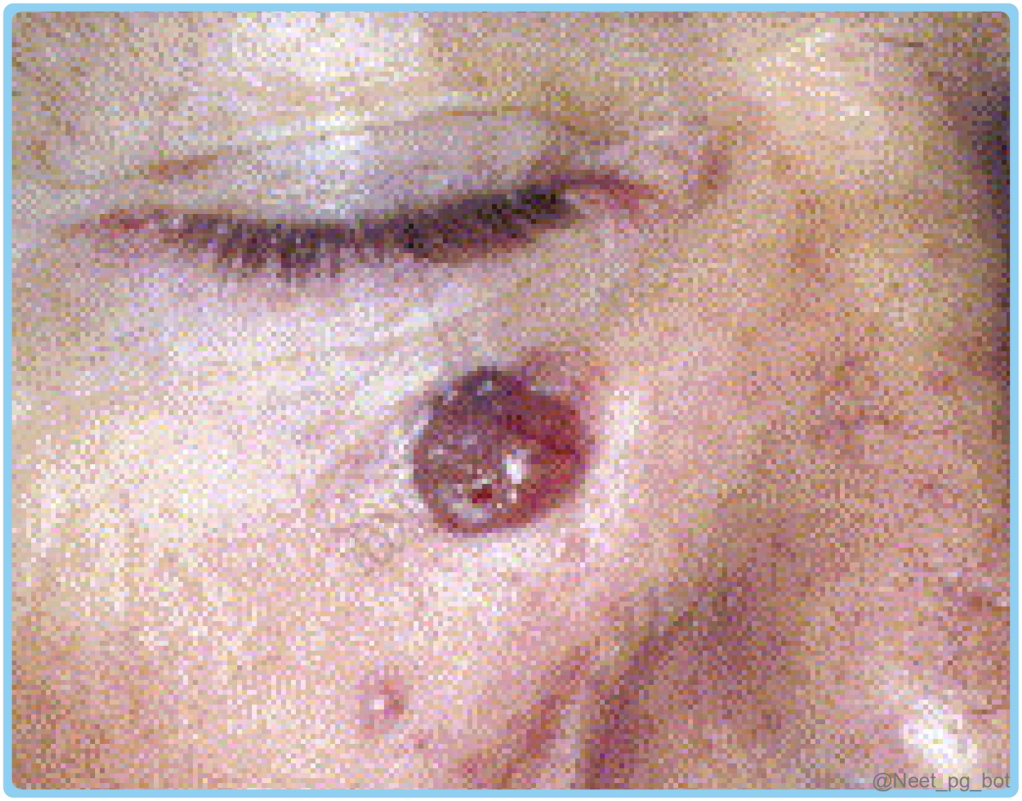
B. Combined Retrograde Pyelogram and Ureteroscopy

C. Intravenous Pyelogram

D. Antegrade pyelography

See Answer in Part B → Q84

@Neet_pg_bot



Q85: Which of the following is not related to disease progression? (Q852689)

A. Duration

B. Depth

C. Site

D. Stage of Cancer

See Answer in Part B → Q85

@Neet_pg_bot

Q86: A patient with diffuse severely contaminated peritonitis underwent laparotomy and was left open after surgery. Which of the following might help? (Q852688)

A. VAC

B. Normal saline soaked gauze

C. Prefer closure after laparotomy

D. Antibiotic soaked gauze

See Answer in Part B → Q86

@Neet_pg_bot

Q87: A patient presents to the emergency department with confusion. On examination, he opens his eyes to pain, shows abnormal flexion to pain, and is disoriented in speech. What is his Glasgow Coma Scale (GCS) score? (Q852690)

A. 11

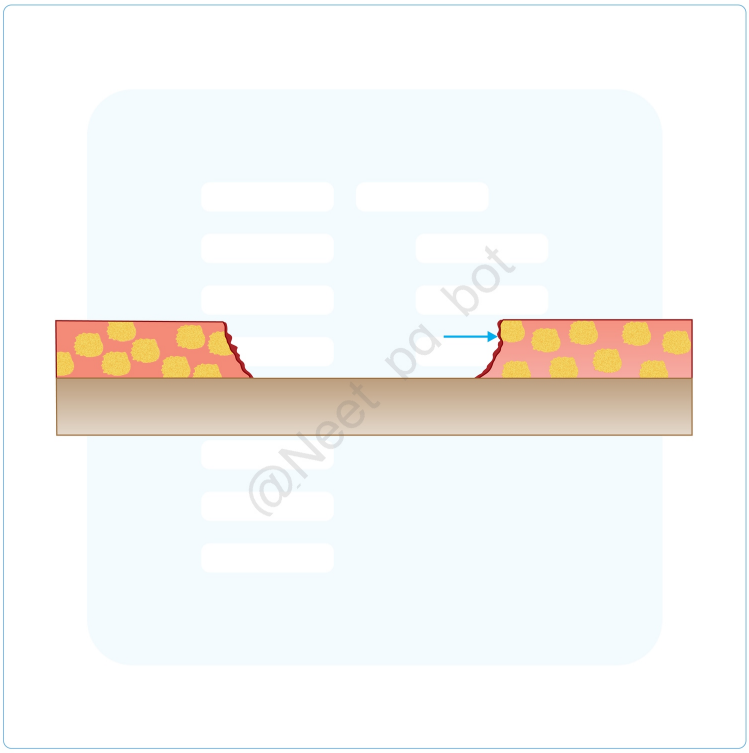
B. 12

C. 10

D. 9

See Answer in Part B → Q87

@Neet_pg_bot



Q88: The given image is of an ulcer, identify the marked structure? (Q852682)

A. Margin

B. Edge

C. Floor

D. Base

@Neet_pg_bot

See Answer in Part B → Q88

@Neet_pg_bot

Q89: In a patient experiencing excessive bleeding, with limbs displaying low temperature and reduced central venous pressure (CVP), what type of shock is observed? (Q859602)

A. Cardiogenic shock

B. Hypovolemic shock

C. Obstructive shock

D. Hypo adrenal shock

See Answer in Part B → Q89

@Neet_pg_bot

Q90: In a hypotensive patient with a head injury, which of the subsequent fluids should be avoided? (Q859606)

A. 0.9% NS

B. 5% Dextrose

C. Ringer lactate

D. 3% saline

See Answer in Part B → Q90

@Neet_pg_bot

Q91: A 30-year-old female presents to the emergency department with burn injuries sustained from a stove explosion. She has burns involving the face with singeing of eyelashes, both upper limbs entirely, and the anterior chest. The burns are partial-thickness, involving the epidermis and part of the dermis. Based on the rule of Nines, what is the approximate total body surface area (TBSA) affected by burns? (Q865330)

A. 33-36%

B. 40-45%

C. 25-28%

D. 50-55%

See Answer in Part B → Q91

@Neet_pg_bot

Q92: Which of the following is incorrect regarding the following dressing? (Q865340)

A. Redressing is done after 4 - 7 days

B. Negative pressure 10-20 mmHg

C. Increase proliferation and protein matrix synthesis

D. Can be continuous & intermittent

See Answer in Part B → Q92

@Neet_pg_bot

Q93: Which of the following cancers is NOT related to obesity? (Q865421)

A. Meningioma

B. Gastric carcinoma

C. Pancreatic carcinoma

D. Multiple myeloma

See Answer in Part B → Q93

@Neet_pg_bot

Q94: A 30-year-old lactating mother presents with pain in her left breast and a fever. On examination, the left breast appears as shown in the image below. There is mild axillary lymphadenopathy on the affected side and the contralateral breast is normal. Repeated aspirations under antibiotic cover were unsuccessful. A USG done showed

fluid collection. What is the next best step in the management of this patient? (Q865425)

A. Incision and drainage

B. Broad-spectrum antibiotics only

C. Breast conservation surgery

D. Punch biopsy

See Answer in Part B → Q94

@Neet_pg_bot

Q95: A 25-year-old male with a history of a road traffic accident presents to the emergency department. His GCS is 8/15, oxygen saturation is 85%, blood pressure is 100/60 mmHg and heart rate is 60 beats per minute. On examination, breath sounds are absent on the right side. What is the next step in management? (Q853038)

A. Start IV fluids, give atropine and secure airway

B. Secure airway, give oxygen, insert ICD, secure IV line

C. Evaluate for head injury and do CT-head

D. ■■■Administer IV dextrose followed by NCCT head

See Answer in Part B → Q95

@Neet_pg_bot

Q96: An 84-year-old man who had a stroke 2 years ago and has been on extended bed rest, develops a pressure ulcer with partial skin thickness loss and a clean base. What is the grade of his pressure sore? (Q853066)

A. 1

B. 2

C. 3

D. 4

See Answer in Part B → Q96

@Neet_pg_bot

Q97: A 35-year-old male had surgery for an ileal perforation. Due to significant contamination, only the sheath was sutured, leaving the wound open. Daily wound irrigation was carried out, and the wound was closed on postoperative day 5. What type of wound-healing mechanism is occurring in this scenario? (Q853067)

A. Primary intention

B. Secondary intention

C. Tertiary intention

D. Quaternary intention

See Answer in Part B → Q97

@Neet_pg_bot

Q98: A friend of yours is teaching you about enhanced recovery after surgery. Which of the following statements he makes is inaccurate? (Q853068)

A. ■■■Prolonged fasting is necessary

B. Epidural anaesthesia recommended in laparoscopic surgery for pain control

C. Reduction of hospital stay by 2-3 weeks

D. Beta-blockers are given after major surgery done under general anaesthesia to improve the outcome

See Answer in Part B → Q98

@Neet_pg_bot

Q99: During laparoscopic port placement, injury to which abdominal wall vessels must be avoided while inserting the trocar?During laparoscopic surgery, where shouldn't the trocar be inserted? (Q852687)

A. Superior epigastric artery

B. Inferior epigastric artery

C. Abdominal aorta

D. Both A and B

See Answer in Part B → Q99

@Neet_pg_bot

Q100: A 45-year-old male patient was brought to the emergency department following a road traffic accident.O/E, he had multiple injuries all over his body and was found to be in class III hemorrhagic shock. The percentage of blood loss would be between: (Q852705)

A. 5-15%

B. 30-40%

C. >40%

D. 15-30%

See Answer in Part B → Q100

@Neet_pg_bot

Q101: A 20-year-old male presents to the outpatient department with a swelling on his wrist. He reports fluctuation in size , mild numbness in the hand , and occasional pain . What is the most likely diagnosis? (Q852713)

A. Lipoma

B. Ganglion cyst

C. Dermoid cyst

D. Hematoma

See Answer in Part B → Q101

@Neet_pg_bot

Q102: A patient with dilated tortuous veins of the leg presented to the OPD and is diagnosed with varicose vein of grade C4a. What is the best preferred treatment? (Q852721)

A. Compression

B. Endothermal ablation

C. Non endothermal non tumescent ablation

D. Open surgery

See Answer in Part B → Q102

@Neet_pg_bot

Q103: A 45-year-old man is found unconscious after a fall from a ladder. In the emergency department, his eyes do not open even in response to pain; he is making incomprehensible sounds, and he exhibits abnormal flexion in response to painful stimuli. What is his Glasgow Coma Scale (GCS) score? (Q852706)

A. 5

B. 6

C. 7

D. 8

See Answer in Part B → Q103

@Neet_pg_bot

Q104: A woman, a few weeks after delivery, complains of bloody discharge from nipple and fever. On examination, diffuse lump under areola. What is the diagnosis? (Q852719)

A. Galactocele

B. Lactational mastitis

C. Mondor disease

D. Fibrocystic disease

See Answer in Part B → Q104

@Neet_pg_bot

Q105: The ureter is safe in which type of hysterectomy? (Q852722)

A. Open laparotomy

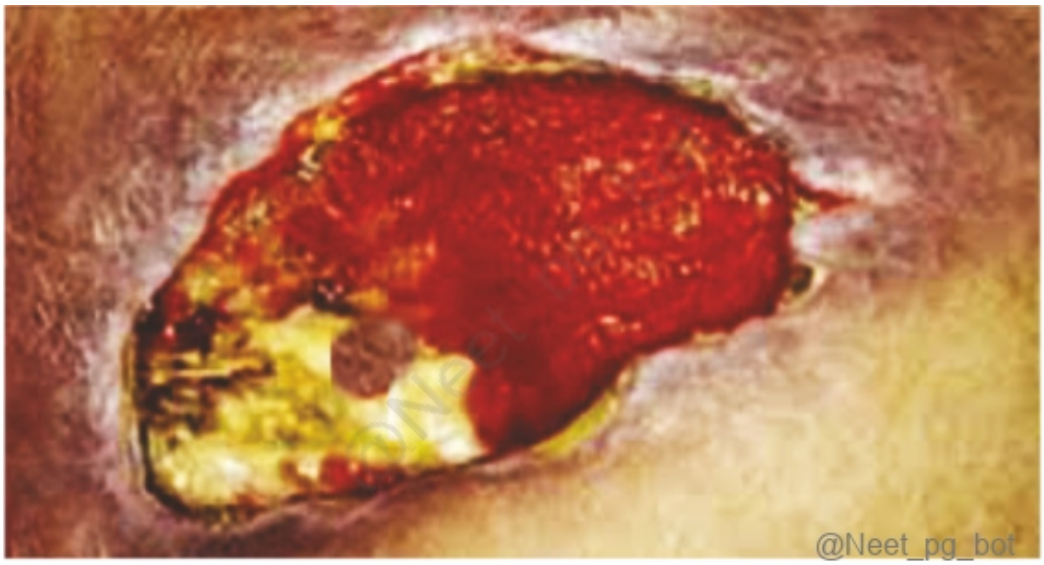
B. Laparoscopy

C. Robotic

D. Vaginal

See Answer in Part B → Q105

@Neet_pg_bot



Q106: Identify the grade of the condition given in the image below ? (Q844279)

A. Grade 1

B. Grade 2

C. Grade 3

D. Grade 4

See Answer in Part B → Q106

@Neet_pg_bot

Q107: What is the ideal pressure setting for vacuum-assisted closure (VAC) therapy? (Q844308)

A. -125 mm Hg

B. 60 to 80 mm Hg

C. 130 mm Hg

D. 80 to 100 mm Hg

See Answer in Part B → Q107

@Neet_pg_bot

Q108: A 20-year-old chronic alcoholic presents with severe hematemesis. An ultrasound (USG) shows distention of the portal vein, and the liver appears hyperechoic. Pantoprazole has been administered. What is the next appropriate step in management? (Q844303)

A. Initiate a course of broad-spectrum antibiotics

B. Order a liver biopsy to assess for fibrosis

C. Administer intravenous fluids and electrolyte replacement

D. Perform an endoscopy to look for varices

See Answer in Part B → Q108

@Neet_pg_bot

Q109: Which of the following is a complication of Total Parenteral Nutrition (TPN) in a sepsis patient in the ICU? (Q844304)

A. Hyperlipidemia

B. Hyperglycemia

C. Hyperglyceridemia

D. Hypoglycemia

See Answer in Part B → Q109

@Neet_pg_bot

Q110: Which of the following is characteristic of hypovolemic shock? (Q860374)

A. Increase in cardiac output

B. High vascular resistance

C. Increase in venous pressure

D. Increased mixed venous saturation

See Answer in Part B → Q110

@Neet_pg_bot

Q111: Identify the type of ulcer shown in the image below: (Q860399)

A. Venous ulcer

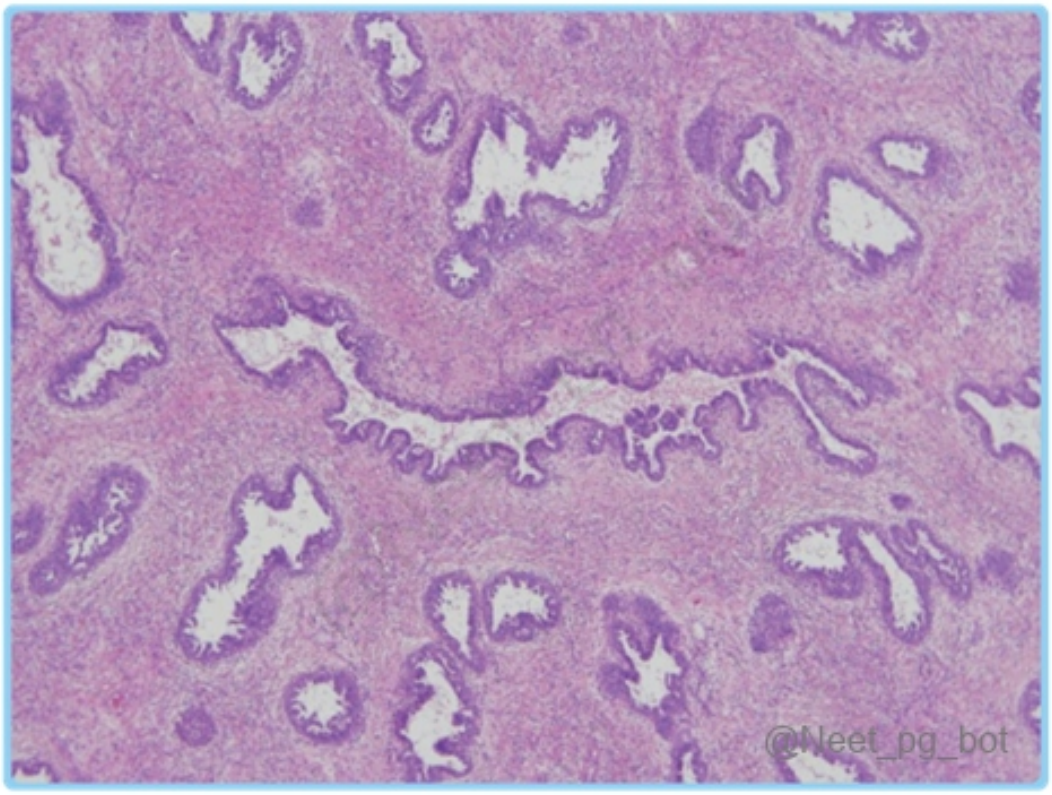
B. Malignant ulcer

C. Arterial ulcer

D. Trophic ulcer

See Answer in Part B → Q111

@Neet_pg_bot



Q112: A 30-year-old female who is receiving cyclosporine A following renal transplantation develops multiple and bilateral breast lumps that regress after cessation of the treatment. Biopsy image is given below. What is the most likely diagnosis? (Q860452)

A. Fat necrosis

B. Phyllodes tumour

C. Fibroadenoma

D. Carcinoma breast

See Answer in Part B → Q112

@Neet_pg_bot

Q113: A 65-year-old male presents to the outpatient department with a swelling in the back of his neck that has been present for almost a year. The swelling has not increased in size. On examination, it is non-pulsatile, and the slip sign is positive, with the swelling measuring 3x3 cm. Which of the following statements is most likely true? (Q860457)

A. High chances of malignant transformation

B. FNAC necessary for diagnosis

C. PET scan necessary for staging

D. Excision can be done if the patient requests it

See Answer in Part B → Q113

@Neet_pg_bot

Q114: A 47-year-old man presents with a chronic non-healing painless ulcer over his scalp for 8 years. He has a history of electric burns to the scalp 8 years ago. The examination findings are shown below. Which of the following statements is true? (Q860461)

A. Radiotherapy is useful

B. It can progress to squamous cell carcinoma

C. No lymphatic spread

D. Long-duration antibiotics will improve the condition.

See Answer in Part B → Q114

@Neet_pg_bot

Q115: A 25-year-old woman presents with severe pain and swelling in her right hand, which is increasing in size and severity. She had a prick injury in the garden 5 days ago. On examination, she cries out in pain when her hand is extended and when the palmar aspect is palpated passively. Which of the following statements is true about the condition? (Q860463)

A. More common in the dorsal aspect of the hand

B. X-ray imaging will aid in the location of the foreign body in all patients

C. It requires incision and drainage

D. Oral analgesics are the mainstay of treatment

See Answer in Part B → Q115

@Neet_pg_bot

Q116: A patient fell from a train onto the railway track and injured both his legs severely. He was urgently taken to the hospital, and the following procedure was performed (image shown below). What is the rationale for performing this procedure? (Q860466)

A. Better fit for prosthesis

B. Life-saving procedure

C. Reduces risk of cancer

D. Good cosmetic outcomes

See Answer in Part B → Q116

@Neet_pg_bot

Q117: In solid organ transplantation, which of the following organs is associated with a higher incidence of rejection? (Q860491)

A. Lungs

B. Intestine

C. Kidney

D. Liver

See Answer in Part B → Q117

@Neet_pg_bot

Q118: A 55-year-old female patient with chronic pancreatitis undergoes a Puestow procedure. What is the most preferred route for supplementary nutrition in this patient? (Q860504)

A. TPN (Total Parenteral Nutrition)

B. Oral feeding

C. Feeding gastrostomy

D. Feeding jejunostomy

See Answer in Part B → Q118

@Neet_pg_bot

Q119: A 35-year-old woman, 10 years after mastectomy, notices gradual swelling and heaviness in her right upper limb without pain. On examination, bluish nodules on the skin with no infections are noted. What is the most likely cause of her symptoms? (Q860167)

A. Lymphangiosarcoma

B. Thoracic outlet syndrome

C. Chronic venous insufficiency

D. Recurrent breast cancer

See Answer in Part B → Q119

@Neet_pg_bot

Q120: A patient presents to the emergency room after a road traffic accident with shock and hypotension. The extended focused assessment with sonography for trauma (eFAST) is negative, the X-ray is normal, and the ECG shows bradycardia. The patient's SpO2 is 93%, blood pressure is 80/60 mmHg, and pulse rate is 40/min. Based on this information, what type of shock is most likely? (Q860219)

A. Septic shock

B. Hemorrhagic shock

C. Cardiogenic shock

D. Neurogenic shock

See Answer in Part B → Q120

@Neet_pg_bot

Q121: In patients at risk of refeeding syndrome, which of the following electrolyte imbalances is typically not associated with this condition? (Q860221)

A. Hypokalemia

B. Hyperkalemia

C. Hypocalcemia

D. Hypophosphatemia

See Answer in Part B → Q121

@Neet_pg_bot

Q122: Identify the edges of the lesion given in the image: (Q860254)

A. Everted

B. Rolled out

C. Sloping

D. Punched out

See Answer in Part B → Q122

@Neet_pg_bot

Q123: A patient following a road traffic accident (RTA) with a crush injury presents with crepitus and a reddish-brown wound within 3 days after amputation. What is the most likely condition? (Q860260)

A. Gas gangrene

B. Impetigo

C. Tetanus

D. Cellulitis

See Answer in Part B → Q123

@Neet_pg_bot

Q124: Arrange the stages of wound healing in the correct sequence: (Q860267)

A. Proliferation, hemostasis, inflammation, remodeling

B. Inflammation, remodeling, hemostasis, proliferation

C. Hemostasis, inflammation, proliferation, remodeling

D. Remodeling, proliferation, hemostasis, inflammation

See Answer in Part B → Q124

@Neet_pg_bot

Q125: Which of the following is considered a “sure sign” of abdominal wound dehiscence in a post-operative hypotensive patient? (Q860272)

A. Increased bowel sounds

B. Persistent abdominal pain

C. Serosanguinous drainage from the wound

D. Widening of the abdominal scar with palpable edges

See Answer in Part B → Q125

@Neet_pg_bot

Q126: An elderly chronic smoker male is diagnosed with squamous cell carcinoma of the lower lip with no lymph node involvement. What is the treatment of choice? (Q860276)

A. Radiotherapy

B. Combined chemoradiotherapy

C. Wide local excision with negative borders

D. Wide local excision with frozen section

See Answer in Part B → Q126

@Neet_pg_bot

Q127: In a triage setting, which of the following categories requires the highest priority intervention? (Q860294)

A. Red

B. Yellow

C. Green

D. Black

See Answer in Part B → Q127

@Neet_pg_bot

Q128: What type of skin graft is used in the image shown? (Q860305)

A. Split thickness

B. Full thickness

C. Wolfe graft

D. Local flap

See Answer in Part B → Q128

@Neet_pg_bot

Q129: A female patient presents to the outpatient department 10 days postpartum with complaints of a fluctuant breast mass with tenderness, high-grade fever, and cracked nipples. What is the most probable diagnosis? (Q860324)

A. Breast engorgement

B. Breast abscess

C. Acute mastitis

D. Fibroadenoma

See Answer in Part B → Q129

@Neet_pg_bot

Q130: What kind of wound is an open cardiac massage? (Q857262)

A. Clean

B. Contaminated

C. Dirty

D. Clean Contaminated

See Answer in Part B → Q130

Q131: Identify the incision made and marked in the image. (Q857292)

A. Robson

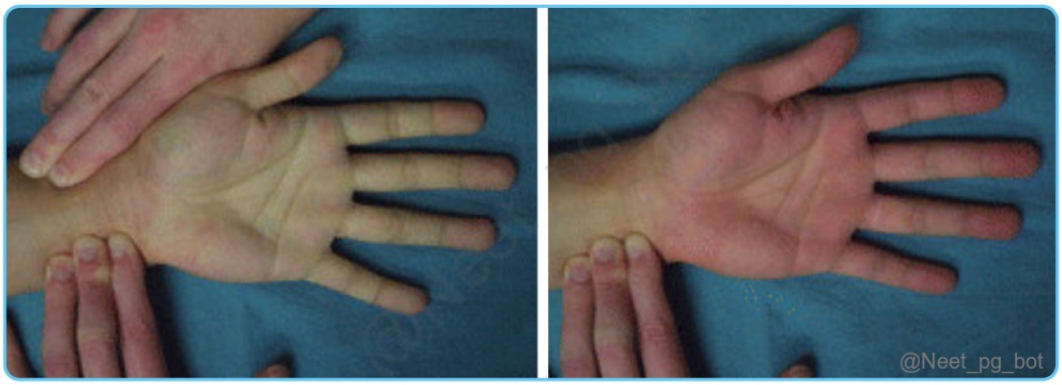
B. Maylard

C. Gibson Abernathy

D. Kocher's

See Answer in Part B → Q131

@Neet_pg_bot



Q132: Identify the test provided in the image below. (Q857294)

A. Allen’s test

B. Adson’s test

C. Elevated arm stress test

D. Nicoladoni’s test

See Answer in Part B → Q132

@Neet_pg_bot

Q133: Smoking increases the risk of which of the following diseases? Duct ectasia Fibroadenoma Mondor disease Breast carcinoma (Q857295)

A. 2, 3

B. 1, 4

C. 2, 3, 4

D. 1, 3, 4

See Answer in Part B → Q133

@Neet_pg_bot

Q134: A 25-year-old male patient is brought to the casualty after a road traffic accident (RTA) with suspected pelvic fractures. On examination, he is found to be in hypovolemic shock. What is the earliest treatment for control of haemorrhage in this case? (Q857297)

A. Immediate internal fixation

B. Multiple blood transfusions

C. Use bedsheets to compress the pelvis

D. Emergency external fixation

See Answer in Part B → Q134

@Neet_pg_bot

Q135: A soldier arrives at a referral hospital 24 hours after experiencing a shrapnel injury to his right thigh caused by a high-speed projectile. He expresses significant discomfort at the site of the wound. Upon examination, there is evidence of crepitus. Which of the following microorganisms is the probable culprit behind his current state? (Q857804)

A. Clostridium septicum

B. Clostridium difficile

C. Clostridium novyi

D. Clostridium perfringens

See Answer in Part B → Q135

@Neet_pg_bot

Q136: A 32-year-old female undergoes emergency laparotomy for perforation peritonitis. Which of the following is the surest sign of wound dehiscence? (Q857853)

A. Copious sero-sanguinous discharge

B. Rebound tenderness

C. Hemorrhage

D. Hypotension

See Answer in Part B → Q136

@Neet_pg_bot

Q137: What should be the next course of action in the management of a 30-year-old breastfeeding mother who is experiencing pain and fever in her left breast? The left

breast appears abnormal as depicted in the provided image. There is slight swelling of the lymph nodes in the armpit on the affected side, while the opposite breast appears normal. Despite multiple attempts at draining the fluid with the use of antibiotics, it was unsuccessful. An ultrasound examination revealed the presence of fluid collection. (Q793402)

A. Incision an drainage

B. Broad spectrum antibiotics only

C. Breast conservation surgery

D. Punch biopsy

See Answer in Part B → Q137

@Neet_pg_bot

Q138: A barber aged 42 years presented with a healed ulcer as below, over the lower medial aspect of the right leg. On examination, he has varicose veins on both his legs. What is the most likely type of ulcer he had? (Q859836)

A. Neuropathic ulcer

B. Arterial ulcer

C. Venous ulcer

D. Tubercular ulcer

See Answer in Part B → Q138

@Neet_pg_bot

Q139: False regarding deep second-degree burns: (Q859883)

A. Heal by scar deposition

B. No blanching

C. Damage to the deeper dermis

D. Completely painless

See Answer in Part B → Q139

@Neet_pg_bot

Q140: What is the diagnosis based on the image below? (Q859893)

A. Botryomycosis

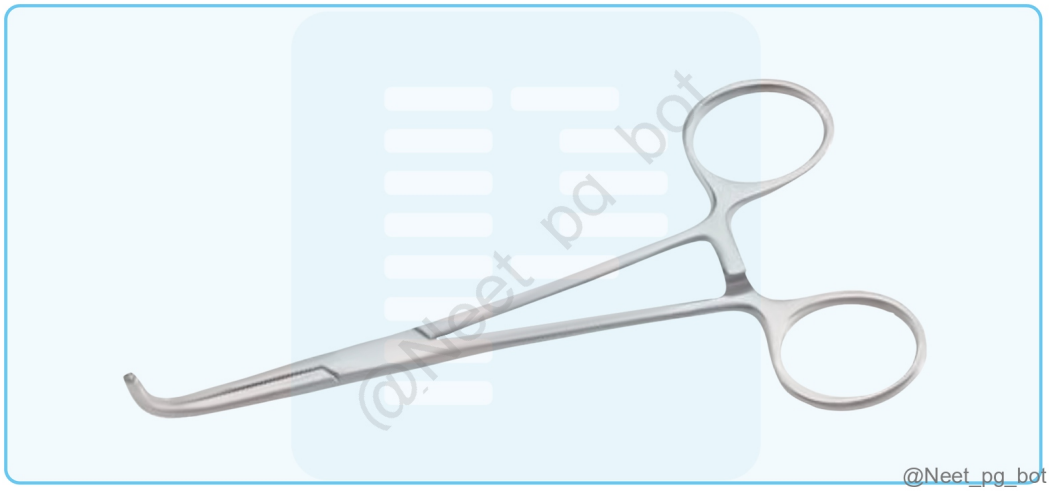
B. Erysipelas

C. Ecthyma

D. Carbuncle

See Answer in Part B → Q140

@Neet_pg_bot



Q141: Identify the surgical instrument depicted in the provided image. (Q854778)

A. Mixter Forceps

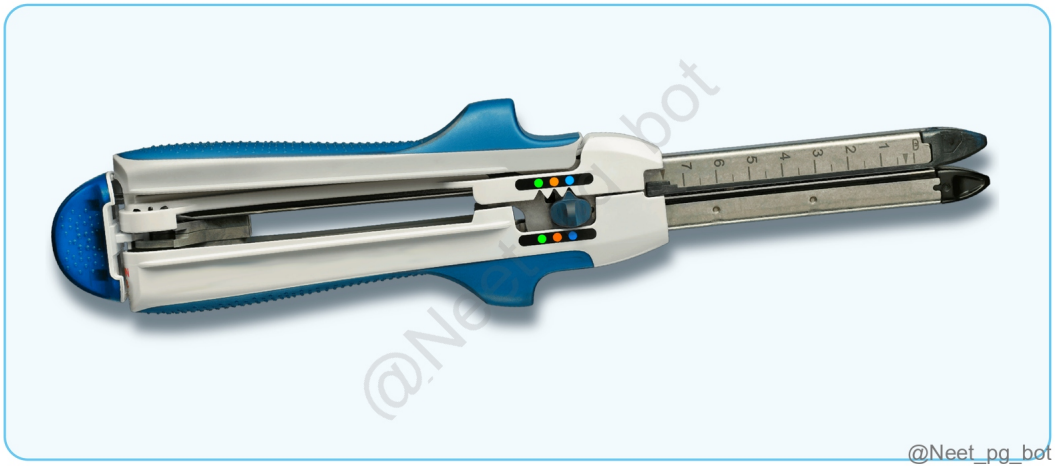
B. Rampley Forceps

C. Kocher Forceps

D. Adson Forceps

See Answer in Part B → Q141

@Neet_pg_bot



Q142: Please determine the instrument provided. (Q857871)

A. Linear stapler

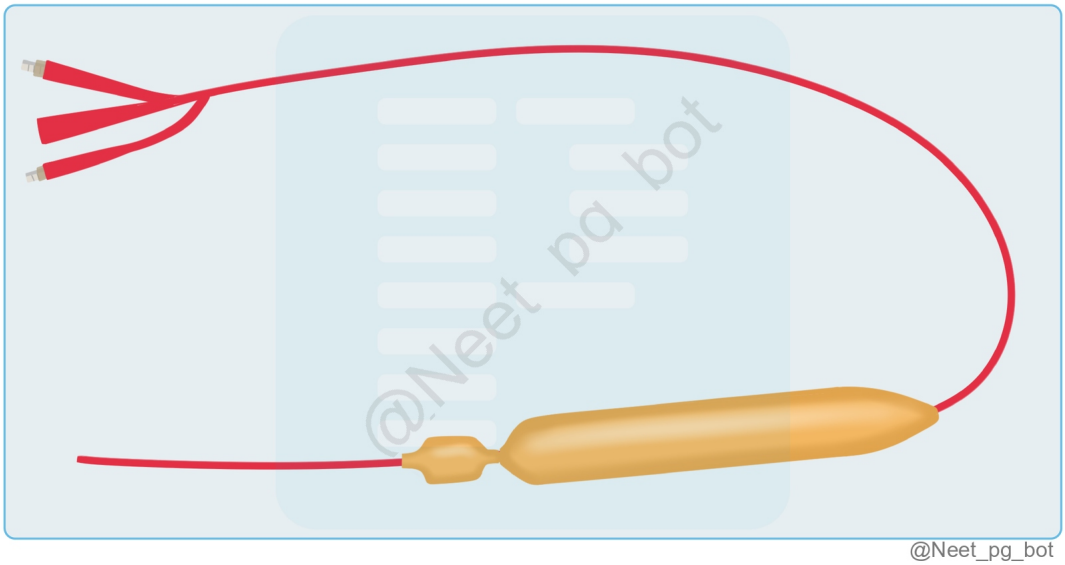
B. Skin stapler

C. Circular stapler

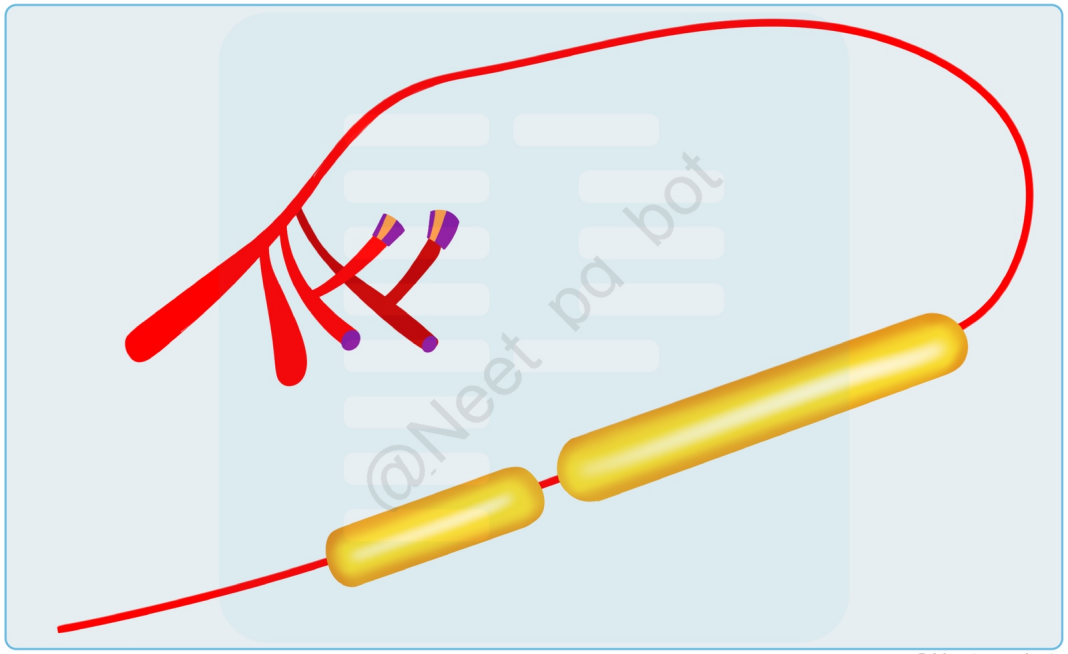
D. Curved stapler

See Answer in Part B → Q142

@Neet_pg_bot



Q143: Which of the following are used to stop oesophagal variceal bleeding? A. B. C. D. (Q856236)



A. A, B & C

B. A and B only

C. B and C

D. A, B and D

@Neet_pg_bot

@Neet_pg_bot

@Neet_pg_bot

Q144: A 38-year-old man was brought to the emergency department after sustaining an RTA and injury to the lower chest. On presentation, the patient is stable, and vitals are normal . Chest radiography showed clear lung fields. What is the next step in management? (Q801160)

A. eFAST

B. Tube thoracostomy

C. CECT chest

D. CECT abdomen

See Answer in Part B → Q144

@Neet_pg_bot

Q145: Which of the following CT findings is not an indication to perform angiography in a splenic trauma patient under conservative management? (Q793370)

A. Subcapsular hematoma covering 40% surface area.

B. Significant hemoperitoneum

C. Presence of pseudoaneurysm

D. Contrast extravasation

See Answer in Part B → Q145

@Neet_pg_bot

Q146: What would be the subsequent course of action for this injury depicted in the image after a three-day period following a Road Traffic Accident (RTA)? (Q793911)

A. Debridement of necrotic tissue with primary closure

B. Debridement of necrotic tissue and hyperbaric oxygen

C. Amputation

D. Clean and close with rotation flap

See Answer in Part B → Q146

@Neet_pg_bot

Q147: What is the likely reason behind the occurrence of surgical emphysema in the patient following an emergency tracheostomy performed outside of the hospital? (Q793917)

A. Puncture of posterior wall

B. High tracheostomy

C. Blockage of the tube

D. Tight suture

See Answer in Part B → Q147

@Neet_pg_bot

Q148: Which of the following is not included in the AAST grading system for splenic trauma? (Q793921)

A. Parenchymal destruction

B. Vascular involvement

C. Adjacent organ involvement

D. Hematoma

See Answer in Part B → Q148

@Neet_pg_bot

Q149: What guidance would you provide to the female patient prior to undergoing laparoscopic surgery? (Q793926)

A. Eat full before surgery.

B. Drink plenty of water before surgery.

C. Enema on the night before surgery

D. NPO for specific hours before surgery

See Answer in Part B → Q149

@Neet_pg_bot

Q150: Which of the following tests is not conducted before a blood transfusion for a person with RTA, when a family member is volunteering for blood donation? (Q793932)

A. Hepatitis A

B. Hepatitis B

C. Hepatitis C

D. HIV 1 & 2

See Answer in Part B → Q150

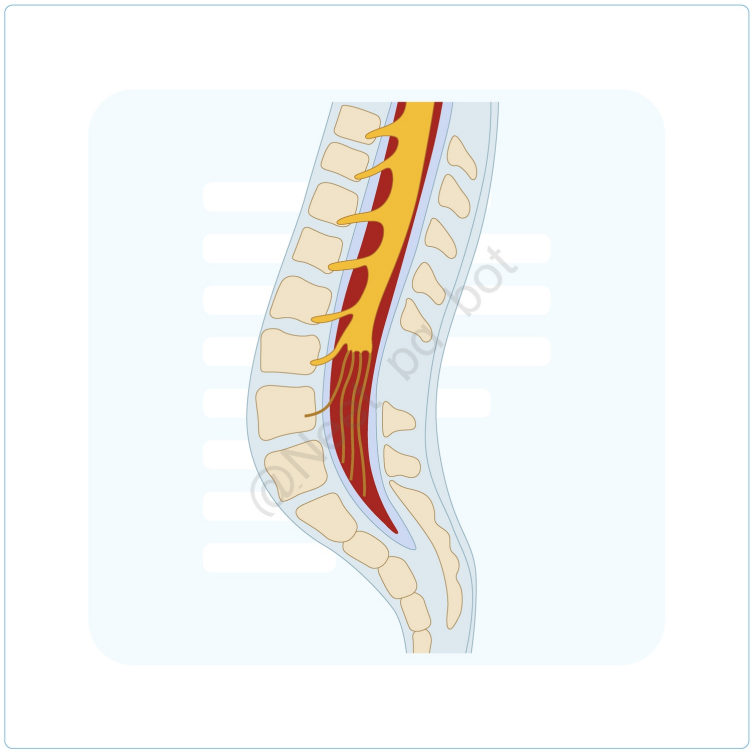
Part B — All Answers & Explanations

• [01_Neurosurgery] 001 Cerebrovascular Diseases

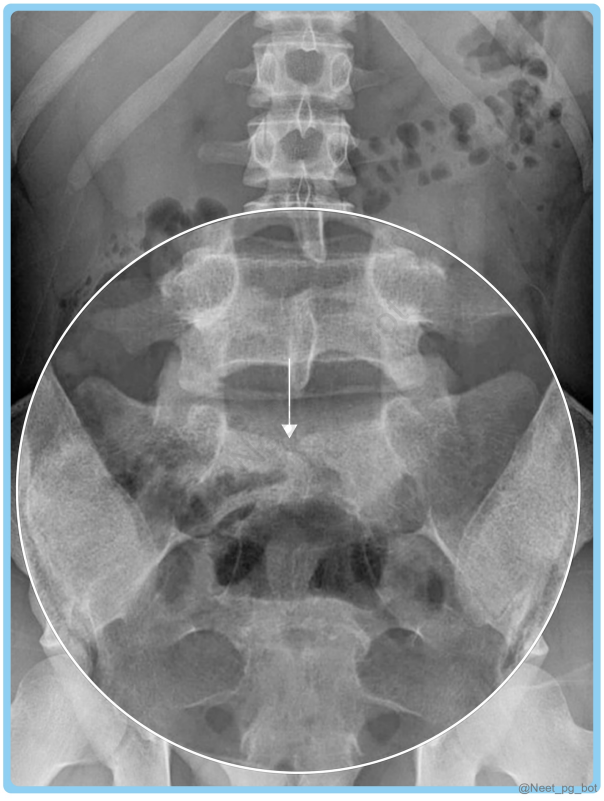
« Back to Folder Directory

[01_Neurosurgery] 001 Cerebrovascular Diseases — Quick Jump

Q1 (p. 1120) *Q2 (p. 1122)* *Q3 (p. 1124)* *Q4 (p. 1125)* *Q5 (p. 1126)* *Q6 (p. 1128)*
Q7 (p. 1130) *Q8 (p. 1132)* *Q9 (p. 1134)* *Q10 (p. 1135)* *Q11 (p. 1137)* *Q12 (p. 1138)*



Q1: A 25-year-old asymptomatic patient undergoes a routine lumbar spine X-ray for an unrelated complaint. The radiologist notices an incidental finding on the image. Which of the following findings would be inconsistent with spina bifida occulta? (Q849163)

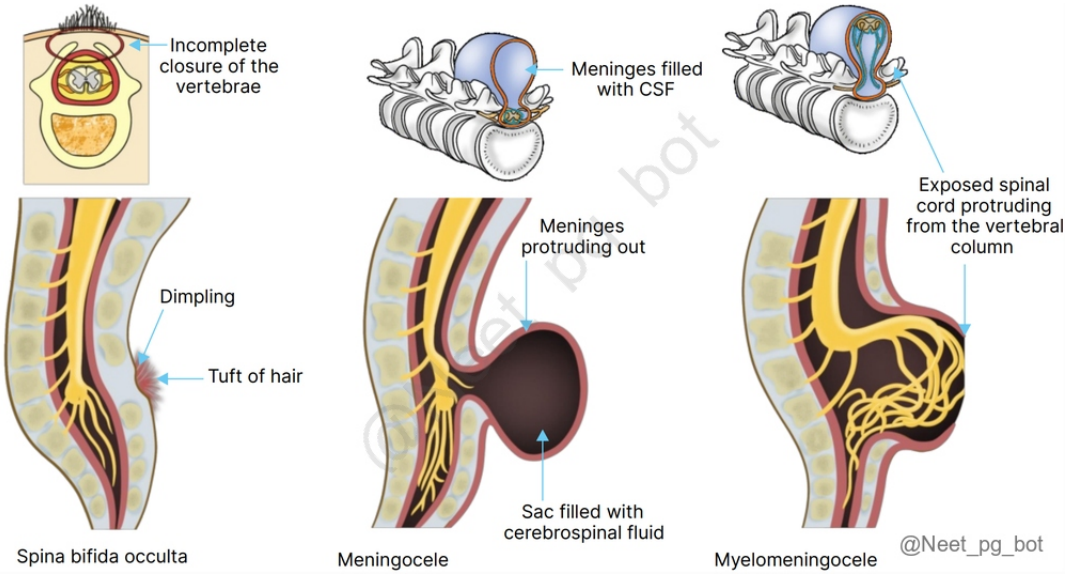


A. Tuft of hair or dimple over the affected area

B. Often asymptomatic and found incidentally on imaging

C. Failure of vertebral arches to fuse with intact spinal cord and meninges

D. Visible sac with cerebrospinal fluid and neural elements protruding through a defect



Correct Answer: D. Visible sac with cerebrospinal fluid and neural elements protruding through a defect

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Spina bifida occulta is characterised by: Failure of vertebral arches to fuse with the spinal cord and meninges remaining within the spinal canal (Option C). It is often asymptomatic and discovered incidentally on imaging (Option B). External signs like a tuft of hair or dimple over the affected area (Option A). In contrast, a visible sac containing cerebrospinal fluid and neural elements protruding through a defect (Option D) indicates spina bifida aperta , specifically meningocele and myelomeningocele, not spina bifida occulta.

References:

Schwartz's Principles of Surgery, 11th edition, Pg 1872

↑ *Back to this question in Part A*

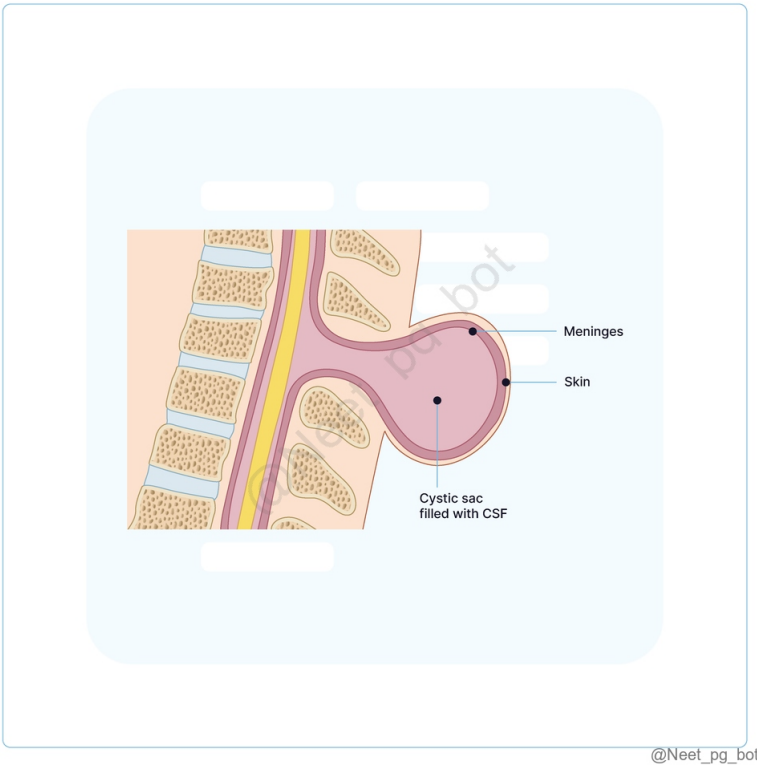
@Neet_pg_bot

Q2: A 28-year-old pregnant woman at 20 weeks of gestation undergoes a routine ultrasound, which reveals a fluid-filled sac at the lower back of the fetus. Which statement about myelomeningocele is most accurate? (Q849164)

A. Protrusion of meninges through a vertebral defect

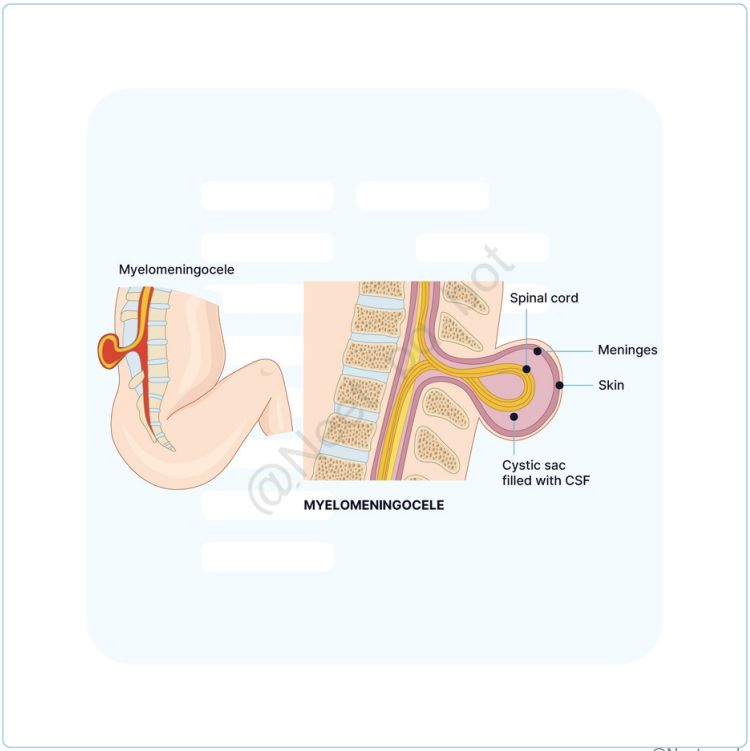
B. Sac contains cerebrospinal fluid but no neural elements.

C. Better prognosis than other spina bifida types



D. Includes spinal cord tissue within the protruding sac.

Correct Answer: D. Includes spinal cord tissue within the protruding sac.



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Myelomeningocele involves the herniation of the spinal cord, meninges, and cerebrospinal fluid through a vertebral defect. The presence of spinal cord tissue within the sac differentiates myelomeningocele from other forms of spina bifida, such as meningocele , in which only the meninges and cerebrospinal fluid are present in the sac without spinal cord involvement. Feature Meningocele Myelomeningocele Definition Protrusion of meninges through a vertebral defect (Option A) Protrusion of meninges and spinal cord through a vertebral defect (Option D) Sac contents Cerebrospinal fluid only. Cerebrospinal fluid and neural tissue. Neural involvement No neural elements in the sac (Option B) Spinal cord and/or nerve roots in the sac Skin coverage Often covered by skin Usually not covered by skin (open lesion) Neurological deficits Typically mild or absent Often severe Hydrocephalus risk Lower risk Higher risk Prognosis Generally better (Option C) Generally worse Surgical complexity Less complex More complex Long-term complications Fewer More frequent and severe Associated anomalies Less common More common

@Neet_pg_bot

@Neet_pg_bot

References:

Schwartz's Principles of Surgery, 11th edition, Pg 1872 Bailey & Love's Short Practice of Surgery, 28th edition, Pg 522, 719

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: Which of the following medications, when taken during pregnancy, is most strongly associated with an increased risk of myelomeningocele in the developing fetus? (Q849165)

A. Metformin

B. Valproic acid

C. Amoxicillin

D. Levothyroxine

Correct Answer: B. Valproic acid

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Valproic acid (anti-convulsant) is most strongly associated with an increased risk of myelomeningocele when taken during pregnancy. Metformin, amoxicillin, and levothyroxine are not specifically associated with significantly increased myelomeningocele risk (Options A, C, and D ruled out) Other drugs associated with increased risk of neural tube defects: Medication Primary Use Valproic acid Epilepsy, Bipolar disorder Carbamazepine Epilepsy, Trigeminal neuralgia Phenytoin Epilepsy Topiramate Epilepsy, Migraine prevention Methotrexate Cancer, Autoimmune diseases Trimethoprim Urinary tract infections Sulfasalazine Inflammatory bowel disease, Rheumatoid arthritis Mycophenolate mofetil Organ transplant rejection prevention Isotretinoin Severe acne Lithium Bipolar disorder

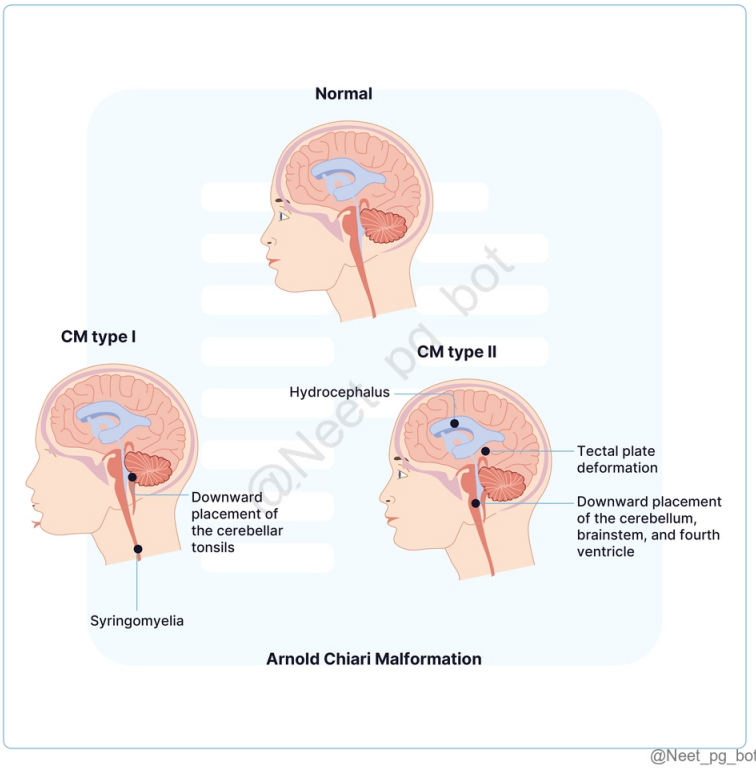
@Neet_pg_bot

Q4: Which of the following is most commonly associated with Arnold-Chiari malformation type II? (Q849166)

A. Syringomyelia

B. Myelomeningocele

C. Adult-onset headaches



D. Scoliosis

Correct Answer: B. Myelomeningocele

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Arnold-Chiari malformation type II is almost always associated with myelomeningocele, a severe form of spina bifida where the spinal cord and meninges protrude through a defect in the spine. Feature Chiari I Chiari II Myelomeningocele Rare Almost always present Age at diagnosis Often adolescence/adulthood Usually, infancy or prenatal Syringomyelia Can occur More frequent Herniated structures Cerebellar tonsils only Cerebellar tonsils, vermis, brainstem Hydrocephalus Less common Very common

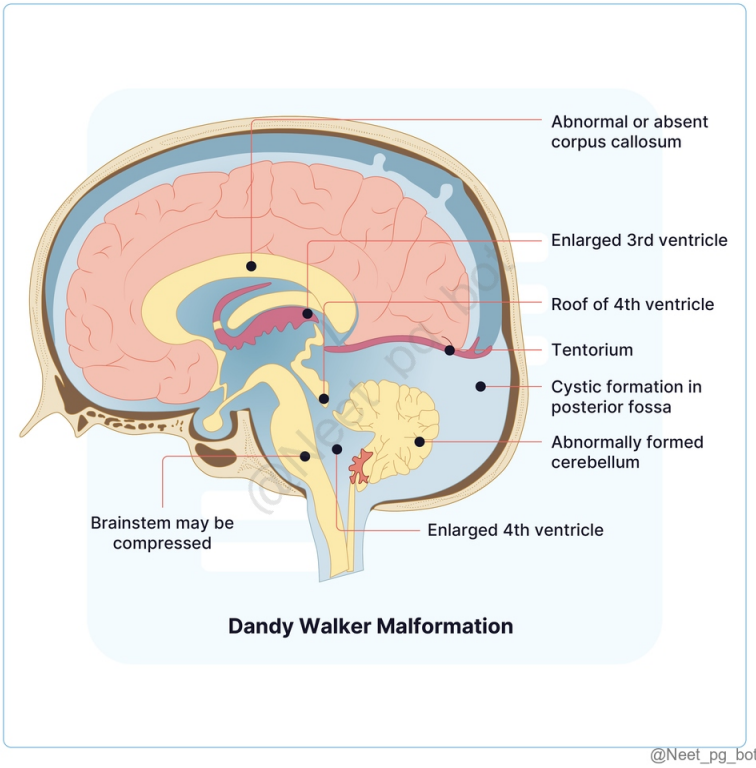
@Neet_pg_bot

Q5: Which of the following is NOT part of the classic triad of Dandy-Walker malformation? (Q849167)

A. Cystic dilatation of the fourth ventricle

B. Complete or partial agenesis of the cerebellar vermis

C. Enlarged posterior fossa



D. Hydrocephalus

Correct Answer: D. Hydrocephalus

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hydrocephalus is not part of the classic triad of Dandy-Walker malformation. Dandy-Walker Malformation: Most frequent posterior fossa malformation and is due to the developmental failure of the fourth ventricle's roof. The classic triad consists of: Cystic dilatation of the fourth ventricle (Option A) Complete or partial agenesis of the cerebellar vermis (Option B) Enlarged posterior fossa with elevation of the tentorium cerebelli (Option C) Clinical Presentation: Macrocephaly (most common manifestation). Rapid head growth with prominent occiput. Possible long tract signs and cerebellar ataxia. Delayed motor/cognitive milestones. Associated Anomalies: CNS abnormalities in 70% of cases, including: Agenesis of posterior cerebellar vermis and corpus callosum Cortical dysplasia Polymicrogyria Diagnosis: MRI is the imaging modality of choice Treatment: Shunt placement for cystic cavity in patients with hydrocephalus.

MRI of a Dandy - Walker Variant Showing

(A) Axial T2W

(B, C) Coronal T1W

(D) Shows hypoplasia of the inferior vermis with anterosuperior rotation

@Neet_pg_bot

Q6: A 42-year-old male is brought to the emergency department after collapsing at home. His family reports that he suddenly screamed in pain, clutching his head and describing it as the "worst headache of his life," followed by several episodes of vomiting. On examination, he is confused, has significant neck stiffness (nuchal rigidity), and shows marked photophobia. There is no history of recent head trauma. A non-contrast CT scan of the brain is shown below. Which of the following is the most common cause of this patient's condition? (Q849169)

A. Smoking

B. Rupture of a berry aneurysm

C. Severe hypertension

D. Arteriovenous malformation

Correct Answer: B. Rupture of a berry aneurysm

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient’s presentation of a 'thunderclap' headache during activity, in the absence of trauma, combined with the CT findings of blood in the basal cisterns, is pathognomonic for a spontaneous Subarachnoid Hemorrhage (SAH) ." Subarachnoid Hemorrhage: Causes: Ruptured Berry Aneurysm: The most common cause of spontaneous SAH . Most frequently located in the Anterior Communicating Artery of the Circle of Willis. (Option B) Arteriovenous Malformation (AVM): A less common cause of spontaneous SAH, more frequently associated with intraparenchymal bleeds in younger patients. (Option D) Perimesencephalic SAH : Bleeding is confined to the basal cisterns due to venous bleeding and is associated with a better prognosis. Risk factors: Female sex Hypertension (Option C) Smoking & Cocaine use (Option A) Genetic disorders (e.g., adult polycystic kidney disease , Marfan syndrome) Symptoms: Thunderclap Headache : Sudden and severe headache. Associated with Seizures (10%), Unresponsiveness (50%) and Vomiting (70%) Diagnosis: CT Scan : First-line imaging , effective within 12 hours of onset, and its sensitivity decreases after one week. Lumbar Puncture : Used if CT is negative but SAH is suspected. Digital Subtraction Angiography (DSA) : Gold standard for visualising aneurysms. Management: Surgical or endovascular intervention and addressing complications such as vasospasm and electrolyte imbalances . Early and effective treatment is crucial for improving outcomes.

Bailey & Love’s Short Practice of Surgery, 28th edition, Pg - 708, 709

↑ *Back to this question in Part A*

Q7: A 55-year-old patient presents with a sudden severe headache, brief loss of consciousness, nausea, and vomiting. Neurological examination shows decreased consciousness and mild focal deficits. A non-contrast CT scan of the head is provided. What is the most probable diagnosis? (Q849170)

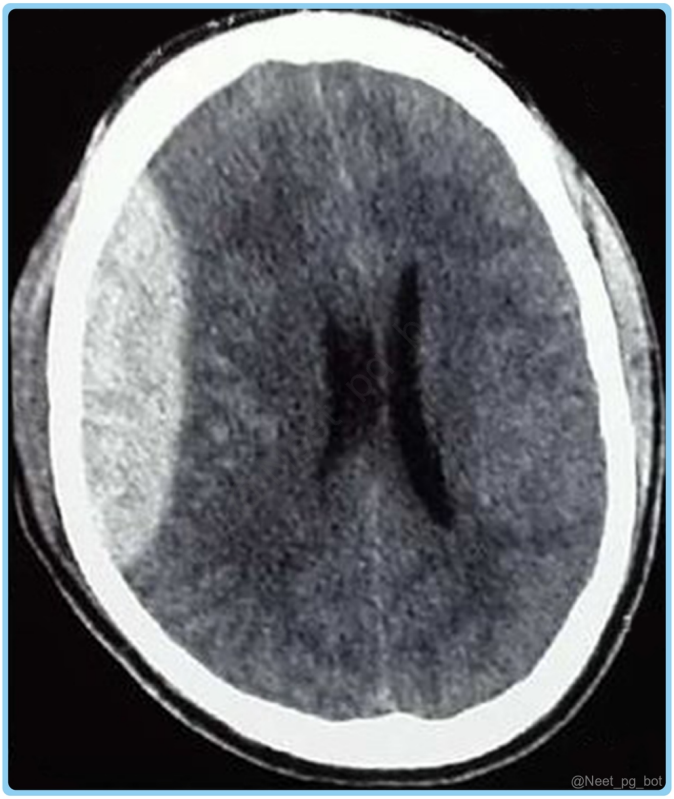
A. Subdural Hematoma (SDH)

B. Extradural Hematoma (EDH)

C. Subarachnoid Hemorrhage

D. Periventricular Hemorrhage

Correct Answer: A. Subdural Hematoma (SDH)



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Given the clinical scenario and radiological findings showing a crescent-shaped blood collection that follows the brain's contours and crossing suture lines , the most probable diagnosis is Subdural Hematoma. Features Subdural Hematoma Extradural Hematoma (Option B) Location Between Dura and Arachnoid Between

Dura and Skull CT Appearance Crescent-shaped Crosses suture lines Biconvex or lens-shaped Well-defined & Localized, Won’t cross suture lines Common Causes Tearing of bridging veins , often due to blunt trauma / acceleration-deceleration injuries Rupture of the middle meningeal artery or vein due to skull fracture or trauma Onset Develop over days to weeks; Acute SDH can occur rapidly Usually develop rapidly Management Craniotomy / Craniectomy , if significant. Conservative management for smaller, stable cases. Burr hole drainage is preferred for significant chronic cases Urgent surgical evacuation for significant or deteriorating cases.

Bailey & Love's Short Practice of Surgery, 28th edition, Page - 365, 366, 367

↑ *Back to this question in Part A*

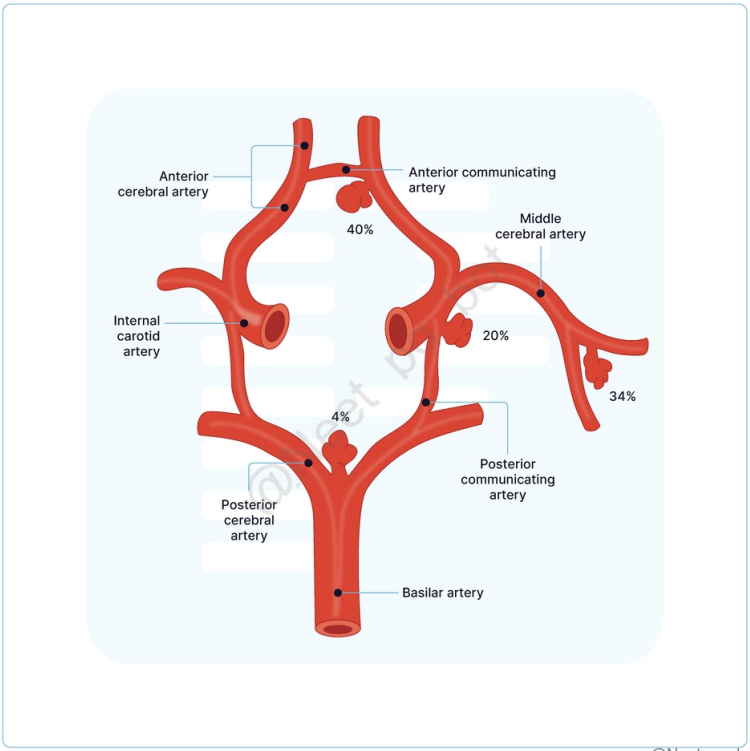
@Neet_pg_bot

Q8: A 52-year-old male with a history of hypertension and smoking presents with sudden onset of nausea, vomiting, and confusion. On examination, he has a decreased level of consciousness and neck stiffness. A non-contrast CT scan reveals subarachnoid haemorrhage. Which of the following statements about Berry aneurysms is not true? (Q849173)

A. Associated with connective tissue disorders like Marfan's syndrome.

B. Absence of smooth muscle and intimal elastic lamina.

C. Most commonly seen at the bifurcation of the vertebrobasilar arteries.



D. Unruptured cases are asymptomatic

Correct Answer: C. Most commonly seen at the bifurcation of the vertebrobasilar arteries.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Berry aneurysms are most commonly found at the bifurcations in the anterior circulation of the Circle of Willis, such as the junction of the anterior cerebral and anterior communicating artery , not at the bifurcation of the vertebrobasilar arteries. It is the most common type of intracranial aneurysm. Saccular & typically located in the anterior circulation of the Circle of Willis. Common Sites: Junction of Anterior Communicating and Anterior Cerebral Artery (Most Common) > Bifurcation of MCA (2nd Most Common) > Junction of PCA and Internal Carotid Artery > Intracranial Carotid Bifurcation > Bifurcation of Vertebrobasilar (Option C) Structural Features: Absence of Smooth Muscle and Intimal Elastic Lamina (Option B) Wall Composition: Thickened, hyalinised intima Clinical Presentation: Ruptured Berry Aneurysm: Can cause subarachnoid haemorrhage (SAH) or intracerebral haemorrhage and the most common rupture site is the dome or apex. Unruptured Berry Aneurysm: Usually asymptomatic and often discovered incidentally. (Option D) Treatment: Endovascular Coil Occlusion: Preferred method. Surgical Clipping: Used if endovascular methods are unsuitable. Conditions Associated with Berry Aneurysms: Fibromuscular Dysplasia (FMD) Marfan's Syndrome (Option A) Ehlers-Danlos Syndrome Coarctation of aorta Autosomal dominant Polycystic Kidney disease

Sabiston's Textbook of Surgery, 21 edition, Pg - 1887, 1888

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 45-year-old man with a recent dental infection presents with persistent headaches, fever, and confusion. He exhibits focal neurological deficits and seizures. The radiological findings are provided. Given his clinical presentation and imaging, what is the most appropriate next step in the management of this patient? (Q849174)

A. Initiate IV antibiotics and immediate surgical drainage

B. Start oral antibiotics and monitor with CT every 48 hours

C. Administer high-dose corticosteroids and supportive care

D. Begin antiepileptic medications and refer for op follow-up.

Correct Answer: A. Initiate IV antibiotics and immediate surgical drainage

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Given the history of a recent dental infection, along with imaging showing a ring-enhancing lesion in the frontal lobe and symptoms of fever, confusion, and seizures, the most likely diagnosis is a Brain abscess. The mainstay treatment includes both surgical intervention and antibiotic therapy. Brain Abscess: Pathology: Direct Spread: From air sinus infections or following brain surgery. Hematogenous Spread: Typically associated with respiratory infections, endocarditis, or dental infections. Symptoms include fever, confusion, seizures, focal

neurological deficits and raised ICT. Most common in the frontal lobe , but are also frequently found in the parietal lobe, particularly in cases of hematogenous spread. Imaging: CT Scan (Initial Choice) : Shows hypodense oedema initially, progressing to a ring-enhancing mass as the abscess matures. MRI (IOC): Identifies restricted diffusion Management: (Mainstay: Surgery + Antibiotics) Early Surgical Drainage: Essential for effective treatment. Antibiotics: IV antibiotics are administered for approximately 6 weeks. Prophylactic Anticonvulsants: Considered due to a high risk of seizures. Multiple smaller abscesses: IV Antibiotics. Steroids: Reduce oedema and alleviate symptoms of mass effect.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 706, 707

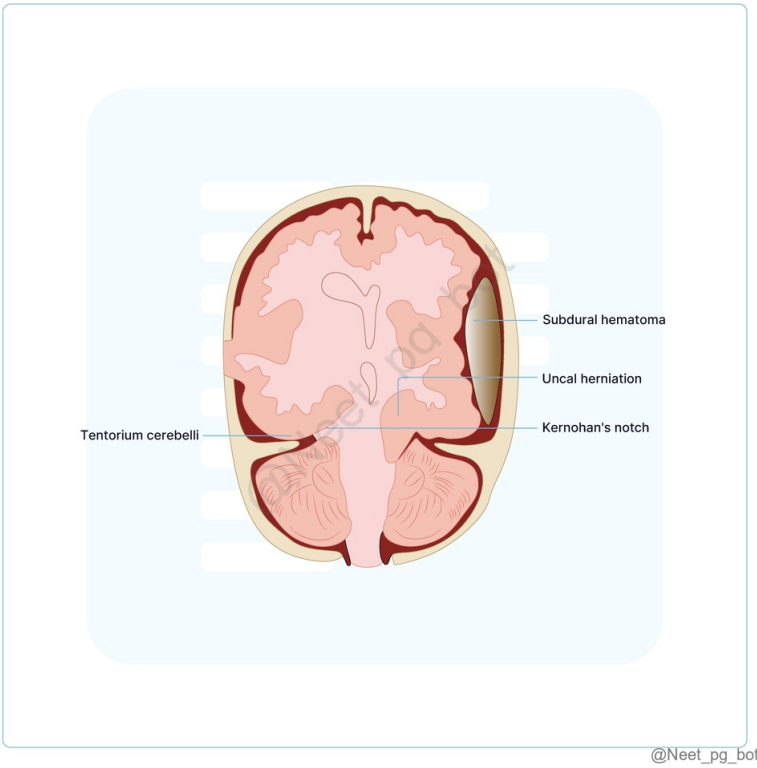
↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 58-year-old patient presents with a significant right-sided brain tumour. During the neurological examination, the patient exhibits right-sided weakness. Which of the following best accounts for this presentation? (Q849175)

A. Kernohan notch phenomenon

B. Brown-Sequard syndrome



C. Tullio phenomenon

D. Uhthoff's phenomenon

Correct Answer: A. Kernohan notch phenomenon

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Kernohan notch phenomenon is a false localizing sign where a large intracranial mass (SOL) causes motor paralysis on the ipsilateral (same) side as the lesion. Mechanism: Mass Effect: A large mass (e.g., right-sided subdural hematoma or tumor) causes uncal herniation, pushing the midbrain toward the opposite side. Contralateral Compression: The opposite (left) cerebral peduncle is forced against the tough, sharp edge of the tentorium cerebelli (the "notch"). Indentation: This creates a physical indentation (Kernohan's notch) in the motor fibers of that peduncle. Paradoxical Result: Because the motor fibers in the left peduncle have not yet crossed (decussated) to the other side of the body, damaging them results in weakness on the right side of the body. Clinical Presentation: Ipsilateral Hemiparesis: Weakness occurs on the same side as the primary mass. This is "false localizing" because normally, a right-sided brain mass causes left-sided weakness. Ipsilateral CN III Palsy: The oculomotor nerve on the side of the mass is often compressed, leading to a "blown pupil" and ptosis on the same side as the tumor. Brown-Sequard Syndrome (Option B) involves damage to one side of the spinal cord, leading to specific patterns of sensory and motor deficits which don't match the brain tumour scenario. Tullio Phenomenon (Option C) is associated with inner ear disorders causing dizziness and hearing problems, and it is not relevant to motor deficits from a brain tumour. Uhthoff's Phenomenon (Option D) involves the worsening of neurological symptoms with heat in conditions like multiple sclerosis, which is not related to a brain tumour's mass effect.

@Neet_pg_bot

SRB’s Manual of Surgery, 6th Edition, Page - 1077, 1081

↑ *Back to this question in Part A*

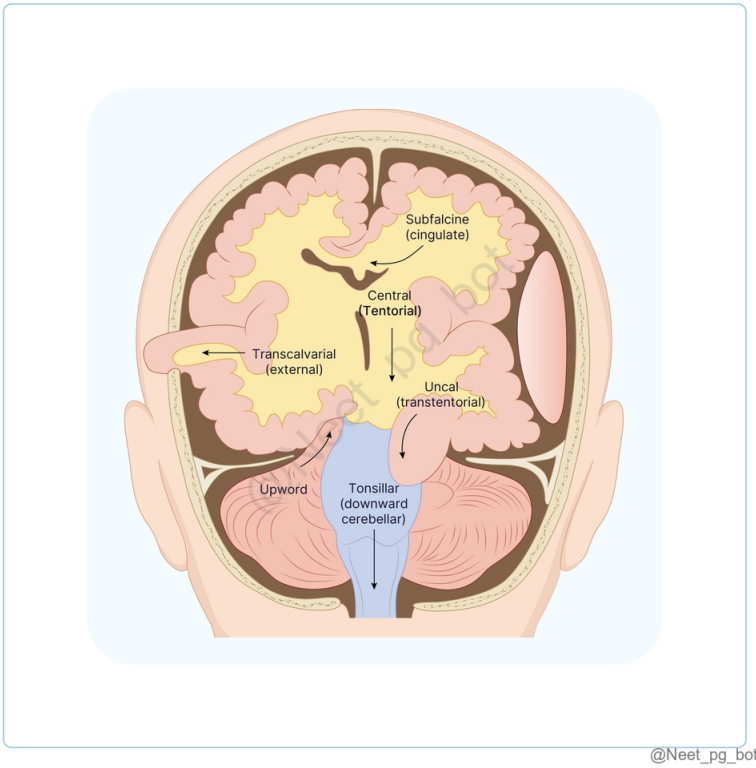
@Neet_pg_bot

Q11: A 62-year-old man is brought to the emergency department after a fall from a ladder. He has a GCS score of 9 (E2V3M4), and his right pupil is dilated and nonreactive. The CT scan shows a large right-sided subdural hematoma with a significant midline shift to the left. BP: 180/100 mmHg, HR: 52 beats/minute with irregular breathing patterns. Which type of brain herniation is most likely occurring in this patient? (Q849177)

A. Subfalcine herniation

B. Tonsillar herniation

C. Upward transtentorial herniation



D. Uncal herniation

Correct Answer: D. Uncal herniation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient is most likely experiencing uncal herniation based on the following findings: Large Right-Sided Subdural Hematoma: Creates a space-occupying lesion, leading to significant mass effect. Significant Midline Shift to the Left : Indicates severe displacement of brain structures. Dilated and Nonreactive Right Pupil: A classic sign of uncal herniation due to oculomotor nerve compression. Decreased Level of Consciousness (GCS 9): Resulting from brainstem compression. Signs of Cushing's Triad: I ncluding hypertension, bradycardia, and irregular breathing, indicative of increased intracranial pressure. Uncal herniation occurs when the medial temporal lobe (uncus) is displaced downward through the tentorial notch, compressing the ipsilateral oculomotor nerve and brainstem .

@Neet_pg_bot

References:

Bailey & Love's Short Practice of Surgery, 28th edition, page 360, 361

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 62-year-old man undergoes emergent decompressive craniectomy for a large right hemispheric infarct with significant mass effect. Post-surgery, he remains comatose and, six hours later, develops pinpoint pupils and irregular breathing. A stat CT scan shows resolution of the midline shift but reveals new bilateral hyperdense lesions in the midbrain. What is the most likely explanation for these new CT findings? (Q849179)

A. Contrast extravasation

B. Hemorrhagic transformation of infarct

C. Duret haemorrhage

D. Hypertensive microbleeds

Correct Answer: C. Duret haemorrhage

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The new CT findings are most consistent with Duret haemorrhage , characterised by small, linear or flame-shaped haemorrhages primarily in the midbrain and upper pons. It is typically caused by the rapid displacement of the brainstem, which can occur due to significant mass effects or sudden changes in intracranial pressure, such as those seen after decompressive surgery. This results from stretching and tearing the perforating branches of the basilar artery. Clinically present with persistent coma, pinpoint pupils, and irregular breathing suggest brainstem dysfunction, suggesting brainstem dysfunction. Contrast extravasation (Option A) would be unusual without recent contrast administration and typically doesn't present with bilateral midbrain lesions. Hemorrhagic transformation of infarct (Option B) : While possible, this would typically occur in the area of the original infarct (right hemisphere), not in the midbrain. Hypertensive microbleeds (Option D) usually occur over time and are more commonly found in other areas of the brain, not specifically bilateral in the midbrain.

Q1: A 7-year-old child presents with a headache which gets worse in the morning, associated with nausea, vomiting, and vertigo. The radiograph revealed a type of brain tumour in the 4th ventricle. Which of the following is the investigation of choice in this case? (Q849223)

A. MRI

B. Ultrasonography

C. X-ray

D. CT scan

Correct Answer: A. MRI

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation suggests Ependymoma , and the investigation of choice for this condition is MRI. Origin: Arises from the cuboidal or columnar epithelium lining the ventricular system in the cerebral hemisphere In children , ependymoma is typically located in the 4th ventricle , whereas in adults, it commonly arises from the filum terminale in the lumbosacral region. MRI is the investigation of choice, and it is treated by resection followed by EBRT (External Radiation Beam Therapy) Ultrasound (Option B) , CT scan (Option D), and X-ray (Option C) might help detect it , but cannot be confirmed.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 40-year-old man presents with symptoms of spinal cord compression, including back pain and weakness in the legs. MRI reveals a spinal tumour. Which of the following statements about spinal tumours is NOT true? (Q849239)

A. Osteoblastic metastases are often associated with prostate cancer

B. Ependymomas are the most common intramedullary tumours in adults

C. The malignant primary tumour usually involves the vertebral body

D. Most common metastases to the spine are from the Lungs

Correct Answer: D. Most common metastases to the spine are from the Lungs

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The most common metastases to the spine are from Breast malignancies followed by Lung. . Tumor Category Type Description Extradural Tumors (55%) Metastatic Tumors The most common spine tumours, with the most common metastases, are Breast (21%), Lung (14%), Prostate (7.5%), and RCC. Osteolytic Mets Lung cancer, RCC, Multiple myeloma. Osteoblastic Mets Prostate cancer. (Option A) Primary Tumors (2%) Benign Osteoid osteoma, osteoblastoma, chondroma, chondroblastoma, giant cell tumours, hemangioma, and lymphangioma typically occur in posterior elements. Intermediate Aggressive osteoblastoma, chordoma. Malignant Osteosarcoma, chondrosarcoma, Ewing's sarcoma, neuroectodermal tumours, lymphoma, fibrosarcoma, and liposarcoma It usually involves the vertebral body. (Option C) Intradural Tumors (40%) Extramedullary They arise from the meninges or nerve roots. Examples include meningiomas (dural-based, often in the thoracic spine) and schwannomas (benign, from the nerve sheath). Neurofibromas are fusiform and can grow within nerve roots. Intramedullary Arise within spinal cord parenchyma; include ependymomas (most common in adults) (Option B) and astrocytomas (common in children).

Schwartz's Principles of Surgery, 11th Edition, Pages 1859-1860.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 55-year-old man with a history of immunosuppression is suspected for Primary CNS lymphoma and evaluated. Which of the following is not accurate about this condition? (Q849238)

A. Often shows a dramatic but short-lived response to steroids.

B. Steroids should be withheld before biopsy.

C. Shows no response to steroids.

D. Diagnosis is confirmed with a stereotactic biopsy.

Correct Answer: C. Shows no response to steroids.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Primary CNS lymphoma typically shows a dramatic but short-lived response to steroids . (Option A) Steroids have a cytolytic effect on the tumour cells and should be withheld before biopsy to ensure accurate diagnosis. (Option B) Cytolytic effect of steroids causes partial/complete resolution on CT. Hence, it is also called a Ghost cell tumour . Primary CNS lymphoma is a rare but increasingly common tumour of the central nervous system, particularly in immunocompromised individuals such as those with AIDS or transplant recipients. Imaging typically shows hyperdense, enhancing lesions. Diagnosis: Confirmed via stereotactic biopsy. (Option D) Treatment : Chemotherapy (especially high-dose methotrexate) and Radiation therapy (EBRT) AIDS patient - Include highly active antiretroviral therapy (HAART).

References:

Sabiston’s Textbook of Surgery, 21st Edition, Page 1896.

↑ *Back to this question in Part A*

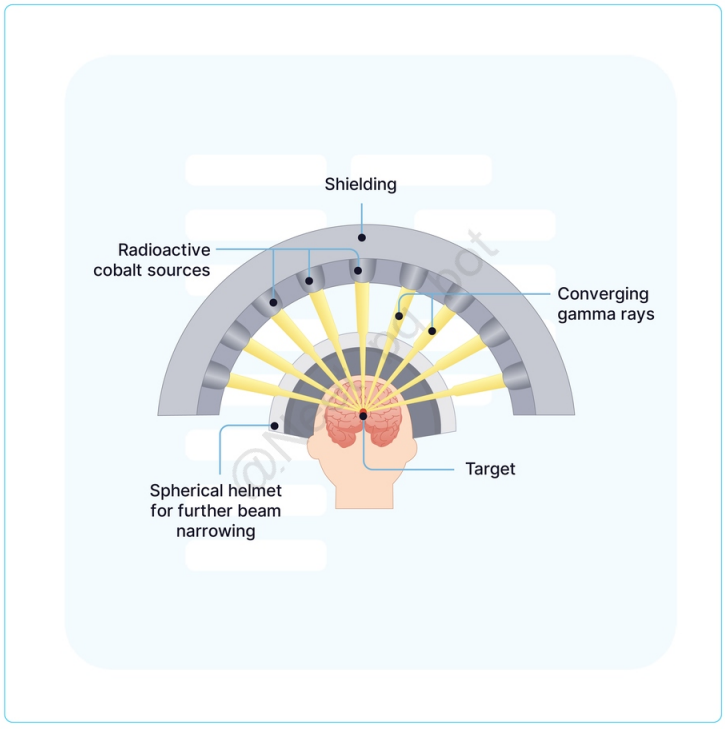
@Neet_pg_bot

Q4: A 65-year-old patient with a small brain metastasis is being considered for Stereotactic Radiosurgery (SRS). Which statement correctly describes Stereotactic Radiosurgery (SRS)? (Q849237)

A. Delivers broad radiation to treat the entire brain.

B. Delivers a focused dose of radiation to the tumour from multiple angles.

C. Requires prior surgical removal of the tumour.



D. Used for large, invasive tumours needing extensive surgery.

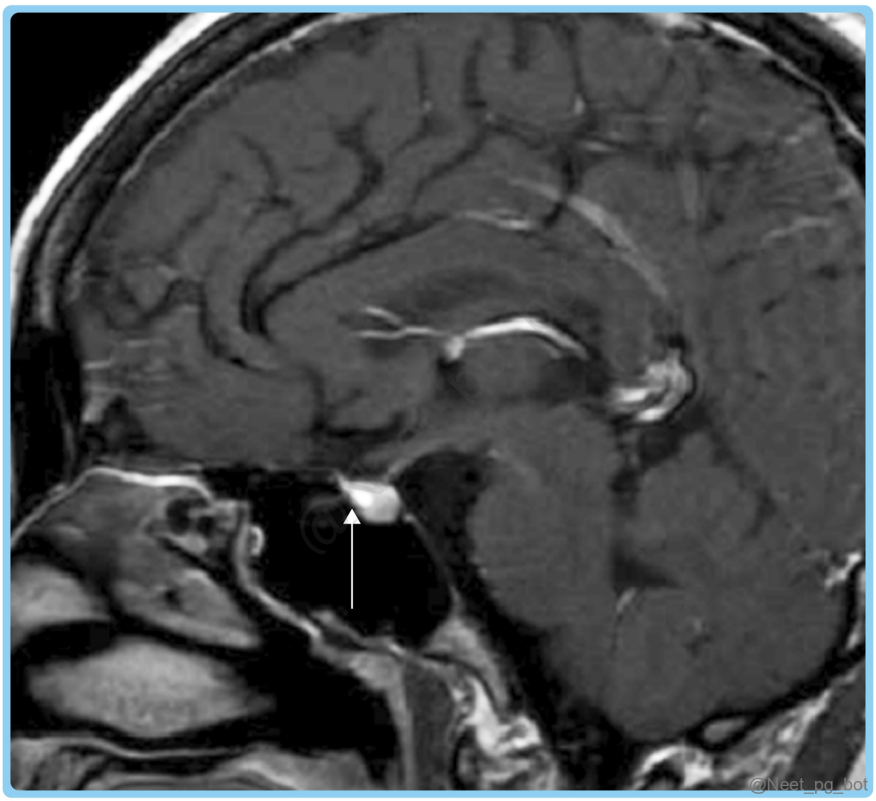
Correct Answer: B. Delivers a focused dose of radiation to the tumour from multiple angles.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Stereotactic Radiation Surgery (SRS) delivers a high dose of targeted radiation to a specific brain volume, minimizing damage to surrounding tissue. Non-surgical radiation therapy to treat functional brain abnormalities and small tumours. Techniques: Gamma Knife (Source: Cobalt-60): Focuses radiation from multiple directions on a single point. Modified Linear Accelerator (Source: High-energy X-rays): Delivers radiation in multiple arcs to minimise damage to surrounding tissue. Applications: SRS is Commonly used in conditions like Brain tumours Benign lesions of cranial nerves Arteriovenous malformations (AVMs) Trigeminal neuralgia Risks: Radiation necrosis Damage to surrounding brain structures

@Neet_pg_bot

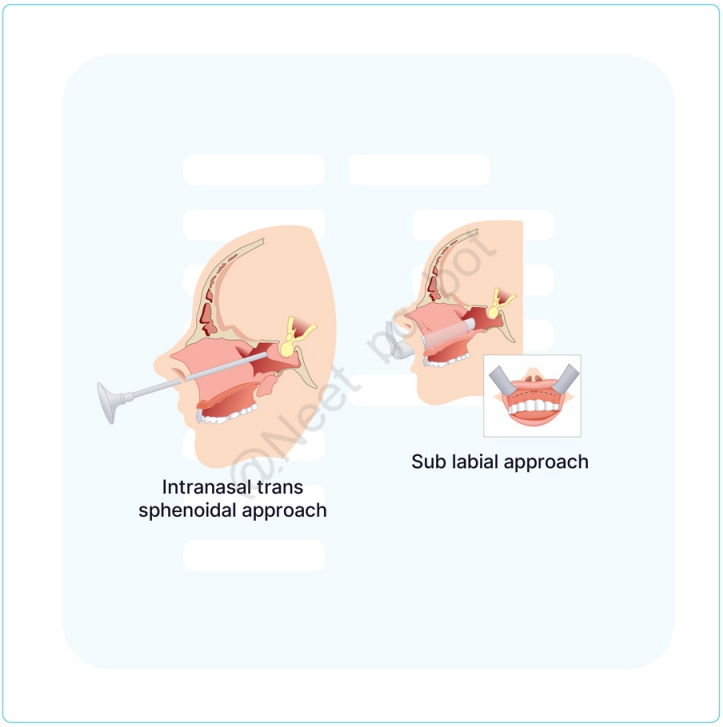


References:

Sabiston’s Textbook of Surgery, 21st Edition, Page 1906.

↑ *Back to this question in Part A*

@Neet_pg_bot



Q5: A 32-year-old woman visits your clinic with complaints of missed periods and noticeable visual disturbances over the past few months. She also reports frequent headaches and mild galactorrhea. MRI shows the findings given in the image. What visual defect is most commonly associated with this condition? (Q849236)

Correct Answer: Unknown

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The given clinical scenario, with Amenorrhea and Galactirhea and an MRI showing mass in the Sella tunica, most probably indicates Pituitary Adenoma (Prolactinoma). The most common visual defect associated with Pituitary Adenoma is Bitemporal hemianopia, which results from the compression of Binasal fibres that cross at the Optic Chiasma. It is the most common Suprasellar mass in adults . Classification: Microadenomas : <10 mm; often incidental or present with endocrine symptoms. Macroadenomas : >10 mm; may cause visual field deficits due to mass effect. Clinical features: Visual Defect : Compression of the optic chiasm often causes bitemporal hemianopia . Endocrine Symptoms : Amenorrhea, galactorrhea, and other hormonal imbalances. Imaging and diagnosis involve MRI as the primary modality, along with serum prolactin and thyroid function tests and visual field charting. Treatment : Medical management Prolactinomas : Dopamine agonists (e.g., bromocriptine, cabergoline). Growth Hormone-Secreting Tumors : Somatostatin analogues (e.g., octreotide). Surgical managemnt Transsphenoidal Approach : Preferred for most cases; craniotomy may be needed for large tumours. Sublabial Approach Indications : Acute visual deterioration, GH-secreting tumours, Cushing's disease, or large non-functioning adenomas causing symptoms.

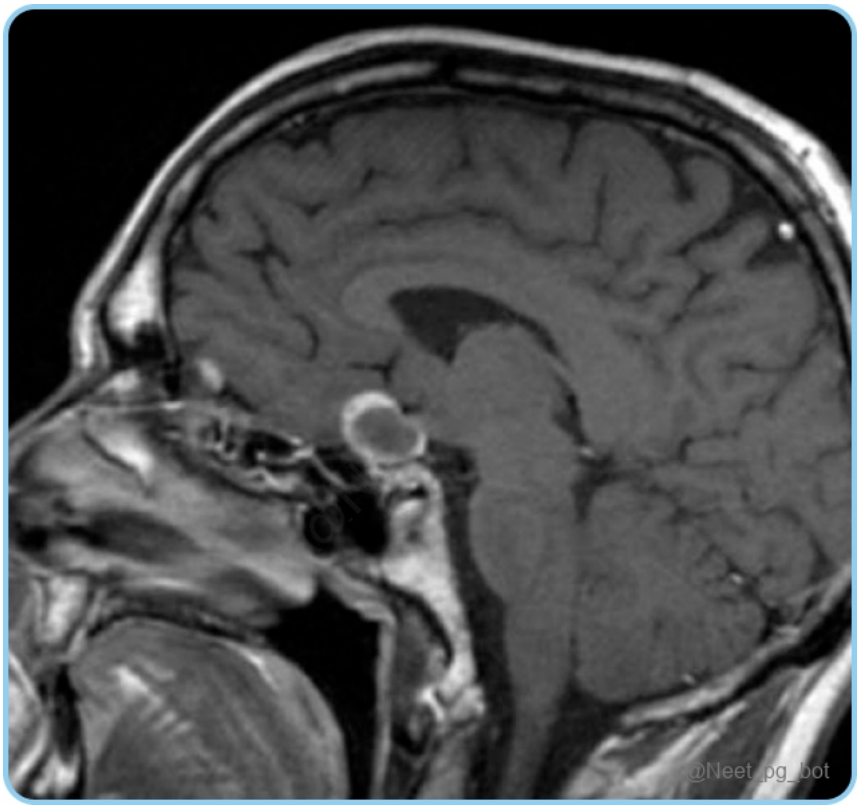
@Neet_pg_bot

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Pages 716-717.

↑ *Back to this question in Part A*

@Neet_pg_bot



Q6: A 6-year-old child presents with headache, vomiting, blurring of vision, weakness, recent aggression, and weight gain. Examination reveals growth retardation and signs of hypopituitarism. MRI findings are noted. Which of the following is not true regarding this condition? (Q849235)

A. Hypopituitarism is the characteristic feature

B. It is more common in children

C. It is derived from pituitary stalk

D. Growth retardation is also observed

Correct Answer: C. It is derived from pituitary stalk

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical triad of visual field defects , hypopituitarism , and suprasellar calcification in a child strongly suggests a Craniopharyngioma . Origin: It is derived from remnants of Rathke's pouch (the craniopharyngeal duct), not the pituitary stalk itself, though it frequently compresses the stalk. Characteristic MRI & Gross Findings: Cystic Component: This is a hallmark of the adamantinomatous type. On MRI, cysts often show high signal on T1 and T2 sequences due to high protein and cholesterol content. "Machinery Oil" Appearance: On gross inspection or surgical aspiration, the cyst contains a thick, brownish-yellow fluid. This is famously described as looking like "machinery oil" or "crankcase oil" and contains shimmering cholesterol crystals. Calcification: Observed in approximately 90% of pediatric cases. While best seen on CT, it appears as "signal voids" (black spots) on MRI. Solid Component: Usually shows strong, heterogeneous enhancement after contrast administration. Clinical Features: It is more commonly seen in children, with the peak incidence between 5 and 10 years of age (Option B). It presents with headache, vomiting, papilledema, hydrocephalus, visual field, abnormality, cranial nerve palsies, sleep difficulty, weight gain, personality changes, etc. Its characteristic features are: Hypopituitarism (Option A) Growth retardation (Option D) Diabetes insipidus Investigations used are MRI and CT. Management is by surgical resection followed by post-op radiotherapy.

Sabiston's textbook of surgery, 21st Edition, Page 1898.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 52-year-old female patient presents with complaints of difficulty understanding speech and tinnitus. On examination, there is unilateral sensorineural hearing loss, reduced corneal sensitivity, and numbness of the face. Which of the following nerves is most commonly involved in this condition? (Q849234)

A. Inferior vestibular nerve

B. Superior vestibular nerve

C. Cochlear nerve

D. Facial nerve

Correct Answer: A. Inferior vestibular nerve

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The given scenario suggests a case of Acoustic neuroma (also known as vestibular schwannoma, neurilemmoma, or eight-nerve tumour), which most commonly involves the inferior vestibular nerve. It is a benign, encapsulated, extremely slow-growing tumour of the VIII cranial nerve. It consists of spindle cells with rod-shaped nuclei lying in rows. The tumour most commonly emerges from the inferior vestibular nerve (Option A) and compresses the superior vestibular nerve (Option B) , cochlear nerve (Option C) and facial nerve (Option D) . Clinical features: Commonly seen in the age group of 40-60 years. Progressive unilateral sensorineural hearing loss Tinnitus Difficulty in understanding speech, Reduced corneal sensitivity Numbness or paresthesia Speech and swallowing problems are seen Ataxia The investigation of choice is MRI with contrast, which shows the appearance of an ice cream cone . BERA is also used to investigate audiological issues. Management includes surgical excision (if the size is more than 3cm) and radiosurgery (for tumours less than 30cc)

References:

Dingra, 8th Edition, Pages 132 - 134. Bailey & Love's Short Practice of Surgery, 28th Edition, Page 717.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 48-year-old male presented with headache, blurring of vision, weakness and loss of balance. His radiological investigations suggested hydrocephalus and pheochromocytoma. A tumour is detected whose radiograph is given below. Which of the following genetic syndromes is most commonly associated with this condition? (Q849233)

A. MEN 1 syndrome

B. VHL syndrome

C. Lynch syndrome

D. Gardner's syndrome

Correct Answer: B. VHL syndrome

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The above features suggest Hemangioblastoma and the associated genetic disorder is VHL (Von Hippel-Lindau) syndrome. Hemangioblastoma is a benign vascular tumour of the central nervous system associated with VHL (Von Hippel-Lindau) syndrome, which consists of the following, Cerebellar hemangioblastoma. Retinal hemangioma RCC(Renal Cell Carcinoma) Renal cyst Pheochromocytoma Epididymal/ broad ligament cyst adenoma Endolymphatic sac tumours Pancreatic neuroendocrine tumors MRI in hemangioblastoma shows a cystic tumour with a non-enhancing wall and enhancing mural nodule , which is managed by surgical resection. Management: Pre-Operative Stabilization: Prioritize the Pheochromocytoma: You must stabilize the adrenal tumor before any neurosurgery to avoid a hypertensive crisis. Medical Blockade: Start α -blockers (e.g., phenoxybenzamine) first, followed by β -blockers . Resection: Perform adrenalectomy once hemodynamically stable. Neurosurgical Intervention: Symptom Relief: If hydrocephalus is acute, place an External Ventricular Drain (EVD) . Tumor Removal: Microsurgical resection of the mural nodule of the hemangioblastoma. The cyst wall itself is usually non-neoplastic and can be left. Long-term Management: Medical Therapy: Consider Belzutifan (HIF-2α inhibitor) for non-emergency tumors. Surveillance: Annual screening for retinal lesions and plasma metanephrines; biennial MRI of the brain, spine, and abdomen.

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Pages 203, 899.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 3-year-old child presented with complaints of severe morning headache associated with nausea, vomiting and seizure. On examination, the doctor suspected a brain tumour and suggested an MRI, which revealed a tumour at the vermis region. Which of the following syndromes is associated with this condition? (Q849224)

A. Gorlin syndrome

B. NF1 syndrome

C. VHL syndrome

D. Turcot's syndrome

Correct Answer: D. Turcot's syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The above features suggest Medulloblastoma, the most common type of primitive neuroectodermal tumour (PNET) and the most common malignant pediatric brain tumour. It predominantly occurs in the first decade of life, with a second peak around age 30. Histology: Characterized by densely packed small round cells with large nuclei and scant cytoplasm. Location: Typically found in the cerebellum (vermis) in children and the lateral cerebellar hemisphere in adults. Clinical Presentation : Symptoms include headache, vomiting, nausea, weakness, papilledema, and ataxia. Diagnosis: MRI is used for imaging. Management: Treatment involves surgical resection followed by radiotherapy and chemotherapy. Association: Medulloblastoma is associated with Turcot's syndrome. Types of Turcot Syndrome: Type 1: Associated with Lynch Syndrome (HNPCC): Caused by mutations in DNA Mismatch Repair (MMR) genes (most commonly MLH1 , MSH2 , or PMS2). Colonic Finding: Few large polyps that have a high tendency to become malignant quickly. Brain Tumor: Most commonly Glioblastoma Multiforme (GBM) or other high-grade astrocytomas. Inheritance: Autosomal recessive (usually). Type 2: Associated with Familial Adenomatous Polyposis (FAP): C aused by a mutation in the APC gene on chromosome 5q21. Colonic Finding: Hundreds to thousands of adenomatous polyps covering the colon. Brain Tumor: Most commonly Medulloblastoma (classically located in the cerebellar vermis, as seen in your case study). Inheritance: Autosomal dominant. Other Extracolonic Manifestations: Since Turcot syndrome is a variant of FAP or Lynch Syndrome, patients often present with other "Gardner-like" or "Lynch-like" features: Skin Lesions: Sebaceous cysts, lipomas, and café-au-lait spots. Eye Findings: Congenital Hypertrophy of the Retinal Pigment Epithelium (CHRPE) - often a diagnostic "clue" found during a funduscopic exam. Other Tumors: Osteomas (especially of the mandible). Desmoid tumors (aggressive fibrous tumors, often in the abdomen). Dental abnormalities (supernumerary teeth). Brain Tumor Syndromes: Syndrome Gene Mutation Primary Brain Tumor Distinguishing Feature Turcot (Type 2) APC Medulloblastoma Thousands of colonic polyps Gorlin PTCH1 Medulloblastoma Basal cell carcinomas, jaw cysts Li-Fraumeni TP53 Astrocytoma / GBM Breast cancer, Sarcomas NF1 NF1 Optic Nerve Glioma Café-au-lait spots, Lisch nodules NF2 NF2 Schwannoma Bilateral acoustic neuromas VHL VHL Hemangioblastoma Renal cell carcinoma, Polycythemia Cowden PTEN Lhermitte-Duclos Breast/Thyroid cancer, Macrocephaly

References:

Schwartz’s Principles of Surgery, 11th Edition, Page 1857.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 45-year-old woman presents with worsening headaches, cognitive issues, and personality changes. MRI reveals a large mass in the left frontal lobe with surrounding oedema, likely a primary brain tumour. What is the overall most common type of primary brain tumour in adults? (Q849181)

A. Medulloblastoma

B. Glioblastoma

C. Meningioma

D. Oligodendroglioma

Correct Answer: C. Meningioma

■ *Listen (English)*

■ *Listen (Hindi)*

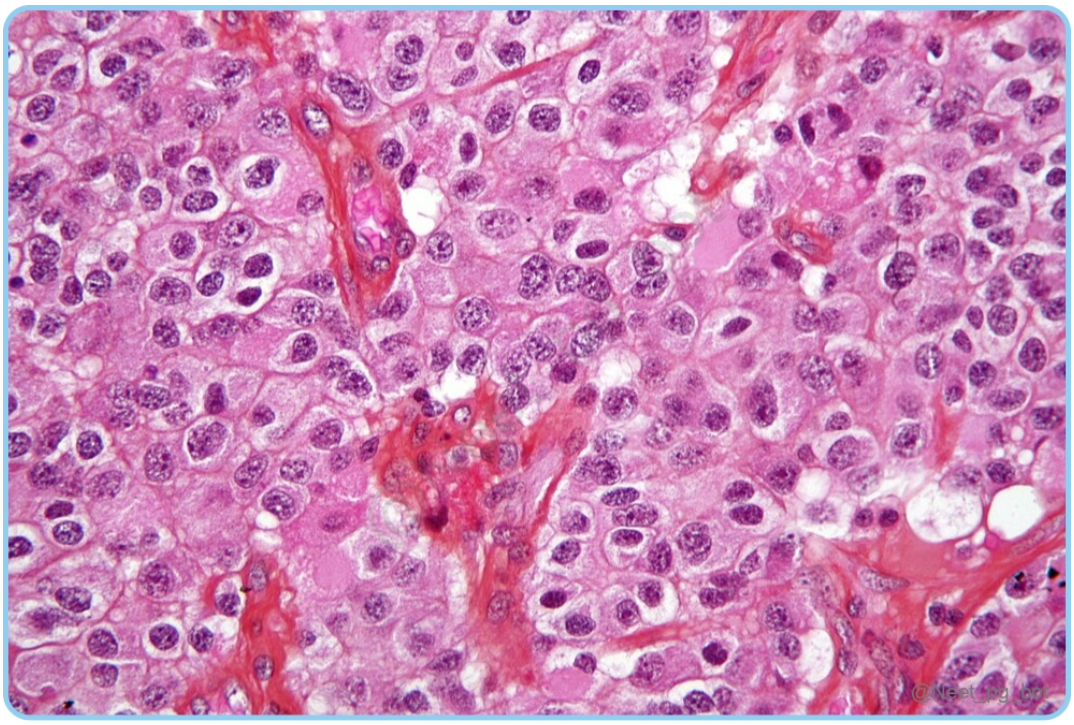
Explanation: Meningiomas are the most common primary brain tumours in adults. They are typically benign and arise from the meninges, the layers of tissue covering the brain and spinal cord. They account for about 36-37% of all primary brain tumours in adults, making them the most frequent type. Depending on their location, meningiomas can cause symptoms such as headaches, seizures, and neurological deficits, including cognitive and personality changes when located in the frontal lobe. The slow-growing nature of these tumours often leads to gradual symptom progression. Medulloblastomas (Option A) are highly malignant tumours originating from the cerebellum and are most commonly seen in children. They typically cause cerebellar dysfunction, such as ataxia, and increased intracranial pressure, leading to headaches and vomiting. These tumours are rare in adults, especially in the frontal lobe. Glioblastomas (GBMs) (Option B) are aggressive, malignant tumours arising from astrocytes and are the most common malignant primary brain tumour in adults. They present rapidly with symptoms like headaches, seizures, cognitive decline, and focal neurological deficits. However, they are less common than meningiomas. Oligodendrogliomas (Option D) originate from oligodendrocytes , which produce the myelin sheath in the central nervous system. These tumours often present with seizures and may occur in the frontal lobe. They are less common than meningiomas, slower-growing than glioblastomas, and have a better prognosis

References:

Bailey & Love’s Short Practice of Surgery, 28th Edition, Pages 714-716.

↑ *Back to this question in Part A*

@Neet_pg_bot

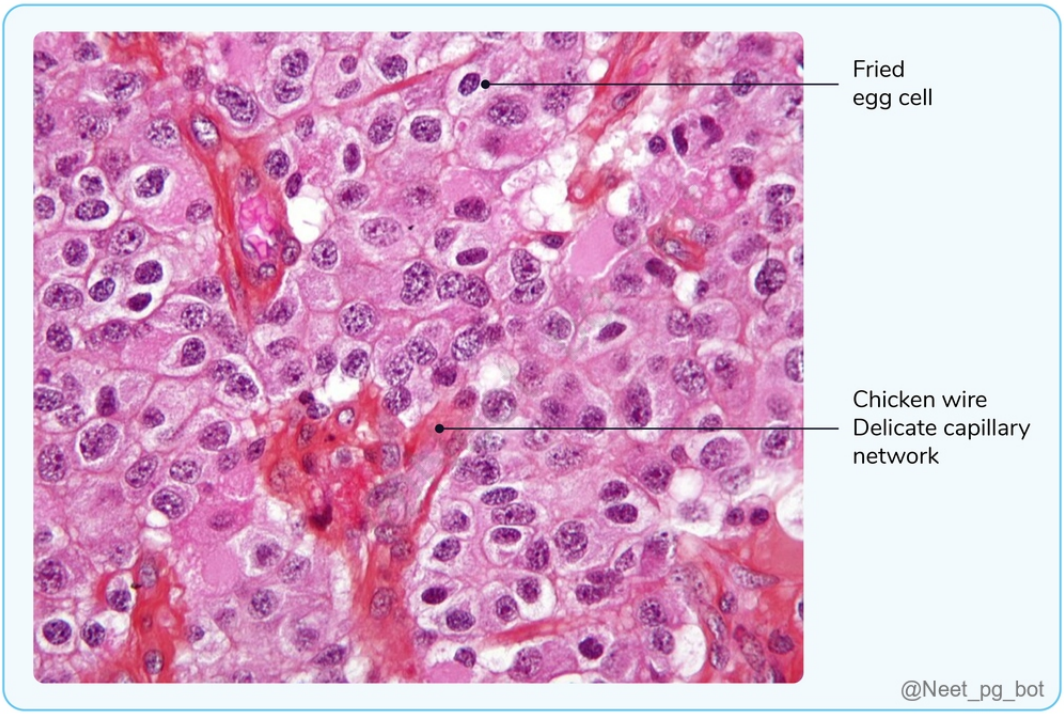


Q11: A 45-year-old male presents with recurrent seizures and headaches. MRI reveals a mass located in the cerebral hemisphere. Histopathological examination of the mass shows cells with a "fried egg" appearance and a chicken-wire capillary pattern. Which of the following is the most likely diagnosis? (Q849222)

A. Meningioma

B. Oligodendroglioma

C. Craniopharyngioma



D. Glioblastoma

Correct Answer: B. Oligodendroglioma

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The given clinical presentation and histopathological features suggest Oligodendroglioma. Oligodendroglioma: Aspect Description Definition Primary brain tumours arise from oligodendrocytes (glial cells supporting neurons). It is often slow-growing and typically occurs in adults aged 40-50. Clinical Features Seizures Headaches Focal neurological deficits Histopathological (HPE) Findings "Fried-egg" appearance of tumour cells Chicken-wire capillary pattern Radiological Findings MRI is preferred for diagnosis. Contrast-enhancing mass in the cerebral hemispheres It may show calcifications and oedema Treatment Surgery: Aim to remove as much of the tumour as possible while preserving brain tissue. 5-ALA fluorescence-guided surgery: Helps visualise tumour cells for more accurate resection. Chemotherapy: Temozolomide is commonly used. Radiation Therapy: Recommended for high-grade tumors or when complete removal is not feasible.

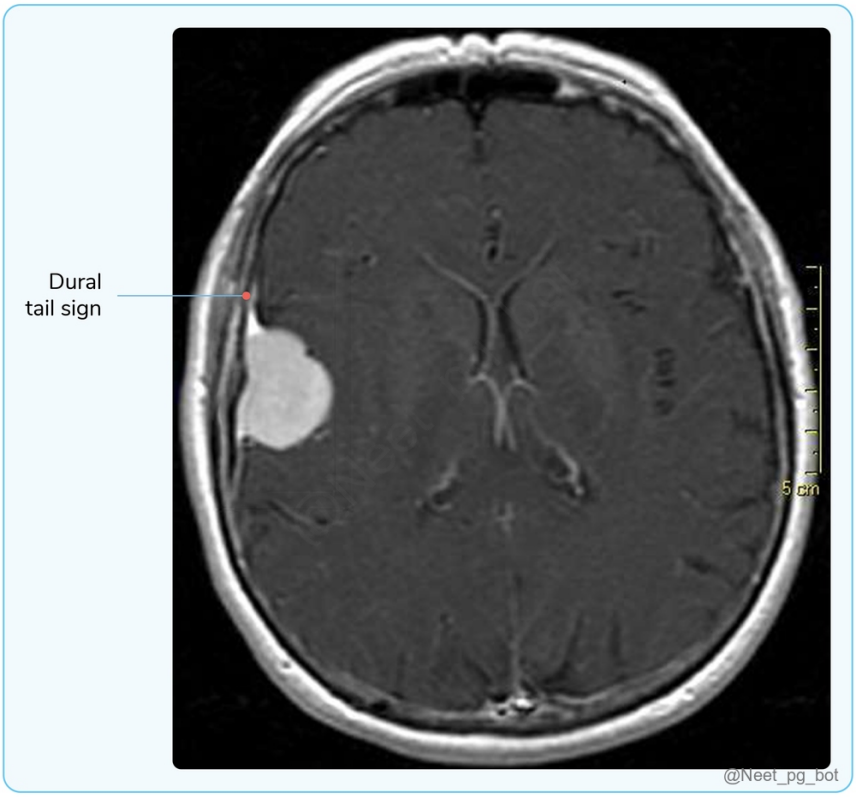
@Neet_pg_bot

Q12: A 55-year-old female presents with headaches and visual disturbances. Imaging studies reveal a well-circumscribed mass in the brain. On histopathological examination, the tumour shows calcifications and cells arranged in whorls. Which of the following radiological findings is most characteristic of this tumour type? (Q849221)

A. Calcified mass

B. Ring enhancement

C. Dural tail sign



D. Vasogenic oedema

Correct Answer: C. Dural tail sign

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient presents with headaches and visual disturbances, and imaging studies reveal a well-circumscribed brain mass and histopathological examination showing calcifications and cells arranged in whorls strongly suggests a diagnosis of meningioma. The dural tail sign is the most characteristic imaging feature associated with meningiomas Meningioma: Aspect Description Definition Benign tumours arise from the meninges surrounding the brain and spinal cord. Clinical Features Headaches Visual disturbances Neurological deficits due to mass effect Vasogenic oedema (brain swelling) Potential for obstructive hydrocephalus (if CSF flow is blocked) Radiological Features Contrast-enhancing mass Dural base attachment Possible calcifications Dural tail sign (specific to meningiomas) Management Surgery (preferred if the tumour is large or symptomatic) Radiotherapy or stereotactic radiosurgery if surgery is risky. Watch-and-wait approach for small, incidental tumours in older patients. Calcified mass (Option A): Calcifications are usually seen in meningiomas but are not as specific as the dural tail sign. Ring enhancement (Option B) pattern is more commonly associated with abscesses or glioblastomas and is not characteristic of meningiomas. Vasogenic oedema (Option D): Meningiomas can cause vasogenic oedema due to the mass effect on surrounding brain tissue. However, this finding is non-specific and can be seen with various other brain tumours.

Sabiston’s Textbook of Surgery, 21st Edition Pages 1896, 1897.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 716.

↑ *Back to this question in Part A*

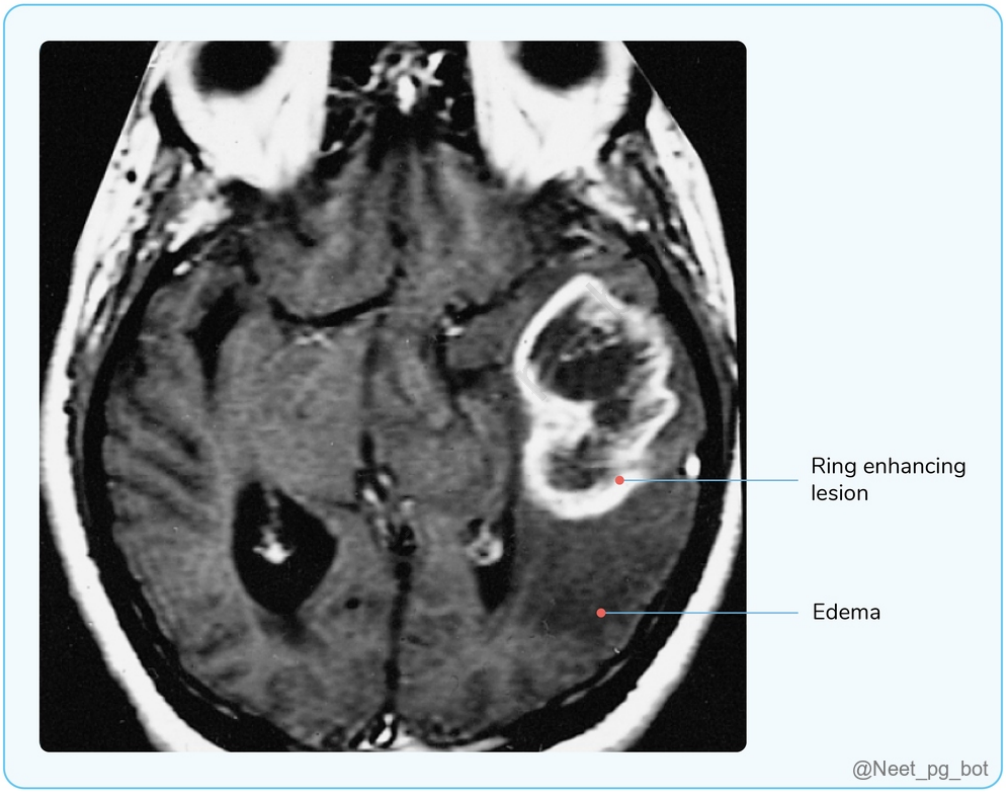
Q13: A 60-year-old patient presents with worsening headaches, focal neurological deficits, and personality changes. MRI imaging reveals a ring-enhancing lesion surrounded by significant oedema. Based on these imaging characteristics, which of the following is the most likely diagnosis and management in recurrent cases? (Q849220)

A. Meningioma, Bevacizumab

B. Glioblastoma Multiforme, Temozolomide

C. Metastatic Brain Tumor, Evacizumab

D. Primary CNS Lymphoma, Doxorubicin



Correct Answer: B. Glioblastoma Multiforme, Temozolomide

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The imaging findings of a ring-enhancing lesion with significant surrounding oedema are characteristic of Glioblastoma Multiforme (GBM), AKA Grade 4 Astrocytoma . It is a Grade IV glioma characterised by ring-enhancing lesions on MRI with surrounding oedema and is associated with poor prognosis. It

is highly aggressive and presents with necrosis and microvascular proliferation. Temozolomide is the current chemotherapy drug of choice for GBM.

References:

Sabiston's Textbook of Surgery, 21 Edition, Pages 1893, 1894.

↑ *Back to this question in Part A*

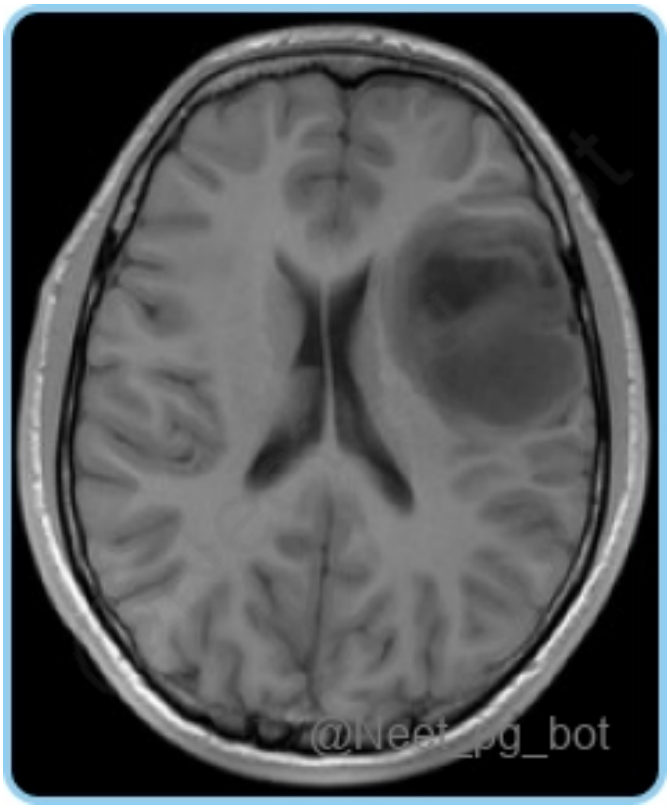
@Neet_pg_bot

Q14: A 45-year-old patient presents with headaches and focal neurological deficits. Imaging reveals a tumour located in the cerebral hemispheres, characterised by infiltrative growth and low cellularity. Which of the following options best describes the likely diagnosis for this tumour? (Q849195)

A. Pilocytic Astrocytoma

B. Diffuse Astrocytoma

C. Anaplastic Astrocytoma



D. Glioblastoma Multiforme

Correct Answer: B. Diffuse Astrocytoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The diffuse astrocytoma fits the clinical description of infiltrative growth and low cellularity and is commonly located in the cerebral hemispheres. Diffuse Astrocytoma Prognosis : Intermediate Common Site : Cerebral hemispheres Histological Features : Infiltrative, low cellularity. These tumours are characterised by their gradual growth and infiltration into surrounding brain tissue. Management : Surgical resection is the primary treatment. Radiation or chemotherapy might be considered based on risk factors or residual disease.

References:

Sabiston's Textbook of Surgery, 21 Edition, Pages 1893, 1894.

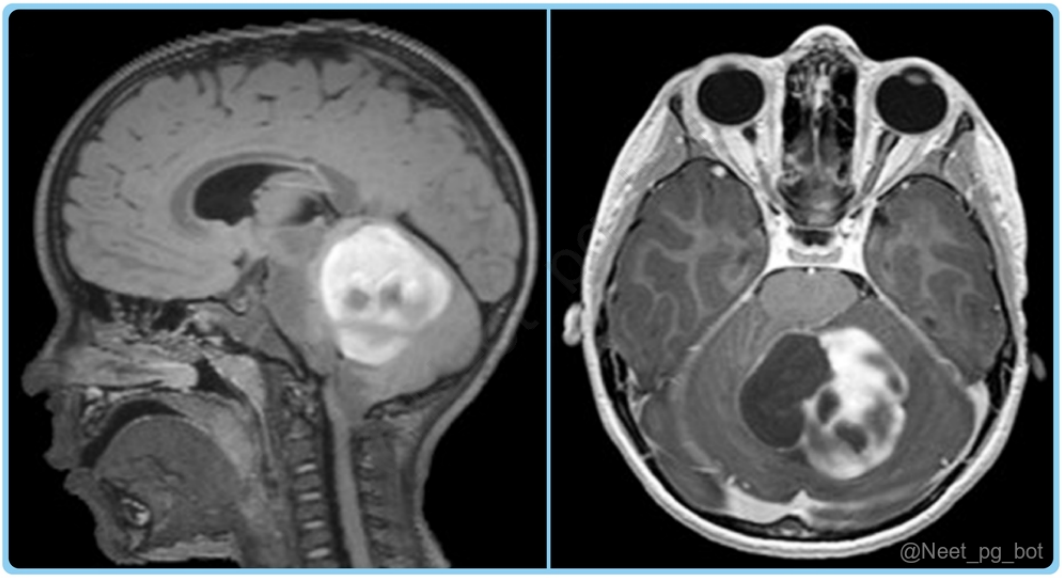
↑ *Back to this question in Part A*

@Neet_pg_bot

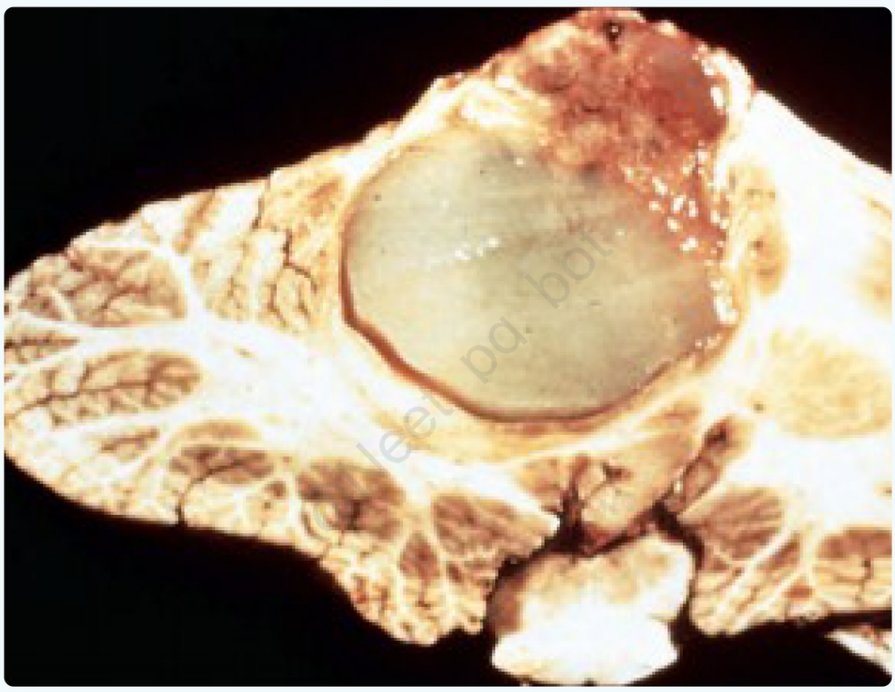
Q15: A 12-year-old child presents with headaches, vomiting, and unsteady gait. Imaging reveals a mass in the posterior fossa. The lesion is surgically resected, and histology reveals a tumour with a low mitotic index. Which of the following best describes the most common location and prognosis of this tumour? (Q849189)

A. Hypothalamus, Poor prognosis

B. Cerebellum, Good prognosis



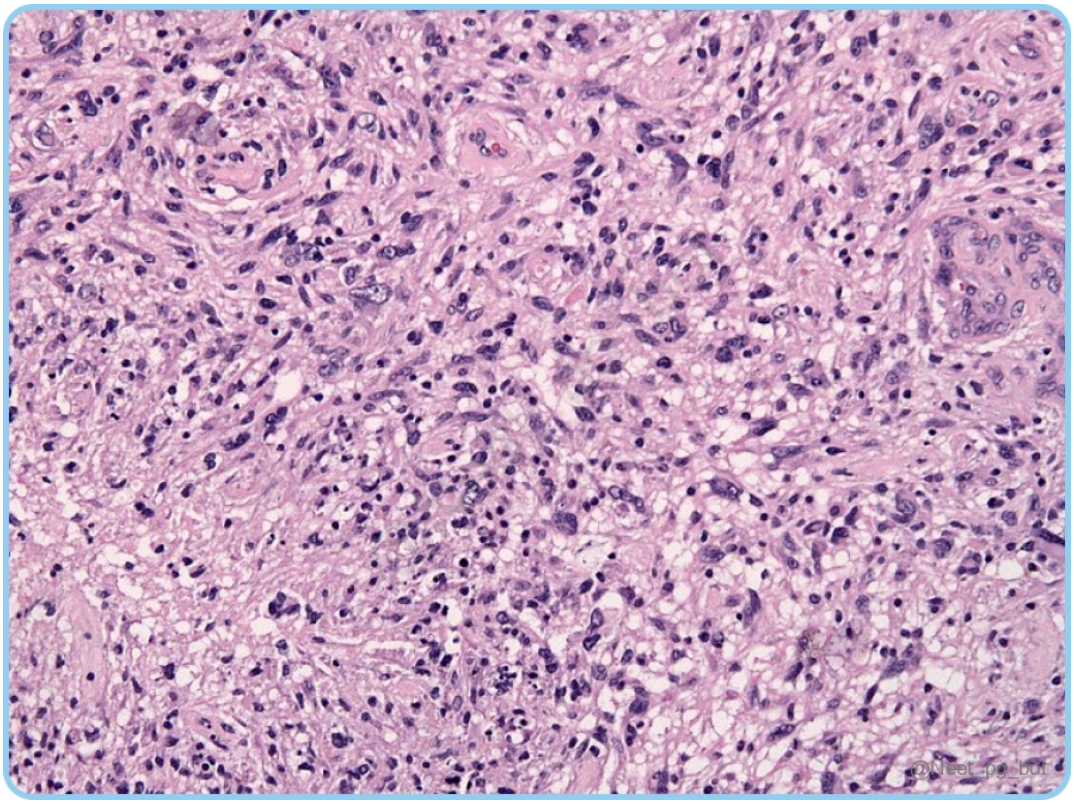
C. Cerebellum, Poor prognosis



D. Hypothalamus, Good prognosis

Correct Answer: B. Cerebellum, Good prognosis

- *Listen (English)*
- *Listen (Hindi)*



Explanation: The given scenario with mass in the posterior fossa is highly suggestive of a tumour in the cerebellum, particularly a pilocytic astrocytoma, which has a good prognosis . It is a low-grade (WHO Grade I), slow-growing, often benign brain tumour primarily affecting children and young adults. They usually arise in the cerebellum but can also be found in the optic pathways, brainstem, and spinal cord. Histologically, it is characterised by Biphasic pattern with dense fibrillary areas and loose microcystic regions. Rosenthal fibres (eosinophilic, corkscrew-shaped fibres) are often present. Clinical features: Symptoms: Increased intracranial pressure (morning headaches, nausea, projectile vomiting) due to 4th ventricle obstruction. Signs: Truncial ataxia (unsteady gait), dysmetria, and papilledema. Diagnosis: MRI: Classic appearance of a large cyst with a brightly enhancing mural nodule . Histology: Rosenthal fibers: Eosinophilic, corkscrew-shaped bundles. Biphasic pattern: Compact piloid cells and loose microcystic areas. GFAP positive: Confirms astrocytic origin. WHO Grade I: Indicates a benign, slow-growing tumor. Management: Surgical resection is the primary treatment and can be curative due to the tumour's well-defined borders. Adjuvant Therapy: Radiation or chemotherapy is rarely needed unless the tumor is unresectable (e.g., optic chiasm involvement). Excellent prognosis , with long-term survival rates exceeding 90% following complete resection. If fully removed, recurrence is rare. Histopathology of Pilocytic astrocytoma

Gross image of pilocytic astrocytoma

@Neet_pg_bot

@Neet_pg_bot

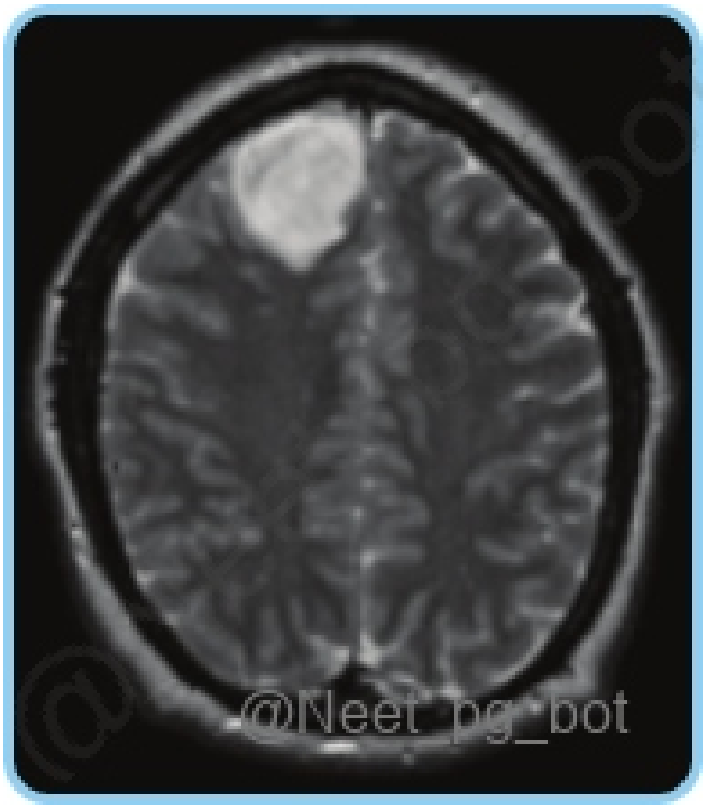
@Neet_pg_bot

Q16: Which type of brain tumour is most likely to cause personality changes, impaired judgment, and difficulty with motor planning? (Q849183)

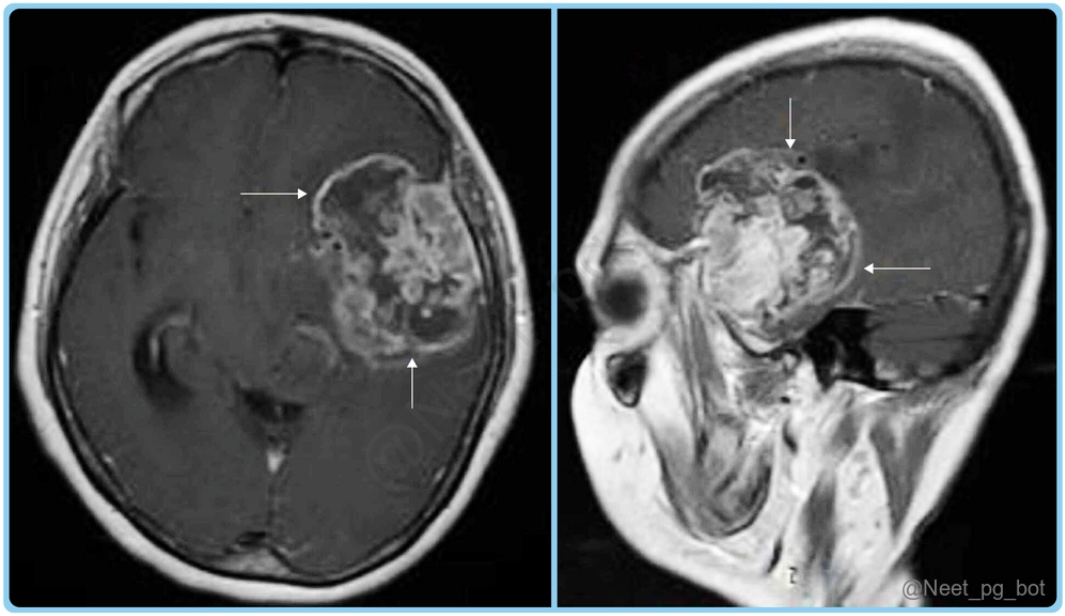
A. Frontal lobe tumors

B. Temporal lobe tumors

C. Occipital lobe tumors



D. Cerebellar tumors



Correct Answer: A. Frontal lobe tumors

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Frontal lobe tumours are most likely to cause personality changes, impaired judgment, and difficulty with motor planning. Functions of the frontal lobe: Executive Functions: The frontal lobe is essential for reasoning, planning, and decision-making, and tumours can impair these abilities, affecting judgment. Personality and Social Behavior: Tumours can lead to significant personality changes and inappropriate behaviour . Motor Planning and Control: The primary motor cortex in the frontal lobe controls voluntary movements, and tumours can disrupt motor planning and execution, leading to difficulties with complex movements. Temporal lobe tumours (Option B) typically cause memory problems (particularly difficulty forming new memories), auditory hallucinations, language comprehension difficulties, and seizures. Occipital lobe tumours (Option C) mainly affect vision and visual processing, causing symptoms such as visual hallucinations, difficulty recognising objects or faces, and partial or complete loss of vision. Cerebellar tumours (Option D) typically cause problems with balance and coordination, difficulty with fine motor skills, nystagmus (involuntary eye movements), and slurred speech.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 714.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 62-year-old man with a 40-pack-year smoking history presents with worsening headaches, confusion, ataxia, and right-sided weakness. A CT scan reveals multiple ring-enhancing brain lesions and further imaging identifies a mass in the right upper lobe of the lung. What is the most likely primary source of brain metastases? (Q849182)

A. Colorectal cancer

B. Prostate cancer

C. Lung cancer

D. Melanoma

Correct Answer: C. Lung cancer

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Lung cancer is the most common cause of brain metastases, accounting for 40-50% of all cases. It is the leading cause of brain metastases, particularly in patients with a history of smoking by hematogenous spread. Symptoms include worsening headaches, confusion, and balance issues, which are consistent with brain metastases. The presence of multiple ring-enhancing brain lesions is typical of metastatic brain disease.

Q1: What is the classification of the head injury of a patient involved in a road traffic accident, based on a GCS score of 10? (Q793536)

A. Moderate traumatic brain injury

B. Severe traumatic brain injury

C. Minor traumatic brain injury

D. Mild traumatic brain injury

Correct Answer: A. Moderate traumatic brain injury

Explanation: Answer option A The GCS (Glasgow Coma Scale) scoring system is used to assess the level of consciousness in patients with traumatic brain injury. It is a scale that ranges from 3 to 15, with lower scores indicating more severe injury and higher scores indicating a better level of consciousness. In this case, the patient's GCS score is 10, which falls in the range of 9-12. According to the GCS scoring system, this indicates moderate traumatic brain injury. The GCS scoring system classifies traumatic brain injury as follows: Severe traumatic brain injury: GCS score of 8 or less Moderate traumatic brain injury: GCS score of 9-12 Minor traumatic brain injury: GCS score of 13-15 with loss of consciousness Mild traumatic brain injury: GCS score of 13-15 without loss of consciousness Therefore, in this case, the patient's head injury is classified as moderate traumatic brain injury based on the GCS score of 10. This indicates that the patient has significant brain injury and may require close monitoring and treatment. Incorrect Choices: Option b. Severe traumatic brain injury is incorrect because GCS score of the patient is 10. Option c. Minor traumatic brain injury is incorrect because GCS score of the patient is 10. Option d. Mild traumatic brain injury is incorrect because GCS score of the patient is 10.

@Neet_pg_bot

Q2: Which of the following is most likely to be seen due to the rupture of a saccular aneurysm? (Q855826)

A. Subdural hemorrhage

B. Subarachnoid hemorrhage

C. Intracerebral hemorrhage

D. Hydrocephalus

Correct Answer: B. Subarachnoid hemorrhage

Explanation: The most common consequence of the rupture of a saccular aneurysm is subarachnoid hemorrhage (SAH) , which is a life-threatening emergency . A saccular aneurysm , also known as a berry aneurysm , is a small, bulging outpouching of a blood vessel at branching points of cerebral arteries. These aneurysms are prone to rupture , and when they do, the blood leaks into the subarachnoid space which lies between the arachnoid and pia mater {{caption_text}} Subdural haemorrhage (Option A) occurs due to the rupture of veins that bridge the subdural space, often from trauma. It is not associated with the rupture of an aneurysm . Intracerebral hemorrhage (Option C) refers to bleeding within the brain tissue itself. It happens due to the rupture of arteries within brain parenchyma, mostly due to hypertension or trauma , not directly from a saccular aneurysm rupture. Hydrocephalus (Option D) is an abnormal accumulation of cerebrospinal fluid (CSF) in the brain, leading to increased intracranial pressure. It can happen due to various factors, but it is not the immediate consequence of an aneurysm rupture itself.

B. D. Chaurasia's Human Anatomy, VOL-3, 8th Edition, Page 216

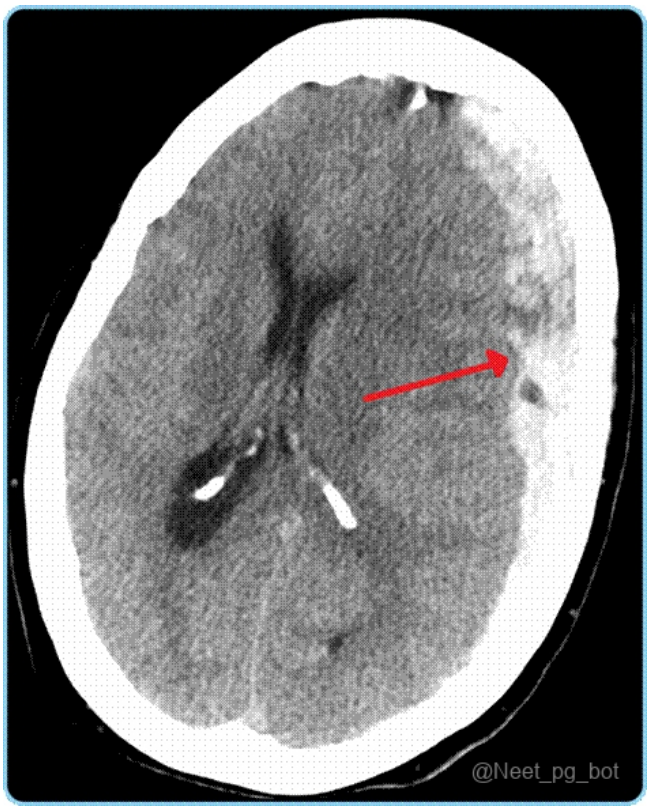
↑ *Back to this question in Part A*

@Neet_pg_bot

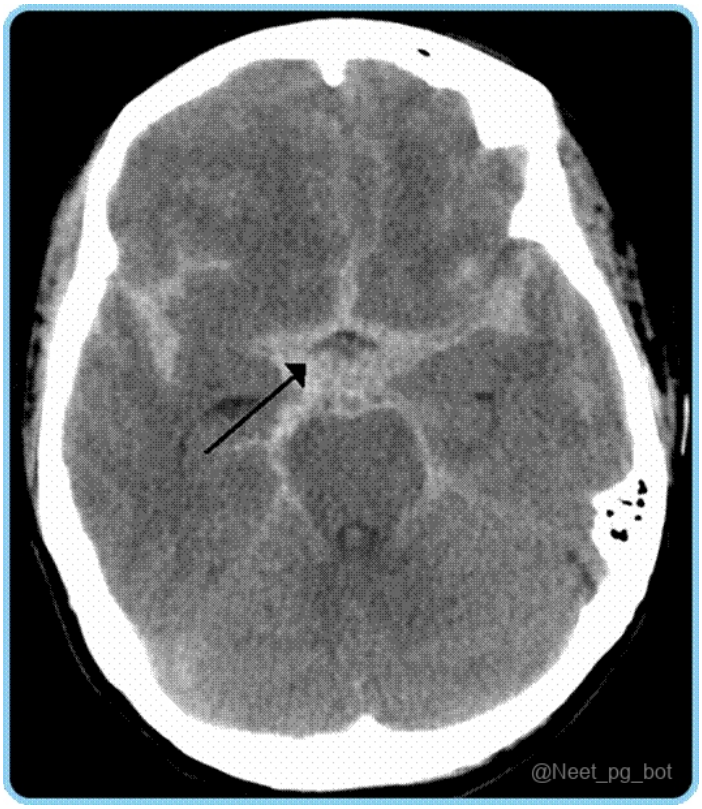
Q3: A cricket player was initially hit on the head with a cricket ball, appearing fine but later collapsing, regaining consciousness to play well, and then found unconscious in the dressing room. What is the probable diagnosis based on the result of the CT scan provided? (Q859882)

A. Extradural hemorrhage

B. Artifact



C. Subdural hemorrhage



D. Subarachnoid hemorrhage

Correct Answer: A. Extradural hemorrhage

Explanation: The most likely diagnosis here, given the sequence of events and CT scan showing the biconvex lens-shaped collection of blood , is Extradural Hemorrhage. It is also called epidural haemorrhage & occurs when there is bleeding between the skull and the dura mater (the outermost layer covering the brain). It is typically caused by trauma, like being hit on the head, which is consistent with the patient's history of being struck by a cricket ball. Clinical features include: Initial Loss of Consciousness Neurological Deterioration Variable Consciousness Levels Posterior Fossa EDH (Rare) Signs of Elevated ICP They are neurosurgical emergencies when symptomatic. Their management includes: Emergency - Burr hole surgery. Definitive - Craniotomy with hematoma evacuation. Artifact (Option B) on a CT scan refers to image distortion or interference that does not represent actual pathology. Given the clear clinical scenario of trauma and the CT finding of a hematoma , an artefact is unlikely to be the cause of the findings. Subdural haemorrhage (Option C) occurs when blood accumulates between the dura mater and the arachnoid membrane . They tend to be crescent-shaped on CT, unlike the biconvex lens-shaped appearance of an extradural haemorrhage. {{caption_text}} Subarachnoid haemorrhage (Option D) refers to bleeding into the subarachnoid space , which is the area between the arachnoid membrane and the pia mater . CT appearance of subarachnoid haemorrhage is usually diffuse , with blood visible in the subarachnoid space, whereas extradural haemorrhage appears as a localised biconvex mass. {{caption_text}}

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 27-year-old man came to the clinic with a headache, palpitations, and sweating. As there is a history of renal problems in his brother and father, he requested an abdominal ultrasound, which revealed the presence of multiple renal and pancreatic cysts. 24-hour urinary metanephrine was sent, which was elevated. What is the most likely diagnosis? (Q859827)

A. Multiple endocrine neoplasia type I

B. Von Hippel-Lindau disease

C. Birt-Hogg-Dube syndrome

D. Tuberous sclerosis

Correct Answer: B. Von Hippel-Lindau disease

Explanation: The most likely diagnosis is Von Hippel-Lindau (VHL) disease , a hereditary condition characterised by the development of multiple cysts in the kidneys, pancreas, and other organs. VHL is an autosomal dominant disorder due to VHL gene mutation on chromosome 3. Patients often have an increased risk of developing pheochromocytomas, which can cause symptoms like headaches, palpitations, and sweating. The elevated urinary metanephrines further support this diagnosis, as they are markers for pheochromocytomas. It is also associated with the development of various tumours like Hemangioblastomas in the CNS (cerebellum and retina) Cysts of the pancreas, liver, and kidneys Renal cell carcinomas Multiple endocrine neoplasia type I (Option A) is a genetic condition characterised by the development of tumours in multiple endocrine glands, and it typically features hyperparathyroidism, pituitary adenomas, and pancreatic tumours, rather than the renal and pancreatic cysts as seen in VHL. Birt-Hogg-Dube syndrome (Option C) is a rare autosomal dominant disorder clinically manifested by fibrofolliculomas, renal cell carcinoma, lung cysts, and spontaneous pneumothorax. It is caused by mutations in the FLCN gene. Though they develop renal tumours, they do not commonly cause pancreatic cysts , pheochromocytomas , or elevated metanephrines . Tuberous sclerosis (Option D), also called Tuberous sclerosis complex (TSC), is an autosomal dominant condition caused by mutations in either the TSC1 or TSC2 gene. It causes benign tumours in various organs, including the brain, kidneys, heart, and skin. It also leads to skin lesions like ash-leaf spots, shagreen patches, and facial angiofibroma. However, pancreatic cysts and pheochromocytomas are not typically associated with tuberous sclerosis.

↑ *Back to this question in Part A*

@Neet_pg_bot

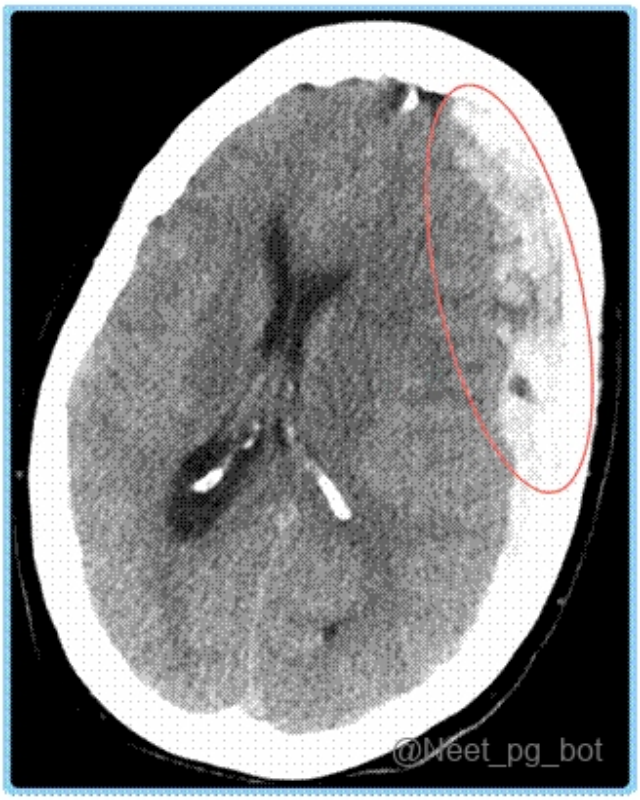
Q5: What is the diagnosis for the unconscious patient brought to the casualty department following a road accident, as depicted in the provided CT scan image? (Q859631)

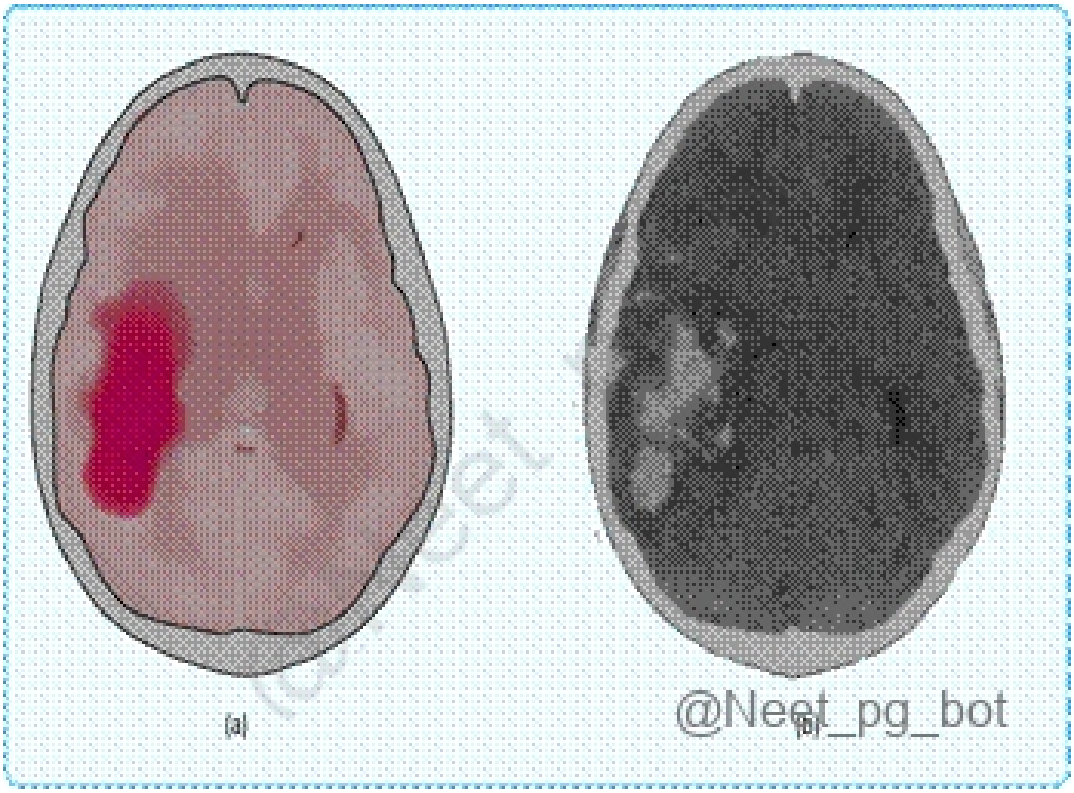
A. Extradural hematoma (EDH)

B. Subdural hematoma (SDH)

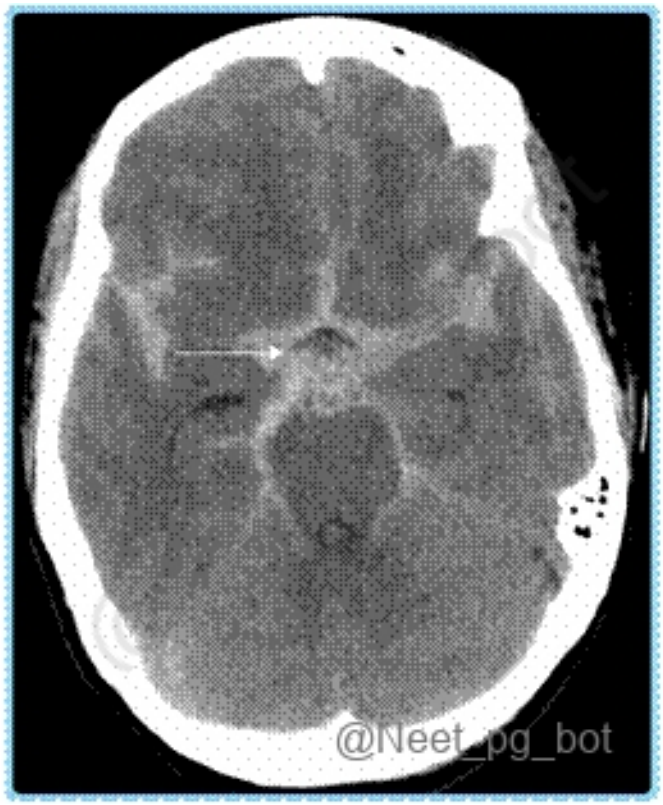
C. Intraparenchymal bleed

D. Subarachnoid hemorrhage (SAH)





Correct Answer: B. Subdural hematoma (SDH)



Explanation: A crescent-shaped or concave collection of blood on a CT scan is characteristic of a subdural hematoma, which often results from trauma, such as a road accident. This type of hematoma occurs between the dura mater and the brain, commonly due to the tearing of bridging veins. Symptoms include Rapid deterioration Loss of consciousness Focal deficits High mortality It can be managed conservatively or it might need surgery based on the type and size of the SDH. Types of brain haemorrhage Type CT Findings Mechanism Epidural or Extradural Hematoma (Option A ruled out) {{caption_text}} Biconvex/lentiform shape Does not cross suture lines Cross-dural venous sinuses Hyperdense Usually unilateral Typically, meningeal artery injury (especially middle meningeal) High-velocity trauma Young patient Always traumatic Subdural Hematoma {{caption_text}} Crescent-shaped Crosses suture lines Can be bilateral Don't cross dural venous sinuses Follows brain surface

Bridging vein tears Can be Traumatic or non-traumatic Elderly patients Extent of brain injury more in SDH than in EDH Intraparenchymal Hematoma (Option C ruled out) {{caption_text}} Irregular shape within brain tissue May have surrounding oedema Direct tissue damage or coagulopathy Subarachnoid Haemorrhage (Option D ruled out) {{caption_text}} Blood in sulci/cisterns Follows CSF spaces Trauma or aneurysm rupture

@Neet_pg_bot

@Neet_pg_bot

Q6: A 15-year-old boy presents with a slow-growing, rubbery, non-tender swelling on the side of the neck, as shown in the image. Examination shows the presence of freckles and light skin patches over the face and trunk. What is the most likely diagnosis? (Q856736)

A. Cystic hygroma

B. Chemodectoma

C. Neural tumour

D. Lipoma

Correct Answer: C. Neural tumour

Explanation: The presence of freckles, light skin patches , and a rubbery swelling in the neck in this 15-year-old boy strongly points to neural tumours. Neurofibromatosis type 1 (NF1) is a genetic disorder that often presents with freckling in the axillary (called Crowe's sign) or inguinal areas and café-au-lait spots (the skin patches). These skin findings are characteristic of the disorder. Neurofibromas , are benign neural tumours that arise from the nerve sheath and commonly appear as soft, rubbery, non-tender swellings in affected areas like the neck. Cystic hygroma (Option A) is a type of cavernous haemangioma , present since the time of birth, which is benign and grows rapidly in years, often over the neck or axilla. It is not associated with freckles or café-au-lait spots. Chemodectoma (Option B) (Paragangliomas) arise from paraganglia , which are clusters of neuroendocrine cells located in various parts of the body. They are commonly found in the head and neck regions . Freckles and skin patches are not typically associated with them but rather with Peutz-Jeghers syndrome . Lipomas (Option D) are benign fatty tumours that can occur in various body parts, including the neck. They are usually soft, movable , and painless , but they do not present with freckles or café-au-lait spots .

@Neet_pg_bot

Q7: Calculate the Glasgow Coma Scale (GCS) of a patient admitted after a road traffic accident and receiving mechanical ventilation. The patient demonstrates a response by opening their eyes upon verbal command and exhibits spontaneous movement in all four limbs. (Q856539)

A. Eyes-2, Verbal-1, Motor-5

B. Eyes-2, Verbal-NT, Motor-5

C. Eyes-3, Verbal-1, Motor-6

D. Eyes-3, Verbal-NT, Motor-6

Correct Answer: D. Eyes-3, Verbal-NT, Motor-6

Explanation: Eyes-3, Verbal-NT, Motor-6 indicates that the patient opens eyes spontaneously, but the verbal response is not testable (NT), and the patient exhibits purposeful motor response. Since the verbal response is not provided, the total GCS score cannot be determined. Eyes-2, Verbal-1, Motor-5 (Option A) suggests that the patient opens their eyes in response to pain, gives an inappropriate verbal response, and exhibits localized motor response.The total GCS score would be 8. Eyes-2, Verbal-NT, Motor-5 (Option B) indicates that the patient opens their eyes in response to pain, but the verbal response is not testable (NT), and the patient exhibits a localized motor response. Since the verbal response is not provided, the total GCS score cannot be determined. Eyes-3, Verbal-1, Motor-6 (Option C) suggests that the patient opens their eyes spontaneously, gives an inappropriate verbal response, and exhibits purposeful motor response. The total GCS score would be 10. Glasgow Coma Scale (GCS): Eye Opening (E) Spontaneous 4 Eyes open without stimulation. To verbal command 3 Eyes open in response to speech. To pain 2 Eyes open in response to painful stimuli. No response 1 No eye opening. Verbal Response (V) Oriented 5 Correctly answers questions about self, location, and time. Confused 4 Speech is coherent but disoriented. Inappropriate words 3 Random or unrelated words in response. Incomprehensible sounds 2 Moaning or groaning without forming words. No response 1 No verbal sounds. Motor Response (M) Obeys commands 6 Follows simple motor commands (e.g., "Lift your arm"). Localizes pain 5 Purposefully moves to remove painful stimulus. Withdraws from pain 4 Flexion response to painful stimuli. Abnormal flexion (decorticate posturing) 3 Flexion of arms with extension of legs in response to pain. Abnormal extension (decerebrate posturing) 2 Extension of arms and legs in response to pain. No response 1 No motor movement. Calculating the Total GCS Score Formula : GCS = E (Eye opening) + V (Verbal response) + M (Motor response). Range : 3 to 15.

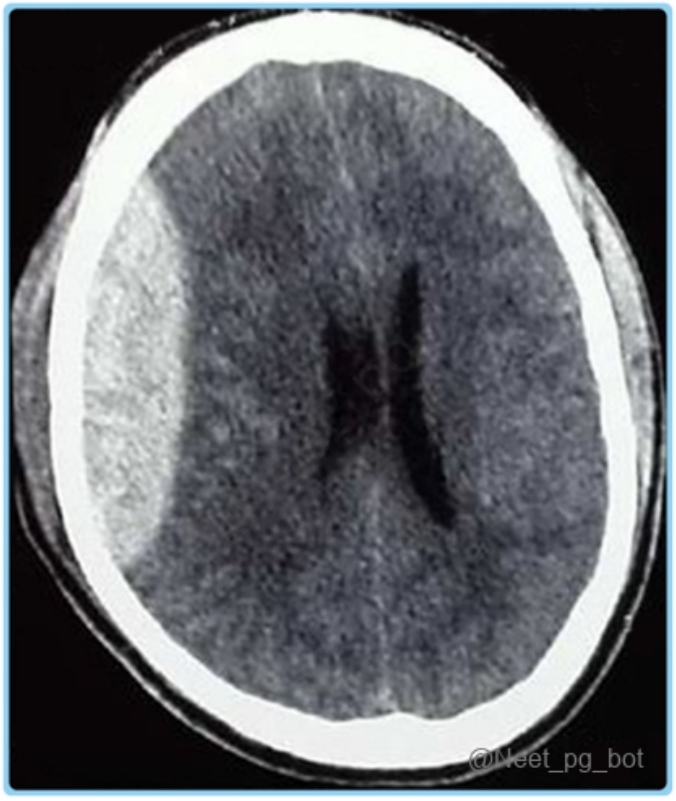
↑ *Back to this question in Part A*

@Neet_pg_bot



Q8: What potential diagnosis should be considered for a patient admitted to the Emergency department following a road traffic accident exhibiting an altered level of consciousness and a Glasgow Coma Scale (GCS) score of 10, as depicted in the provided CT scan? (Q857436)

A. Subdural hematoma

B. Intracerebral hemorrhage

C. Extradural hematoma

D. Hemorrhagic contusion

Correct Answer: C. Extradural hematoma

Explanation: The CT scan shows a biconvex (lentiform), hyperdense collection between the skull and dura. This shape is characteristic of an extradural (epidural) hematoma . Clinically, the patient has a GCS of 10 after an RTA, consistent with a space-occupying lesion causing mass effect and altered consciousness. Extradural hematomas are typically due to middle meningeal artery injury from a temporal bone fracture and classically appear as a lens-shaped hyperdensity on CT. Subdural hematoma (Option A) is commonly seen due to injury in cortical bridging veins. In the CT scan, the lesion is seen as a concave-convex lesion in the subdural space. Intracerebral hemorrhage (Option B) Commonly seen due to rupture of an aneurysm inside the brain. The CT scan usually shows a well-defined hyperdensity and is usually surrounded by hypodense edema. Hemorrhagic contusion (Option D) Usually seen as small punctate hyperdense foci in the CT.

https://www.ncbi.nlm.nih.gov/books/NBK518982/

↑ *Back to this question in Part A*

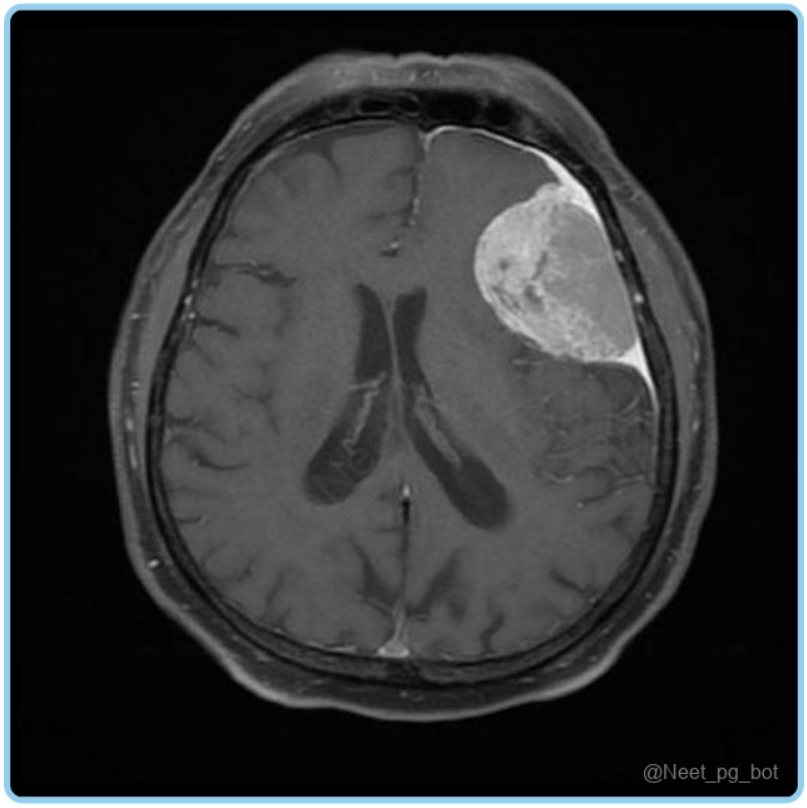
@Neet_pg_bot

Q9: An old lady sustained a fall and developed a headache and neurological symptoms a few days later. What is your diagnosis? (Q855261)

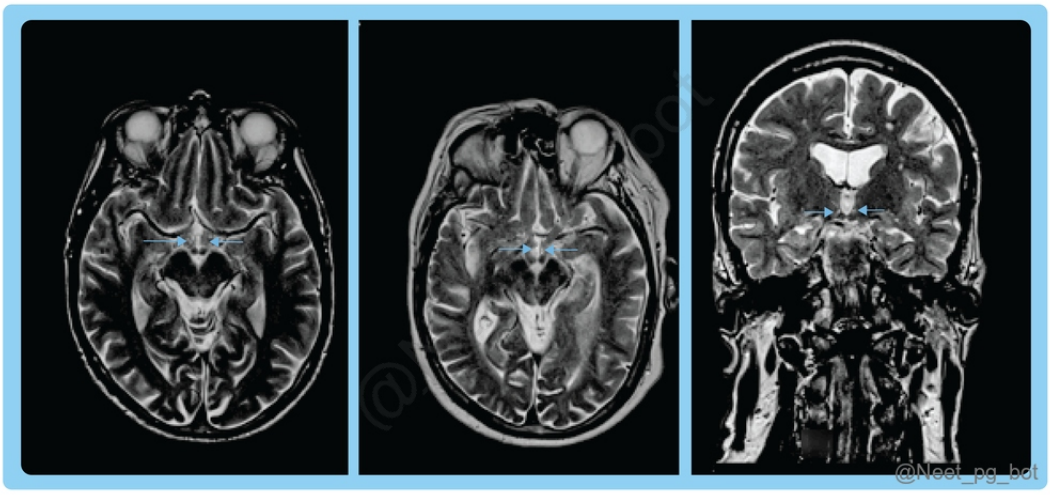
A. Multi-infarct dementia

B. Frontal lobe meningioma

C. Korsakoff disease



D. Subdural hematoma



Correct Answer: D. Subdural hematoma

Explanation: In the given scenario, a fall followed by headache and neurological symptoms suggests a Subdural Hematoma (SDH) , which can occur from torn bridging veins and lead to headache, altered mental status, and focal neurological deficits. Subdural Hematoma (SDH) Causes Tearing of bridging veins , often due to blunt trauma / acceleration-deceleration injuries. Mechanism High-energy injury: Rupture of cortical surface vessels . Low-energy injury: Venous bleeding , common in older adults on anticoagulants. Clinical Presentation Variable presentation depending on injury severity and timing. Signs of raised intracranial pressure: Headache, reduced consciousness, focal neurological deficits. CT Appearance Diffuse concave hyperdense (acute), isodense (subacute), or hypodense (chronic) lesions over the brain surface, often crossing suture lines. {{caption_text}} Management Depends on size, location, and clinical status: 1. Large or worsening hematomas: Urgent evacuation by craniotomy or craniectomy. 2. Smaller, stable bleeds: Conservative management initially, with surgery if needed. Multi-infarct dementia (Option A) occurs due to multiple small strokes over time, leading to gradual cognitive decline rather than acute symptoms after trauma. On imaging, multiple small infarcts are seen, often in subcortical or deep brain areas, not an acute blood collection like in a subdural hematoma. {{caption_text}} Frontal lobe meningioma (Option B) is a slow-growing tumour that usually causes gradual symptoms like seizures or focal deficits, not acute neurological changes after a fall. On CT or MRI, it appears as a well-defined mass, often calcified, with possible brain compression, but not as an acute blood collection like in a subdural hematoma. {{caption_text}} Korsakoff disease (Option C) is caused by chronic alcohol use leading to thiamine deficiency and results in severe memory impairment, not acute symptoms after a fall. Imaging may show brain atrophy, especially in the mammillary bodies, but no acute haemorrhage or mass effect like a subdural hematoma. {{caption_text}}

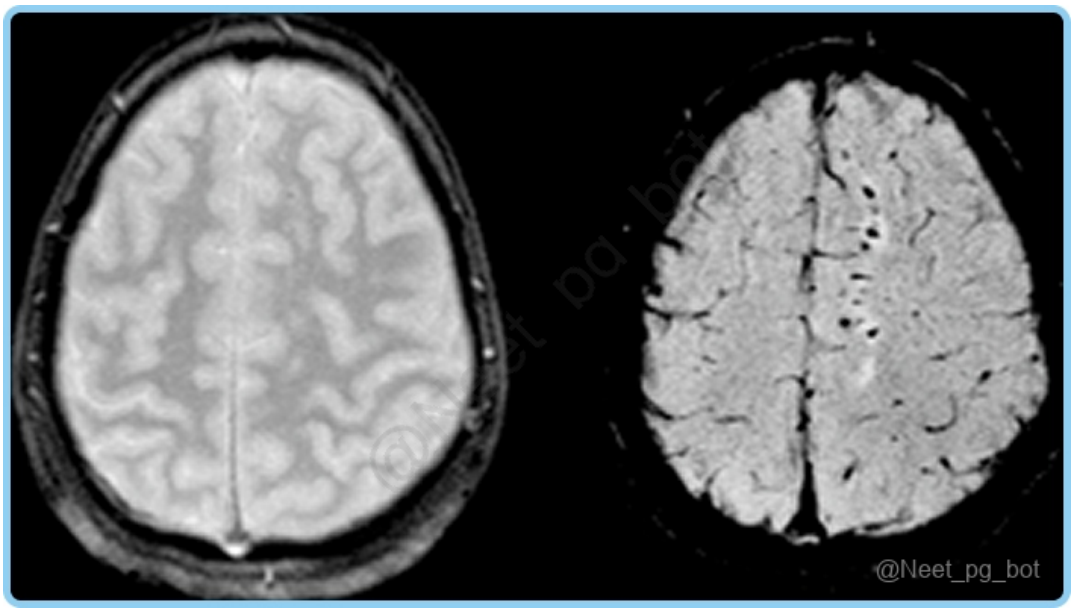
Bailey & Love's Short Practice of Surgery, 28th Edition, Page 365-367, 711.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 34-year-old woman was brought to the AIIMS emergency following a road traffic accident. She was hemodynamically stable, and her GCS score was 3. She was intubated and sent for non-contrast C,T which was found to be normal. What is the most likely diagnosis? (Q855175)

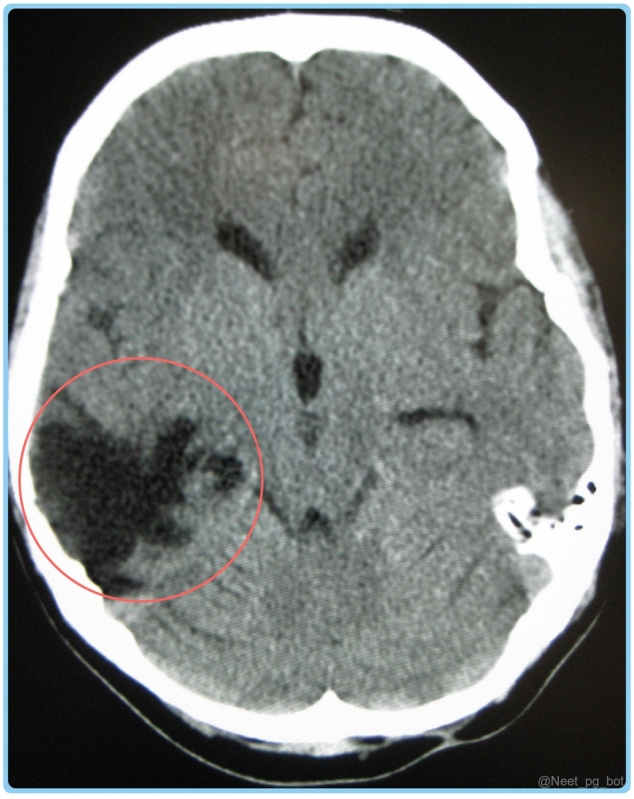
A. Subdural hemorrhage



B. Extradural hemorrhage

C. Diffuse axonal injury

D. Cerebral contusion



Correct Answer: C. Diffuse axonal injury

Explanation: In this road traffic accident scenario with a low GCS score of 3 and a normal CT scan, the most likely diagnosis is Diffuse Axonal Injury (DAI) , which often appears normal on CT despite causing severe neurological damage. Diffuse Axonal Injury (DAI) A form of primary brain injury caused by widespread damage to axons due to rotational acceleration and deceleration forces, often associated with high-energy trauma. Cause Rotational forces: High-energy accidents involving rapid acceleration and deceleration (e.g., motor vehicle collisions). Trauma: Blunt force impacts that cause the brain to rotate within the skull. Clinical Features Impaired arousal : Often presents as coma or reduced consciousness due to damage in critical brain areas (e.g., pontine reticular activating system, bilateral thalami). Neurological deficits: Poor neurological examination despite the absence of obvious radiographic global brain injury. Irreversible consequences: DAI is often associated with severe and lasting neurological impairment. Investigations CT scan: May show hemorrhagic foci in the corpus callosum and dorsolateral rostral brainstem in severe cases. MRI: More sensitive than CT . It shows small haemorrhages and diffuse axonal injury, particularly in patients who fail to improve neurologically. {{caption_text}} Postmortem examination: Confirms the diagnosis with axonal disruption and formation of axon balls. Prognosis Very poor due to high risk of severe disability or death due to extensive brain damage. Subdural hemorrhage (Option A) would usually cause a gradual decline in GCS, and a CT scan would typically show a crescent-shaped blood collection. The normal CT scan, in this case, makes subdural hemorrhage less likely. {{caption_text}} Extradural haemorrhage (Option B) presents with a brief loss of consciousness followed by a lucid interval, and a CT scan typically shows a convex-shaped blood collection. The normal CT, in this case, makes extradural hemorrhage unlikely. {{caption_text}} Cerebral contusion (Option D) can result from trauma and may cause neurological deficits; they typically appear as focal areas of haemorrhage or swelling on a CT scan. A normal CT scan, as seen here, makes this diagnosis less likely. {{caption_text}}

@Neet_pg_bot

Q11: A 30 year male old patient presents to OPD with complaints of recurrent headache and nausea, MRI brain shown. What is the diagnosis? (Q866457)

A. Meningioma

B. Glioma

C. Ependymoma

D. Pilocytic astrocytoma

Correct Answer: A. Meningioma

Explanation: Meningiomas are extra-axial, slow-growing tumors arising from arachnoid cap cells . On MRI (especially with contrast), they frequently show the dural tail sign - thickening and enhancement of the dura adjacent to the tumor. This sign is highly suggestive of meningioma due to reactive dural vascularity and tumor infiltration. Glioma (Option B): Intra-axial tumor without dural attachment; typically does not show dural tail sign.

Ependymoma (Option C): Usually arises from the ventricular system, particularly the 4th ventricle in children, not from dura. Pilocytic astrocytoma (Option D): Commonly seen in children, typically in the cerebellum, and does not exhibit dural tail sign.

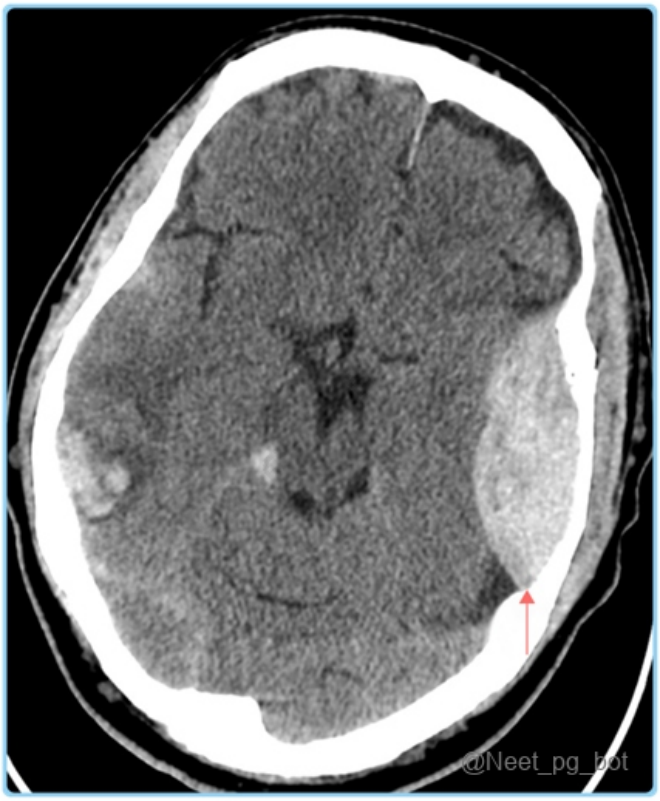
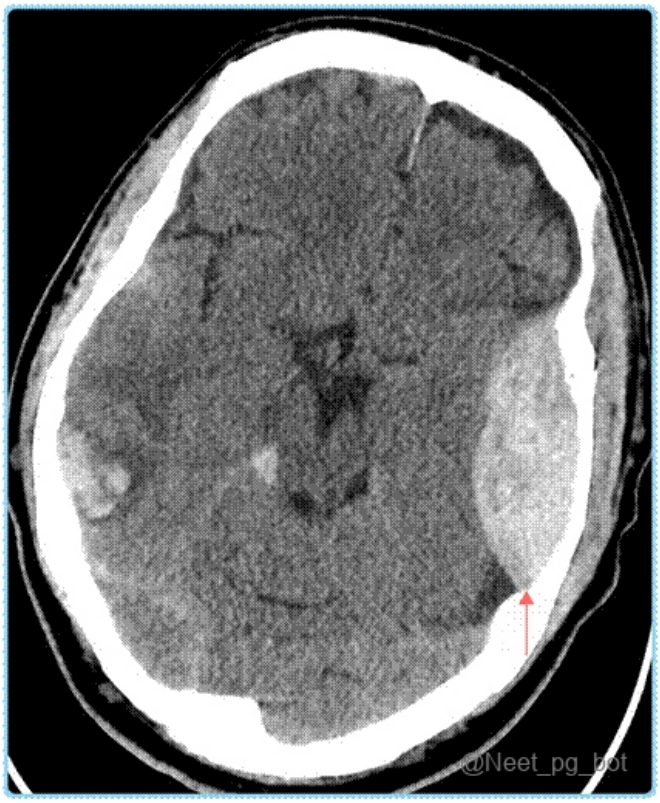
@Neet_pg_bot



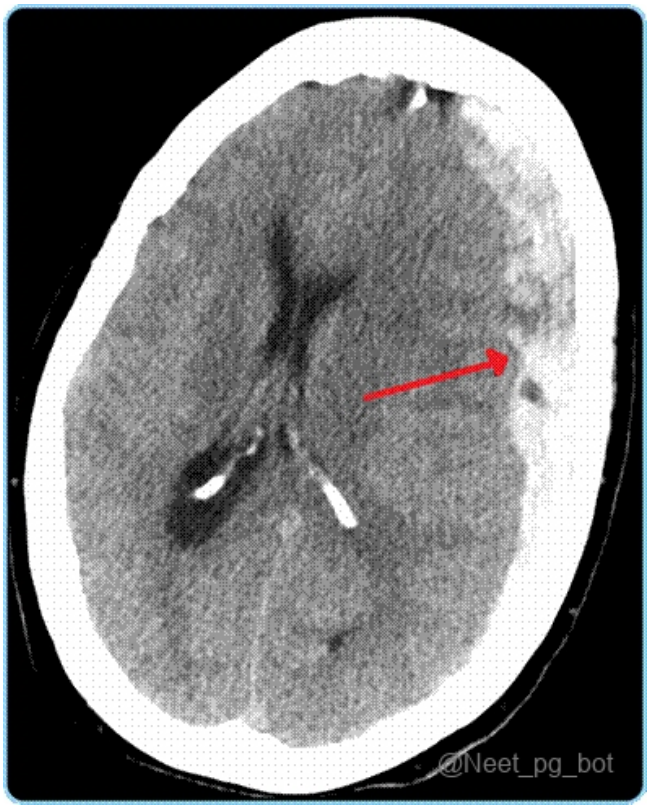
Q12: What is the probable diagnosis for a 30-year-old woman who experienced nausea and vomiting after being involved in a road traffic accident, and was brought to the emergency room unconscious, based on the findings of the NCCT brain? (Q857856)

A. Extradural hemorrhage

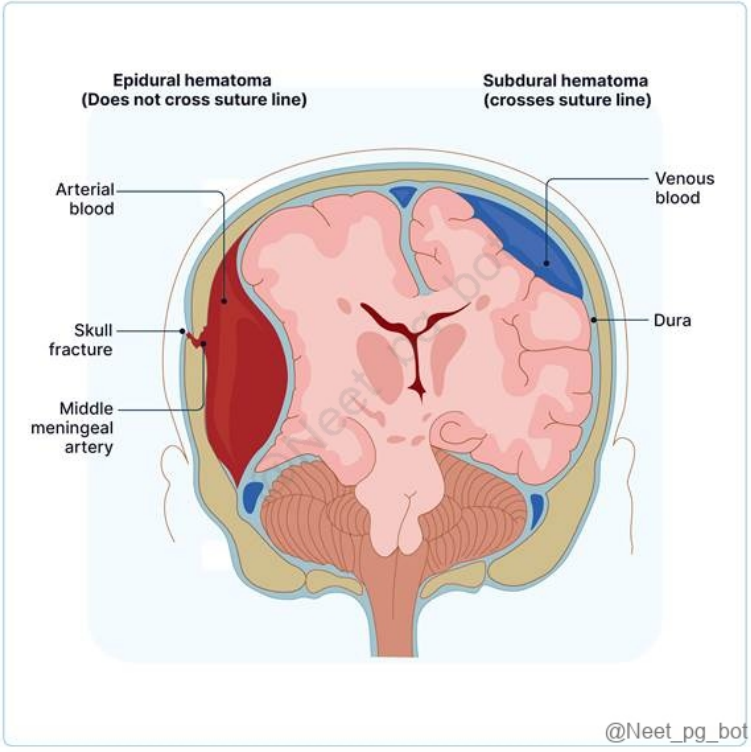
B. Subdural hemorrhage

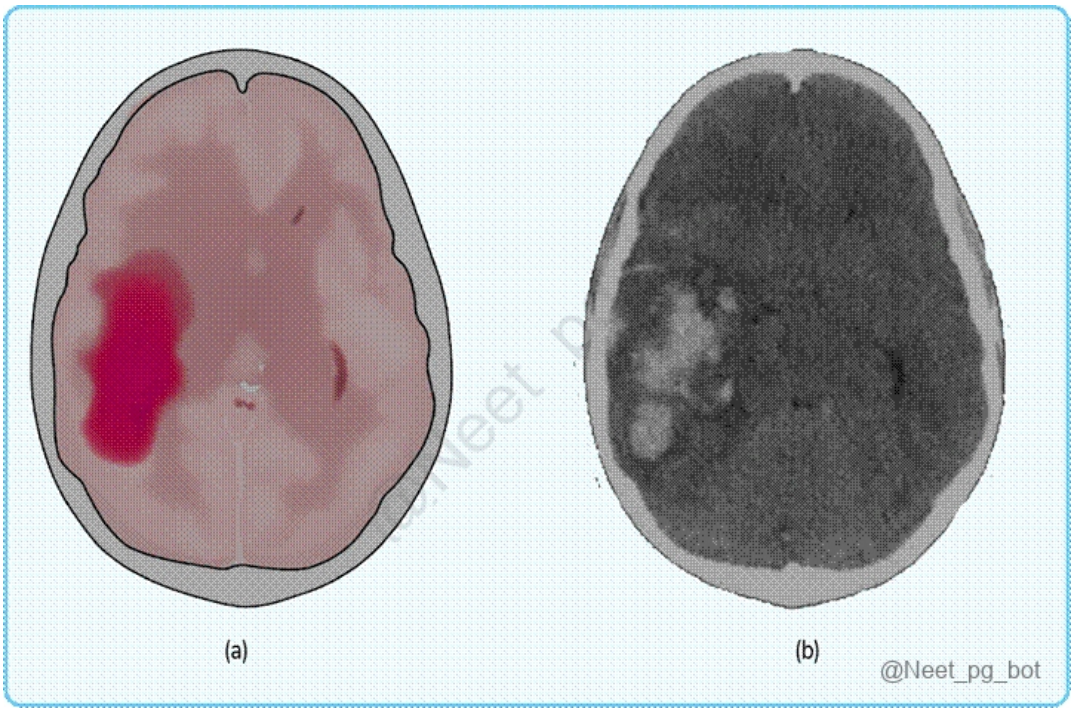


C. Intra-parenchymal hemorrhage

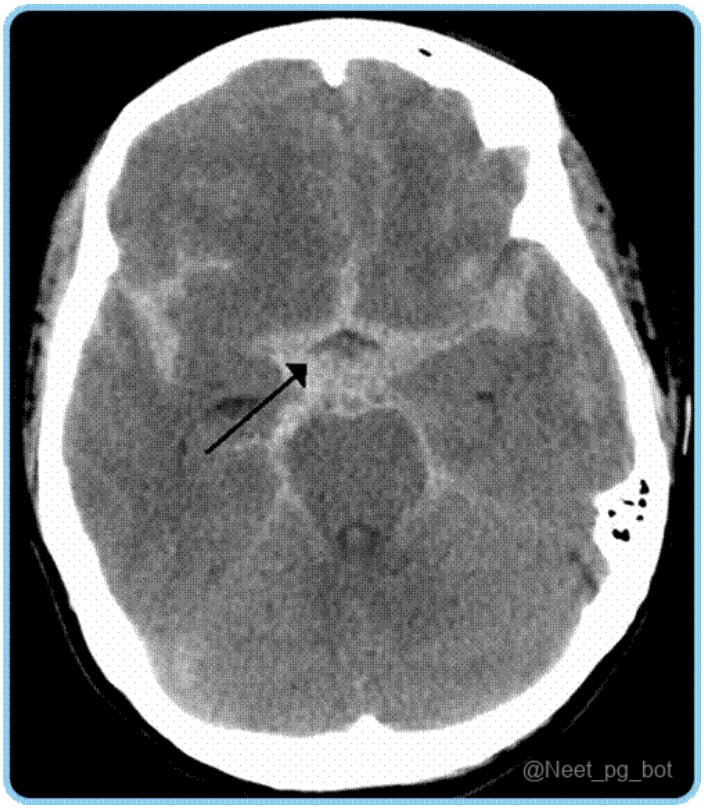


D. Subarachnoid hemorrhage





Correct Answer: A. Extradural hemorrhage



Explanation: The likely diagnosis for a woman presenting with nausea and vomiting after a road traffic accident, and NCCT head showing a lens-shaped or biconvex hematoma between the inner surface of the skull and the outer layer of the dura mater, is Extradural Hemorrhage (Epidural Hemorrhage) . Aspect Epidural Hematoma (EDH) (Option A) Subdural Hematoma (SDH) (Option B ruled out) Mechanism Rupture of an artery, often the middle meningeal artery, usually due to a skull fracture, commonly in the temporal bone. Two contexts: High-energy injury: Rupture of cortical surface vessels. Low-energy injury: Venous bleeding, common in older adults on anticoagulants. Clinical Presentation Classic: Transient loss of consciousness, lucid interval, rapid neurological decline. Headaches are common. Brain compression signs: Contralateral hemiparesis, reduced consciousness, ipsilateral pupillary dilation. Variable presentation depending on injury severity and timing. Signs of raised intracranial pressure: Headache, reduced consciousness, focal neurological deficits. CT Appearance Lentiform (lens-shaped or biconvex) hyperdense lesion between the skull and the brain. {{caption_text}} Diffuse concave hyperdense (acute), isodense (subacute), or hypodense (chronic) crescent-shaped lesions over the brain surface, often crossing suture lines. {{caption_text}} Management Neurosurgical emergency; requires immediate evacuation, usually by craniotomy. Depends on size, location, and clinical status: 1. Large or worsening hematomas: Urgent evacuation by craniotomy or craniectomy. 2. Smaller, stable bleeds: Conservative management initially, with surgery if needed. Summary EDH often follows a predictable course with a lucid interval. SDH has a more variable presentation and distinct CT appearance. Intra-parenchymal hemorrhage (Option C) involves bleeding within the brain tissue, appearing as a high-density, irregular mass on NCCT. It is commonly associated with hypertension or stroke, not trauma. While unconsciousness may suggest a severe injury, the imaging would not show the "lens-shaped" hematoma seen in extradural hemorrhage. {{caption_text}} Subarachnoid hemorrhage (Option D) involves bleeding between the brain and arachnoid mater, often from a ruptured aneurysm. On NCCT, it appears as diffuse blood in the sulci. While trauma and unconsciousness may raise suspicion, it doesn't show the biconvex hematoma seen in extradural hemorrhage. {{caption_text}}

@Neet_pg_bot

Epidural hematoma
(Does not cross suture line)
Subdural hematoma
(crosses suture line)
Arterial blood
Venous blood
Skull fracture

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: What is the most appropriate course of action for the management of a patient who presents to the emergency department with a severe headache and has a blood pressure reading of 160/100 mmHg, along with a CT scan showing evidence of a subarachnoid haemorrhage? (Q855267)

A. Nimodipine

B. Angiography

C. Surgery

D. Fibrinolytic therapy

Correct Answer: B. Angiography

Explanation: In a patient presenting with a subarachnoid haemorrhage (SAH) and a severe headache, angiography is the most appropriate next step. This is crucial for identifying the source of the haemorrhage, such as an aneurysm or arteriovenous malformation (AVM). Subarachnoid Hemorrhage: Causes: Most common: Trauma Ruptured Aneurysm : Most commonly located in the Circle of Willis. Arteriovenous Malformation (AVM) Perimesencephalic SAH : Bleeding is confined to the basal cisterns due to venous bleeding and is associated with a better prognosis. Risk factors: Female sex Hypertension Smoking & Cocaine use Genetic disorders (e.g., adult polycystic kidney disease , Marfan syndrome) Symptoms: Thunderclap Headache : Sudden and severe headache. Associated with Seizures (10%), Unresponsiveness (50%) and Vomiting (70%) Diagnosis: CT Scan : First-line imaging , effective within 12 hours of onset, and its sensitivity decreases after one week. Fisher Grading for SAH on CT: Grade I No bleeding. Grade II Diffuse SAH with layers <1mm thick. Grade III Localised clots or SAH layers >1mm thick. Grade IV SAH minimal/absent, with intracerebral/intraventricular haemorrhage. Lumbar Puncture : Used if CT is negative but SAH is suspected. Digital Subtraction Angiography (DSA) : Gold standard for visualising aneurysms. Management: Surgical or endovascular intervention and addressing complications such as vasospasm and electrolyte imbalances . Early and effective treatment is crucial for improving outcomes. Nimodipine (Option A) is a calcium channel blocker commonly used in the management of SAH to prevent vasospasm, a frequent complication. However, it is not the immediate next step after the diagnosis of SAH. Surgery (Option C) may be needed to treat the cause of SAH, such as a ruptured aneurysm. However, angiography is generally performed first to identify the location and extent of the aneurysm before proceeding with surgery. Fibrinolytic therapy (Option D) is not typically used in the acute management of SAH. It is designed to dissolve intravascular clots and improve blood flow in ischemic conditions, but it is not indicated for SAH.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 708,709

↑ *Back to this question in Part A*

@Neet_pg_bot

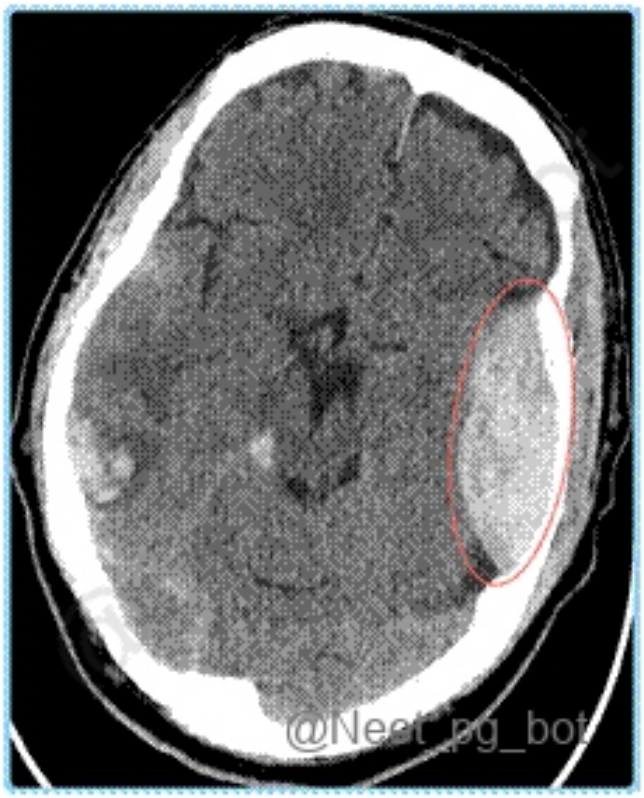
Q14: A 50-year-old patient presents with confusion and ataxia following trauma one week ago. He has a history of alcohol dependence, with his last intake 2 weeks ago. A CT scan reveals the following findings. What is the most likely diagnosis? (Q855207)

A. Extradural hemorrhage

B. Subdural hemorrhage

C. Intra-parenchymal hemorrhage

D. Subarachnoid hemorrhage



Correct Answer: B. Subdural hemorrhage

Explanation: Given the clinical scenario and radiological findings showing a crescent-shaped blood collection that follows the brain's contours and crosses suture lines , the most probable diagnosis is Subdural Hematoma. Features Subdural Hematoma Extradural Hematoma (Option A) Location Between Dura and Arachnoid Between Dura and Skull CT Appearance Crescent-shaped Crosses suture lines Biconvex or lens-shaped Well-defined & Localized, Won’t cross suture lines Common Causes Tearing of bridging veins , often due to blunt trauma / acceleration-deceleration injuries Rupture of the middle meningeal artery or vein due to skull fracture or trauma Onset Develop over days to weeks; Acute SDH can occur rapidly Usually develop rapidly Management Craniotomy / Craniectomy , if significant. Conservative management for smaller, stable cases. Burr hole drainage is preferred for significant chronic cases Urgent surgical evacuation for significant or deteriorating cases.

{{caption_text}} {{caption_text}} Intra-parenchymal hemorrhage (Option C) is a type of hemorrhage that involves bleeding within the brain tissue itself and is typically associated with conditions like hypertension, cerebral amyloid angiopathy, or direct traumatic brain injury. Subarachnoid Hemorrhage (Option D) typically causes sudden severe headache, often described as a "thunderclap," and is seen on CT as blood in the subarachnoid space, often with associated hydrocephalus. It does not usually present with the crescent-shaped lesions seen in SDH.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 365-367

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: What is the Glasgow Coma Scale (GCS) score of a patient who was admitted to the emergency room after being involved in a road traffic accident and, on examination, opens his eyes in response to a painful stimulus, speaks inappropriately, and withdraws his limbs in response to a painful stimulus? (Q855182)

A. E2V2M3

B. E3V3M3

C. E2V3M4

D. E3V2M2

Correct Answer: C. E2V3M4

Explanation: Eye-opening (E) : The patient opens their eyes in response to a painful stimulus, which corresponds to E2 (eye-opening to pain). Verbal response (V) : The patient speaks inappropriately, corresponding to V3 (inappropriate words). Motor response (M) : The patient withdraws their limbs in response to a painful stimulus, which corresponds to M4 (withdraws to pain). Glasgow Coma Scale (GCS): Category Response Score Eye Opening (E) Spontaneous 4 To speech 3 To pain 2 None 1 Verbal Response (V) Oriented 5 Confused conversation 4 Inappropriate words 3 Incomprehensible sounds 2 None 1 Motor Response (M) Obeys commands 6 Localizes to pain 5 Withdraws from pain 4 Abnormal flexion (decorticate) 3 Abnormal extension (decerebrate) 2 No response 1 Head Injury Severity: Clinical Classification Minor head injury GCS 15 with no LOC (loss of consciousness) Mild head injury GCS 14 or 15 with LOC Moderate head injury GCS 9 - 13 Severe head injury GCS 3 - 8 The GCS-P score is calculated by subtracting the Pupil Reactivity Score (PRS) from the Glasgow Coma Scale (GCS) total score: GCS-P = GCS - PRS. Pupils Unreactive to Light Pupil Reactivity Score Both Pupils 2 One Pupil 1 Neither Pupil 0 GCS-P score can range from 1 to 15 GCS-P score values between one and 8 denote a severe injury

@Neet_pg_bot

Q16: Which of the following conditions is associated with perineural invasion? (Q854781)

A. Adenoid cystic carcinoma

B. Pleomorphic adenoma

C. Mucoepidermoid tumour

D. Pancreatic cancer

Correct Answer: A. Adenoid cystic carcinoma

Explanation: Adenoid cystic carcinoma is known for its tendency to invade along nerves (perineural invasion) , which is a key feature of its aggressive nature. Adenoid cystic carcinoma: This type of cancer primarily affects the submandibular and sublingual salivary glands, with approximately half of the cases occurring in minor salivary glands, especially in the palate. It is relatively rare in the parotid gland. Clinical features: Facial nerve palsy Pain or numbness High risk of distant metastasis, especially - lung. Histopathology of adenoid cystic carcinoma: Type: Unencapsulated, infiltrative biphasic neoplasm. Cell Types: Variable proportions of epithelial and myoepithelial cells. Patterns: Cribriform: Cells around sharply punched-out cylindromatous spaces with basophilic matrix. It is the most common type and has a better prognosis. Tubular: Bilayered tubules with a true lumen. Solid: Sheets and nests of tumour cells without a lumen. Carries poor prognosis. Nuclear Features: Small, angulated, hyperchromatic

nuclei with scant cytoplasm. Perineural Invasion: Common in adenoid cystic carcinoma. High-Grade Transformation: Can occur Immunohistochemistry: Ductal cells: Positive for c-KIT. Myoepithelial cells: Positive for p63 and SMA. Incorrect Options: Pleomorphic adenoma (Option B) : This tumour generally does not show perineural invasion unless it undergoes a malignant transformation. Even in cases of malignancy, vascular invasion is more commonly seen than perineural invasion. Mucoepidermoid tumour (Option C) : While mucoepidermoid tumours can invade surrounding tissues, including nerves, perineural invasion is less common compared to adenoid cystic carcinoma. Pancreatic cancer (Option D) can invade adjacent structures and spread to distant organs, but perineural invasion is not a characteristic feature of this type of cancer.

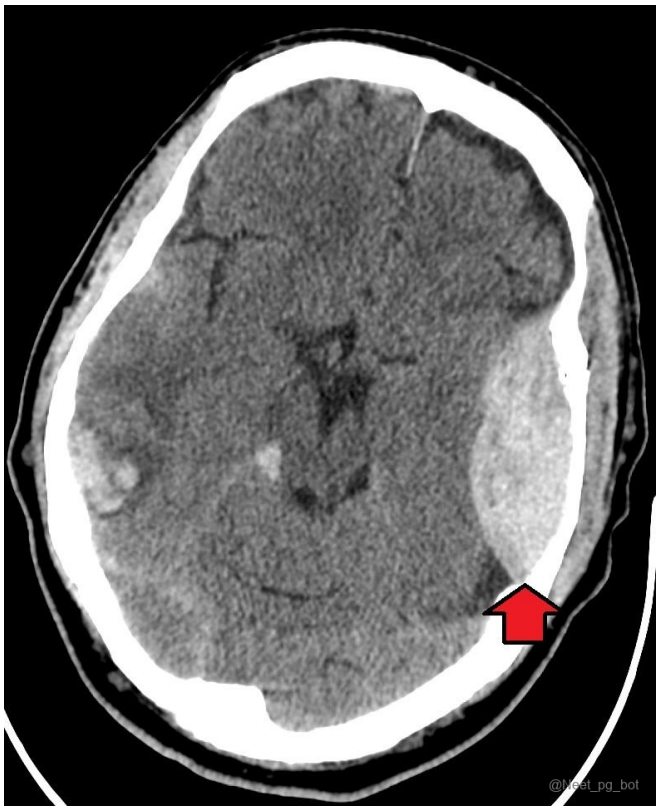
SRB's Manual of Surgery, 6th Edition, Page 405

↑ *Back to this question in Part A*

@Neet_pg_bot



Q17: A 32-year-old patient had a RTA and was brought to the ER. On examination, his GCS was E2M4V2 and his CT scan is given below. Which of the following is the preferred treatment in this condition? (Q820167)

A. Ventilation

B. Craniotomy with evacuation of hematoma

C. Anticoagulants

D. Steroids

Correct Answer: B. Craniotomy with evacuation of hematoma

Explanation: Correct option B - Craniotomy with evacuation of hematoma CT scan shows extradural hematoma. Extradural hematoma causes increased intracranial pressure, leading to brain compression and potential life-threatening complications. Craniotomy with evacuation of hematoma can relieve pressure on the brain and prevent further damage. Incorrect options: Option A, C and D are not the treatment of extradural hematoma.

↑ *Back to this question in Part A*

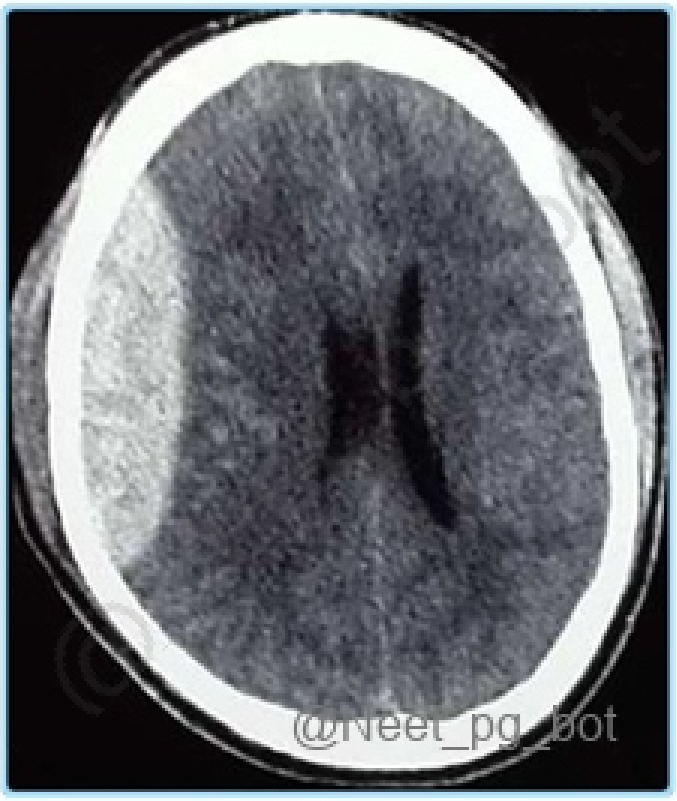
@Neet_pg_bot

Q18: Which type of intracranial hemorrhage is most likely depicted in the image given below? (Q860287)

A. Extradural hemorrhage

B. Subarachnoid hemorrhage

C. Subdural hematoma



D. Intraparenchymal hemorrhage

Correct Answer: C. Subdural hematoma

Explanation: The given image shows a crescent-shaped blood collection that follows the brain's contours and crosses suture lines , the most probable diagnosis is Subdural Hematoma. Features Subdural Hematoma Extradural Hematoma (Option A) Location Between Dura and Arachnoid Between Dura and Skull CT Appearance Crescent-shaped Crosses suture lines Biconvex or lens-shaped Well-defined & Localized, Won’t cross suture lines Common Causes Tearing of bridging veins , often due to blunt trauma / acceleration-deceleration injuries Rupture of the middle meningeal artery or vein due to skull fracture or trauma Onset Develop over days to weeks; Acute SDH can occur rapidly Usually develop rapidly Management Craniotomy / Craniectomy , if significant. Conservative management for smaller, stable cases. Burr hole drainage is preferred for significant chronic cases Urgent surgical evacuation for significant or deteriorating cases. {{caption_text}} {{caption_text}} Incorrect Options: Intra-parenchymal hemorrhage (Option D) is a type of hemorrhage that involves bleeding within the brain tissue itself and is typically associated with conditions like hypertension, cerebral amyloid angiopathy, or direct traumatic brain injury. Subarachnoid Hemorrhage (Option B) typically causes sudden severe headache, often described as a "thunderclap," and is seen on CT as blood in the subarachnoid space, often with associated hydrocephalus. It does not usually present with the crescent-shaped lesions seen in SDH.

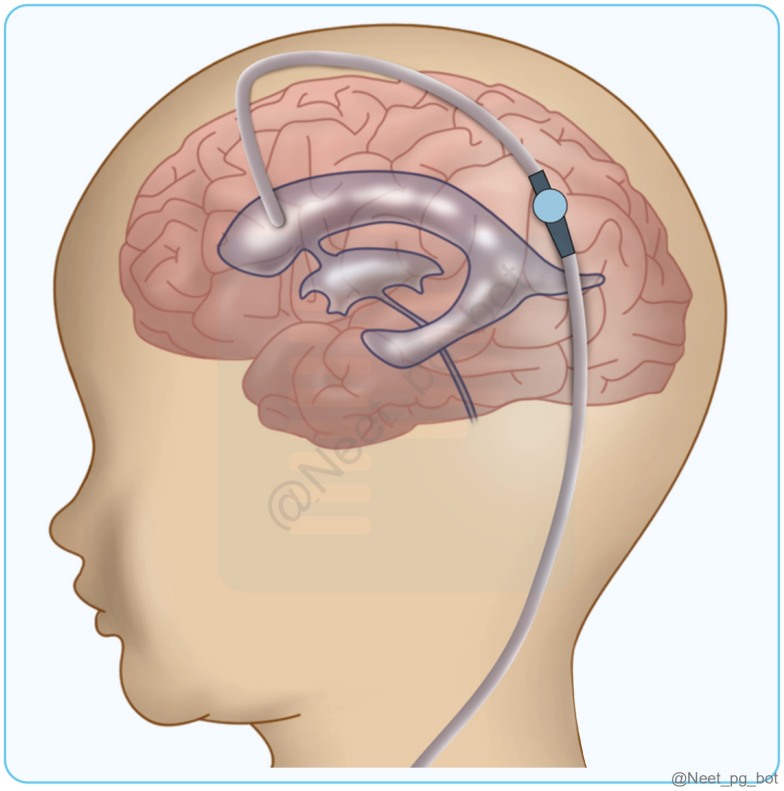
Bailey & Love's Short Practice of Surgery, 28th Edition, Page 365-367

↑ *Back to this question in Part A*

@Neet_pg_bot

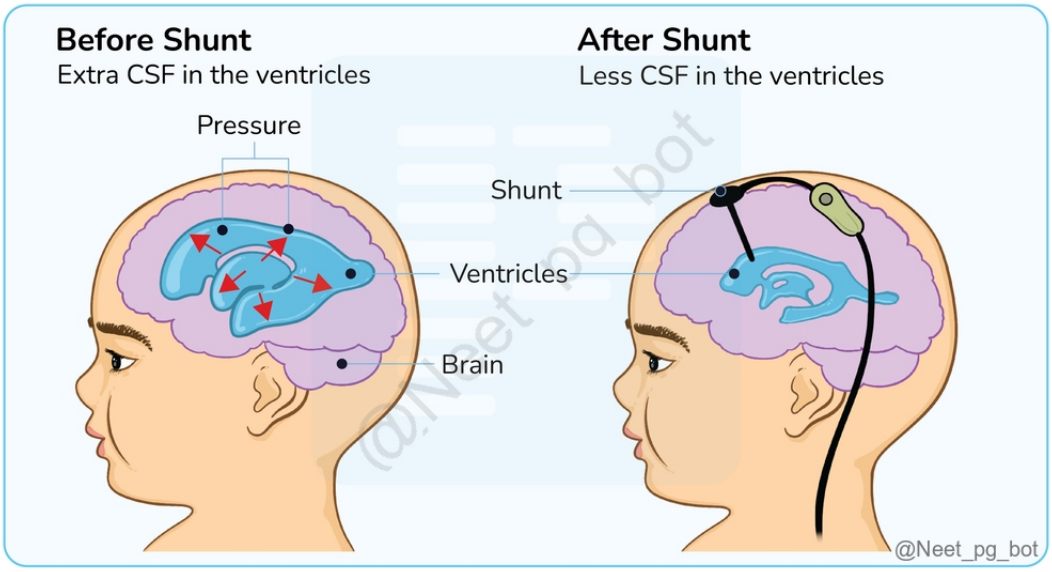


Q19: A 7-year-old boy is brought with complaints of headache, and vomiting for a few days. He had undergone a ventriculoperitoneal (VP) shunt placement for hydrocephalus a year ago. What is the most common cause of shunt malfunction in this patient? (Q860460)

A. Shunt infection

B. Shunt obstruction

C. Shunt tip migration



D. Shunt disconnection

Correct Answer: B. Shunt obstruction

Explanation: Shunt obstruction is the most common cause of VP shunt malfunction. This can occur anywhere along the length of the shunt, but it often happens at the distal catheter (the part of the shunt that drains into the peritoneum). A Ventriculoperitoneal (VP) shunt is generally considered for long-term management of hydrocephalus . It is implanted surgically to divert excess cerebrospinal fluid (CSF) from the ventricles of the

brain to the peritoneal cavity , where it can be absorbed by the body. Management of Hydrocephalus: Medical : Acetazolamide and furosemide can temporarily reduce CSF production but are not effective long-term. Surgical: (CSF Diversion) Ventriculoperitoneal Shunt: Valved tubing from the ventricle to the peritoneal cavity. Endoscopic Third Ventriculostomy: It is a useful treatment for certain cases of hydrocephalus, especially when there is an obstructive pattern that can be bypassed surgically and not always suitable for all patients and is considered an alternative to shunt placement Intrauterine Treatment : Results are generally poor except in cases associated with fetal meningomyelocele. Complications: Shunt occlusion (headache, papilledema, vomiting, altered mental status) and bacterial infection leading to meningitis/peritonitis (fever, headache, meningismus), typically caused by Staphylococcus epidermidis. Other options: Option A: Shunt infection Although infection is a common early complication (first few months), it is not the most common cause overall. Infections usually present with fever, erythema over tract, CSF pleocytosis, which are not mentioned in this case. Option C: Shunt tip migration Migration can occur but is far less common than obstruction. Usually presents with abdominal symptoms if the peritoneal end migrates, or subcutaneous swelling if dislodged—not seen here. Option D: Shunt disconnection Occurs due to breakage at connector sites, especially in growing children. Again, not as common as obstruction, and often presents with palpable discontinuity along the shunt tract.

Nelson Textbook of Pediatrics, 21st Edition, Page 3080

↑ *Back to this question in Part A*

@Neet_pg_bot

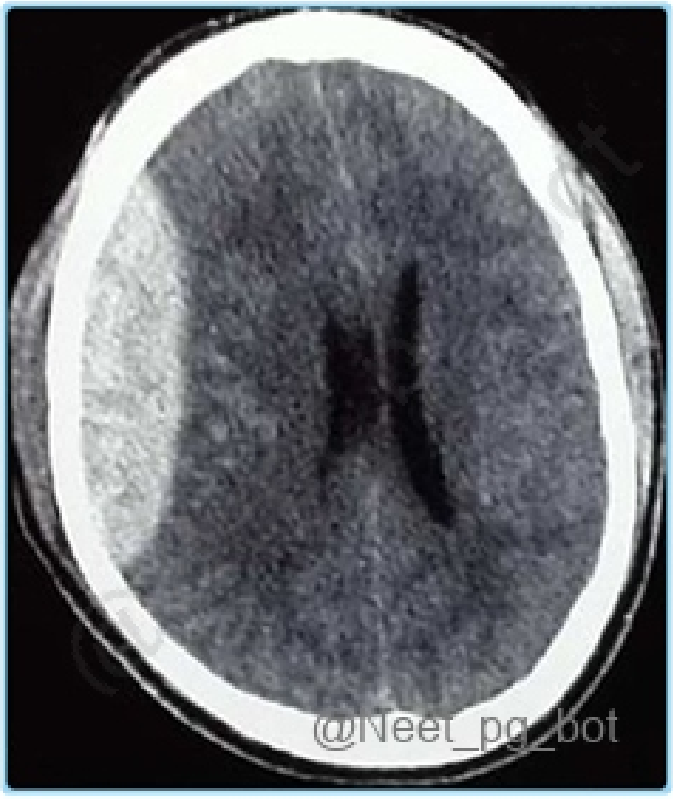
Q20: A 65-year-old patient with a history of thromboembolic stroke, currently taking warfarin and aspirin, presents with a headache and confusion after a fall in the toilet. A non-contrast CT of the head is given in the image. What is the next best step in management? (Q860383)

A. Aspirin + Clopidogrel

B. Vitamin K + FFP + Neurosurgery consultation

C. IV Mannitol

D. Observation



Correct Answer: B. Vitamin K + FFP + Neurosurgery consultation

Explanation: The given image shows a crescent-shaped blood collection that follows the brain's contours and crosses suture lines , the most probable diagnosis is Subdural Hematoma. In a patient on warfarin with a subdural hematoma (SDH), the primary concern is managing the anticoagulation effect and addressing the hemorrhage. The next best step involves: Vitamin K to reverse the effects of warfarin. FFP (Fresh Frozen Plasma) to provide clotting factors. Neurosurgery consultation to assess the need for surgical intervention (e.g., evacuation of the hematoma). Features Subdural Hematoma Extradural Hematoma (Option A ruled out) Location Between Dura and Arachnoid Between Dura and Skull CT Appearance Crescent-shaped Crosses suture lines Biconvex or lens-shaped Well-defined & Localized, Won’t cross suture lines Common Causes Tearing of bridging veins , often due to blunt trauma / acceleration-deceleration injuries Rupture of the middle meningeal artery or vein due to skull fracture or trauma Onset Develop over days to weeks; Acute SDH can occur rapidly Usually develop rapidly Management Craniotomy / Craniectomy , if significant. Conservative management for smaller, stable cases. Burr hole drainage is preferred for significant chronic cases Urgent surgical evacuation for significant or deteriorating cases. {{caption_text}} {{caption_text}} Incorrect Options: Aspirin + Clopidogrel (Option A) would not be appropriate because they both increase bleeding risk and do not address the anticoagulation from warfarin. IV Mannitol (Option C) is used to reduce intracranial pressure, but the priority in this case is reversing anticoagulation and

consulting neurosurgery. Observation (Option D) alone is not sufficient, especially with the anticoagulant therapy involved and the size of the SDH shown on CT, which may require surgical intervention.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 365-367

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 25 year patient had a Road traffic accident was initially conscious but later became unconscious and subsequently died. On postmortem examination, multiple petechial haemorrhages are seen in the corpus callosum, what is the probable diagnosis (Q866463)

A. EDH

B. Diffuse axonal injury

C. Subdural hematoma

D. SAH

Correct Answer: B. Diffuse axonal injury

Explanation: The scenario depicts diffuse axonal injury (DAI), which is a severe form of traumatic brain injury caused by shearing forces during rapid acceleration–deceleration (as in high-speed RTA). Pathology: Axonal disruption at the gray–white junction, corpus callosum, and brainstem. Postmortem finding: Multiple petechial hemorrhages in these areas. Clinical course: Often the patient becomes unconscious immediately or shortly after injury and remains comatose; some may have a brief lucid period. Mortality is high. DAI hallmark: Microscopic or small petechial hemorrhages at the gray–white junction and corpus callosum . Poor prognosis; often diagnosed by MRI (CT may be normal). Epidural hematoma (EDH) (Option A): Classically due to middle meningeal artery rupture; features a lucid interval , biconvex hyperdensity on CT, localized, not petechial hemorrhages in corpus callosum. Subdural hematoma (SDH) (Option C): Due to bridging vein rupture; appears crescent-shaped on CT; not characterized by multiple petechial hemorrhages in deep white matter. SAH (Option D): Presents with thunderclap headache; due to aneurysmal rupture or trauma, but hemorrhage is in subarachnoid space, not localized petechiae in corpus callosum.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: Which of the following is the next step in the management of an old patient who has undergone complete excision of glioblastoma ? (Q793556)

A. Chemotherapy with Bevacizumab

B. No further management

C. Chemoradiation

D. Radiotherapy

Correct Answer: D. Radiotherapy

Explanation: Correct Option D - Radiotherapy: After complete excision of glioblastoma, the next step in management typically involves adjuvant therapy to target any residual tumor cells and prevent recurrence. Radiotherapy, also known as radiation therapy, is a crucial component of adjuvant treatment for glioblastoma. It helps to destroy any remaining cancer cells in the brain following surgery, reducing the risk of tumor recurrence and improving overall survival rates. Therefore, radiotherapy is the appropriate next step in the management of an old patient who has undergone complete excision of glioblastoma. Incorrect Options: Option A - Chemotherapy with Bevacizumab: While chemotherapy is an essential component of the treatment for glioblastoma, particularly in conjunction with radiotherapy, the use of Bevacizumab (Avastin) specifically is not typically the next step after complete excision of the tumor. Bevacizumab is a monoclonal antibody that targets vascular endothelial growth factor (VEGF) and is often used in the treatment of recurrent glioblastoma or as a second-line therapy. It is not typically the first choice for adjuvant treatment immediately following surgical excision. Option B - No further management: This option is incorrect because after surgical excision of glioblastoma, adjuvant treatment is essential to target any remaining cancer cells and prevent recurrence. Without further management, there is a high risk of tumor recurrence, which can lead to worsening symptoms and reduced survival rates. Therefore, no further management is not an appropriate option in this scenario. Option C - Chemoradiation: While chemoradiation (combining chemotherapy and radiotherapy) is a common treatment approach for glioblastoma, it is typically used as initial treatment or as adjuvant therapy following partial surgical resection. Complete excision of the tumor reduces the need for immediate chemoradiation as the primary treatment modality. Therefore, opting for chemoradiation immediately after complete excision may expose the patient to unnecessary side effects without clear benefit.

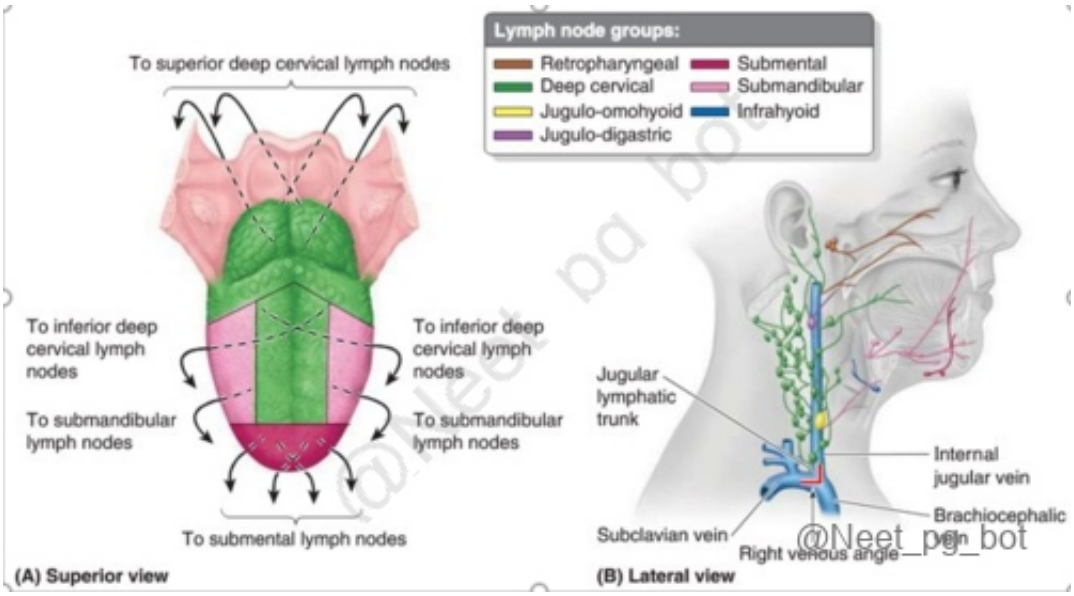
Q1: A 55-year-old male presents with a 2 cm ulcerative lesion located on the lateral border of the anterior portion of the tongue, closer to the tip. During surgical planning, which group of lymph nodes is the most likely initial site of lymphatic drainage for this lesion? (Q849605)

A. Level I

B. Level II

C. Level III



D. Level IV

Correct Answer: A. Level I

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The lymphatic vessels from the anterior lateral tongue drain primarily to the submandibular lymph nodes . The tip of the tongue drains to the submental nodes and then the submandibular nodes. The submental nodes are classified as Level Ia , and the submandibular nodes are classified as Level Ib . Together, Level Ia and Level Ib make up Level I . Level II (Option B): This is often the second station of drainage after Level I. While oral tongue cancers frequently metastasize to Level II, it is not typically the initial site. Level III & IV (Option C &D): These levels are further down the lymphatic chain. Involvement of these nodes usually occurs after the cancer has already spread to the upper levels (I and II) and indicates more advanced disease.

SRB's Manual of Surgery, Edition 6, page no: 359,382,383,384

↑ *Back to this question in Part A*

@Neet_pg_bot

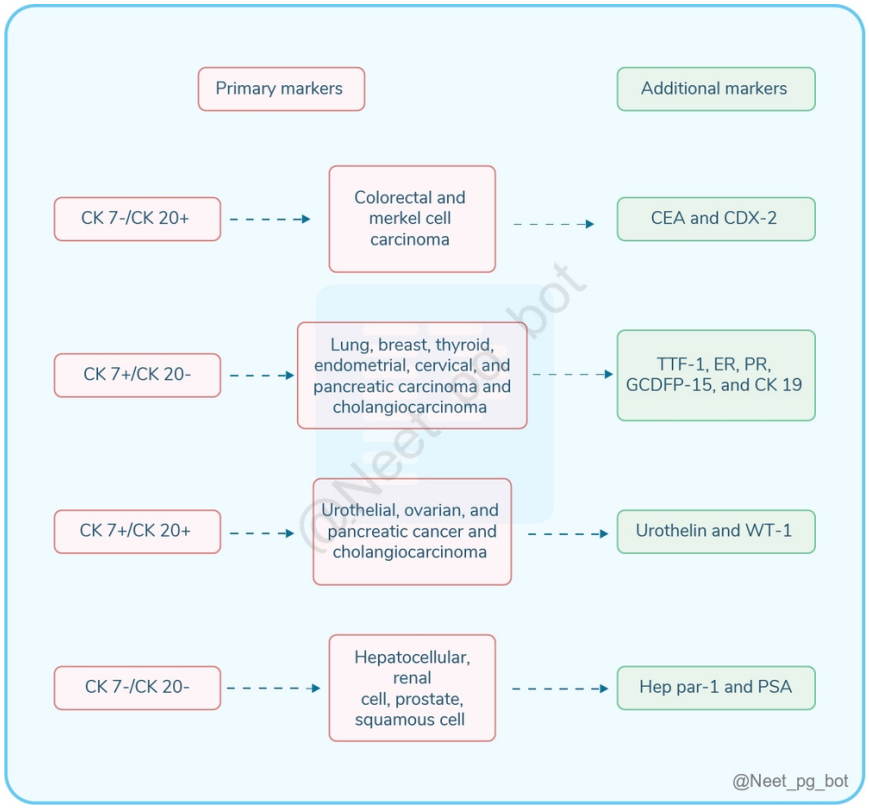
Q2: A 65-year-old patient presents with metastatic adenocarcinoma, but the primary tumor site remains unidentified. Which of the following is the most appropriate next step in the workup to help locate the primary tumor? (Q849630)

A. Complete blood count

B. PET scan

C. Start chemotherapy

D. Exploratory surgery



Correct Answer: B. PET scan

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Carcinoma of unknown primary origin (CUP) r efers to metastatic cancer where the primary tumor is not identified at initial presentation. The most appropriate next step to locate the primary tumor is imaging studies, among which a PET scan is particularly useful. Diagnostic Workup: Clinicopathologic diagnosis: Evaluation of

family and personal history: Identifies potential primary sites and risk factors. Physical examination: H/o previous surgeries and lesions. Biopsy and pathology: Fine-needle aspiration or core biopsy. Light microscopy with hematoxylin-and-eosin staining identifies the cancer type. Immunohistochemical tests: Immunohistochemical markers: These are peroxidase-labeled antibodies against specific tumor antigens, and help determine the tumor lineage. For e.g.: PSA and thyroglobulin (prostate and thyroid cancers). Cytokeratin stains: CK 7 and CK 20 determine tumor origin. Serum Tumor Markers and Cytogenetics: Tumor markers: PSA (for adenocarcinoma with bone metastasis), beta-human chorionic gonadotropin, alpha-fetoprotein (for germ cell tumors). Cytogenetics: Occasionally used to rule out lymphoma. Imaging Studies: CT scan: Abdominal and pelvic CT to locate the primary tumor and evaluate the disease extent. Mammography: Recommended for women with metastatic adenocarcinoma. MRI: Effective for assessing isolated axillary lymph node metastases and suspected occult primary breast carcinoma. PET Scan: Useful in non-cervical carcinoma of unknown primary origin (CUP) to guide biopsy and assess disease extent. (Option B) Advanced Techniques: Gene expression profiling: Uses DNA microarrays and RT-PCR to predict tumor origin based on gene expression patterns.

Bailey & Love's Short Practice of Surgery, Edition 28, page no:811

SRB's Surgical Operations, Edition 6, page no:440

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 58-year-old male is scheduled for a neck dissection due to metastatic squamous cell carcinoma of the oral cavity. Which incision will the surgeon choose to provide optimal access to all cervical lymph node levels? (Q849619)

A. Macfee incision

B. Modified Schobinger incision

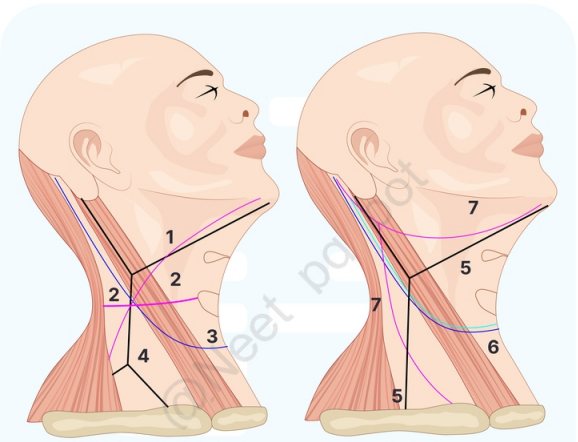
C. Y-shaped incision

D. Modified Macfee incision

Correct Answer: B. Modified Schobinger incision

■ *Listen (English)*

■ *Listen (Hindi)*



Explanation: Modified Schobinger Incision is the most preferred incision for adequate access to all levels of the neck lymph nodes. Types of Incisions in Neck Dissection 1. Macfee Incision: Two horizontal parallel incisions. Provide the best scar cosmesis. Limited access to deeper structures. 2. Modified Macfee Incision: Improves access to all neck node levels and a narrow bridge, thus facilitating an easier dissection of the spinal accessory nerve. 3. Reversed Hockey Stick Incision: Long anterior skin flap, superior access to all five lymph node levels.

@Neet_pg_bot

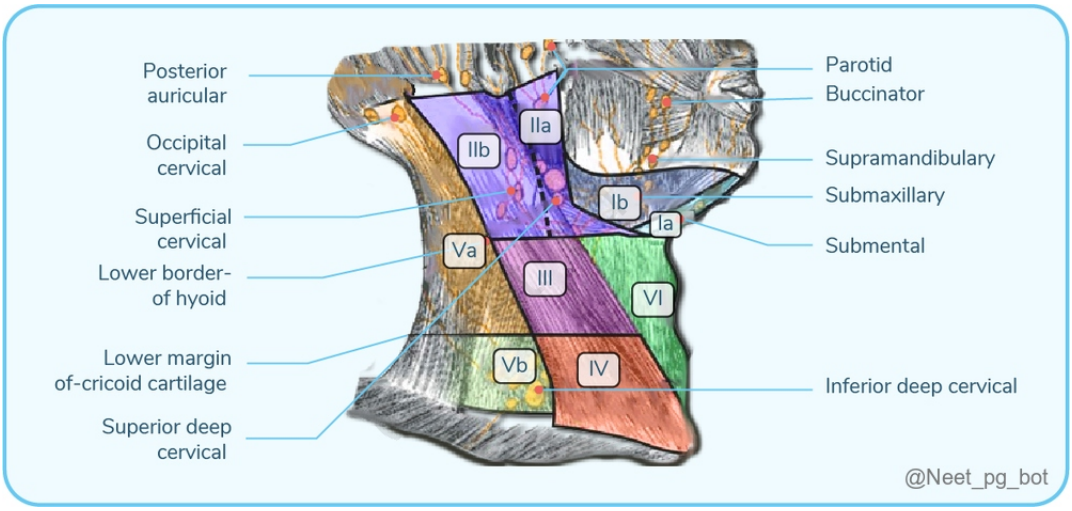
Q6: A 60-year-old female diagnosed with oral cavity cancer presents with a non-healing ulcer on her lower lip. Which of the following lymph node levels is most likely involved in this patient? (Q849618)

A. Levels IV and V

B. Levels II, III and IV

C. Levels I, II and III



D. Level VII

Correct Answer: C. Levels I, II and III

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Levels of lymph nodes of neck: Levels Lymph nodes Boundaries Associated primary malignancy I Ia: Submental Anterior belly of digastric muscle, hyoid bone, midline, mandible. Floor of mouth, Anterior tongue, Mandibular alveolar ridge, Lower lip (Option C) Ib: Submandibular nodes Anterior and posterior bellies of digastric muscle, inferior border of mandible. Oral cavity (Option C) Anterior nasal cavity Mid-face soft tissues Submandibular gland II Upper jugular group Skull base, horizontal plane extending from hyoid bone and sternocleidomastoid. IIa: Anterior to the spinal accessory nerve. IIb: Posterior to the spinal accessory nerve. Nasal and oral cavities, (Option C) Nasopharynx Oropharynx Hypopharynx Larynx, (Option B) Major salivary glands. III Middle jugular group Strap muscles, sternocleidomastoid, horizontal plane from inferior border of cricoid cartilage. Oral cavity Nasopharynx Oropharynx Hypopharynx Larynx (Option B) IV Lower jugular group Strap muscles, sternocleidomastoid, and clavicle. Hypopharynx Oropharynx Larynx (Option B) Thyroid gland (Option A) Cervical esophagus V Posterior triangle group Va: Lateral to SCM muscle, inferior and medial to splenius capitis and trapezius, superior to the spinal accessory nerve. Nasopharynx Oropharynx Thyroid gland (Option A) Vb: Lateral to SCM muscle, medial to trapezius, inferior to the spinal accessory nerve, superior to the clavicle. VI Anterior compartment group Hyoid bone, suprasternal notch, lateral extent of the strap muscles bilaterally. Lower lip Soft tissues of the chin VII Superior mediastinal nodes Inferior to the suprasternal notch in the upper mediastinum. Nasopharynx Pharyngeal wall Oropharynx (Option D)

@Neet_pg_bot

Q7: A 35-year-old male presents with a smooth, tender swelling in the right lower jaw in relation to tooth caries. A panoramic radiograph shows a well-defined radiolucency around the roots of the lower right first molar. What is the most likely diagnosis?

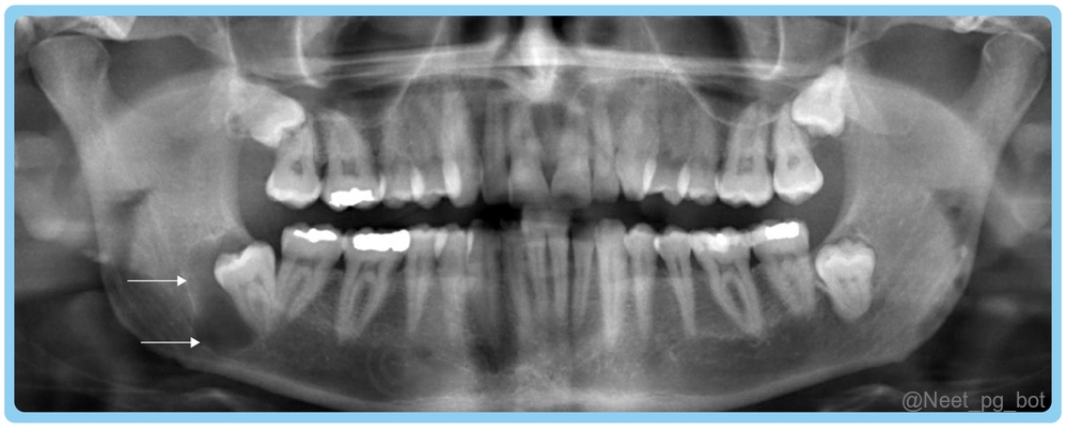
(Q849612)

A. Dentigerous cyst

B. Dental cyst

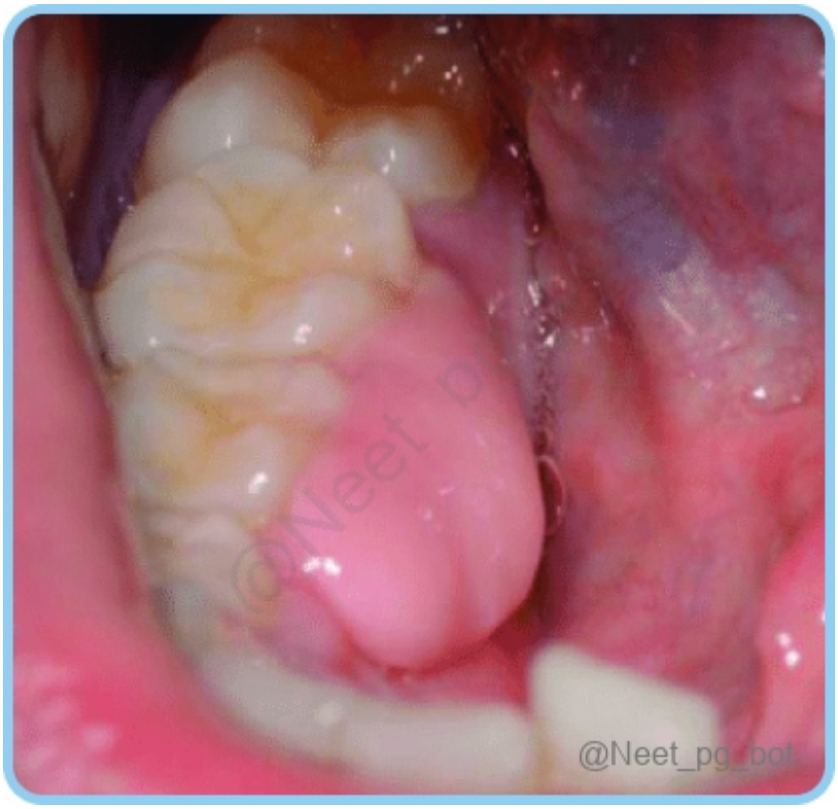
C. Ameloblastoma

D. Epulis



Correct Answer: B. Dental cyst

■ *Listen (English)*



■ *Listen (Hindi)*

Explanation: Feature Ameloblastoma (Option C) Dentigerous Cyst (Option A) Dental Cyst (Option B) Description Arises from dental epithelium, probably from the enamel/ dental lamina. Occurs commonly in the mandible or maxilla, occasionally in the skull base Locally malignant tumor Unilocular cystic swelling arising to the dental epithelium from an unerupted tooth. Common in the lower jaw but can also occur in the upper jaw. Occurs over the crown of an unerupted tooth; commonly seen in relation to premolars or molars. Occurs under the root of a chronically infected dead erupted tooth. Clinical Features Painless, Progressively enlarging swelling in the jaw (usually mandible), Smooth and hard, with an intact inner table. Painless, Smooth, hard swelling over the crown of an unerupted tooth, Causes expansion of the outer table of the mandible. Smooth, tender swelling in the jaw related to a caries tooth, Causes expansion of the jaw bone. Investigations Orthopantomogram (OPG): Honeycomb appearance CT scan Biopsy Orthopantomogram (OPG): Tooth within the cyst, which is well defined. Orthopantomogram (OPG): Circular radiolucent area in relation to the root of a normally erupted tooth. Treatment Segmental resection of mandible or hemimandibulectomy with reconstruction of the mandible. Small cyst: Excision of the cyst. Large cysts: Initial marsupialization followed by excision. Extraction of unerupted tooth. Antibiotics, Drainage or excision of the cyst with extraction of the infected tooth. Epulis (Option D) is swelling arising from the mucoperiosteum of gums (gingiva).

@Neet_pg_bot

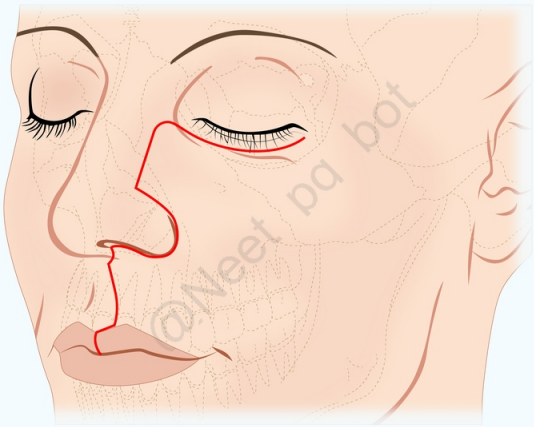
Q8: A 55-year-old male presents with a large tumor involving the floor of the maxillary sinus, causing facial swelling and nasal obstruction. During surgery, the surgical team uses the approach shown in the image. Identify the type of incision used in this procedure. (Q849611)

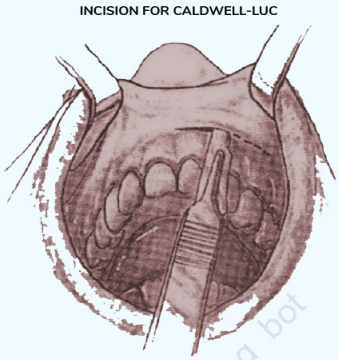
A. Caldwell-Luc Incision

B. Weber-Fergusson Incision

C. Modified Blair Incision

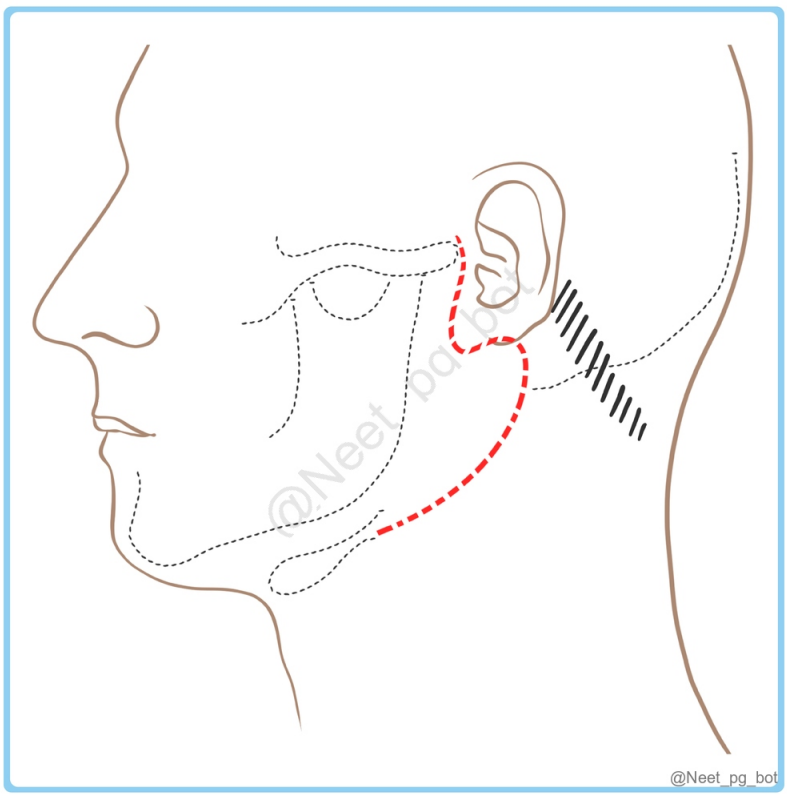


D. Lateral Rhinotomy Incision

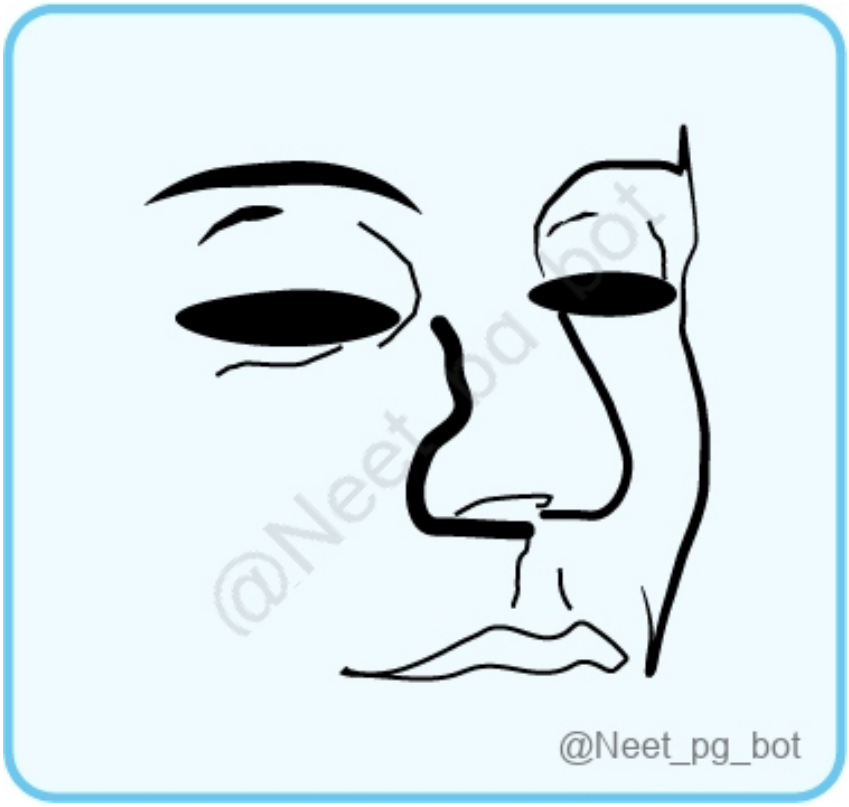


Correct Answer: B. Weber-Fergusson Incision

- *Listen (English)*
- *Listen (Hindi)*



Explanation: Weber-Fergusson Approach: Provides access to the maxilla and periorbital area. Uses: Partial/total maxillectomy for malignant or extensive benign tumors of maxillary sinus and nasal cavity; midfacial tumor resections. Caldwell-Luc incision (Option A) is placed 3 mm above the line of reflection and runs laterally for 3.5 - 4 cm parallel to the teeth, starting at the canine ridge. Uses: Access to maxillary sinus for antrostomy, removal of cysts or foreign bodies, biopsy; now largely replaced by endoscopic sinus surgery. Modified Blair incision (Option C): It combines the inverted L-shaped preauricular incision of Blair with a cervical limb extending into the neck. Uses: Superficial or total parotidectomy, parotid tumors, some temporomandibular joint and upper neck procedures; designed to give wide exposure with acceptable cosmesis. Lateral rhinotomy incision (Option D) is placed in the nasofacial groove. Uses: Wide exposure of nasal cavity, ethmoid and frontal sinuses, upper nasal septum, and anterior skull base tumors when endoscopic access is inadequate. Lateral rhinotomy is an established approach to the midfacial skeleton.



@Neet_pg_bot

Q9: A 55-year-old male patient requires mandibular reconstruction following the resection of a tumor. The surgeon is considering different bone graft options. Which of the following bone grafts is not likely to be chosen for bony reconstruction of the mandible? (Q849610)

A. Fibula bone graft

B. Iliac crest bone graft

C. Tibia bone graft

D. Scapula bone graft

Correct Answer: C. Tibia bone graft

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The tibia is generally avoided in modern maxillofacial reconstruction for several reasons: Poor Vascular Anatomy: Unlike the fibula, which has the reliable peroneal artery, the tibia does not have a well-defined segmental blood supply that allows it to be easily harvested as a vascularized free flap . Donor Site Morbidity: Removing a significant portion of the tibia severely compromises the weight-bearing capability of the leg, leading to a high risk of proximal or distal fractures . Cortical Density: The bone is often too dense and brittle to be easily contoured (osteotomized) to mimic the shape of the jaw. Mandibular Reconstruction: Gold Standard Flap Reconstruction with composite free flaps is considered the gold standard for segmental mandibular defects. Choice of Flap Depends on defect site, size, complexity, patient comorbidities, and surgeon’s training and preference. Anterior Defect More challenging to reconstruct than posterior defects; crucial for achieving satisfactory function. Graft used (Options A, B & D) Fibula Iliac crest Scapula Radius

↑ *Back to this question in Part A*

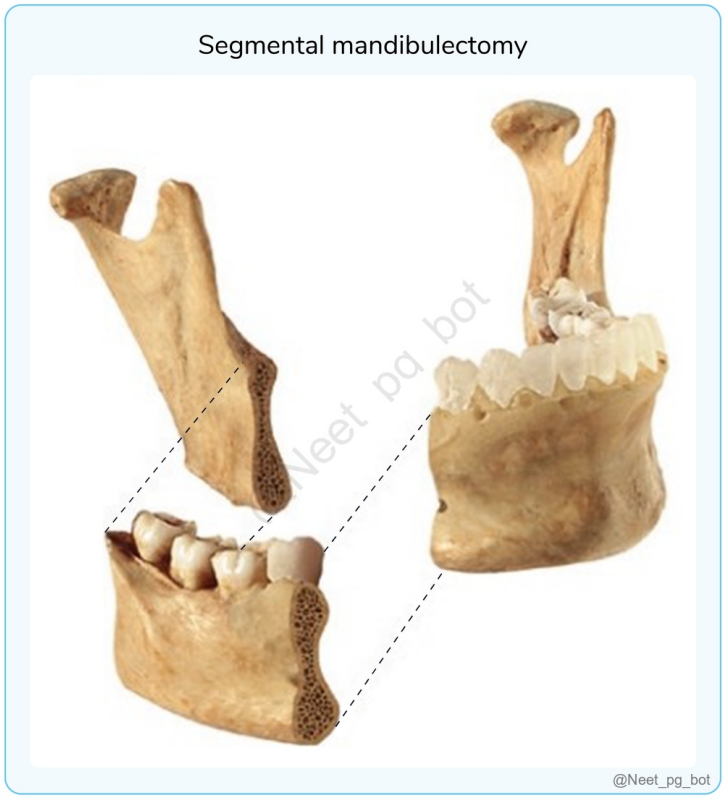
@Neet_pg_bot

Q10: A patient is scheduled for segmental mandibulectomy due to a lower alveolar tumor invading the mandible. Which statement accurately describes this procedure? (Q849609)

A. Preserves mandible continuity.

B. Suitable for tumors not invading the mandible.

C. Removes the entire height of the mandible.



D. Resection of partial thickness of the mandible.

Correct Answer: C. Removes the entire height of the mandible.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Feature Segmental Mandibulectomy Marginal Mandibulectomy Definition Removal of the full height of the invaded section of the mandible. (Option C) Removal of a partial thickness of the mandible. (Option D) Continuity of mandible Loss of continuity of the lower border. Continuity of the lower border remains intact. (Option A) Indication Tumor invading the mandible, often through the dental root leading into the mandibular canal and cancellous bone. Tumor is close to the mandible but does not invade it. (Option B) Image

References:

Bailey & Love Edition 28 page no:821 SRB Surgery Edition 6 page no: 372,373

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 65-year-old male with lower alveolar squamous cell carcinoma presents with an ulcerated mass, extensive cortical bone erosion, invasion beyond the inferior alveolar canal. What is the most appropriate treatment? (Q849608)

A. Radiotherapy

B. Local excision with marginal resection

C. Segmental mandibulectomy

D. Marginal resection, along with block dissection

Correct Answer: C. Segmental mandibulectomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: If there is more than superficial cortical erosion of the mandible, the marrow space is at risk of harboring malignancy and thus, segmental mandibulectomy is required for adequate margin control. Lower Alveolar Cancer: Mostly seen in men. Squamous cell carcinoma(SCC) is the most common malignancy of the lower alveolus. Tumor Spread: Can extend to the cheek, floor of the mouth, retromolar trigone, or hard palate. May invade underlying bone and spread rapidly along the neurovascular bundle. Nodal metastases commonly occur in submandibular and upper jugular nodes. Surgery: Preferred treatment method. Early Lesions (tumors adherent to periosteum): Treated by local excision with marginal resection of the mandible. Extensive Lesions (bone invasion present): Require wide excision, potentially involving segmental or hemimandibulectomy. Nodal Involvement: Block dissection may be performed if nodes are palpable. Management of Lower Alveolar Carcinoma: Stage Bone Involvement Surgical Choice Rationale Early (T1/T2) None or strictly superficial Wide Local Excision No bony invasion; periosteum acts as a barrier. Early (T1/T2) Erosion of alveolar crest only Marginal Mandibulectomy Preserves the lower border for structural continuity. Advanced (T3) Deep cortical invasion Segmental Mandibulectomy Required if $<1\text{ cm}$ of healthy bone height would remain. Advanced (T4a) Invasion of Mandibular Canal Segmental Mandibulectomy The IAN canal is a "highway" for spread; continuity must be broken. Recurrent Prior Radiation / Osteonecrosis Segmental + Free Flap Irradiated bone cannot heal via marginal resection.

Sabiston Textbook of Surgery, Edition 21, page no:780

Dhingra's ENT, Edition 8, page no: 268

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A patient presents with 2.5 cm ulceroproliferative adenoid cystic carcinoma on the left side of the hard palate. Imaging shows no evidence of bone invasion or lymph node involvement. Which of the following is the most appropriate management strategy? (Q849607)

A. Wide local excision with frozen section control

B. Partial maxillectomy with ipsilateral neck dissection

C. Partial maxillectomy without neck dissection

D. Radiotherapy alone

Correct Answer: C. Partial maxillectomy without neck dissection

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: For an adenoid cystic carcinoma of the hard palate, partial maxillectomy is the appropriate surgical approach to ensure adequate margins. Despite the absence of clinical bone invasion, microscopic invasion is common in these tumors. Elective neck dissection is generally not performed for adenoid cystic carcinomas of the hard palate due to their low propensity for lymphatic spread. Carcinoma of the Hard Palate Salivary gland tumors in the palate are often malignant, with adenoid cystic carcinoma being common. Adenoid cystic carcinoma : Present as a single, solid, smooth swelling with an ulcer on the summit. Squamous cell carcinoma : Characterized by an ulcer with raised and everted edges. Upper deep cervical lymph nodes are involved in 25% of cases. Malignant tumors can invade the periosteum, bone, maxilla, sinus, or nose. Treatment Wide excision with removal of the underlying palatal bone. Maxillectomy: Partial or total, often done using the Weber-Ferguson incision . Reconstruction: With a myocutaneous flap and dental prosthesis. Postoperative radiotherapy and neck block dissection are often required. Management Protocol by Depth of Invasion: Depth / Findings Stage Management Strategy Superficial (Mobile) T1 Wide Local Excision: Must include the underlying periosteum to ensure a safe deep margin. Intermediate (Fixed) T2 Partial Maxillectomy: Removal of the tumor with a cuff of the underlying palatal bone. Deep (Bone Erosion) T3 Infrastructure Maxillectomy: Removal of the hard palate and alveolar ridge while preserving the orbital floor. Extensive (Sinus/Nasal) T4a Total Maxillectomy: Removal of the entire maxilla; may require orbital exenteration if the orbit is involved. Reconstruction Options After Maxillectomy: Reconstructing the palate is vital for speech (preventing hypernasality) and swallowing (preventing nasal regurgitation). 1. Prosthetic Rehabilitation (Obturator): Mechanism: A specialized dental prosthesis (like a high-tech denture) that plugs the hole in the palate. Advantages: Allows direct visualization of the surgical cavity for tumor surveillance; easy to adjust. Best for: Small to medium defects where the patient has enough teeth to anchor the device. 2. Local/Regional Flaps: Palatal Island Flap: For very small defects; uses adjacent palatal mucosa. Temporalis Muscle Flap: The muscle is tunneled under the zygomatic arch to fill the maxillary void. FAMM Flap (Facial Artery Myomucosal): Uses cheek tissue. 3. Microvascular Free Flaps (Gold Standard for Large Defects): Radial Forearm Free Flap (RFFF): Excellent for thin, pliable tissue to close the palatal "roof" without adding bulk. Anterolateral Thigh (ALT) Flap: Used when more bulk is needed to fill a large maxillectomy cavity. Fibula Free Flap: Used if the alveolar ridge and teeth need to be reconstructed for dental implants.

Sabiston Textbook of Surgery, 21st edition, Pages: 780, 791

SRB’s Manual of Surgery, Edition 6, page no: 388,389

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A female who chews betel quid has pale, fibrous oral mucosa and a 2 cm interincisal opening. Biopsy revealed increased collagen deposition in the lamina propria. Which of the following is the most likely complication of this condition if left untreated? (Q849606)

A. Candidiasis

B. Malignant transformation

C. Bilateral submandibular gland hypertrophy

D. Spontaneous remission of fibrosis

Correct Answer: B. Malignant transformation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's presentation is consistent with oral submucous fibrosis (OSMF). The most significant long-term complication of untreated OSMF is malignant transformation. Oral submucous fibrosis is considered a potentially malignant disorder due to its significant risk of progressing to oral squamous cell carcinoma. Regular follow-up and screening of OSMF patients are crucial for the early detection of any malignant changes. Management should focus on habit cessation, nutritional support, and addressing fibrosis to potentially reduce the risk of malignant transformation. Complications of Oral Submucous Fibrosis (OSMF): Malignant Transformation: Development of Squamous Cell Carcinoma (SCC). The fibrosis causes chronic hypoxia and atrophy of the epithelium, making it more susceptible to carcinogens. Progressive Trismus: Increasing inability to open the mouth due to vertical fibrous bands, leading to poor oral hygiene and malnutrition. Hearing Loss: Fibrosis can involve the opening of the Eustachian tube in the nasopharynx, leading to conductive hearing loss or serous otitis media. Speech and Swallowing Defects: Involvement of the soft palate and tongue reduces mobility, causing "hot potato" voice and dysphagia. Nutritional Deficiencies: Limited intake of solid food often leads to iron and vitamin B12 deficiencies, which further thins the oral mucosa (a vicious cycle). Candidiasis (Option A): While oral candidiasis can occur in OSMF patients due to an altered oral environment, it is not considered a major complication of untreated OSMF. Bilateral submandibular gland hypertrophy (Option C) is not a typical complication of OSMF. In fact, OSMF may lead to atrophy of salivary glands rather than hypertrophy. Spontaneous remission of fibrosis (Option D): OSMF is a progressive condition and does not undergo spontaneous remission. Without intervention, the fibrosis typically worsens over time.

↑ *Back to this question in Part A*

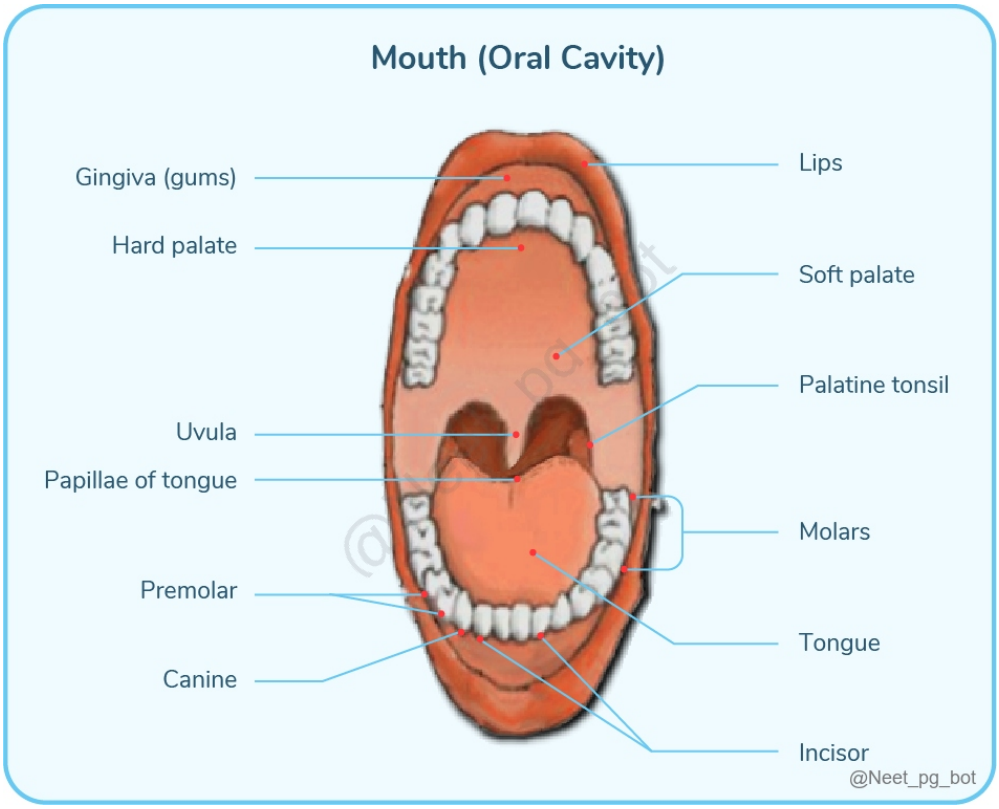
@Neet_pg_bot

Q14: Which of the following statements about the extent of the oral cavity is false? (Q849562)

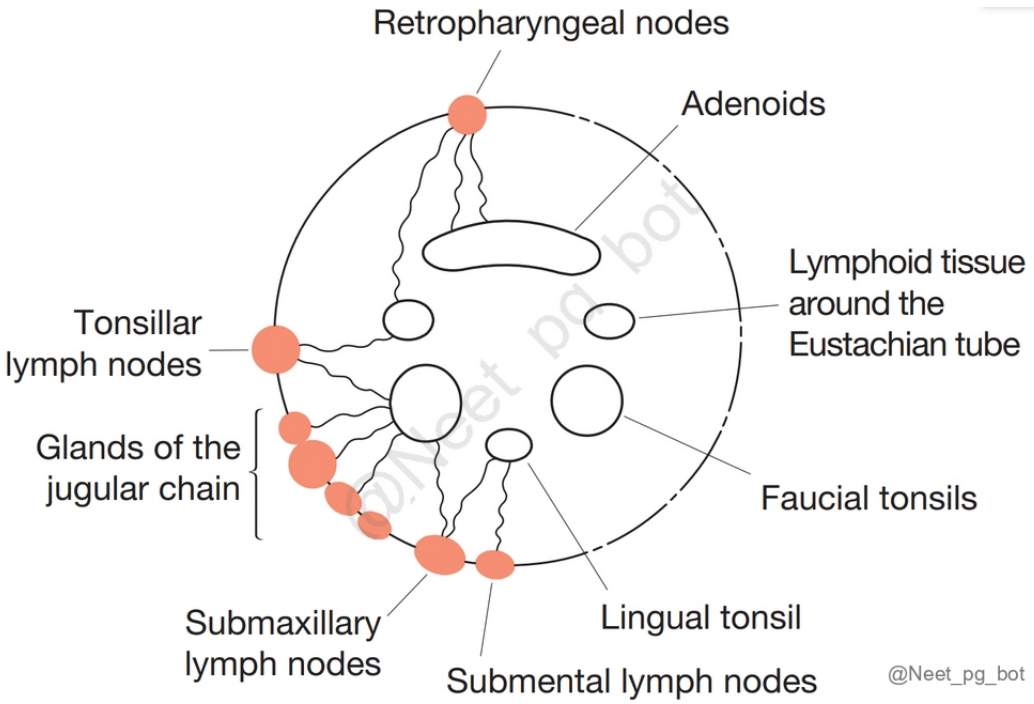
A. The anterior border of the oral cavity begins at the vermillion border.

B. Superiorly, the oral cavity includes the soft palate up to the uvula.

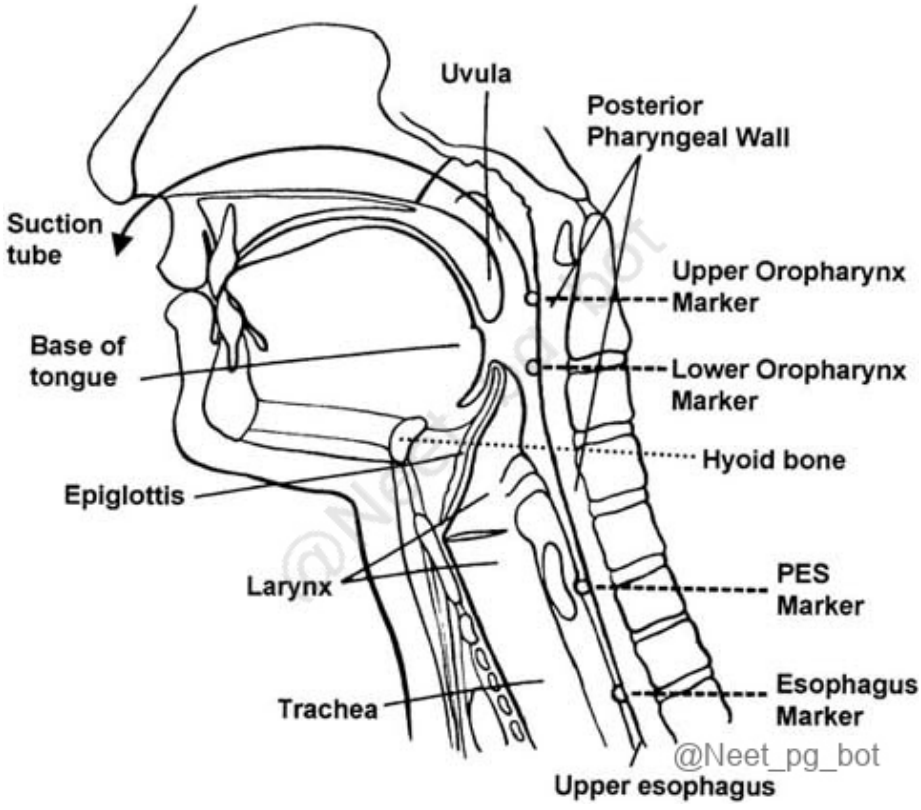
C. The posterior extent of the oral cavity ends at the circumvallate papillae of the tongue.



D. The tonsils are not a part of the oral cavity.



Correct Answer: B. Superiorly, the oral cavity includes the soft palate up to the uvula.



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The soft palate is a part of the oropharynx and is not included in the oral cavity. The extent of the oral cavity is as follows: Anteriorly, it starts from the vermillion border of the lip (Option A) . Superiorly, it extends up to the junction of hard palate and soft palate. It extends postero - inferiorly up to the junction of the anterior 2/3rd and the posterior 1/3rd of the tongue, i.e., till the circumvallate papillae (Option C) . And laterally till the anterior tonsillar pillars . The tonsils , uvula, and soft palate are part of the oropharynx, which shows different characteristics from the oral cavity. Waldeyer's ring: Posterior pharyngeal wall:

References:

Bailey & Love's Short Practice of Surgery, 28th edition, pg: 813. Schwartz Principles of Surgery, 11th edition, pg: 630.

↑ *Back to this question in Part A*

Q15: A 65-year-old patient presents with a 2.5 cm ulcerative lesion on the right side of his lower lip confirmed as squamous cell carcinoma. Which of the following statements is correct regarding the primary lymphatic drainage and surgical management of this lesion? (Q849594)

A. Drains to submental nodes; level I neck dissection is sufficient.

B. Drains to ipsilateral submandibular nodes; levels I-III neck dissection is recommended.

C. High risk of contralateral metastasis; bilateral neck dissection is needed.

D. Drains to preauricular and parotid nodes; requires superficial parotidectomy.

Correct Answer: B. Drains to ipsilateral submandibular nodes; levels I-III neck dissection is recommended.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The lymphatic drainage of the lower lip is primarily to the submental (level IA) and submandibular (level IB) nodes . There's a significant risk of occult nodal metastasis for a lesion of this size, especially one close to the commissure. Therefore, a selective neck dissection, including levels I-III on the ipsilateral side, is typically recommended even in N0. Management 1. Early Stage (T1-T2N0): Wide local excision with 1 cm margins Consider elective neck dissection for tumors >2 cm or >4 mm depth Reconstruction: Primary closure, local flaps, or skin grafts 2. Advanced Stage (T3-T4 or N+): Wide local excision with ≥1 cm margins Neck dissection (comprehensive or selective based on nodal status) Complex reconstruction (local/regional flaps, free tissue transfer) Adjuvant radiotherapy or chemoradiotherapy based on pathological findings 3. Management of the Neck: Elective neck dissection for high-risk tumors (>2 cm, >4 mm depth) Therapeutic neck dissection for clinically positive nodes Levels typically addressed: I-III for N0 neck, I-V for N+ neck Other options: Option A: Drains to submental nodes; level I dissection is sufficient Submental (Ia) drainage is more typical for midline lower-lip lesions. A 2.5 cm lateral lesion drains primarily to Ib, and Level I alone is inadequate. Option C: Bilateral neck dissection is needed Contralateral metastasis is uncommon except in midline or advanced (T3/T4) lesions. This lesion is lateral → unilateral dissection is adequate. Option D: Drains to preauricular/parotid nodes These nodes are involved in upper lip, cheek, and cutaneous facial SCC, not lower lip. Parotidectomy is not indicated.

References:

Sabiston Textbook of Surgery, 21st edition, Pages: 777, 779. SRB’s Manual of Surgery, Edition 6, page no 375,376

↑ *Back to this question in Part A*

Q16: A 72-year-old farmer presents with a 3.5 cm exophytic lesion on his lower lip. Biopsy confirms well-differentiated squamous cell carcinoma with 8 mm depth of invasion. There are no palpable lymph nodes. Which of the following is the correct management strategy? (Q849593)

A. Wide local excision with 5 mm margins and neck observation.

B. Wide local excision with 1 cm margins and ipsilateral neck dissection.

C. Wide local excision with 1 cm margins and bilateral neck dissection.

D. Radiotherapy alone.

Correct Answer: B. Wide local excision with 1 cm margins and ipsilateral neck dissection.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: For a T2 lesion (>2 cm but ≤4 cm) with >5 mm depth of invasion, wide local excision with at least 1 cm margins is recommended. The risk of occult cervical metastasis is 20–30% . Therefore, ipsilateral selective neck dissection (levels I-III) is appropriate for unilateral lesions not crossing the midline even when neck is clinically N0 Management of Carcinoma lip: Early Stage (T1-T2N0) Wide local excision with 1 cm margins Consider elective neck dissection for tumors >2 cm or >4 mm depth Reconstruction: Primary closure, local flaps, or skin grafts Advanced Stage (T3-T4 or N+) Wide local excision with ≥1 cm margins Neck dissection (comprehensive or selective based on nodal status) Complex reconstruction (local/regional flaps, free tissue transfer) Adjuvant radiotherapy or chemoradiotherapy based on pathological findings Reconstruction Options Wedge excision and primary closure (for small lesions) Local flaps: Abbe-Estlander, Karapandzic, nasolabial Regional flaps: Forehead, cervicofacial Free tissue transfer: Radial forearm free flap, anterolateral thigh flap Management of the Neck Elective neck dissection for high-risk tumors (>2 cm, >4 mm depth) Therapeutic neck dissection for clinically positive nodes Levels typically addressed: I-III for N0 neck, I-V for N+ neck Radiotherapy Adjuvant: For positive margins, perineural invasion, multiple positive nodes Definitive: For patients unfit for surgery or refusing surgery Brachytherapy: Can be considered for select early-stage lesions Chemotherapy Not routinely used in early-stage disease May be combined with radiotherapy in locally advanced cases Follow-up and Surveillance Regular follow-up visits: Every 1-3 months for the first year, then gradually decreasing frequency Wide local excision with 5 mm margins and observation (Option A): A 5 mm margin is insufficient for invasive SCC of this size. Observation is unsafe because depth >4 mm warrants neck management. Wide local excision with 1 cm margins and bilateral neck dissection (Option C): Bilateral neck dissection is not indicated unless midline involvement or clinical nodal disease is present. The lesion is unilateral, so ipsilateral dissection is adequate. Radiotherapy alone (Option D): RT is reserved for medically unfit patients or for adjuvant therapy. Primary RT is inferior to surgery in resectable lip cancers.

Sabiston Textbook of Surgery, 21st edition, Pages: 777, 779.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 62-year-old male with recurrent squamous cell carcinoma of the oral cavity is being considered for immunotherapy using pembrolizumab. Which of the following correctly describes the mechanism of action of the drug? (Q849592)

A. Inhibits VEGF to prevent tumor angiogenesis

B. Blocks PD-1 receptor, enhancing T-cell anti-tumor activity

C. Targets EGFR to inhibit tumor cell proliferation

D. Activates NK cells to induce antibody-dependent cellular cytotoxicity

Correct Answer: B. Blocks PD-1 receptor, enhancing T-cell anti-tumor activity

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Pembrolizumab is a monoclonal antibody that targets the programmed cell death-1 (PD-1) receptor. By blocking PD-1, it prevents the interaction between PD-1 and its ligands (PD-L1 and PD-L2). This blockade enhances T-cell function and anti-tumor immune responses. In oral cavity cancers, this leads to improved tumor cell recognition and destruction by the immune system. Inhibiting VEGF to prevent tumor angiogenesis (Option A) is the mechanism of action for drugs like bevacizumab. Targeting EGFR to inhibit tumor cell proliferation (Option C) describes the mechanism of action for cetuximab. Activating NK cells to induce antibody-dependent cellular cytotoxicity (Option D) is more closely associated with drugs like cetuximab, which can induce ADCC.

Bailey & Love's Short Practice of Surgery, 28th Edition, 830.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 59-year-old male with T2N2bM0 squamous cell carcinoma of the buccal mucosa underwent surgery. The postoperative histopathology report reveals close surgical margin (< 5 mm) and extracapsular extension in two lymph nodes. What is the most appropriate adjuvant treatment for this patient? (Q849591)

A. Radiotherapy alone

B. Chemotherapy alone

C. Concurrent chemoradiotherapy

D. Observation and close follow-up

Correct Answer: C. Concurrent chemoradiotherapy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Concurrent chemoradiotherapy is the most appropriate adjuvant treatment for this patient due to the presence of high-risk features: close surgical margins and extracapsular extension (ECE) in lymph nodes. In this case, the close margin and ECE in multiple nodes warrant the addition of chemotherapy to radiotherapy to improve locoregional control and overall survival. Indications for Adjuvant Therapy: Therapy Indications Radiotherapy alone Intermediate risk features: T3 or T4a primary tumors N2 or N3 nodal disease (without extracapsular extension) Perineural invasion Lymphovascular invasion Single node >3 cm or multiple positive nodes Close margins (between 5mm and 1cm) Concurrent chemoradiotherapy High-risk features: Positive surgical margins Extracapsular extension of nodal disease T4b tumors N3 nodal disease Multiple positive nodes with extracapsular extension Specific indications pT3 or pT4 primary tumors N2 or N3 neck disease Perineural invasion Vascular embolism Lymphatic invasion Considerations for chemotherapy addition Age <70 years Good performance status No significant comorbidities

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 829.

↑ *Back to this question in Part A*

@Neet_pg_bot

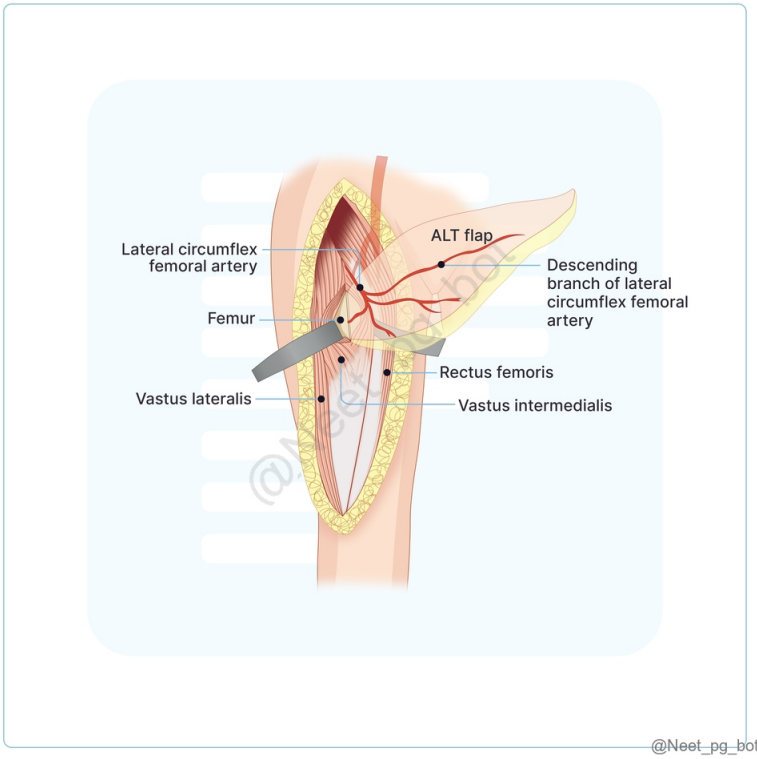
Q19: A 58-year-old male with a 6 cm x 4 cm defect involving more than 50% of the tongue after excision for a T3N1M0 squamous cell carcinoma needs reconstruction. Which of the following flaps would be most appropriate for reconstruction for this patient? (Q849590)

A. Radial forearm free flap

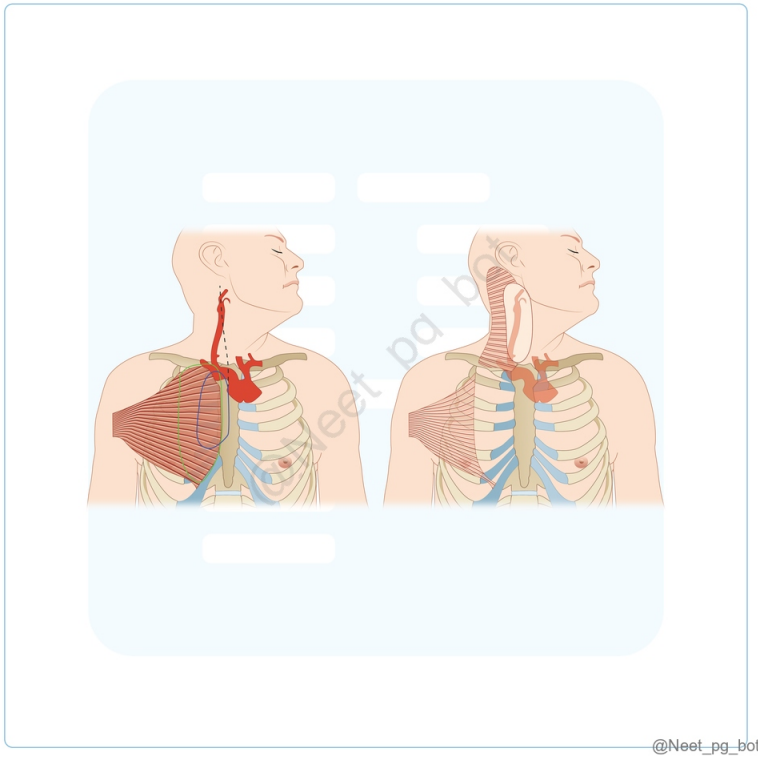
B. Anterolateral thigh free flap

C. Pectoralis major myocutaneous flap

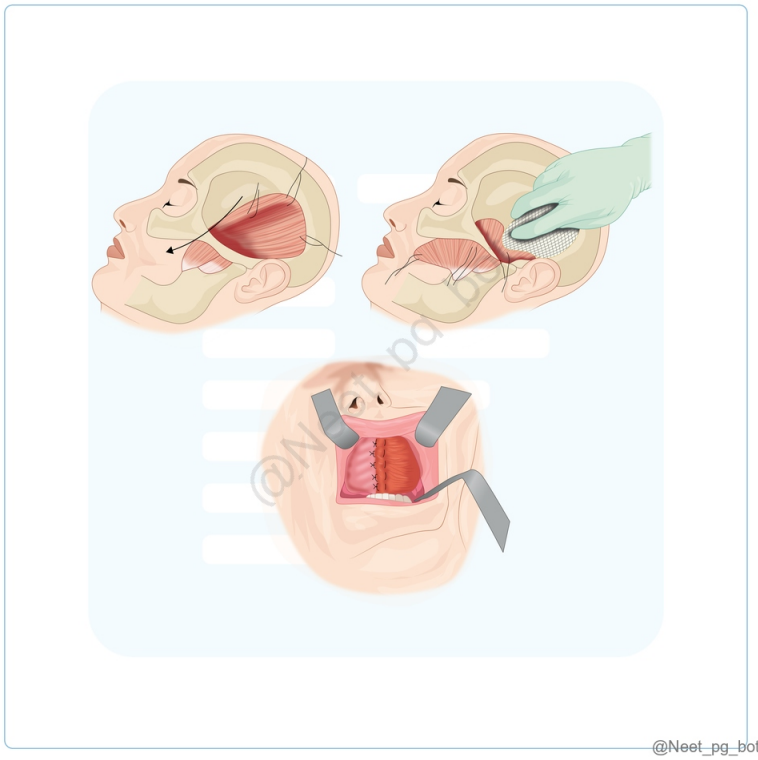
D. Supraclavicular artery island flap



Correct Answer: A. Radial forearm free flap



■ *Listen (English)*



■ *Listen (Hindi)*

Explanation: The radial forearm free flap (RFFF) is the most appropriate choice for reconstructing this oral cavity defect involving a significant portion of the mobile tongue. In this case, where more than 50% of the mobile tongue is involved, the RFFF would provide the best functional outcome in terms of speech and swallowing. The RFFF is considered the gold standard for tongue reconstruction due to its: Thin and pliable nature, allowing for better mobility and articulation Long vascular pedicle, facilitating easier anastomosis Large surface area that can be harvested Minimal bulk, which is crucial for preserving tongue function Ability to provide sensate reconstruction if needed Anterolateral Thigh (ALT) Free Flap (Option B): Versatile for larger defects of the mandible, floor of mouth, or pharynx, especially in patients who are poor candidates for free flap surgery. Can be thinned for intraoral use. Minimal donor site morbidity Fibula Free Flap: Gold standard for mandibular reconstruction. Can provide bone, muscle, and skin. Pectoralis Major Myocutaneous Flap (Option C): Workhorse pedicled flap for head and neck. Useful for salvage cases or when free flaps are contraindicated. Submental Island Flap: Regional flap for small to medium intraoral defects. Good color match for facial skin. Temporalis Muscle Flap: For palate and maxillary defects. Proximity to defect site. Supraclavicular artery island flap (Option D) is a regional flap that, while useful for some head and neck reconstructions, lacks the pliability and thinness required for optimal tongue reconstruction. It's more suitable for cutaneous defects of the face and neck.

@Neet_pg_bot

Q20: A 62-year-old male presents with a T2N1M0 squamous cell carcinoma of the lateral border of the tongue. According to the latest National Comprehensive Cancer Network (NCCN) guidelines, what is the most appropriate initial management for this patient? (Q849589)

A. Wide local excision of the primary tumor only.

B. Definitive radiotherapy with concurrent chemotherapy.

C. Surgery followed by adjuvant radiotherapy.

D. Neoadjuvant chemotherapy followed by surgery.

Correct Answer: C. Surgery followed by adjuvant radiotherapy.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: According to the AJCC classification, T2N1M0 squamous cell carcinoma of the tongue is Stage III . The correct treatment for this T2N1M0 with Stage III squamous cell carcinoma of the tongue is surgery followed by adjuvant radiotherapy. For T2N1M0 oral cavity cancers, the standard of care is surgical resection of the primary tumor with appropriate margins, along with neck dissection for the clinically positive lymph nodes. Adjuvant radiotherapy is typically recommended for patients with intermediate to high-risk features, which include positive lymph nodes. Preservation of radiotherapy as an adjuvant treatment, which can address microscopic disease and reduce the risk of locoregional recurrence. Multidisciplinary approach for oral cancer: Stage Treatment Early-stage (I-II) Surgery is the mainstay of treatment. Radiotherapy can be an alternative in select cases. Locally advanced (III-IVA/B) Resectable: Surgery followed by adjuvant therapy (radiotherapy or chemoradiotherapy) based on pathological risk factors. Unresectable: Concurrent chemoradiotherapy or radiotherapy alone for patients unfit for chemotherapy. Metastatic (IVC) Palliative chemotherapy, immunotherapy, or best supportive care. Surgical management: Wide local excision with 1-1.5 cm margins Neck dissection for clinically node-positive disease and elective neck dissection for high-risk node-negative disease Reconstruction to optimize functional and aesthetic outcomes. Adjuvant Therapy in Oral Cavity Cancer: Adjuvant therapy refers to additional treatment given after primary treatment (usually surgery) to reduce the risk of cancer recurrence. In oral cavity cancer, it typically involves radiation therapy, chemotherapy, or a combination of both. Risk Category Pathological Findings Recommended Adjuvant Therapy High Risk Positive Margins or Extracapsular Spread (ECS/ENE) Chemoradiotherapy (CRT) (Cisplatin + Radiation) Intermediate Risk T3/T4 primary, N2/N3 nodes, PNI, or LVSI Radiotherapy (RT) alone Low Risk T1/T2, negative margins, N0, no PNI/LVSI Observation PNI: Perineural Invasion LVSI: Lymphovascular Space Invasion ENE: Extranodal Extension (the most significant negative prognostic factor) Risk Factors for Oral Cavity SCC: External Carcinogens Tobacco: The most common risk factor (synergistic with alcohol). Alcohol: Acts as a solvent for tobacco carcinogens and produces acetaldehyde. Betel Quid/Areca Nut: Specific to South Asia; leads to Oral

Submucous Fibrosis . UV Radiation: Primarily for Lip Cancer . Biological/Other Factors HPV (Human Papillomavirus): While strongly linked to Oropharyngeal cancer (tonsils/base of tongue), it is less common in the Oral Cavity (mobile tongue/floor of mouth). Chronic Irritation: Ill-fitting dentures or jagged teeth (minor risk). Diet: Low intake of fruits and vegetables (Vitamin A/C deficiency). Immunosuppression: Post-transplant patients have higher rates of aggressive SCC.

@Neet_pg_bot

Q21: A male presents with a painful 2.5 cm ulceroproliferative growth on the right lateral border of the tongue with induration extending to the floor of the mouth and a single, firm, mobile 1.5 cm lymph node palpable in the right submandibular region. The CT scan shows no mandible or extrinsic muscle involvement. What is the correct TNM staging for this patient? (Q849570)

A. T2N1M0

B. T3N1M0

C. T4aN1M0

D. T2N2aM0

Correct Answer: A. T2N1M0

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The correct staging for this patient's oral cavity cancer is T2N1M0. Staging of Oral Cavity Cancer (AJCC 8th Edition): T (Primary Tumor): Tx: Primary tumor cannot be assessed. Tis: Carcinoma in situ. T1: Tumor ≤2 cm, ≤5 mm depth of invasion (DOI). T2: Tumor ≤2 cm, DOI >5 mm and ≤10 mm; or tumor >2 cm but ≤4 cm , and ≤10 mm DOI. T3: Tumor >4 cm; or any tumor >10 mm DOI. T4a: Moderately advanced local disease - Invades through cortical bone, deep/ extrinsic muscle of tongue, maxillary sinus, or skin of the face. T4b: Very advanced local disease - Invades masticator space, pterygoid plates, skull base, or encases internal carotid artery. N (Regional Lymph Nodes): Nx: Regional lymph nodes cannot be assessed. N0: No regional lymph node metastasis. N1: Metastasis in a single ipsilateral lymph node , ≤3 cm in greatest dimension . N2: N2a: Metastasis in a single ipsilateral node, >3 cm but ≤6 cm in greatest dimension. N2b: Metastasis in multiple ipsilateral nodes, all ≤6 cm). N2c: Metastasis in bilateral or contralateral lymph nodes, all ≤6 cm. N3: N3a: Metastasis in a lymph node >6 cm in greatest dimension, ENE(-). N3b: Metastasis in any node(s) with clinically overt ENE(+). M (Distant Metastasis): M0: No distant metastasis M1: Distant metastasis Stage Grouping: Stage 0 Tis N0 M0 Stage I T1 N0 M0 Stage II T2 N0 M0 Stage III T3 N0 M0 or T1-3 N1 M0 Stage IVA T4a N0-1 M0 or T1-4a N2 M0 Stage IVB

Any T N3 M0 or T4b Any N M0 Stage IVC Any T Any N M1

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: A 55-year-old patient presents with a non-healing ulcer in the oral cavity and is diagnosed with carcinoma oral cavity. Which of the following statements regarding carcinoma oral cavity is most accurate? (Q849569)

A. Distant metastasis is common.

B. Ulcer lasting over 3 weeks is significant.

C. Adenocarcinoma is the most common oral cancer.

D. Oral carcinoma is the least common among head and neck tumors.

Correct Answer: B. Ulcer lasting over 3 weeks is significant.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Clinical features of oral carcinoma: Signs Symptoms Non-healing ulcer (>3 weeks duration) (Option B) Persistent neck swelling/ lymphadenopathy Pigmented lesion with a progressive increase in size Lesion with associated induration Soft-tissue lesion with associated radiographic changes Unexplained tooth mobility Sensory nerve deficit Chronic otalgia Trismus of unknown etiology Dysphagia Sore tongue Metastasis : HPV-negative cervical node metastasis has a bad prognosis. Most metastases occur in Level I and Level II on neck lymph nodes. Distant metastasis is rare (Option A) Adenocarcinoma is the most common oral cancer (Option C): The most common cancer of the oral cavity is squamous cell carcinoma, not adenocarcinoma. Oral carcinoma is the least common among head and neck tumors (Option D): Oral carcinoma is the most common head and neck tumor.

References:

Bailey and Love’s Short Practice of Surgery, 28th edition, pg: 818. Sabiston’s principles of surgery, 21st edition, pg: 778. SRB’s textbook of surgery, 6th edition, pg: 363.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A patient who had developed a buccal squamous cell carcinoma was treated by complete resection and radiation therapy. After his treatment was completed and he had clear margins after the resection, he developed a new tumor in his oral cavity on his tongue. What is the basis of this development of a second primary tumor? (Q849568)

A. Field defect

B. Field effect

C. Field cancerization

D. All of the above

Correct Answer: D. All of the above

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Field cancerization, field defect, or field effect refers to the condition in which a particular site is completely exposed to carcinogens often and hence has a tendency to develop a malignancy entirely or at multiple sites instead of at just one focal point. This explains the recurrence of tumors and the development of second primary tumors after the removal of the first, particularly in the oral cavity. Field cancerization is a process of transforming a precancerous lesion into a cancerous one. Prolonged exposure to carcinogens like tobacco and alcohol in the oral cavity leads to widespread epithelial changes, resulting in multifocal carcinoma. Criteria for a second primary to be due to field cancerization: The neoplasm must be distinct and anatomically separate (dysplastic mucosa around a tumor depicts a multicentric primary neoplasm and not a new primary tumor). A potential second primary due to metastasis or local relapse must be excluded (tumor after 3 years of first diagnosis or new tumor at least 2cm of normal epithelium away from the first one).

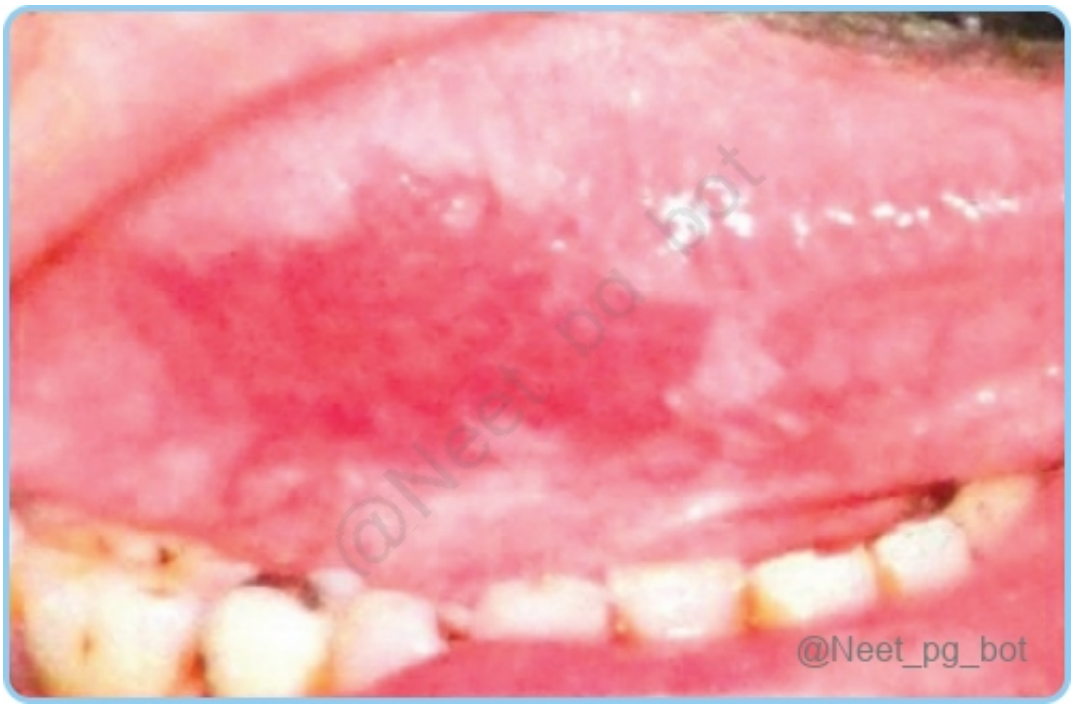
https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4419611/

↑ *Back to this question in Part A*

@Neet_pg_bot



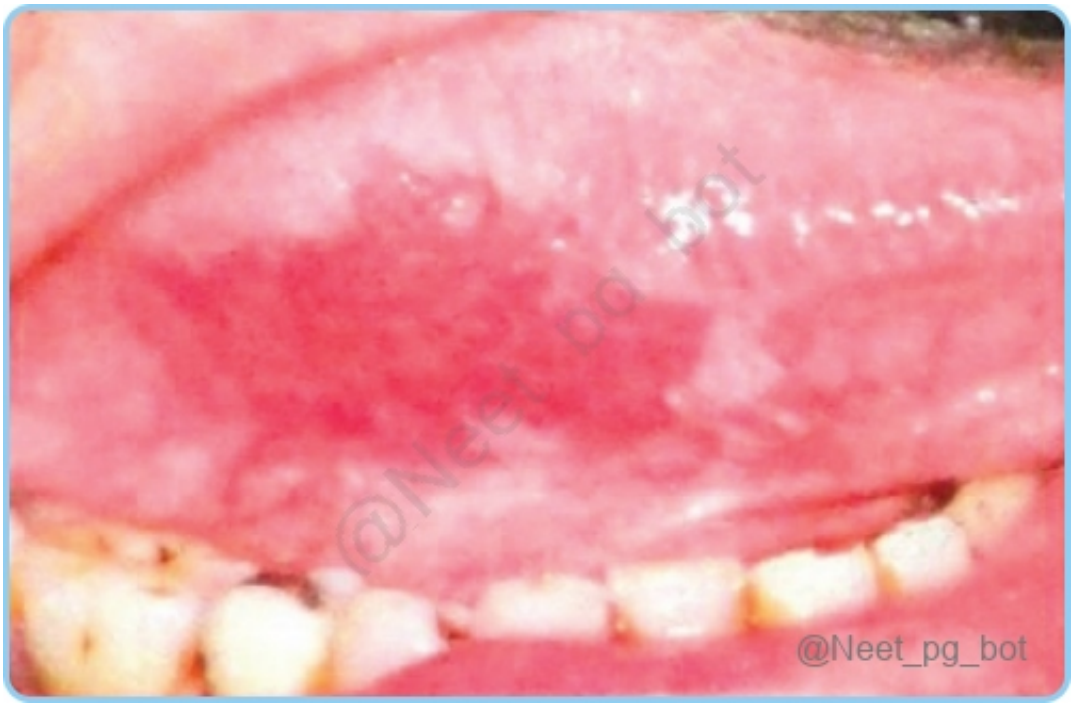
Q24: A 45-year-old female comes to the clinic with a reddish patch on her tongue, as shown in the figure. She gives a history of chewing pan masala for more than 15 years. She has no difficulty in opening her mouth and has no other comorbidities. What is the most probable diagnosis? (Q849565)

A. Oral submucosal fibrosis

B. Erythroplakia

C. Plummer-Vinson syndrome

D. Leukoerythroplakia



Correct Answer: B. Erythroplakia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The condition here is erythroplakia. Erythroplakia is a bright red velvety plaque that cannot be characterized clinically or pathologically as any other disease. Has a higher malignant potential than leukoplakia. Types : Homogenous Speckled Granular Erythroplakia interspersed with leukoplakia Management : Biopsy for diagnosis Surgical excision Strict follow-up

References:

SRB's Textbook of Surgery, 6th edition, pg: 360, 791.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: A 50-year-old patient comes to the OPD concerned about a newly developed whitish discolouration in his mouth. On examination, a white plaque-like lesion was found in his buccal mucosa, which could not be rubbed off. What is the most likely diagnosis? (Q849564)

A. Leukoplakia

B. Erythroplakia

C. Speckled leukoplakia

D. Chronic hyperplastic Candidiasis

Correct Answer: A. Leukoplakia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical scenario here points to the diagnosis of leukoplakia . Leukoplakia is defined as a white patch or plaque that cannot be rubbed off, and cannot be characterized clinically or pathologically as any other disease. It is a premalignant lesion and is painless/non-tender . Types : Homogenous Nodular Speckled Hairy:

Associated with EBV. It is not actually hairy but appears so due to the corrugation caused by severe hyperkeratosis and acanthosis. Common in AIDS patients. Management : Biopsy to rule out carcinoma and confirm diagnosis. Stop smoking/ alcohol/ betel quid. Excision, skin grafting if needed. Regular follow-up. Isotretinoin, tocopherol, and beta-carotene. CO2 laser.

References:

Bailey & Love's Short Practice of Surgery, 28th edition, pg: 815. SRB's textbook of Surgery, 6th edition, pg: 359, 360,361.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q26: A 45-year-old male comes to the hospital after noticing abnormal growth on the right side of his mouth. He has had a habit of smoking and chewing betel quid for more than 20 years. On further evaluation, he also gives a history of a red lesion present in the same location before the current state. Which of the following, in this case, is not a risk factor for oral carcinoma? (Q849563)

A. Age above 40 years

B. Erythroplakia

C. Smoking

D. Betel quid

Correct Answer: A. Age above 40 years

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In the above scenario, the patient's age is not a factor in increasing the risk of oral carcinoma. Oral carcinoma is one of the most common cancers in India. Risk factors: Tobacco/ pan masala (Option C) Alcohol Betel quid(areca nut, catechu, slaked lime wrapped in a piper betel leaf) (Option D) Previous exposure to radiation Chronic infections Immunosuppression Hereditary diseases like Fanconi anemia and Li-Fraumeni syndrome. Active HPV Premalignant lesions Potentially/premalignant lesions: Leukoplakia Erythroplakia (Option B) Erythroleukoplakia Proliferative verrucous leukoplakia (PVL) Oral submucous fibrosis Oral lichen planus Lupus erythematosus Epidermolysis bullosa Dyskeratosis congenita

Q19 (p. 1266)

Q1: A 45 y/o woman undergoes a superficial parotidectomy for a pleomorphic adenoma. Which of the following is a known complication associated with this condition or its treatment? (Q849649)

A. Permanent facial nerve paralysis is common after parotidectomy.

B. Pleomorphic adenomas rarely recur after surgical excision.

C. Radiotherapy for pleomorphic adenoma is risk-free and only used as a primary treatment.

D. Frey’s syndrome is characterized by sweating and flushing in the preauricular area during meals.

Correct Answer: D. Frey’s syndrome is characterized by sweating and flushing in the preauricular area during meals.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Frey’s syndrome, also known as gustatory sweating, can occur after parotidectomy due to aberrant nerve regeneration, leading to sweating and flushing in the preauricular area during meals. This complication has an incidence of about 10%. Complications of Pleomorphic Adenoma: Tumor-related Complications: Recurrence: Pleomorphic adenomas can recur after surgery (Option B) , especially if not completely excised. Factors contributing to recurrence include tumour spillage during surgery, inadequate surgical margins, and microscopic extensions (pseudopods). Malignant Transformation: Although typically benign, pleomorphic adenomas can undergo malignant transformation into carcinoma ex pleomorphic adenoma. This risk increases in long-standing tumours (over 15 years) or recurrent tumours, with a risk exceeding 15%. Indicators of malignant transformation include sudden tumour growth, pain, tissue fixation, skin ulceration, and facial nerve involvement. Treatment-Related Complications: Surgical Complications (Parotidectomy): Facial Nerve Injury: Common (30% temporary weakness), but permanent paralysis can occur (rarely). (Option A) Risk factors include tumour size, location, and surgical technique. Hemorrhage: Significant bleeding is rare but may require transfusion or re-operation. Infection: Postoperative infection risk can be minimized with sterile techniques and prophylactic antibiotics. Sialocele: Accumulation of saliva in tissue pockets due to duct damage during surgery. Frey's

Syndrome: Characterized by sweating, flushing, and pain in the preauricular area during meals, with a 10% incidence. Cosmetic Deformities: Includes scarring, hollowing of the retromandibular area, and earlobe numbness due to great auricular nerve injury. Complications of Other Treatments: Radiotherapy (Option C): Used in cases of recurrence, high-grade transformation, or incomplete excision. Risks include xerostomia, damage to surrounding tissues, and potential secondary malignancies. Fine-Needle Aspiration Cytology (FNAC): Generally safe, but can cause bleeding or, rarely, tumour seeding along the needle track.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 28-y/o male presents with a painless, soft swelling in the submandibular region that has been gradually enlarging over the past 2 months. On examination, the swelling is dumbbell-shaped, fluctuant, and bidigitally palpable. The overlying mucosa appears thick with a bluish hue. Fine needle aspiration yields a viscous, "egg white-like" fluid with high amylase content, confirming the diagnosis. What is the most appropriate treatment for this patient? (Q849658)

A. Incision and drainage of the cyst

B. Marsupialization (unroofing) of the ranula

C. Surgical excision of the ranula and involved sublingual gland

D. Observation and follow-up

Correct Answer: C. Surgical excision of the ranula and involved sublingual gland

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical scenario suggests that this is a case of plunging ranula. Surgical excision of both the ranula and the involved sublingual gland is the definitive treatment. This approach reduces the risk of recurrence and addresses the underlying cause of the ranula. Plunging Ranula Definition When a ranula extends into the submandibular region through the deeper part of the posterior margin of the mylohyoid muscle it is called a plunging ranula. Key Features Painless, soft, fluctuant dumbbell-shaped swelling in the submandibular region or sublingual area. It is bidigitally palpable. May have a bluish hue and thick overlying mucosa. Often presents with both oral and cervical components. Typically occurs in the third decade of life. Diagnosis Based on history, clinical features, and imaging. Fine needle aspiration yields a viscous, "egg white-like" fluid with high amylase content. Ultrasonography or CT shows a well-circumscribed cystic mass extending through the mylohyoid muscle. Treatment Surgical excision of the ranula and involved sublingual gland is the definitive treatment. Recurrence is

possible if the sublingual gland is not completely removed. Incision and drainage of the cyst (Option A) may provide temporary relief but are not definitive treatments for a plunging ranula. This approach does not address the underlying cause and is associated with a high risk of recurrence. Marsupialization (unroofing) of the ranula (Option B): While marsupialization can be used for smaller ranulas, it is less effective for plunging ranulas, which often require complete excision to prevent recurrence. Observation and follow-up (Option D): Observation alone is not appropriate for a plunging ranula, as the cyst is likely to continue growing and causing further symptoms. Definitive surgical treatment is required to prevent complications and recurrence.

www.ncbi.nlm.nih.gov/pmc/articles/PMC3303342/

www.ncbi.nlm.nih.gov/pmc/articles/PMC5771944/

SRB's Manual of Surgery, 6th Edition, Page 357

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 16 y/o female has a painless, soft, fluctuant swelling in the anterior floor of her mouth that has increased in size over a few weeks. There is no history of trauma or infection. What is the most appropriate next step in confirming the diagnosis? (Q849657)

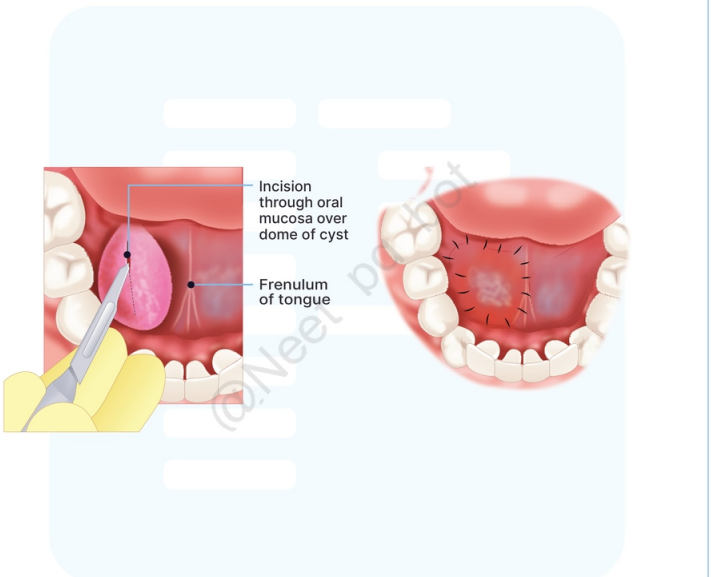
A. Magnetic Resonance Imaging

B. Computed Tomography

C. Incisional biopsy

D. Aspiration of the lesion

Correct Answer: A. Magnetic Resonance Imaging



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: MRI is the most appropriate imaging modality to confirm the diagnosis of a ranula. It provides detailed information about the extent of the lesion and helps differentiate it from other lesions, such as lymphangiomas. Ranula Definition Ranulas are a type of extravasation mucocele , caused by the rupture of the main duct or obstructed acini of the sublingual gland. They appear as bluish swellings on the floor of the mouth and resemble the belly of a frog. Location Commonly found in the anterior floor of the mouth. When it extends through the mylohyoid muscle, it presents as a submental swelling known as a "plunging ranula." Symptoms Typically soft, fluctuant, and painless unless infected. Diagnosis Confirmed through Magnetic Resonance Imaging (MRI) Ultrasound Aspiration of thick sticky saliva differentiates it from a lymphangioma. Treatment Removal of the sublingual gland is preferred. Incision, drainage, and marsupialization have low success rates. Although marsupialization is often adequate, it has a higher recurrence rate compared to sublingual gland excision. OK-432 injection Botulinum toxin injections CT (Option B): Although CT can be used to visualize the lesion, MRI is preferred due to its superior soft tissue contrast and ability to better delineate the extent of the lesion, especially in cases of plunging ranulas. Incisional biopsy (Option C) is generally not indicated for diagnosing a ranula. The

diagnosis is typically made based on clinical presentation and imaging. Biopsy may be reserved for atypical cases where malignancy or another condition is suspected. Aspiration of the lesion (Option D): Aspiration of thick sticky saliva can help differentiate a ranula from a lymphangioma. However, it is often used as a supplementary diagnostic method alongside imaging, rather than the first line of investigation.

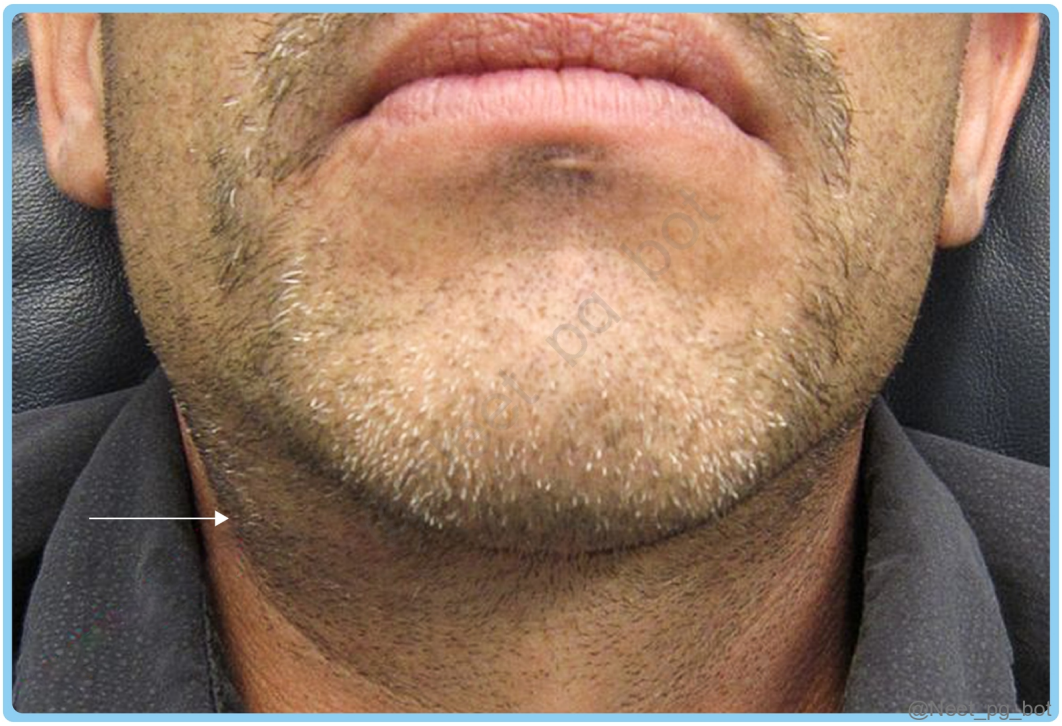
↑ *Back to this question in Part A*

@Neet_pg_bot



Q4: A 52 y/o male has recurrent pain and swelling in the left lower jaw, worsening over several months. On examination, there is a significant swelling of the right submandibular gland, but no palpable stone. A CT scan shows an 8 mm stone deep within the submandibular gland, inaccessible by sialendoscopy. What is the best next step in management? (Q849656)

A. Endoscopic removal of the stone

B. Ductal slitting for stone extraction

C. External shock wave lithotripsy (ESWL)

D. Gland excision

Correct Answer: C. External shock wave lithotripsy (ESWL)

- *Listen (English)*
- *Listen (Hindi)*

Explanation: ESWL is an appropriate treatment for larger stones (7–10 mm) that are not easily accessible via endoscopy. It uses shock waves to break the stone into smaller fragments that can then pass through the duct or be removed by other means. Sialolithiasis Definition Formation of salivary gland stones within the gland ducts Commonly Affected Age 30 to 60 years Commonly Affected Gland Submandibular gland (85%), due to its ascending duct course and the mucinous, viscous saliva it produces, leads to stagnation and stone formation. Risk Factors Duct abnormalities Inflammation Increased calcium content in saliva Chronic dehydration Medications causing decreased salivary flow Clinical Features Cyclical postprandial swelling, dryness, asymmetrical gland enlargement, palpable stone, possible abscess formation. Submandibular Swelling Diagnostic Methods Conventional Radiographs : Initial diagnostic test, but may miss small stones. CT Scanning, USG, Magnetic Resonance Sialogram : More sensitive, especially for small stones. Sialography : Gold standard; involves dye injection for diagnosis and potential therapeutic use. Sialendoscopy : Direct visualization and removal of stones, safer than open surgery. CT- Wharton’s duct Sialolithiasis Treatment Options Small Distal Stones (<5 mm) : Endoscopic removal (Option A) Large Distal Stones (>5 mm) : Duct slitting (Option B) Impacted Stones : Transoral route Intraparenchymal Stones (5–7 mm) : Endoscopic extraction Large Stones (7-10 mm) : May require transoral slitting or external shock wave lithotripsy (ESWL) Hilar Stones : Endoscopic removal Gland Removal : Last resort if other treatments fail (Option D)

Wharton's duct Sialolithiasis

@Neet_pg_bot

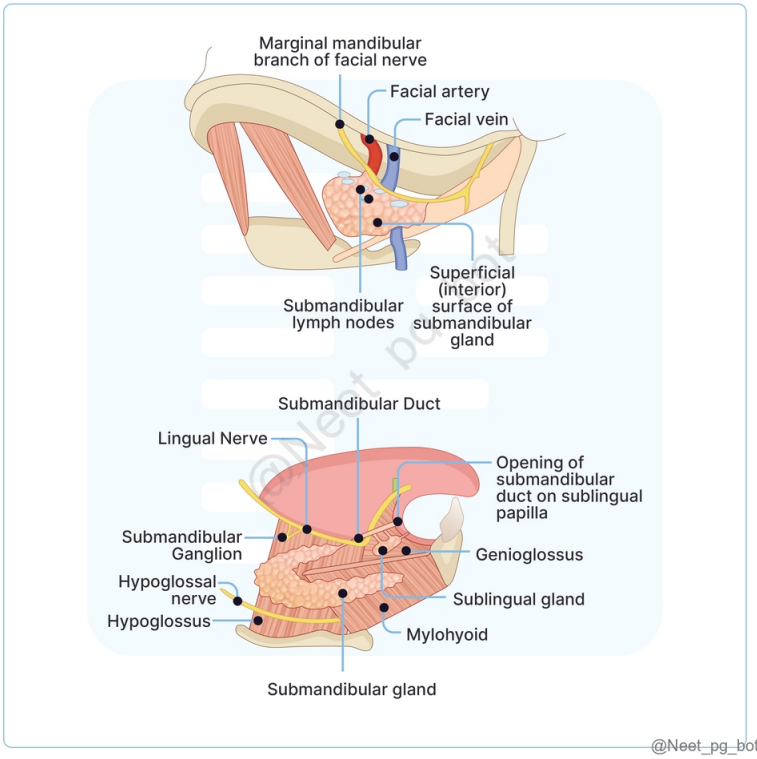
Q5: A 45 y/o woman is undergoing surgery for the removal of a submandibular gland mass. Postoperatively, she complains of numbness and a burning sensation of her tongue. Which nerve is most likely to have been injured during the procedure? (Q849655)

A. Facial Nerve

B. Lingual Nerve

C. Hypoglossal Nerve



D. Glossopharyngeal Nerve

Correct Answer: B. Lingual Nerve

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The lingual nerve , a branch of the mandibular division of the trigeminal nerve (V3), is the most commonly injured nerve during submandibular gland surgery. This is due to its course, which brings it into proximity to the submandibular gland and its duct, making it highly susceptible to damage during surgical procedures in this area. The lingual nerve originates from the posterior division of the mandibular nerve (V3) in the infratemporal fossa. It then descends and moves forward, initially positioned medially to the lateral pterygoid muscle and deep to the ramus of the mandible. As it enters the floor of the mouth, it lies superficial to the hyoglossus muscle and deep to the submandibular duct. The nerve loops under the duct, passing from lateral to medial, before ascending to supply sensory innervation to the anterior two-thirds of the tongue. This intricate course places the lingual nerve close to the submandibular gland, making it particularly susceptible to injury during surgical procedures in this area. Facial Nerve (Option A): The facial nerve is responsible for motor innervation to the muscles of facial expression. It is more commonly at risk during parotid gland surgeries rather than submandibular gland surgeries . Hypoglossal Nerve (Option C): The hypoglossal nerve supplies motor innervation to the muscles of the tongue. While it runs near the submandibular gland, it is usually located deeper and more posteriorly compared to the lingual nerve, making it less likely to be injured during submandibular gland surgery. Glossopharyngeal Nerve (Option D): The glossopharyngeal nerve primarily provides sensory innervation to the oropharynx and the posterior third of the tongue. It is anatomically distant from the submandibular gland and is not typically at risk during submandibular gland surgery.

@Neet_pg_bot

Q6: A 60 y/o man with a diagnosis of adenoid cystic carcinoma has undergone surgical resection of a tumour located in the palate. Postoperative imaging reveals no residual tumour but shows the involvement of regional lymph nodes. What is the most appropriate additional treatment for this patient? (Q849654)

A. Additional surgical resection

B. External beam radiotherapy

C. Preoperative chemotherapy

D. Observation and regular follow-up

Correct Answer: B. External beam radiotherapy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: External beam radiotherapy is the most appropriate additional treatment given the involvement of regional lymph nodes. Adenoid cystic carcinoma is considered to be a radio-sensitive tumour, and as such, radiotherapy is often used in its management, usually in the postoperative setting. Radiotherapy is effective in targeting residual microscopic disease and reducing the risk of recurrence in the lymph nodes which is crucial in managing adenoid cystic carcinoma. Additional surgical resection (Option A): Further surgical intervention might be considered if there were residual diseases or if the tumour had not been completely removed. However, in this case, the imaging shows no residual tumour but regional lymph node involvement. Additional surgery might not address the lymph node involvement effectively and could increase the risk of complications. Preoperative chemotherapy (Option C): Chemotherapy is not typically used as a preoperative treatment for adenoid cystic carcinoma. It is not as effective as radiotherapy in the context of adenoid cystic carcinoma and is generally reserved for cases with distant metastases or palliative care. Observation and regular follow-up (Option D): While regular follow-up is essential to monitor for recurrence, observation alone is inadequate given the lymph node involvement.

References:

Bailey and Love’s Short Practice of Surgery, 28th Edition, Page 841, 842, 843

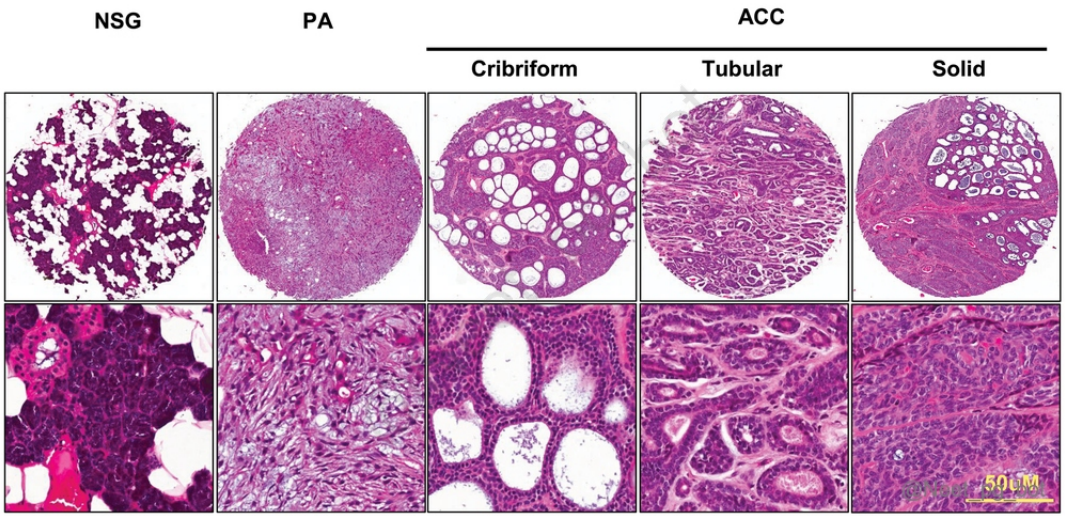
@Neet_pg_bot

Q7: A 60 y/o man presents with a slow-growing, painless mass in the submandibular region. O/E, the mass is firm and non-tender and biopsy reveals a tumor with a combination of tubular and solid histological patterns. Imaging shows perineural invasion extending towards the base of the skull. Which histopathological type in this carcinoma is associated with the worst prognosis? (Q849653)

A. Cribriform

B. Tubular

C. Solid



D. Papillary

Correct Answer: C. Solid

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical features suggest adenoid cystic carcinoma which is a slow-growing malignant tumor composed of both epithelial and myoepithelial cells. It is notable for its tendency to spread along nerve pathways. The solid pattern is linked to the worst prognosis due to its aggressive nature, higher propensity for recurrence, and increased risk of metastasis. It often necessitates more extensive surgical intervention. This type of cancer primarily affects the submandibular and sublingual salivary glands, with approximately half of the cases occurring in minor salivary glands, especially in the palate. It is relatively rare in the parotid gland. Clinical features: Facial nerve palsy Pain or numbness High risk of distant metastasis especially - lung. Histopathology of adenoid cystic carcinoma: Type: Unencapsulated, infiltrative biphasic neoplasm. Cell Types: Variable proportions of epithelial and myoepithelial cells. Patterns: Cribriform (Option A) : Cells around sharply punched-out cylindromatous spaces with basophilic matrix. Most common type and has a better prognosis. Tubular (Option B) : Bilayered tubules with a true lumen. Solid (Option C): Sheets and nests of tumour cells without a lumen. Carries poor prognosis. Nuclear Features: Small, angulated, hyperchromatic nuclei with scant cytoplasm. Perineural Invasion: Common in adenoid cystic carcinoma. High-Grade Transformation: Can occur. Immunohistochemistry: Ductal cells: Positive for c-KIT. Myoepithelial cells: Positive for p63 and SMA. Management Based on Risk Classification: 1. Low-Risk Disease: Criteria: Small tumors (T1), negative surgical margins, no perineural invasion (PNI), and no lymph node involvement. Management: Primary Surgery: Wide local excision with the goal of "negative" (clear) margins. Observation: Postoperative radiotherapy may be omitted in very select, small, low-grade tumors with widely clear margins, though many surgeons still favor radiation due to the "skip lesions" common in ACC. 2. Intermediate-Risk Disease: Criteria: T2 tumors, close surgical margins (< 5mm), or the presence of Perineural Invasion (PNI). Management: Surgery + Adjuvant Radiotherapy: Surgery remains the first step, but External Beam Radiotherapy (EBRT) is mandatory to address potential microscopic spread along nerve sheaths. 3. High-Risk Disease: Criteria: T3/T4 tumors, positive surgical margins, Solid growth pattern (>30%) , lymph node involvement, or extensive perineural invasion (especially extending to the skull base). Management: Radical Surgery: Aggressive resection, often including sacrifice of involved nerves and regional neck dissection if nodes are involved. Postoperative Radiotherapy (PORT): High-dose EBRT is essential. In cases of skull base extension, Neutron Beam Therapy or Proton Therapy may be used as they offer superior dose distribution for ACC compared to conventional photons. Systemic Therapy: Chemotherapy (e.g., Cisplatin-based) is occasionally used as a radiosensitizer, though its impact on long-term survival for ACC is still being debated. Papillary (Option D): Papillary is not a recognized histological type for adenoid cystic carcinoma, making it an irrelevant option in this context.

SRB's Manual of Surgery, 6th Edition, Page 405

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which immunohistochemical marker helps to distinguish acinic cell carcinoma from secretory carcinoma? (Q849652)

A. p53

B. Mammaglobin

C. S100

D. Ki-67

Correct Answer: B. Mammaglobin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Mammaglobin is a protein commonly expressed in secretory carcinoma but not in acinic cell carcinoma. The absence of mammaglobin in acinic cell carcinoma is a key feature used to distinguish it from secretory carcinoma, making it a useful diagnostic marker. Acinar cell carcinoma Tumor cells resemble normal serous acinar cells. They are rarely malignant. Immunohistochemically they are positive for DOG1 and SOX10 and negative for mammaglobin. Treatment: Radical excision p53 (Option A) is a tumour suppressor gene that is often used to assess mutations in various cancers but is not specific for distinguishing these two types of

carcinoma. S100 (Option C) is a protein expressed in various cell types and can be positive in many salivary gland tumours, including acinic cell carcinoma. However, it is not specific enough to differentiate acinic cell carcinoma from secretory carcinoma, as it can be positive in both tumour types. Ki-67 (Option D): Ki-67 is a proliferation marker used to assess the growth rate of tumour cells. While it provides information on the aggressiveness of a tumour, it is not specific to acinic cell carcinoma or secretory carcinoma and cannot be used to differentiate between the two.

@Neet_pg_bot

Q9: A 45 y/o female has a firm, enlarging swelling below her left ear for 6 months. O/E, the swelling is hard and nodular, with no signs of facial nerve involvement. FNAC shows malignant cells, and imaging reveals a tumour in both lobes of the parotid gland with no distant metastases. What is the most likely diagnosis? (Q849651)

A. Pleomorphic adenoma

B. Mucoepidermoid carcinoma

C. Adenoid cystic carcinoma

D. Warthin's tumor

Correct Answer: B. Mucoepidermoid carcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Mucoepidermoid carcinoma is the correct diagnosis in this scenario. Mucoepidermoid carcinoma is the most common malignant tumour of the parotid gland, particularly in adults. The slow-growing, firm, and nodular swelling in the parotid region, combined with the FNAC findings of malignancy , strongly indicates this type of carcinoma. The absence of facial nerve involvement and the slow progression further support this diagnosis, as these features are typical of low- to intermediate-grade mucoepidermoid carcinoma. High-grade carcinoma typically is locally aggressive and shows nodal metastases. Pleomorphic adenoma (Option A): This is a benign salivary gland tumour and the most common neoplasm of the parotid gland. It typically presents as a painless, mobile, and slow-growing mass. Adenoid cystic carcinoma (Option C): While adenoid cystic carcinoma

is another malignant salivary gland tumour, it is more commonly associated with minor salivary glands and tends to show a propensity for perineural invasion, often leading to early facial nerve involvement. Warthin's tumor (Option D) or Cystadenoma lymphomatosum, is a benign salivary gland tumor, commonly found in the parotid gland. It typically presents as a painless, cystic mass, often in older males.

Bailey and Love's Short Practice of Surgery, 28th Edition, Page 839, 840

SRB's Manual of Surgery, 6th Edition, Page 404, 405

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: Which of the following statements about Warthin's tumour and its diagnostic features is correct? (Q849650)

A. It is best identified on imaging by its hypoechoic appearance and confirmed with FNAC.

B. A Tc99 pertechnetate scan showing a "hotspot" is indicative of Warthin's tumour.

C. HPE shows mucin-secreting cells

D. Warthin's tumour generally exhibits low uptake on Tc99 pertechnetate scans

Correct Answer: B. A Tc99 pertechnetate scan showing a "hotspot" is indicative of Warthin's tumour.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Warthin's tumour shows increased uptake on Tc99 pertechnetate scans because of its high mitochondrial content. Histopathological features include papillary structures, cystic spaces, oncocytic epithelial cells, and lymphoid stroma. Tc99 Pertechnetate Scan: Purpose : Assesses salivary gland function and detects abnormal areas. Hot Spot : Increased uptake of the radioactive tracer (Option D) , indicating high mitochondrial content typical of Warthin's tumour. Histopathology (HPE) (Option C): Papillary Structures: Finger-like projections extending into cystic spaces. Cystic Spaces: Fluid-filled cavities within the tumor. Oncocytic Epithelial Cells: Two layers of cells with abundant mitochondria lining the papillary and cystic areas. Lymphoid Stroma: Supporting tissue with lymphocytes and germinal centres, resembling lymph node tissue. It is best identified on imaging by its hypoechoic appearance and confirmed with FNAC (Option A): While FNAC is used for diagnosis, Warthin's tumour typically shows a "hot spot" on Tc99 pertechnetate scans due to high mitochondrial content, not just hypoechoic appearance. FNAC might not always reveal the distinct features of Warthin's tumour.

SRB's Manual of Surgery, 6th Edition, Page 403, 404

↑ *Back to this question in Part A*

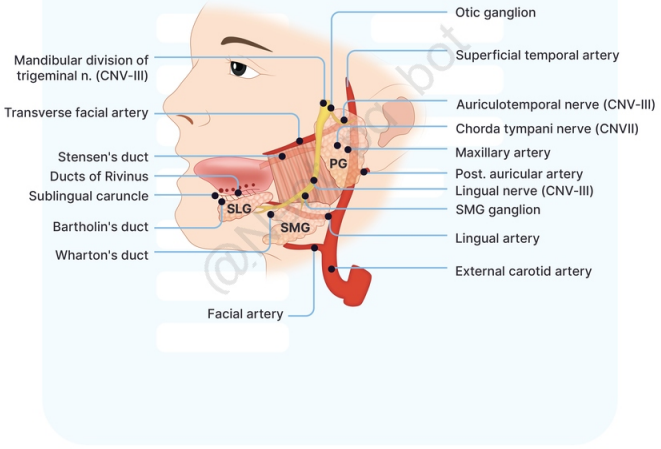
@Neet_pg_bot

Q11: Which of the following salivary glands secretes saliva through Stensen’s duct? (Q849640)

A. Parotid gland

B. Submandibular gland

C. Sublingual gland



D. Minor salivary glands

Correct Answer: A. Parotid gland

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The parotid gland is the largest salivary gland and secretes saliva through Stensen’s duct , which opens into the oral cavity near the upper second molar. They are primarily serous glands that produce watery saliva. The duct emerges from the anterior surface of the parotid gland, travels over the masseter muscle, pierces the buccinator muscle, and opens into the oral cavity opposite the crown of the upper second molar tooth. Gland Duct Parotid gland Stensen’s Duct Submandibular gland (Option B) Wharton’s Duct Sublingual gland (Option C) Ducts of Rivinus Minor salivary glands (Option D) Numerous small ducts

Bailey and Love's Short Practice of Surgery, 28th Edition, Page 831, 833

SRB's Manual of Surgery, 6th Edition, Page 394, 395

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 35 y/o female has a slowly enlarging, painless, well-defined mass in the left parotid gland, present for two years. O/E there is no facial nerve involvement. Ultrasound shows a well-lobulated, hypoechoic lesion, and FNAC suggests a benign neoplasm. What is the most appropriate next step in management? (Q849648)

A. Observation and follow-up

B. Radiotherapy

C. Surgical excision with a margin of normal tissue

D. Enucleation of the tumour

Correct Answer: C. Surgical excision with a margin of normal tissue

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation and findings suggest a diagnosis of Pleomorphic Adenoma . Surgical excision with a margin of normal tissue is the most appropriate management for pleomorphic adenoma. The goal is to remove the tumor completely with a margin of normal tissue to prevent recurrence and avoid spillage of tumor cells. This approach minimizes the risk of malignant transformation and recurrence. Pleomorphic Adenoma : Clinical Presentation : Painless, well-defined, solitary, mobile masses. Commonly located in the parotid glands (>80% of cases). Can also occur in the submandibular gland and hard palate. Sudden growth of facial nerve palsy may suggest malignant transformation (rare). Imaging : USG: Well-lobulated, hypoechoic lesions with possible calcifications. CT: Provides detailed anatomical imaging along with the extent of the tumor. MRI: Helps differentiate between benign and malignant tumors Fine-Needle Aspiration Cytology (FNAC) : Differentiates between inflammatory conditions and tumors- high sensitivity and specificity Histopathology : Gross Examination: Tumors are well-circumscribed, nodular, and firm, with a white to tan cut surface. May show cartilaginous areas; large tumors may exhibit degeneration or cystic changes. Microscopy: A mixture of epithelial, myoepithelial, and stromal components. Possible malignant changes: Ductal atypia, diffuse fibrosis, or necrosis Treatment: Surgical Excision of the tumor along with a cuff of normal tissue. Enucleation (Option D) is not recommended due to the risk of capsular breach, tumor spillage, and recurrence. Observation and follow-up(Option A): Although the tumor is benign and asymptomatic, observation is not appropriate because pleomorphic adenomas can undergo malignant transformation over time. Radiotherapy(Option B): It is generally reserved for malignant tumors or cases where surgical excision is not possible.

References:

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 839, 840, 842

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 50 y/o female with swelling and pus discharge from the left cheek for two weeks, worsening with eating, recently had a superficial parotidectomy. Examination reveals a small external opening at the parotid region with saliva-like discharge. What is the best initial management? (Q849647)

A. Antibiotics and observation

B. Sialography to evaluate the fistula

C. Surgical exploration and repair

D. Anticholinergic therapy with hyoscine bromide

Correct Answer: D. Anticholinergic therapy with hyoscine bromide

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation and findings suggest a diagnosis of Parotid Fistula. Anticholinergic therapy is the most appropriate initial management. It reduces salivary secretion, which can decrease the flow through the fistula, potentially allowing it to close spontaneously. This non-invasive approach is preferred before considering more aggressive interventions like surgery. Parotid Fistula Definition : A parotid fistula is an abnormal connection involving the parotid gland or its ducts, leading to saliva leakage. It can be: Internal: Draining into the mouth External: Draining onto the skin Discharge : Duct fistula: Typically profuse Gland fistula: Minimal discharge Risk Factors Surgical Trauma: Direct injury to the Stensen's duct or inadequate closure of the parotid fascia (Epstein's fascia). Post-op Infection: Abscess formation or sialadenitis that breaks down healing tissue. Distal Obstruction: A stone (sialolith) or stricture in the main duct that forces saliva out the surgical wound. Poor Healing: History of radiation therapy , uncontrolled diabetes, or malnutrition. Malignancy: Extensive resections for invasive tumors that compromise skin integrity. Investigations: Sialography: Identifies the origin of the fistula (gland, duct, or ductules) Other Imaging: Fistulogram, CT fistulogram, and MRI for detailed anatomy Discharge Study: Amylase content analysis to confirm saliva Management : Conservative : Anticholinergics (e.g., hyoscine bromide): Reduce salivary secretion. Radiotherapy: Low-dose radiation for longstanding fistulas. Surgical : Exploration and Repair: Dissect and repair the fistula tract; techniques like Newman Seabrock's operation may be used. Duct Repositioning: Redirects the duct into the oral mucosa. Auriculotemporal Nerve Sectioning: Reduces salivary flow by disrupting nerve supply. Total Conservative Parotidectomy: Last resort for persistent fistulas Antibiotics and observation (Option A): Antibiotics may help with infection, but they don't address the salivary fistula itself. Sialography to evaluate the fistula (Option B): Sialography helps identify the origin and extent of the fistula but is not the initial management step. It is used primarily when planning surgery if conservative treatments fail. Surgical exploration and repair (Option C): Surgical intervention is reserved for cases where conservative management fails or the fistula persists long-term.

References:

SRB's Manual of Surgery, 6th Edition, Page 399

↑ *Back to this question in Part A*

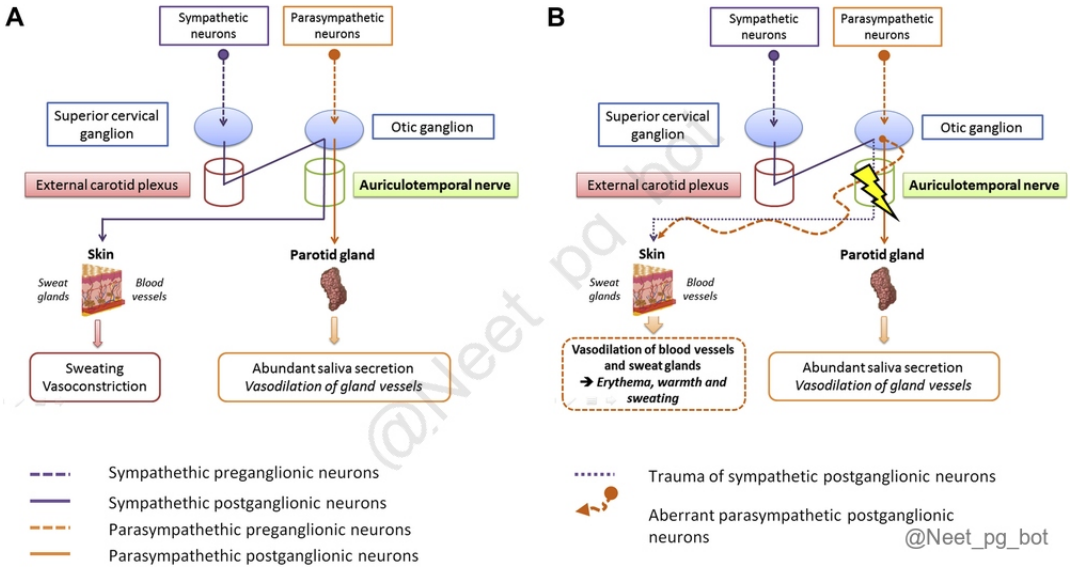
@Neet_pg_bot

Q14: A 60 y/o male undergoes a parotidectomy for a benign tumour located in the superficial lobe of the parotid gland. On the second postoperative day, he notices sweating and flushing in the area just in front of his ear when he eats. The patient also reports mild numbness of the earlobe. Which of the following nerves is most commonly affected? (Q849646)

A. Facial nerve

B. Auriculotemporal nerve

C. Great auricular nerve



D. Hypoglossal nerve

Correct Answer: B. Auriculotemporal nerve

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given clinical presentation suggests Frey's Syndrome, also known as gustatory sweating, is the most likely cause of the sweating and flushing the patient experiences while eating, resulting from damage to the auriculotemporal nerve , which carries the parasympathetic fibres to the parotid gland. This condition occurs due to the aberrant regeneration of parasympathetic nerve fibres, leading to the cross-innervation of sweat glands in the area. Complications of Parotidectomy: Complication Description Temporary Facial Palsy Mostly the lower branches of the facial nerve - the marginal mandibular nerve. Most patients recover over time. Infection Rare, as parotidectomy is a clean procedure. Aseptic precautions and timely drain removal reduce the risk. Hematoma Formation Uncommon. Careful intraoperative hemostasis can prevent it. Larger hematomas may indicate a bleeding disorder and require management. Sialocele Formation Occurs if the main ductal system is exposed. Preventable with subcapsular dissection. Treatment: Anticholinergics, aspiration, and pressure dressings. Retromandibular area hollowing Can occur post-surgery Reduced by placing autologous fat grafts during the surgery. Frey's Syndrome Also known as gustatory sweating; Caused by the cross-innervation of sweat glands by regenerating nerve fibres of the auriculotemporal nerve. (Option B) For mild cases : Give antiperspirants; Severe cases : Botulinum toxin injections or tympanic neurectomy. Permanent Facial Nerve Weakness D/t transection of the facial nerve during the surgery. (Option A) Facial Numbness Permanent numbness of the earlobe, D/t transection of the great auricular nerve during the surgery. (Option C) Pathophysiology: A, Normal physiology of auriculo-temporal nerve, and B: In case of injury of the auriculo-temporal nerve. The hypoglossal nerve (Option D) causes deviation of the tongue towards the affected side. It does not supply the parotid gland or front of the ear.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 45 y/o patient presents with a parotid gland tumour located deep to the facial nerve. The tumour has been identified as malignant and has extended beyond the parotid gland. Given these findings, which surgical approach is most appropriate for this patient? (Q849645)

A. Radical parotidectomy

B. Total conservative parotidectomy

C. Superficial parotidectomy

D. Adequate parotidectomy

Correct Answer: A. Radical parotidectomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This procedure involves the complete removal of the parotid gland along with any involved facial nerve branches. It is typically indicated for malignant tumors that have extended beyond the gland, making it the most appropriate choice for this patient's condition. Types of Parotidectomy: Type Description Extracapsular Dissection Tumor removed. No facial nerve dissection. ↓ Chances of temporary facial palsy. Adequate Parotidectomy (Option D) Tumor removal along with some healthy tissue. Aimed to preserve the gland. Challenging if the tumor is near the facial nerve. Superficial Parotidectomy (Option C) Performed when the tumor is located lateral to the facial nerve. Total Parotidectomy Indicated when the tumor is deep to the facial nerve. Total Conservative Parotidectomy (Option B) Involves removing both superficial and deep lobes while preserving the facial nerves. Used for tumors crossing the facial nerve plane. Radical Parotidectomy Complete removal of the parotid gland, including any involved facial nerve branches, for malignant tumors extending beyond the gland. Common Incisions: Modified Blair Incision: A preauricular incision curving under the earlobe and extending along the anterior border of the sternocleidomastoid. Facelift Incision: Similar to the modified Blair incision, but with the posterior part curving into the hairline to avoid a neck incision.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 846, 848

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 62 y/o woman presents with a recurrent adenoid cystic carcinoma of the submandibular gland. The tumour has been surgically resected twice before, and each time, the pathology report showed perineural invasion. What is the most appropriate next step in managing her condition? (Q849644)

A. Repeat surgical excision

B. Radiation therapy

C. Chemotherapy

D. Targeted therapy

Correct Answer: B. Radiation therapy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Given the tumor's tendency for perineural spread and the risk of local recurrence, radiation therapy is an appropriate adjuvant treatment to help control the disease. Radiation therapy uses high-energy rays to destroy cancer cells and is often used as adjuvant therapy after surgery or as the primary treatment for inoperable tumors. Perineural invasion, common in adenoid cystic carcinoma, refers to cancer spreading along nerves. Radiation therapy targets these tumor extensions to reduce recurrence. Radiotherapy Indications Adenoid cystic carcinomas After surgery for malignant salivary gland tumors High-grade tumors Close/inadequate clearance margin Deep lobe tumor Perineural spread Vascular involvement Multiple neck node involvement Recurrent malignant tumors Recurrent pleomorphic adenoma Repeat surgical excision (Option A) aims to remove salivary gland tumors with negative margins (no cancer cells at the edges of the removed tissue). However, due to perineural invasion and recurrent surgeries, it risks damaging vital structures and incomplete removal, making it unsuitable in this case. Chemotherapy (Option C): It is not typically the first-line treatment for adenoid cystic carcinoma, especially in cases of localized recurrence. Chemotherapy is more often used for systemic control when there is evidence of distant metastases or when other treatments are not feasible. Targeted Therapy (Option D): Targeted therapy uses drugs that specifically target molecules involved in cancer cell growth and survival. Salivary duct carcinomas often express androgen receptors and HER2 receptors, making them potential targets for therapies that block these receptors. However, targeted therapy is not currently a standard treatment for adenoid cystic carcinoma. Note: Neck dissection is usually performed in node-positive tumors, high-grade tumors, and malignant tumors with lymph nodal spread. It is also indicated for salivary duct carcinoma.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 45 y/o woman presents with a progressively enlarging mass in her right parotid gland. The mass is non-tender and has been present for 6 months. An ultrasound revealed a well-defined hypoechoic lesion with no evidence of calcification or increased vascularity. Which of the following is the most appropriate next step for this patient? (Q849643)

A. Sialography

B. Positron Emission Tomography (PET-CT)

C. Core Needle Biopsy

D. Fine-needle aspiration Cytology (FNAC)

Correct Answer: D. Fine-needle aspiration Cytology (FNAC)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: FNAC is a minimally invasive procedure used to extract cells from the suspicious mass using a fine needle, which is then examined under a microscope. FNAC is highly sensitive and specific for distinguishing between inflammatory and neoplastic lesions and between benign and malignant tumours. It is the most appropriate next step for evaluating a parotid gland mass due to its simplicity, safety, and ability to guide further management based on the cytological findings. Sialography (Option A): It involves injecting a contrast dye into the salivary ductal system to visualize it on X-ray. This technique is useful for diagnosing ductal abnormalities such as sialolithiasis (stones) and sialectasis but is not particularly useful for assessing salivary gland tumours. Positron Emission Tomography (PET-CT) (Option B): It is typically used to detect distant metastases in high-grade salivary gland malignancies and to identify primary tumours when metastatic involvement of the salivary glands is suspected. PET-CT is not indicated as a first-line investigation for a parotid mass, especially without suspicion of malignancy. Core Needle Biopsy (Option C): It involves taking a larger sample of tissue compared to FNAC and is more invasive. It is typically reserved for situations where FNAC results are inconclusive or additional tissue is needed for a more accurate diagnosis. Given the availability of FNAC for initial assessment, it is not the most appropriate next step at this stage.

@Neet_pg_bot

Q18: Which is the most common salivary gland tumour found in infants and young children? (Q849642)

A. Pleomorphic adenoma

B. Mucoepidermoid carcinoma

C. Hemangioma

D. Adenoid cystic carcinoma

Correct Answer: C. Hemangioma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hemangiomas are the most common benign vascular tumours seen in infants and young children. They often develop within the first few weeks of life and are the most frequent vascular lesions in early childhood. While many hemangiomas regress on their own, some may need treatment due to complications such as breathing difficulties or vision problems. Pleomorphic adenoma (Option A): This is the most prevalent benign tumour in the salivary glands of adults. It typically affects the parotid gland and contains a mix of epithelial, myoepithelial, and stromal components. Although benign, it can become malignant over time, particularly carcinoma, eg., pleomorphic adenoma. Mucoepidermoid carcinoma (Option B): This malignant tumour is the most common type of salivary gland cancer, especially in children and young adults. It consists of a mix of mucin-producing, intermediate, and squamoid cells, and occurs in the parotid gland. Adenoid cystic carcinoma (Option D): This is a slow-growing malignant tumour of the salivary glands, more often diagnosed in adults during their 50s. It has a notable tendency to invade nerves and is characterized by late distant metastases. Adenoid cystic carcinoma is the most common malignant tumour of the minor salivary glands, particularly on the palate. Salivary gland tumors The most common benign tumour Pleomorphic adenoma The most common benign tumour of infants and young children Hemangioma The most common malignan t tumour Mucoepidermoid carcinoma The most common malignant tumour in children and young adults Mucoepidermoid carcinoma The most common malignant tumour of Minor salivary glands Adenoid cystic carcinoma

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 50 y/o male presents with a swelling in his parotid gland, and a biopsy reveals a Warthin's tumour. Which of the following is most likely a contributing risk factor

for this patient's condition? (Q849641)

A. Radiation exposure in childhood

B. Chronic inflammation of the salivary glands

C. Smoking history

D. Immunocompromised state

Correct Answer: C. Smoking history

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: There is a strong association between smoking and the development of Warthin's tumors. Studies indicate that smokers have up to an 8-fold increased risk of developing this type of tumor compared to non-smokers. Risk factors of salivary gland tumors: Smoking: increases the risk of Warthin’s tumor. Radiation exposure (Option A) - increases the risk of mucoepidermoid CA. Viral infections (EBV, mumps). Recurrent & chronic inflammation (Option B) , eg. chronic Sialadenitis. Sex - More common in females. Environment - Nickel, rubber industries, hair dye. Pathogenesis: The Inclusion Theory: During embryological development, salivary gland tissue becomes trapped within parotid lymph nodes. These "heterotopic" rests later undergo cystic and papillary changes. The Irritant Theory: Smoking is the primary risk factor. Smoking acts as a chronic irritant to these trapped ductal elements, triggering the characteristic lymphoid reaction and metaplasia. Other Factors: While radiation (Option A) is linked to mucoepidermoid carcinoma, it is less strongly associated with Warthin's. Unlike pleomorphic adenoma, Warthin's is rarely associated with genetic mutations like PLAG1. Clinical Features: Demographics: Classically seen in males aged 50–70. Location: Almost exclusively occurs in the parotid gland , usually in the tail (inferior pole). It is the most common salivary tumor to be bilateral or multicentric (multiple spots in one gland). The "Rule of 10s": Roughly 10% are bilateral and 10% are multifocal (multiple tumors in one gland). Presentation: A slow-growing, painless, soft/fluctuant mass. Imaging: On a Technetium-99m pertechnetate scan, it appears as a "hot" spot because the oncocytes concentrate the isotope. Management: Warthin’s tumor is strictly benign with an extremely low rate of malignant transformation (<1%). Observation: A "watch and wait" approach is appropriate for elderly or high-risk surgical patients once confirmed by FNAC. Surgical Excision: The standard treatment is a superficial parotidectomy or a more conservative extracapsular dissection . It is vital to preserve the facial nerve. Immunocompromised state (Option D): Immunocompromised states, such as those seen in patients with HIV or those who have undergone organ transplants, can increase the risk of various head and neck cancers, but they are not specifically linked to Warthin's tumour.

Q25 (p. 1309)					

Q1: A patient is brought to the trauma unit after being assaulted. He presents with severe pain, swelling, and deformity in the lower jaw. Imaging confirms a "bucket handle" fracture of the mandible. What is the most likely nerve to be injured in this type of fracture? (Q849719)

A. Lingual nerve

B. Inferior alveolar nerve

C. Hypoglossal nerve

D. Facial nerve

Correct Answer: B. Inferior alveolar nerve

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Inferior alveolar nerve runs through the mandibular canal and is at risk of injury in fractures of the mandible, especially those involving the body of the mandible, like butterfly fractures. Butterfly Fractures of the Mandible: Also Known As : "Bucket handle" fractures. Type : Bilateral body fractures of the mandible. Common Causes : High-energy impacts (e.g., motor vehicle accidents, assaults). Main Complication : Airway obstruction. Characteristics and Mechanism: Appearance : Fracture creates a "butterfly" pattern. Impact : Significant compromise of mandible’s structural integrity. Injury Mechanism : Involves high-force trauma, potentially leading to additional injuries in surrounding tissues. Management Strategies: Method Indication Details Closed Reduction Non-displaced or minimally displaced fractures Uses intermaxillary fixation (MMF) for stabilization. Open Reduction and Internal Fixation (ORIF) Displaced fractures Surgical realignment and stabilization using plates/screws. Complications: Malocclusion : Misalignment of teeth. Non-union : Failure of the fracture to heal properly. Nerve Injury : Particularly to the inferior alveolar nerve, causing altered sensation in the lower lip. Lingual nerve (Option A) : This nerve is less likely to be injured in a mandibular body fracture as it is located more medially and higher up in the jaw. Hypoglossal nerve (Option C) : This nerve is involved in tongue movement and is not typically affected by mandible fractures. Facial nerve (Option D) : The facial nerve controls facial muscles

and is usually affected by fractures of the zygomatic arch or parotid area, not the mandible.

@Neet_pg_bot

Q3: A 30-year-old male presents to the emergency department after a motor vehicle accident. On assessment, there is bruising around the left eye, and tenderness over the zygomatic arch. Which of the following imaging views is most appropriate for assessing a suspected zygomatic bone fracture? (Q849715)

A. Caldwell's view

B. Water's view

C. Lateral skull view

D. Towne's view

Correct Answer: B. Water's view

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Water’s view plain film x-ray is preferred for evaluating zygomatic arch fractures. Investigations for zygomatic bone fracture: X-ray: water’s view (occipitomental view) is preferred CT scan- best investigation Treatment: Undisplaced fracture: Conservative management Displaced and symptomatic: Open reduction and internal fixation Caldwell's view (Option A) : (Occipitofrontal view) assessing fractures, and pathologies in the frontal and ethmoidal sinuses. Lateral skull view (Option C): Non-angled lateral radiograph of the skull. Useful in basal skull fracture. Towne's view (Option D) : Useful for identifying fractures in the occipital bone.

@Neet_pg_bot

Q4: All of the following are true regarding the clinical presentation of zygomatic bone fracture except? (Q849714)

A. Epistaxis

B. Anesthesia in infra-orbital nerve distribution

C. Flattening of malar prominence

D. Deranged dental occlusion

Correct Answer: D. Deranged dental occlusion

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Deranged dental occlusion is a manifestation of mandibular fracture. Zygomatic bone fracture: (tripod fracture) Fractures in 3 places: Zygomatico-frontal Zygomatico-temporal Infraorbital Clinical features: Swelling and bruising in the cheek. Flattening of the cheek (malar) prominence. (Option C ruled out) Step deformity of the infraorbital region. Epistaxis (Option A) Sensory loss in superior orbital nerve. Sensory loss in infraorbital nerve (Option B) : upper lip, and alar region of the nose. Enophthalmos is due to herniation of the orbital fat across the fracture floor of the orbit into the antrum. Diplopia- entrapment of the inferior rectus muscle restricting upward rotation of the eyeball while looking up. Infraorbital ecchymosis: Panda sign. Subcutaneous emphysema.

@Neet_pg_bot

Q5: A 22-year-old male presents with pain in the jaw and difficulty opening his mouth after a fall from a bicycle, landing directly on his chin. On examination, there is tenderness at the left preauricular region with limited mouth opening. CT scan confirms an undisplaced fracture of the left mandibular condyle. The patient has no other injuries and is otherwise stable. What is the most appropriate management? (Q849708)

A. Open reduction with internal fixation (ORIF)

B. Observation with a soft diet

C. Intermaxillary fixation (IMF)

D. Surgical excision of the condylar head

Correct Answer: C. Intermaxillary fixation (IMF)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Most condylar fractures can be treated with closed reduction with intermaxillary fixation (IMF) and a strict soft diet and analgesic regimen. Investigation of mandibular fracture: X-ray of the mandible: Panoramic view Towne view CT head and face. Treatment: Restoration of dental occlusion is the foundation of mandibular fracture management. Condylar fracture: Closed reduction with IMF elastic guidance and a strict soft diet and analgesic regimen . (Option B) Displaced condylar neck fractures with significant loss of mandibular "font-size:11pt; font-variant:normal; white-space:pre-wrap"> ORIF techniques. (Option A) Displaced mandibular fractures: Antibiotics on admission followed by open reduction and internal fixation (ORIF). Severely comminuted fractures and difficult to fx with titanium plates: Intermaxillary fixation (IMF) with wires. Facial bones heal well after about 4 weeks. Surgical excision of the condylar head (Option D) : In condylar hyperplasia condition.

References:

Bailey and Love Short Practice of surgery, 28e, pg 410

↑ *Back to this question in Part A*

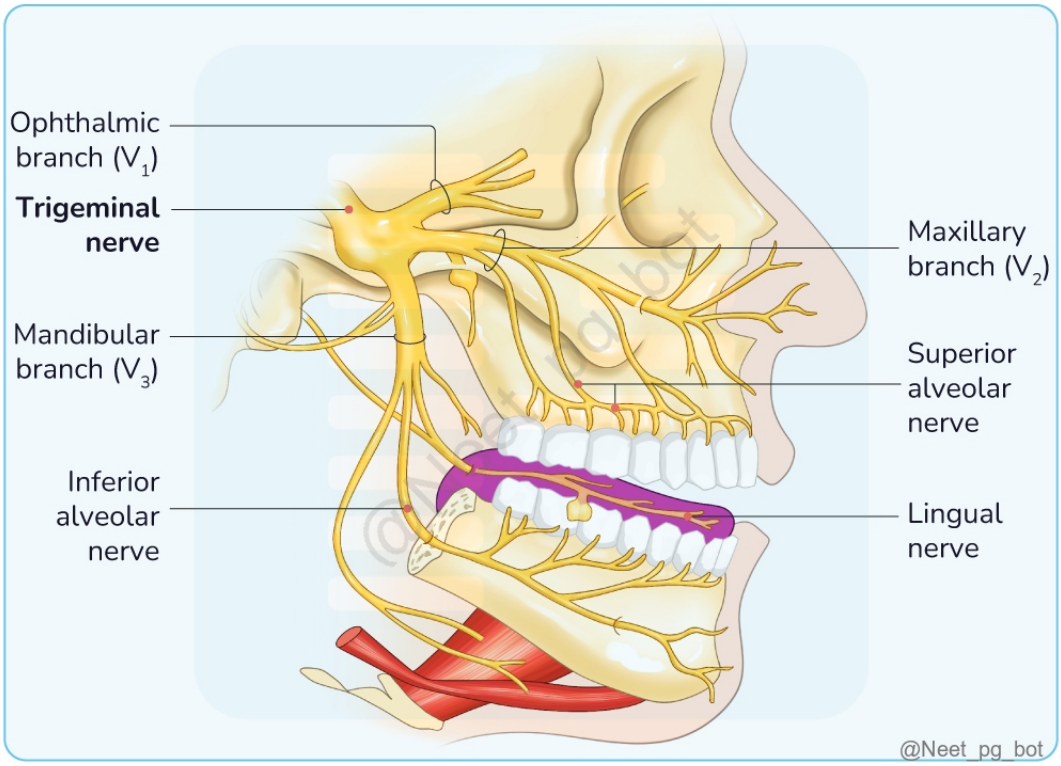
@Neet_pg_bot

Q6: A 24-year-old male presents to the emergency department after a motorcycle accident. He complains of severe pain in his lower jaw, difficulty closing his mouth properly, and numbness in his lower lip on the right side. Physical examination reveals swelling and tenderness over the right jaw, malocclusion, and a palpable step-off in the premolar region. The paresthesia in the patient's lower lip is most likely due to the involvement of which nerve? (Q849707)

A. Facial nerve

B. Inferior alveolar nerve

C. Mental nerve



D. Lingual nerve

Correct Answer: B. Inferior alveolar nerve

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The inferior alveolar nerve, a branch of the mandibular nerve (V3), runs through the mandible and provides sensation to the lower teeth and lower lip. A fracture of the mandible can lead to compression or damage to this nerve, resulting in paresthesia in the lower lip. Mandibular fractures often present with several key clinical features, such as: Pain and tenderness: Especially over the site of the fracture. Malocclusion: A feeling that the teeth do not fit together properly due to misalignment of the fracture segments. Swelling and bruising: Over the area of the fracture. Step deformity: A palpable step-off along the jawline where the fracture has occurred. Paresthesia: Numbness or tingling in the lower lip and chin due to injury to the inferior alveolar nerve, which runs through the mandible. Facial nerve (Option A): primarily responsible for facial expression and not sensation in the lower lip. Mental nerve (Option C): a branch of the inferior alveolar nerve that only supplies the chin and lower lip externally. Isolated involvement of this nerve is uncommon in mandibular fractures. Lingual nerve (Option D): provides sensation to the anterior two-thirds of the tongue, not the lower lip or jaw.

Bailey and love short practice of surgery, ed.28, page 410.

↑ *Back to this question in Part A*

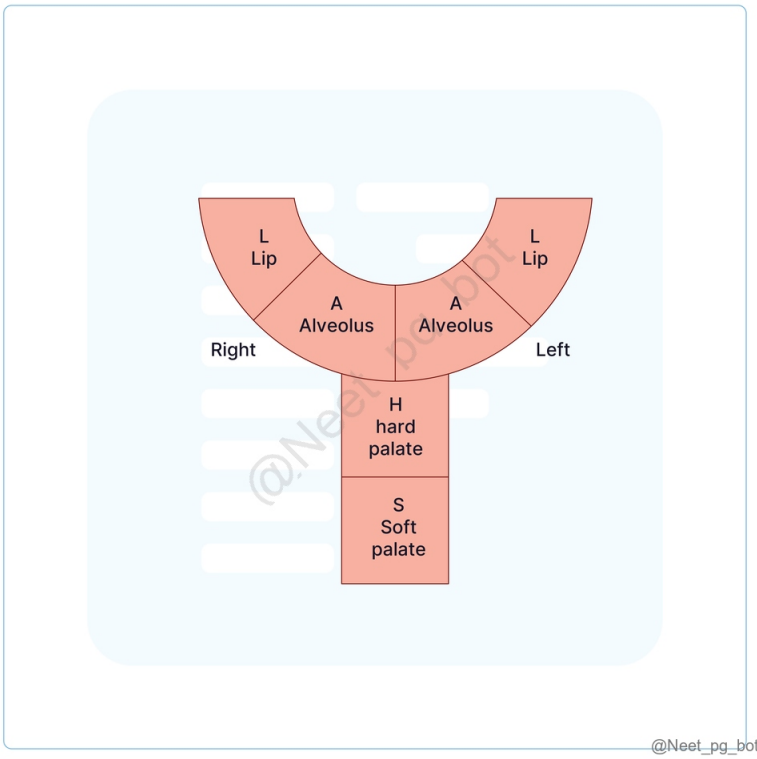
@Neet_pg_bot

Q7: A 3-month-old female infant presents with feeding difficulties and a noticeable facial deformity. On examination, the infant has a unilateral complete cleft involving the left lip, extending through the alveolus and hard palate, with an intact soft palate on the left side. The right side of the lip and palate are completely intact. What is the LAHSHAL classification for this patient's cleft abnormality? (Q849706)

A. 0000HAL

B. LAH0000

C. LAHS000



D. LAHSAL

Correct Answer: A. 0000HAL

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Understanding LAHSHAL Classification: LAHSHAL is a system used to describe cleft lip and palate in a topographic and symmetrical manner, from the patient's right to left : Letter Meaning L Lip A Alveolus H Hard palate S Soft palate Capital letter Complete cleft Lowercase letter Incomplete cleft "0" Normal segment So: The first 3 letters (L-A-H) refer to the right side The last 3 letters (H-A-L) refer to the left side Breakdown of the Case: Left side : Lip cleft → L (complete, hence capital) Alveolus cleft → A Hard palate cleft → H Soft palate is intact → S = 0 Right side : Everything intact → L-A-H = 0-0-0 Putting this into LAHSHAL: Right side (L-A-H) = 0-0-0 Left side (H-A-L) = H-A-L (from back to front) Final Code (Right to Left) = 0000HAL LAH0000 (Option B): Incorrect, implies cleft on right side. LAHS000 (Option C): Incorrect, implies soft palate cleft on right and lip/alveolus normal. LAHSAL (Option D): Implies bilateral complete cleft (both sides involved).

Bailey and Love, Short Practice of Surgery, 28th Edition, Page 741

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A mother brings her apparently normal 20-day-old newborn to the pediatric clinic with a complaint of milk coming through the nasal passages of the baby during feeding. Upon examination, you find the following: This condition is due to the failure

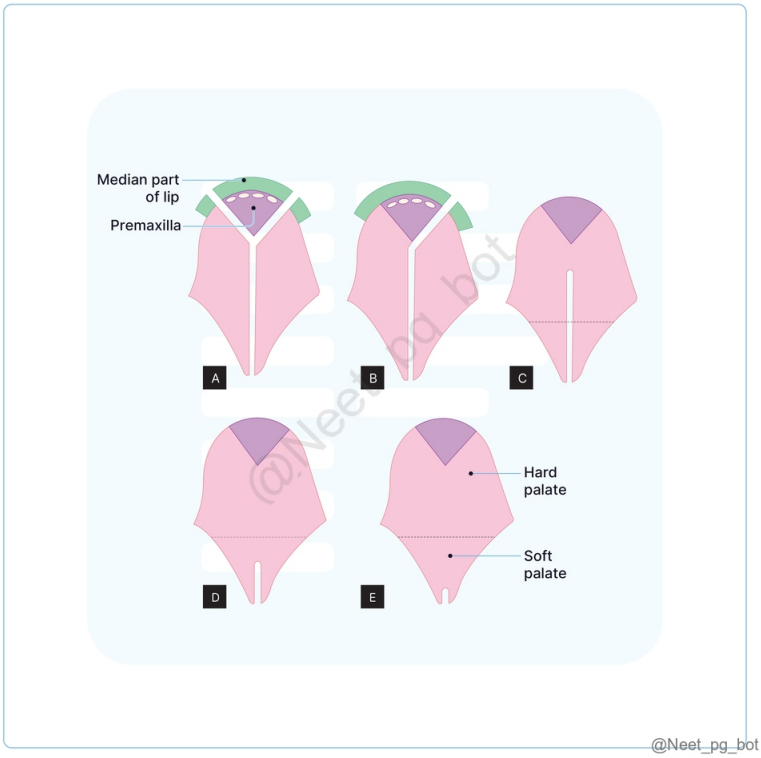
of which of the following processes during embryonic development? (Q849702)

A. Fusion of the maxillary and medial nasal processes

B. Formation of the lateral palatine processes

C. Fusion of the palatal shelves

D. Formation of the primary palate



Correct Answer: C. Fusion of the palatal shelves

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Cleft palate occurs when the palatal shelves fail to elevate and fuse properly during embryonic development, typically between the 6th and 9th weeks of gestation. This results in a gap in the palate, allowing communication between the oral and nasal cavities, as evidenced by milk coming through the nasal passages during feeding. Cleft palate: Defective fusion of the various components of the palate gives rise to clefts in the palate. Complete cleft palate: Bilateral complete cleft (A): Failure of fusion of both palatine processes of maxilla with premaxilla. A y-shaped cleft will be present between primary and secondary palate and between the two halves of secondary palate. It presents as a bilateral cleft of the upper lip also. Unilateral complete cleft (B): Nonfusion of one side palatine process of maxilla with premaxilla. It presents as a unilateral cleft of the upper lip. Incomplete cleft palate: Cleft of hard and soft palate(C): Cleft limited to hard palate. Cleft of soft palate (D): Cleft limited to hard palate. Bifid uvula (E): Cleft limited to uvula. Fusion of the maxillary and medial nasal processes (Option A): This contributes to formation of the upper lip and primary palate . Its failure leads to cleft lip , not cleft

palate. Formation of the lateral palatine processes (Option B): While formation is important, fusion failure (not formation) is responsible for the defect in this case. Formation of the primary palate (Option D): The primary palate forms the region anterior to the incisive foramen; its failure causes anterior clefting , not posterior palatal clefts.

Inderbir Singh's Human embryology, 11th edition, pg 161

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 45-year-old male is diagnosed with a mandibular condyle fracture following an assault. The fracture is associated with malocclusion and facial asymmetry. Which of the following is a common post-surgical complication after open reduction and internal fixation (ORIF) of this fracture? (Q849718)

A. Temporomandibular joint ankylosis

B. Persistent pain and facial contour deformities

C. Complete loss of mandibular function

D. Intraoral hemorrhage

Correct Answer: B. Persistent pain and facial contour deformities

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Mandibular condyle fracture following assault is known as Guardsman fracture. Post-surgical complications of ORIF for mandibular condyle fractures often include persistent pain, malocclusion, and facial contour deformities, particularly in cases with multiple fracture sites. Overview of Guardsman Fractures Definition : Guardsman fractures, also known as mandibular condyle fractures, result from trauma like assaults or accidents. Location : These fractures typically occur in the mandibular condyle, the rounded end of the mandible that connects with the temporal bone. Associated Injuries : Often associated with other mandibular fractures; approximately 50% of mandibular injuries involve multiple fracture sites, complicating treatment and recovery. Management Approaches Surgical Intervention : Common Method : Open reduction and internal fixation (ORIF) is the primary treatment to realign and stabilize the fractured segments. Incision Techniques : Retromandibular Incision : Provides access to the fracture site from behind the mandible. Preauricular Incision : Allows access in front of the ear, particularly useful for accessing the condyle. Surgical Tools : Bone clamps and lag screws are typically used during surgery to achieve proper reduction. Complications : Common Issues : Persistent pain, malocclusion (misalignment of teeth), and facial contour deformities. Risk Factors : The presence of multiple fractures increases the risk of complications, making precise surgical planning crucial. Temporomandibular joint ankylosis (Option A) : Although a possible complication of condyle fractures, it is less common than pain and facial deformities following ORIF. Complete loss of mandibular function (Option C) : This is not a typical complication; ORIF aims to restore function rather than cause complete loss. Intraoral hemorrhage (Option D) : While hemorrhage can occur during surgery, it is not a common post-surgical complication specific to ORIF of the mandibular condyle.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: All of the following statements are true regarding the management of midface fractures, except? (Q849717)

A. Interdental or intermaxillary fixation is not mandatory

B. Reestablish the proper dentoskeletal relationship

C. Immobilize the fractured bone

D. Ensure normal postoperative occlusion

Correct Answer: A. Interdental or intermaxillary fixation is not mandatory

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Interdental or intermaxillary fixation is mandatory in midface fracture particularly in: Le Fort fractures (I, II, III) - to restore proper occlusion and facial height Displaced maxillary fractures - to maintain reduction during healing Comminuted fractures - provides stability during bone healing Dentoalveolar injuries - to stabilize teeth and alveolar segments Purpose of IMF: Establishes proper dental occlusion as a reference point for reduction Maintains reduction while plates and screws are applied Provides postoperative stability during initial healing (typically 4-6 weeks) Acts as a "skeletal splint" to guide proper anatomical alignment Investigation of mandibular fracture: X-ray of the mandible: Panoramic view Towne view CT head and face. Treatment: Restoration of dental occlusion is the foundation of mandibular fracture management. Condylar fracture: Closed reduction with IMF elastic guidance and a strict soft diet and analgesic regimen . Displaced condylar neck fractures with significant loss of mandibular; white-space:pre-wrap"> ORIF techniques. Displaced mandibular fractures: Antibiotics on admission followed by open reduction and internal fixation (ORIF). Severely comminuted fractures and difficult to fix with titanium plates: Intermaxillary fixation (IMF) with wires. Facial bones heal well after about 4 weeks. Reestablish the proper dentoskeletal relationship (Option B): Primary goal of midface fracture treatment Restoration of occlusion, facial width, facial height, facial projection Immobilize the fractured bone (Option C): Essential principle of fracture management Achieved through: rigid internal fixation, intermaxillary fixation, external fixation Ensure normal postoperative occlusion (Option D): Critical endpoint to assess successful treatment

@Neet_pg_bot

Q11: A 3-month-old infant presents to the pediatric clinic with feeding difficulties and nasal regurgitation. On examination, the infant has a cleft involving only the soft palate. There are no other abnormalities or syndromic features observed. When should surgery be planned for this infant with a cleft of only the soft palate? (Q849705)

A. At birth

B. At 6 months

C. After 1 year

D. After 5 years

Correct Answer: B. At 6 months

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Surgery for a cleft of only the soft palate is ideally performed at around 6 months of age. This timing is crucial for optimal speech development and to minimize feeding difficulties, allowing the child to grow and develop normally. Management of cleft lip and cleft palate: Surgical principles: Cleft lip repair: reconnects the muscles around the oral sphincter. Cleft palate repair: anatomically closes the defect, facilitates speech development, minimizes maxillary growth difference and dentoalveolar deformities. Two-stage procedures may be used to minimize dissection. Secondary management (Post op): involves regular review by a multidisciplinary team for hearing, speech, dental development, and facial growth assessment. Surgical techniques: Cleft lip repair Cleft palate repair Millard rotation advancement technique(most widely used) Bardach's Method Le Mesurier's Von Langenbeck Method (bipedicled) Thompson Wardill-Kilner Method/ V-Y plasty (unipedicled) Tennison-Randall Timing of Repair: Cleft lip Unilateral 5-6 months Bilateral 4-5 months Cleft palate Soft palate only 6 months Hard palate only 15-18 months Both soft and hard palate 2 staged Soft palate - 6 months Hard palate - 15-18 months Cleft lip and palate Unilateral 2 staged Cleft lip and soft palate - 5-6 months Hard palate - 15-18 months Bilateral 2 staged Cleft lip and soft palate - 4-5 months Hard palate - 15-18 months

Bailey and love short practice of surgery, ed.28, page 745.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 2-day-old male infant is born with a unilateral cleft lip and palate. He is the first child of healthy, non-consanguineous parents with no significant family history. On physical examination, the infant has a noticeable cleft lip and palate. No other obvious abnormalities are noted. You suspect a syndromic association. Which of the following is the most common syndrome associated with cleft lip? (Q849704)

A. Van der Woude syndrome

B. Pierre Robin sequence

C. Treacher Collins syndrome

D. DiGeorge syndrome

Correct Answer: A. Van der Woude syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Van der Woude syndrome is the most common syndrome associated with cleft lip and/or cleft palate. It is an autosomal dominant disorder characterized by the presence of cleft lip, cleft palate, and lip pits. It is due to mutations in Interferon Regulatory Factor 6 [IRF6]. Cleft Abnormalities: Cleft Lip (CL): Occurs when the maxillary prominence fails to fuse with the intermaxillary segment (merged medial nasal prominences) during the 6th week of gestation. Cleft Palate (CP): Occurs when the palatal shelves (lateral maxillary processes) fail to fuse with each other or with the primary palate/nasal septum during the 7th to 12th weeks Lip Pits: Occur when the persistent lateral grooves of the mandibular process fail to disappear during the 6th week of gestation, resulting in permanent invaginations (depressions) of the lower lip. Other syndromes associated with cleft abnormalities: 1 . Pierre Robin Sequence (Option B) Mechanism: Failure of the mandible to grow normally in utero (<11 weeks) prevents the tongue from descending. The high-positioned tongue then physically blocks the palatal shelves from fusing. The Triad: Micrognathia: A small, recessed lower jaw. Glossoptosis: Posteriors displacement of the tongue into the pharynx. U-shaped Cleft Palate: A wider, rounded cleft (unlike the V-shape in non-syndromic cases). Primary Concern: Upper airway obstruction and feeding difficulties. Infants often need to be placed in a prone (face down) position to keep the tongue forward. 2. Treacher Collins Syndrome (Option C) (Mandibulofacial Dysostosis): Also known as Mandibulofacial Dysostosis , this condition affects the development of the first and second branchial arches. Genetics: Typically autosomal dominant (TCOF1 gene). Craniofacial Features: Malar hypoplasia: Underdeveloped cheekbones and infraorbital ridges. Down-slanting palpebral fissures: Eyes slant downward. Colobomas: Notches in the lower eyelids. Ear Anomalies: Microtia (small ears) or atresia of the external auditory canal, leading to conductive hearing loss. Clefting: Cleft palate occurs in about 30% of cases. Cleft lip is rare. 3. DiGeorge Syndrome (Option D) (22q11.2 Deletion Syndrome): This is the most common microdeletion syndrome in humans and has a highly variable presentation (Velocardiofacial Syndrome). The "CATCH-22" Mnemonic: C: Cardiac defects (notably Tetralogy of Fallot or Interrupted Aortic Arch). A: Abnormal facies (long face, bulbous nose tip). T: Thymic hypoplasia (leading to T-cell deficiency). C: Cleft palate (specifically submucous cleft palate or Velopharyngeal Insufficiency). H: Hypocalcemia (due to hypoparathyroidism). Speech: These patients often have "hypernasal" speech even if a visible cleft is not present, due to muscle dysfunction in the soft palate. 4. Apert Syndrome: Apert is one of the craniosynostosis syndromes, where the skull sutures fuse prematurely. Genetics: Autosomal dominant (FGFR2 gene). Key Features:

Craniosynostosis: Usually the coronal suture, resulting in a tall, flattened forehead (turribrachycephaly). Midface Hypoplasia: The middle of the face appears "sunken," leading to bulging eyes (proptosis). Syndactyly: "Mitten-like" webbing of the fingers and toes is a hallmark. Clefting: Approximately 75% of patients have a high-arched or cleft palate. The palate often contains thick lateral swellings due to an accumulation of acid mucopolysaccharides. 5. Stickler Syndrome: Stickler syndrome is a progressive connective tissue disorder and is the most common identifiable cause of Pierre Robin Sequence. Genetics: Mutations in collagen genes (COL2A1, COL11A1). Key Features: Ocular: Severe myopia (nearsightedness), cataracts, and high risk for retinal detachment . Auditory: Sensorineural hearing loss. Joints: Early-onset osteoarthritis and joint hypermobility. Clefting: Highly associated with cleft palate and the Pierre Robin triad.

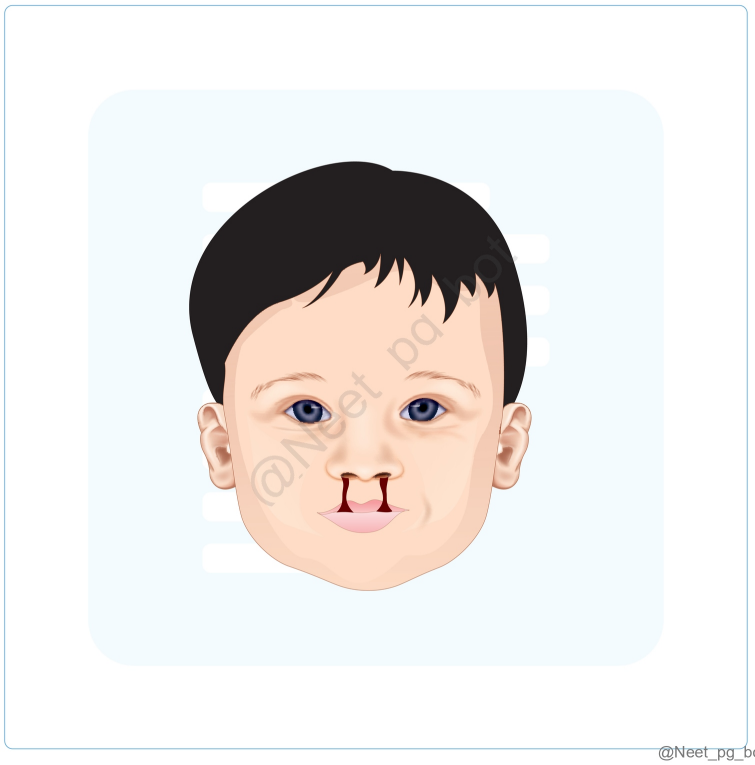
Bailey and Love short practice of surgery, ed. 28, page 741, 742.

Langman’s medical embryology,ed.14, page 307.

↑ *Back to this question in Part A*

@Neet_pg_bot



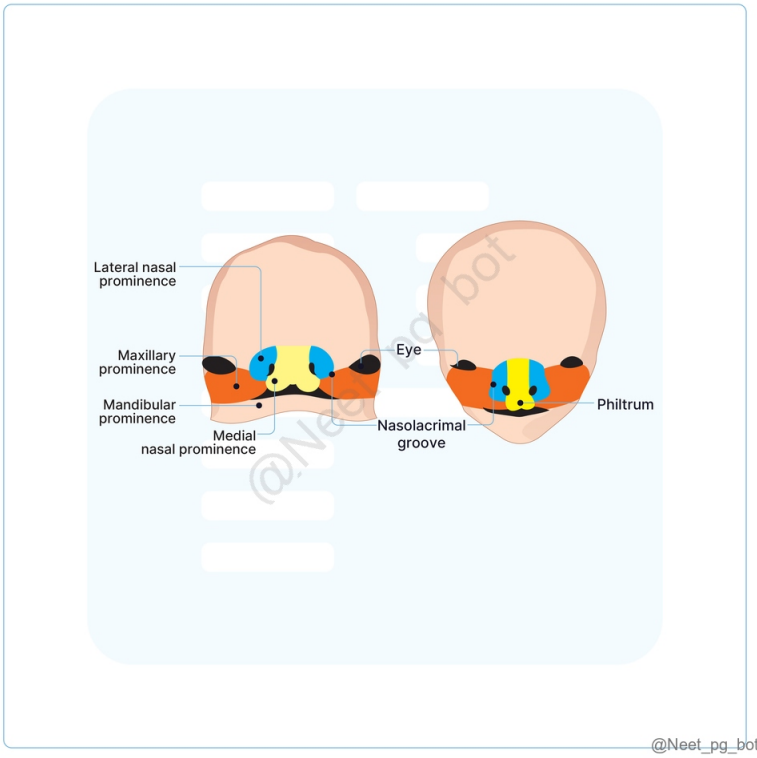
Q13: A 3-day-old male neonate is brought to you by his parents, concerned about the appearance of his face. On examination, the neonate has the appearance as shown in the image. Which of the following embryological events is most likely responsible for this defect? (Q849703)

A. Failure of fusion between the lateral palatine processes and nasal septum.

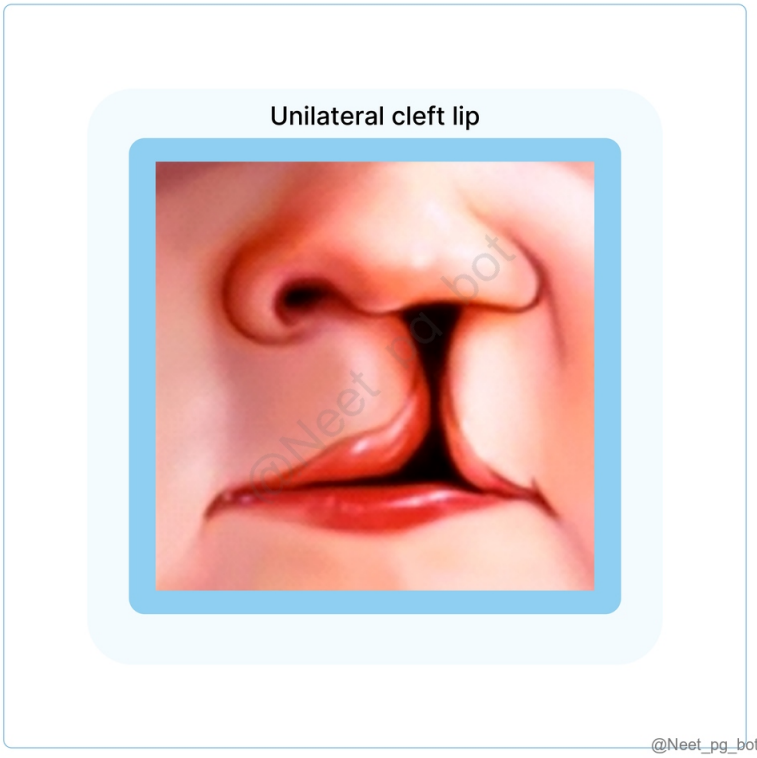
B. Non-fusion of the maxillary prominences and medial nasal prominences.

C. Incomplete fusion of the mandibular prominences.

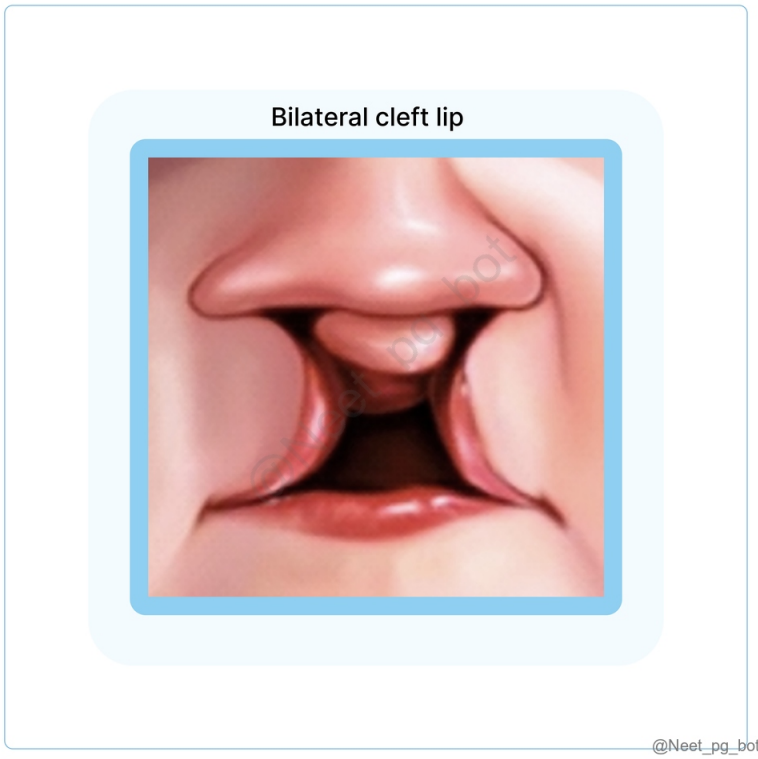
D. Non-fusion of the lateral nasal prominences and the medial nasal prominences.



Correct Answer: B. Non-fusion of the maxillary prominences and medial nasal prominences.



■ *Listen (English)*



■ *Listen (Hindi)*

Explanation: Failure of fusion of both maxillary processes with the medial nasal process results in bilateral cleft lip. Development of The Lip: The upper lip is formed by the two medial nasal prominences and the two maxillary prominences. The lateral nasal prominences do not participate in formation of the upper lip. The lower lip and jaw form from the mandibular prominences that merge across the midline. Cleft lip/ Harelip: Cleft lip and/or palate is the most common congenital abnormality affecting the orofacial region. The upper lip of the hare normally has a cleft. Hence, the term harelip is used for defects of the lips . Unilateral harelip: failure of fusion of maxillary process with medial nasal process on one side. Bilateral harelip: failure of fusion of both maxillary processes with the medial nasal process. Clinical features: Bilateral Presentation: Unlike unilateral clefts, the bilateral version often results in the prolabium (the central part of the lip) and the premaxilla (the central tooth-bearing bone) being displaced forward (protrusion). Nasal Deformity: The nose typically appears flattened with widened nostrils and a shortened columella (the tissue between the nostrils). Feeding Difficulty: Inability to create a seal around a nipple, leading to poor suction and excessive air swallowing. Dental Issues: Misalignment or absence of the maxillary incisors is common as the cleft disrupts the dental lamina. Management: Phase Timing Intervention Neonatal Birth–1 Month Feeding Support: Use of Haberman feeders or obturators; Nasoalveolar Molding (NAM) to align segments. Surgical (Lip) 3–6 Months Cheiloplasty: Surgical repair of the lip (Rule of 10s: 10 weeks old, 10 lbs, 10g hemoglobin). Surgical (Palate) 9–18 Months Palatoplasty: Closure of the palate to allow for normal speech development. Middle Childhood 6–10 Years Speech Therapy & Audiology: Management of hypernasality and "glue ear" (tympanostomy tubes). Adolescence 8–12 Years Alveolar Bone Graft: Using hip bone to fill the gap in the gum line before permanent canines erupt. Final Phase 16–18 Years Orthognathic Surgery & Rhinoplasty: Correcting jaw alignment and nasal aesthetics after growth is complete. Failure of fusion between the lateral

palatine processes and nasal septum (Option A) results in cleft palate . Incomplete fusion of the mandibular prominences (Option C) results in cleft of lower lip. Non-fusion of the lateral nasal prominences and the medial nasal prominences (Option D) results in oblique facial cleft.

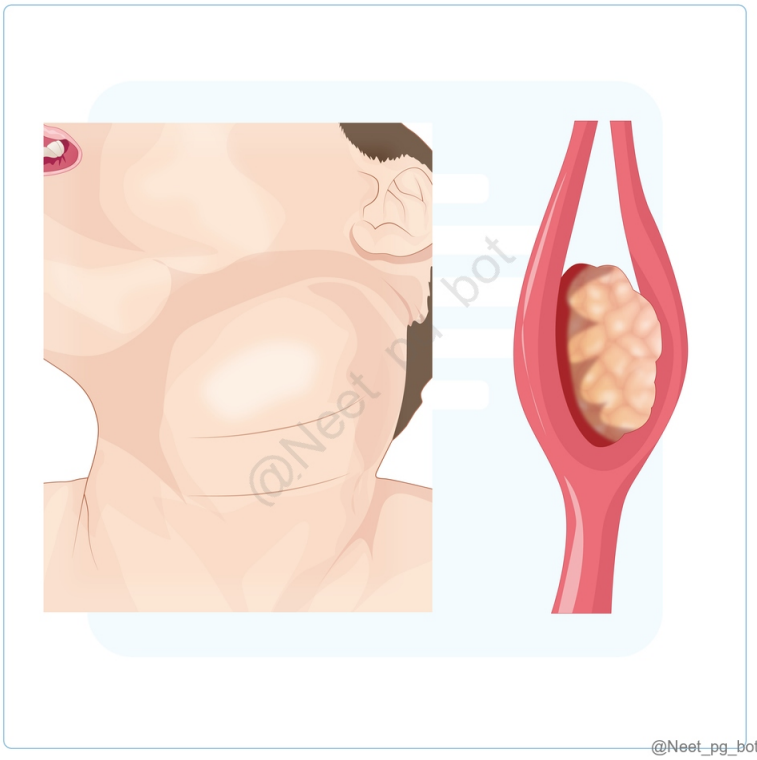
@Neet_pg_bot

Q14: A 60-year-old patient is found to have a carotid body tumor that completely encases the carotid vessels, posing significant surgical challenges. According to the Shamblin classification system, what type of tumor does this describe? (Q849620)

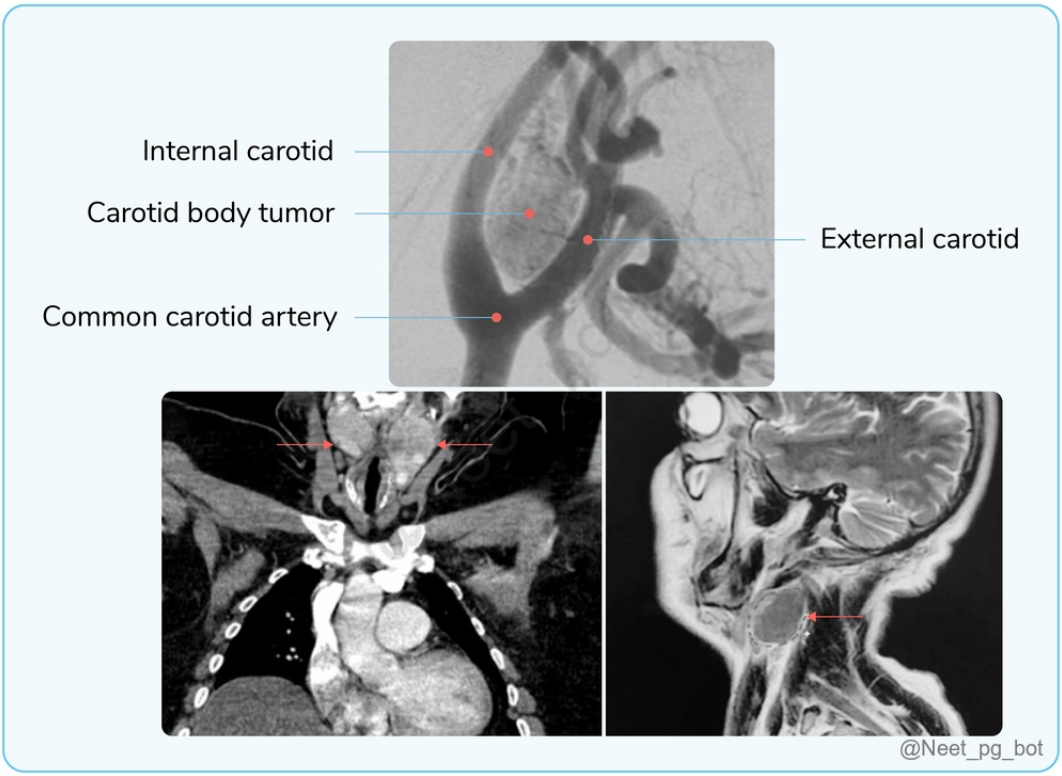
A. Type I

B. Type II

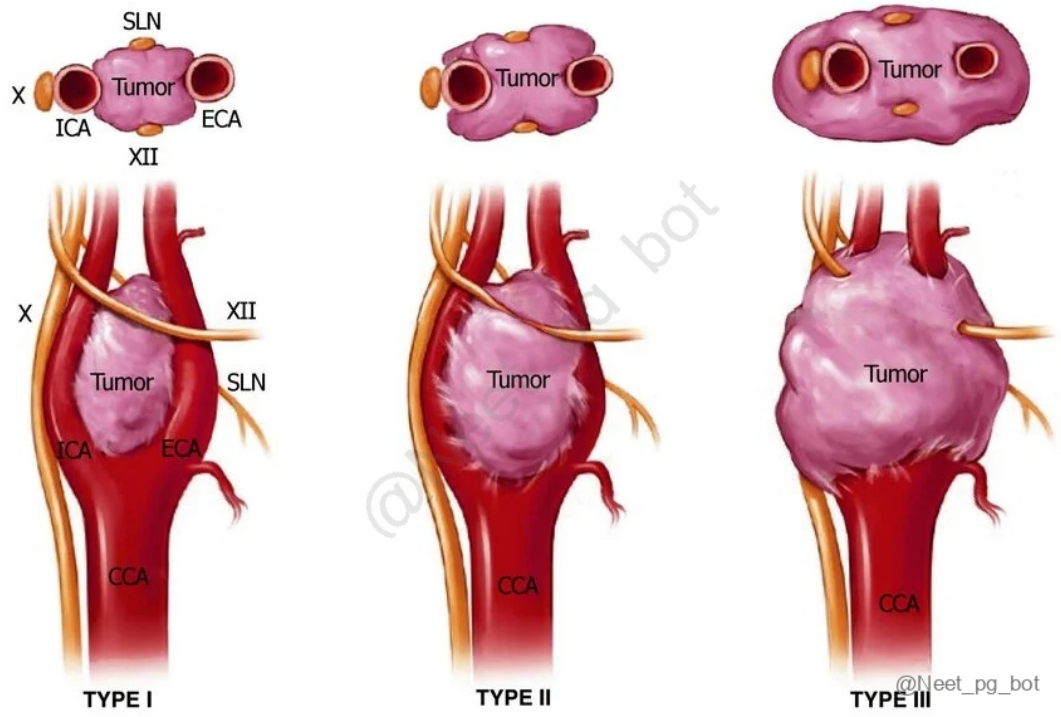
C. Type III



D. Cannot be determined.



Correct Answer: C. Type III



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Type III completely encases the carotid vessels, making surgical resection more challenging. CAROTID BODY TUMOR: Carotid body tumor Details Origin Chemoreceptor cells at the carotid body (carotid bifurcation) Clinical Presentation Slow-growing, painless mass at carotid bifurcation Often pharyngeal mass Firm, rubbery, pulsatile, side-to-side mobility Bruit possible Avoid oral cavity biopsy for para pharyngeal swellings Usually benign; metastases are rare Diagnostic Tools Carotid Angiogram : Visualizes splayed bifurcation and outlines blood vessels MRI: Provides detailed anatomical information Contraindications: Biopsy and fine-needle aspiration (risk of bleeding) Shamblin Classification: Type I: Localized tumor. It involves less than 180° of the vessel circumference. These are easily dissected from the vessels. Type II: Adherent tumor. It surrounds the vessel by more than 180° . These are more difficult to separate and require careful sub-adventitial dissection. Type III: Enclosing tumor. It completely encases (360°) the carotid vessels and bifurcation. These are the most challenging and often require arterial resection and reconstruction.

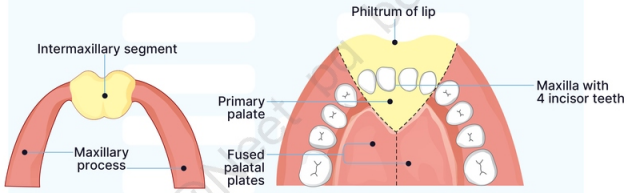
@Neet_pg_bot

Q15: The intermaxillary segment gives rise to all of the following structures EXCEPT: (Q849701)

A. Philtrum of the lip

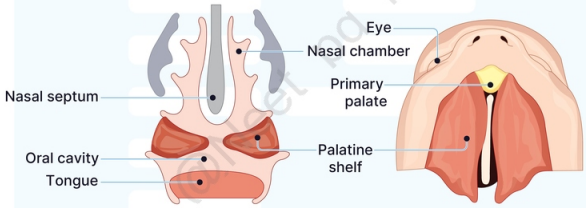
B. Primary palate

C. Secondary palate



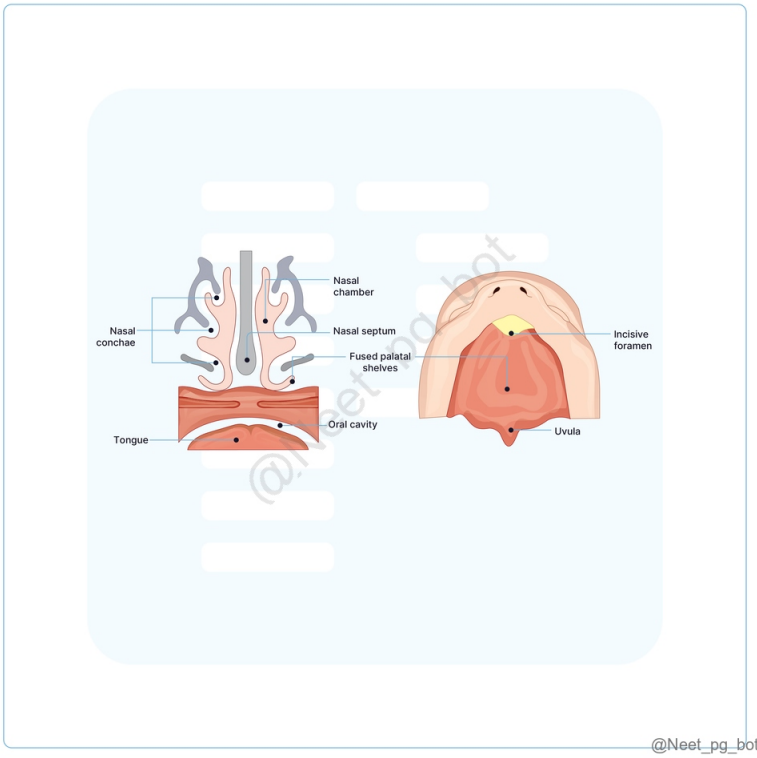
D. Four incisor teeth

Correct Answer: C. Secondary palate



■ *Listen (English)*

■ *Listen (Hindi)*



Explanation: The intermaxillary segment gives rise to the philtrum of the lip, four incisor teeth, and the primary palate. Development of the Lip and the Palate: The Lip: The upper lip is formed by the two medial nasal prominences and the two maxillary prominences. The lateral nasal prominences do not participate in formation of the upper lip. The lower lip and jaw form from the mandibular prominences that merge across the midline. The Palate: Intermaxillary Segment: Formation: Merging of the two medial nasal prominences, both at the surface and at a deeper level, due to the medial growth of the maxillary prominences. Components: Labial Component: Forms the philtrum of the upper lip. Upper Jaw Component: Contains the four incisor teeth. Palatal Component: Develops into the triangular primary palate. Secondary Palate: Origin: The secondary palate is primarily formed by two shelflike outgrowths, known as palatine shelves, from the maxillary prominences. Fusion: The palatine shelves fuse anteriorly with the triangular primary palate. The incisive foramen serves as the midline landmark between the primary and secondary

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 55-year-old male patient with squamous cell carcinoma of the oral cavity undergoes a right radical neck dissection. Three days postoperatively, the patient complains of shoulder weakness and difficulty in lifting his right arm above his shoulder. On physical examination, he has a limited range of motion in the right shoulder and exhibits winging of the scapula on the right side. What is the most likely nerve injured during the neck dissection that could explain this patient’s symptoms? (Q849699)

A. Accessory nerve (CN XI)

B. Phrenic nerve

C. Cervical sympathetic chain

D. Hypoglossal nerve (CN XII)

Correct Answer: A. Accessory nerve (CN XI)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The accessory nerve (cranial nerve XI) innervates the sternocleidomastoid and trapezius muscles. Injury to this nerve during a neck dissection can result in weakness of the trapezius muscle, leading to shoulder weakness , difficulty in lifting the arm above the shoulder , and winging of the scapula. Complications of Neck Dissection: 1. Nerve Injuries: Accessory nerve (CN XI) : (Option A) Shoulder weakness Difficulty lifting the arm above the shoulder Winging of the scapula Marginal mandibular nerve (branch of facial nerve): Asymmetrical smile due to drooping of the corner of the mouth Difficulty in controlling lower lip movements Hypoglossal nerve (CN XII) : (Option D) Tongue deviation towards the injured side Difficulty in speech and swallowing Phrenic nerve (Option B): Diaphragmatic paralysis leading to respiratory difficulties Vagus nerve (CN X): Hoarseness of voice Dysphagia Aspiration due to vocal cord paralysis Cervical sympathetic chain: (Option C ruled out) Horner's syndrome (ptosis, miosis, anhidrosis) 2. Vascular Complications: Hemorrhage: Hematoma: Chyle leak: Injury to the thoracic duct or lymphatic vessels Carotid artery rupture 3. Wound Complications: Infection Wound dehiscence Flap necrosis Seroma

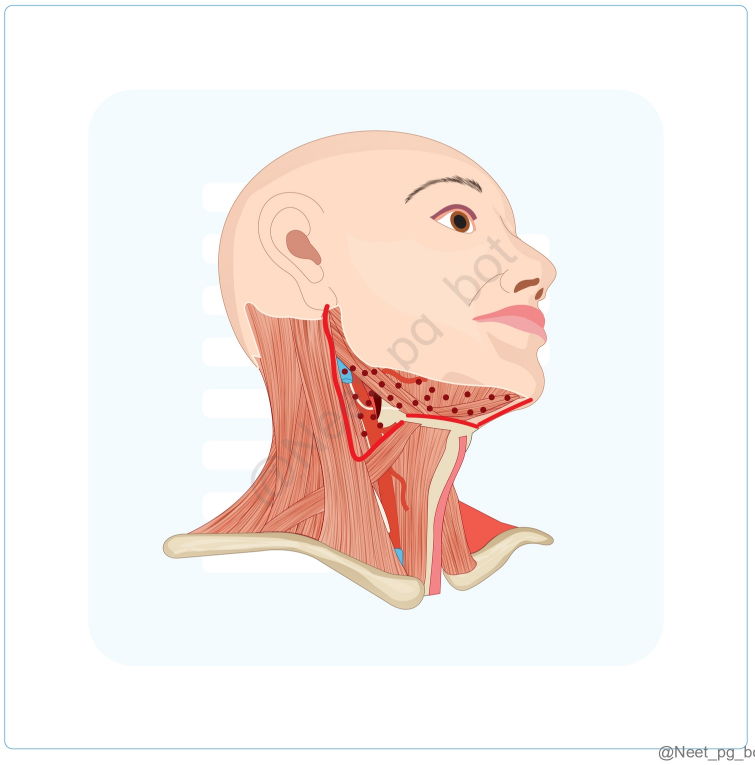
@Neet_pg_bot



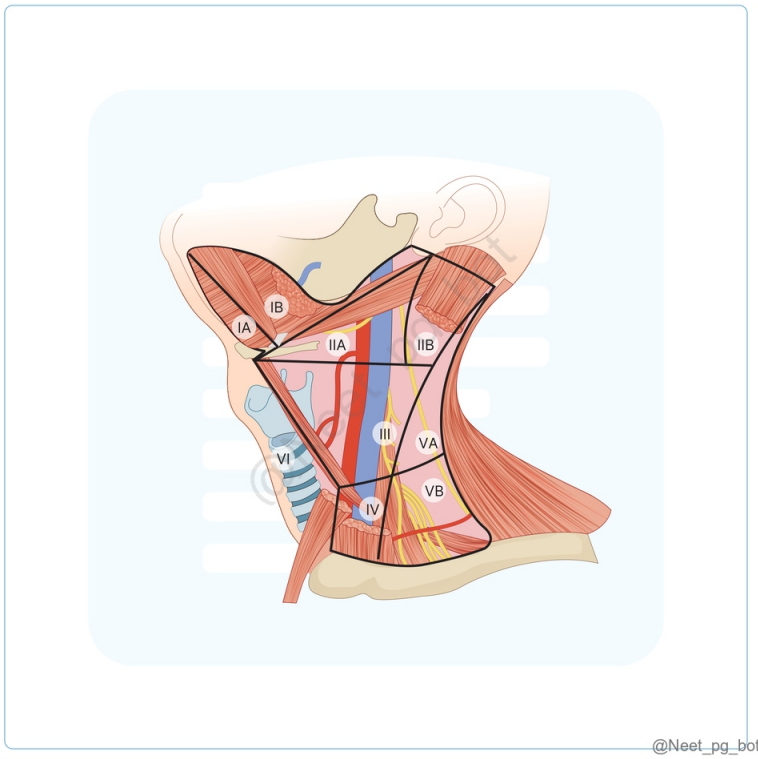
Q18: A 60-year-old male patient presents to the clinic with a non-healing ulcer on the left lateral border of the tongue. Upon examination, the lesion measures 2 cm and has been present for 6 weeks and there is a palpable lymph node in the left submandibular region. After evaluation, the surgeon decides to perform a neck dissection. The image below depicts the lymph nodes to be removed during the procedure. What type of neck dissection is planned for this patient? (Q849698)

A. Radical neck dissection

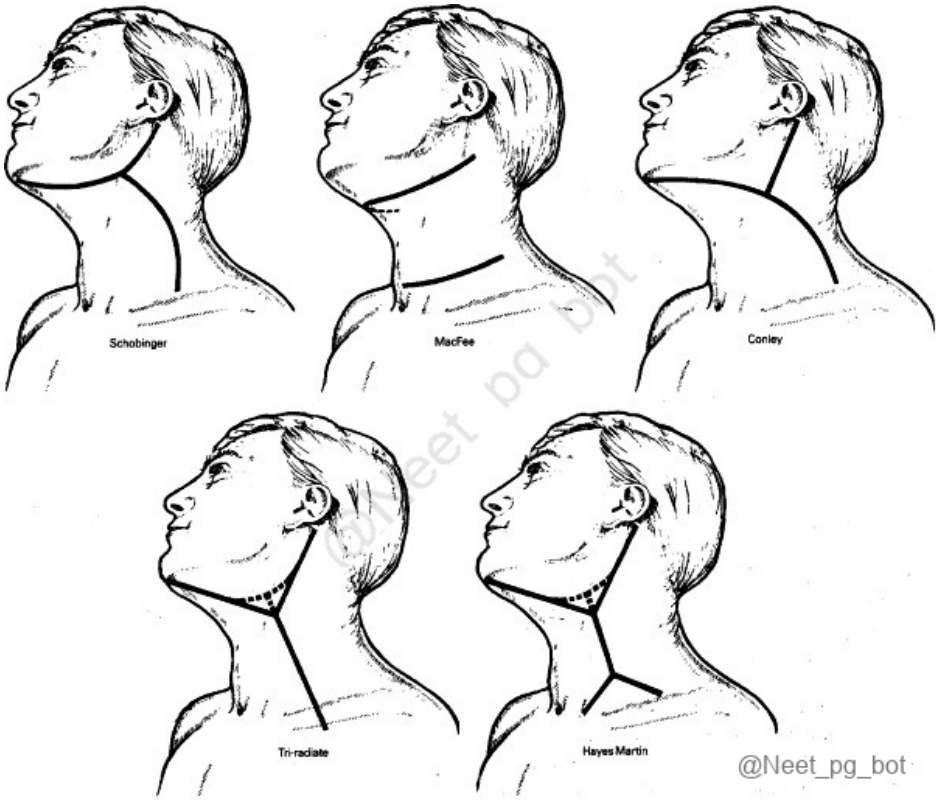
B. Modified radical neck dissection

C. Supraomohyoid neck dissection

D. Extended supraomohyoid neck dissection



Correct Answer: C. Supraomohyoid neck dissection



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The image shows removal of lymph nodes at levels I, II, and III (submental, submandibular, and upper jugular nodes). This procedure is commonly used in cases with early-stage oral cavity cancers with limited nodal involvement and is known as supraomohyoid neck dissection. Levels of Neck nodes Types of Neck Dissections: Dissection LN removed Other structures removed/Preserved Radical Neck Dissection (Option A) I - V CN XI, IJV, and SCM removed Modified Radical Neck Dissection (MRND) I (Option B) I - V CN XI preserved MRND II I - V CN XI, IJV preserved MRND III I - V CN XI, IJV, SCM preserved Extended Neck Dissection I - V CN XI, IJV, SCM removed + one/more LN groups +/- Non lymphatic structures Selective Neck Dissections LN removed Primary site of cancer Supra-omohyoid I - III Oral cavity Extended Supra-omohyoid (Option D) I - IV Oral cavity and oropharynx Postero-Lateral II - V Skin over the posterior scalp and upper neck Lateral II - IV Oropharynx, Hypopharynx, Larynx Anterior/ Central VI Thyroid/ Midline structures Surgical Incisions for Neck Dissections: 1. Schobinger Shape: Large "Y" or "7" (Horizontal limb + Vertical limb). Use: Classic Radical Neck Dissection. Cons: High risk of skin flap necrosis at the "triple point" (junction). 2. MacFee Shape: Two Parallel Horizontal incisions. Use: Patients with previous Radiation . Pros: Best blood supply; protects the carotid artery. Cons: Harder to perform (requires "tunneling"). 3. Conley Shape: Modified Schobinger with a Posterior vertical limb. Use: Better access to the back of the neck. Pros: Moves the scar away from the carotid artery for safety. 4. Tri-radiate Shape: Three limbs meeting in a Central Point . Use: Quick access for large dissections. Cons: High risk of the central tip dying (necrosis); rarely used now. 5. Hayes Martin Shape: Double "Y" configuration. Use: Maximum exposure for very extensive tumors. Cons: Complex scarring and high risk of wound breakdown.

@Neet_pg_bot

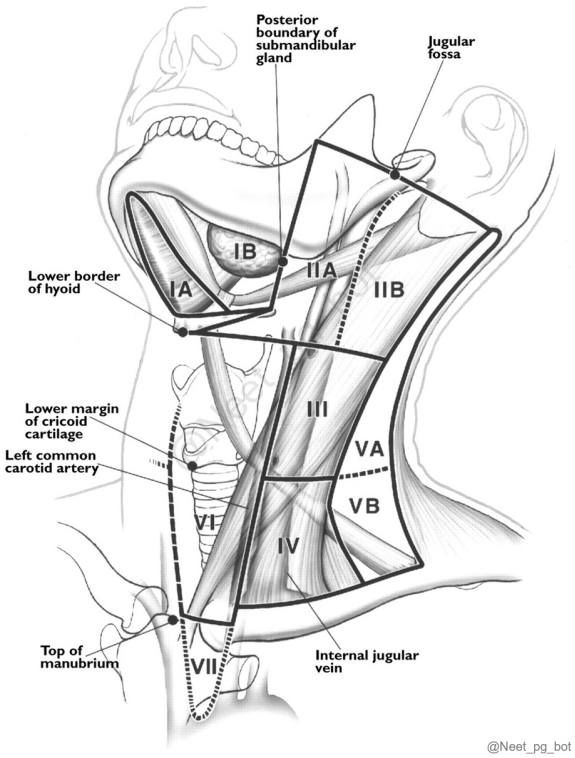
Q19: Which lymph node level in the neck is primarily responsible for draining the thyroid gland? (Q849627)

A. Level Ib

B. Level IIa

C. Level VI



D. Level III

Correct Answer: C. Level VI

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Level VI , also known as the Anterior (Central) Compartment , is primarily responsible for draining the thyroid gland . Lymph Node Level Location Structures Drained Level I Submental and Submandibular Level Ia - Under the chin, between the anterior bellies of the digastric Lower lip, floor of the mouth, tip of the tongue Level Ib Between the mandible and the digastric muscle Upper lip, lateral lower lip, oral cavity, anterior tongue, submandibular gland Level II Upper Jugular (Deep Cervical) Level IIa Upper internal jugular vein, anterior to spinal accessory nerve Oropharynx, nasopharynx, parotid gland, auricle, adjacent scalp Level IIb - Posterior to spinal accessory nerve Similar to Level IIa Level III Middle Jugular (Deep Cervical) Middle third of internal jugular vein, between hyoid bone and cricoid cartilage Level IV Lower Jugular (Deep Cervical) Lower third of internal jugular vein, from cricoid cartilage to clavicle Level V Posterior Triangle Group Level Va - Posterior to SCM, above the cricoid cartilage Nasopharynx, scalp, supraclavicular fossa Level Vb - Posterior to SCM, below the cricoid cartilage Thyroid gland, hypopharynx, esophagus Level VI Anterior (Central) Compartment Between the carotid arteries, from hyoid bone to suprasternal notch Level VII Superior Mediastinal Below the suprasternal notch, in the superior mediastinum

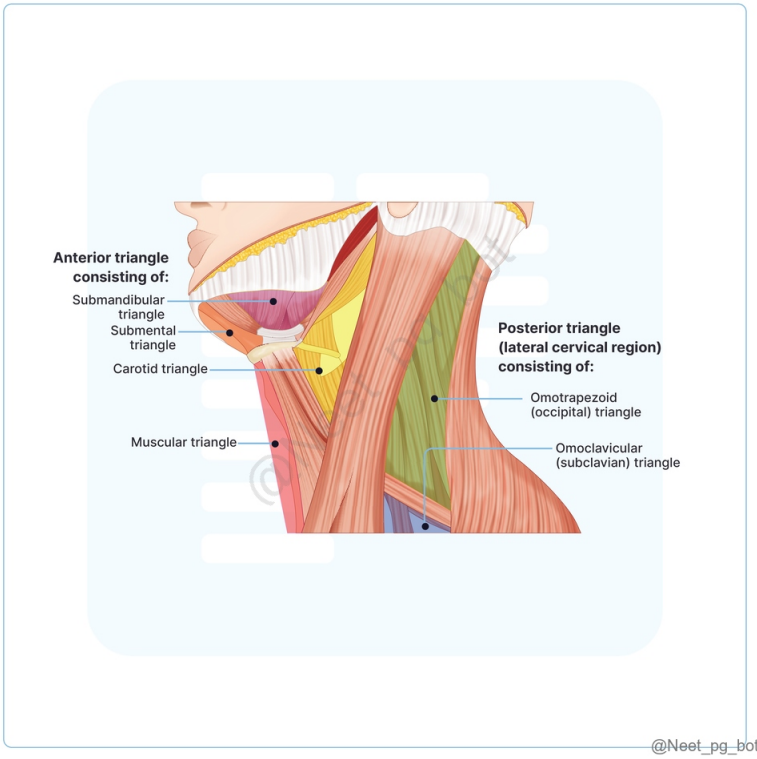
@Neet_pg_bot

Q20: Which of the following nerves is most likely to be injured during surgery in the posterior triangle of the neck, potentially leading to weakness in shoulder elevation? (Q849626)

A. Hypoglossal Nerve (CN XII)

B. Vagus Nerve (CN X)

C. Phrenic Nerve



D. Spinal Accessory Nerve (CN XI)

Correct Answer: D. Spinal Accessory Nerve (CN XI)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Spinal Accessory Nerve (CN XI) is most likely to be injured during surgery in the Posterior Triangle of the neck. Injury to the spinal accessory nerve can lead to weakness in shoulder elevation and difficulty with scapular movements because the trapezius muscle is affected. The Hypoglossal Nerve (Option A) is found in the carotid triangle, primarily controlling tongue movements. The Vagus Nerve (Option B) runs within the carotid sheath in the carotid triangle. The Phrenic Nerve (Option C) runs along the anterior scalene muscle and is more associated with the lower neck and thoracic region, controlling the diaphragm. Triangles of Neck: Anterior Triangle Triangle Boundaries Contents Submental Triangle Hyoid bone Anterior bellies of the digastric muscles Submental lymph nodes Submandibular Triangle Mandible Anterior and posterior bellies of the digastric muscle Submandibular gland, lymph nodes Carotid Triangle SCM Superior belly of the omohyoid muscle Posterior belly of the digastric muscle Common carotid artery (bifurcation into internal and external carotid arteries) Muscular Triangle SCM Superior belly of the omohyoid Midline of the neck Infrahyoid muscles Triangle Boundaries Contents Posterior Triangle Occipital Triangle SCM Trapezius Inferior belly of omohyoid Spinal accessory nerve (CN XI), brachial plexus trunks, cervical plexus Supraclavicular (Subclavian) Triangle Clavicle SCM Inferior belly of omohyoid Subclavian artery and vein, external jugular vein, supraclavicular lymph nodes

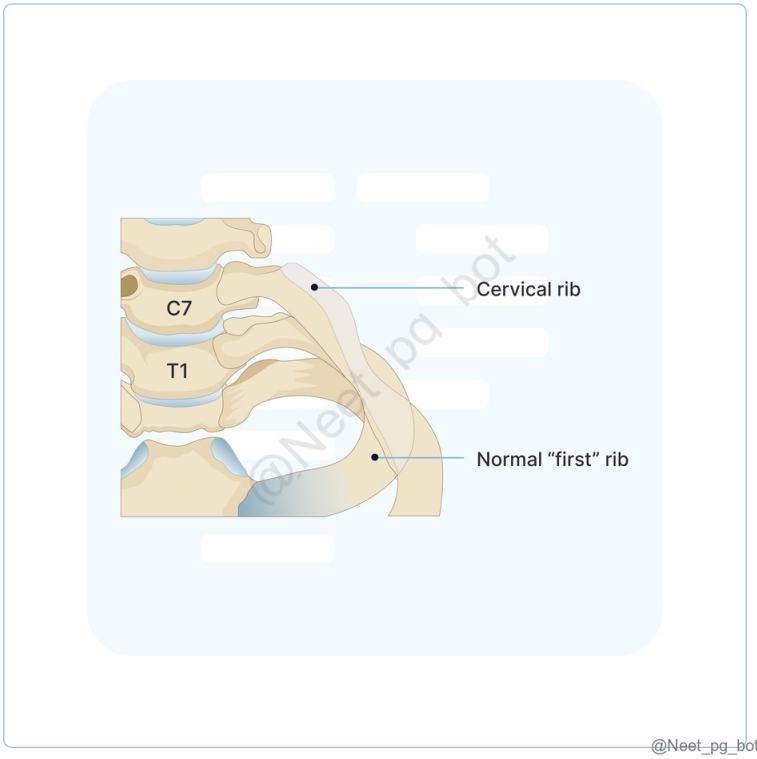
@Neet_pg_bot

Q21: Which of the following conditions is most commonly associated with a cervical rib? (Q849625)

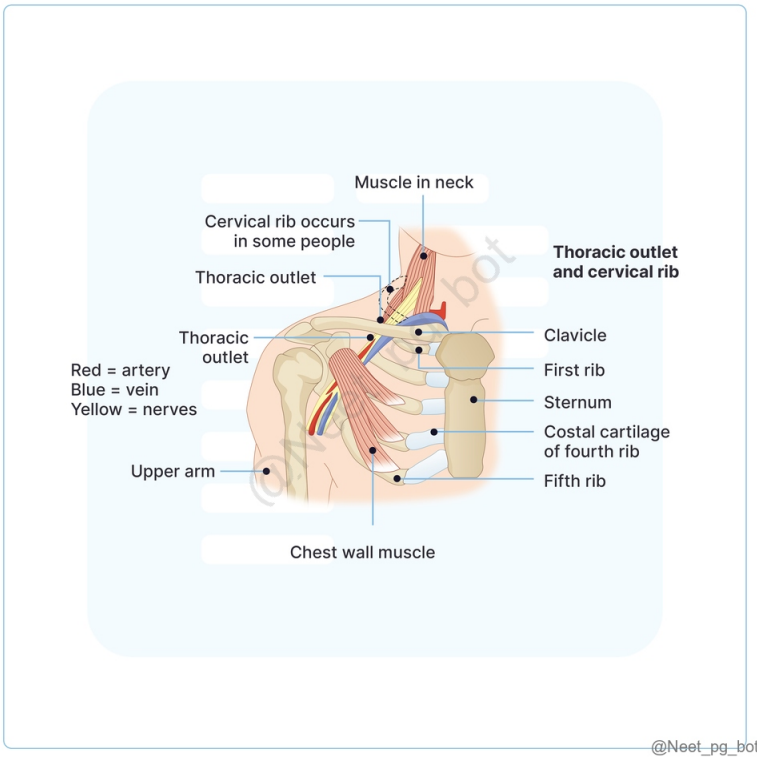
A. Rotator Cuff Tear

B. Cervical Spondylosis



C. Thoracic Outlet Syndrome

D. Pancoast’s syndrome



Correct Answer: C. Thoracic Outlet Syndrome

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Thoracic Outlet Syndrome (TOS) is the condition most commonly associated with a cervical rib. Definition : A cervical rib is an extra rib that arises from the seventh cervical vertebra (C7), located above the first rib. Cervical ribs can be present on one side (unilateral) or both sides (bilateral) of the body. Prevalence : It is a congenital anomaly present in about 0.5% to 1% of the population. Symptoms : Many individuals are asymptomatic. When symptoms occur, they may include neck pain, shoulder pain, or numbness/tingling in the arm and hand, supplied by segment T1. Symptoms arise due to compression of nearby structures such as nerves (e.g., brachial plexus) or blood vessels (e.g., subclavian artery), leading to conditions like Thoracic Outlet Syndrome (TOS) , common condition associated with a cervical rib, resulting from compression of neurovascular structures. Diagnosis : Typically diagnosed via imaging studies such as X-ray (neck). Treatment : Mild cases: Sling exercises. Severe cases: Scalenotomy (Resection of scalenus anterior muscles). Troublesome cases: Excision of cervical rib. Types of cervical rib: Complete cervical rib: When it reaches up to the 1 cervical rib. Bulbous end. Tapering end. Fibrous Band: If the end is replaced by a fibrous band. Rotator Cuff Tear (Option A ruled out) : Sometimes cause pain radiating down the arm, and shoulder movement is likely to be abnormal. There are no neurological symptoms . Not associated with cervical rib. Cervical spondylosis (Option B ruled out): It is degenerative arthritis of the spine and rarely involves the T1 nerve root. Not associated with cervical rib. Pancoast’s syndrome (Option D ruled out): It is apical carcinoma of the bronchus invading structures at the root of the neck causing pain, numbness and weakness of the hand. Not associated with cervical rib.

@Neet_pg_bot

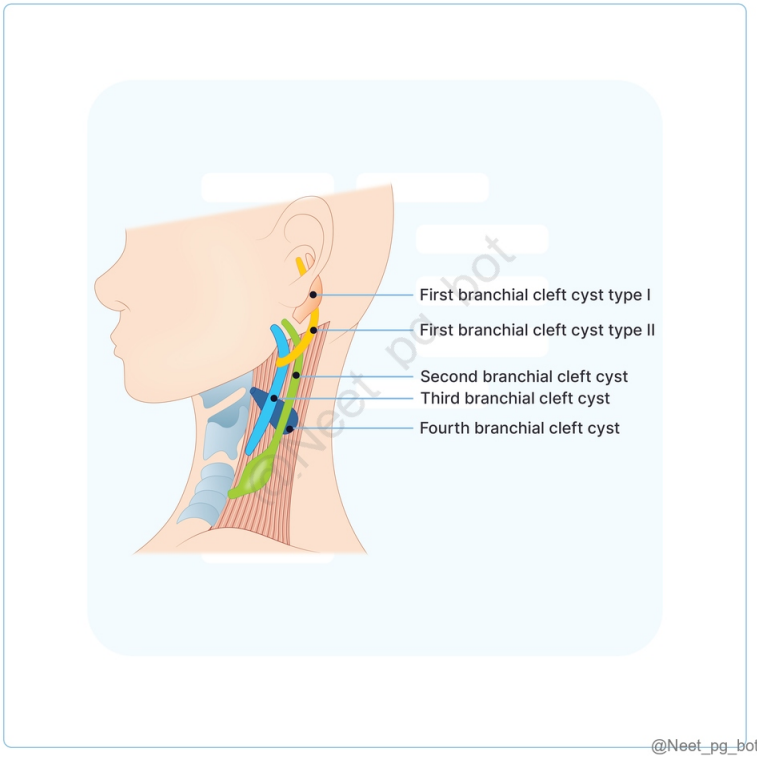
Q22: Which branchial cleft remnant typically passes behind the carotid artery? (Q849624)

A. First branchial cleft remnant

B. Second branchial cleft remnant

C. Third branchial cleft remnant



D. Fourth branchial cleft remnant

Correct Answer: C. Third branchial cleft remnant

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The third branchial cleft remnant typically passes behind the carotid artery, often traversing between the glossopharyngeal and vagus nerves. First branchial cleft remnants (Option A) are typically found near the external auditory canal and do not pass behind the carotid artery. Second branchial cleft remnants (Option B) are commonly located along the anterior border of the sternocleidomastoid muscle but do not typically pass behind the carotid artery. Fourth branchial cleft remnants (Option D) are rarer and typically have a different course, often involving the lower neck and potentially the mediastinum, rather than passing behind the carotid artery.

↑ *Back to this question in Part A*

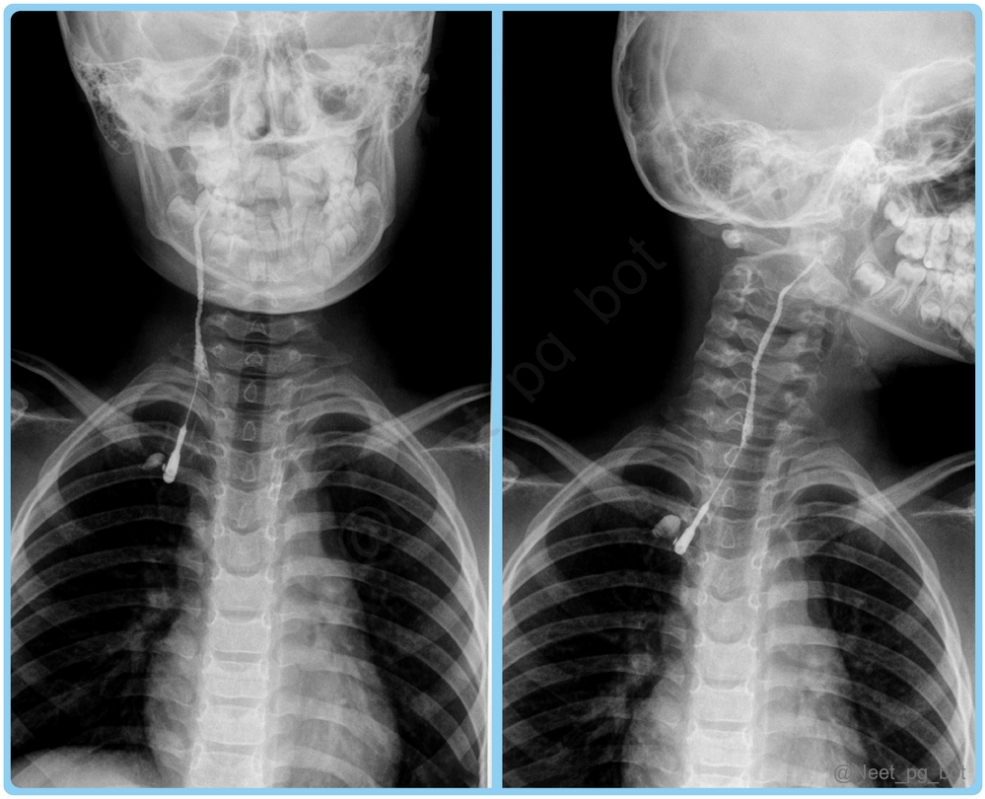
@Neet_pg_bot

Q23: A branchial fistula typically presents with which of the following characteristics? (Q849623)

A. A midline neck mass that moves with swallowing

B. A lateral neck opening that drains mucus or saliva

C. A neck swelling that enlarges after a respiratory infection



D. A solid mass in the posterior triangle of the neck

Correct Answer: B. A lateral neck opening that drains mucus or saliva

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A branchial fistula typically presents as a small opening on the lateral aspect of the neck, often along the anterior border of the sternocleidomastoid muscle. A branchial fistula is a congenital abnormality resulting from the incomplete obliteration of the branchial clefts or pouches during embryonic development. Origin : Typically arises from the second branchial cleft (most common), which fails to close properly. Anatomy : The fistula is a complete ciliated columnar epithelium tract that connects the skin of the neck to the pharynx or tonsillar fossa. External Opening : Usually found along the anterior border of the sternocleidomastoid muscle in the lower third of the neck. Internal Opening : Typically located in the tonsillar fossa or near the pharyngeal wall. Location & Level: The "Classic" Site: The opening is most commonly found at the junction of the middle and lower thirds of the anterior border of the SCM. Anatomical Path: If it is a complete fistula, the tract travels upward, passing between the internal and external carotid arteries (deep to the second arch structures and superficial to the third). Internal Opening: It typically ends in the tonsillar fossa (supratonsillar fossa). Clinical Presentation : May present with a small opening on the neck that drains mucus or saliva. Can be associated with recurrent neck infections or abscesses. Swelling or discharge near the external opening is common. Diagnosis : Diagnosis is usually based on clinical examination. Imaging studies (e.g., ultrasound, fistulogram, or CT scan) may be used to delineate the fistula tract. Branchial sinus fistulography right side Treatment : Surgical excision of the entire fistula tract is the treatment of choice. Incomplete removal can lead to recurrence.

Gray's Anatomy: The Anatomical Basis of Clinical Practice, 42nd Edition, Page 581

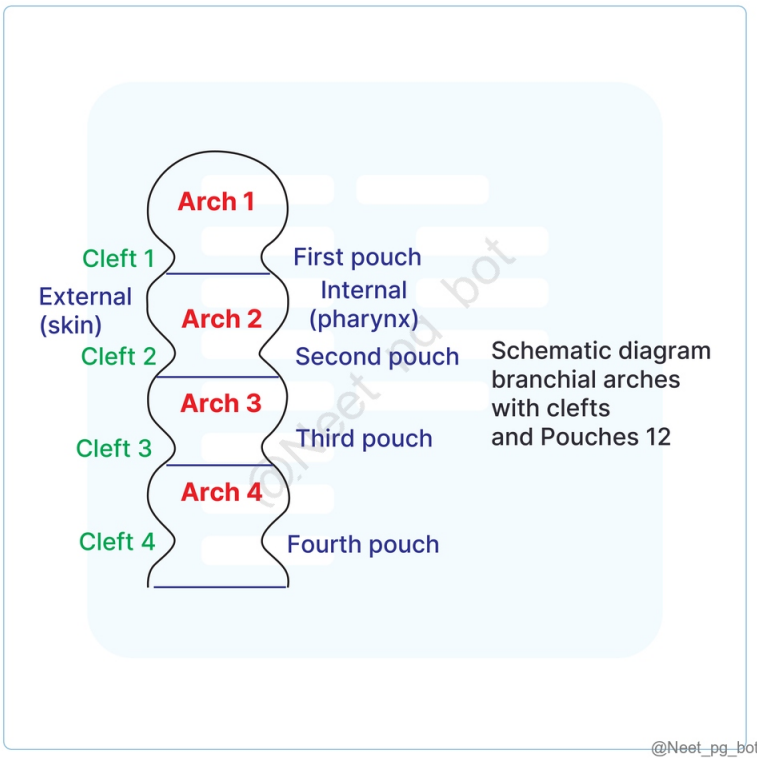
↑ *Back to this question in Part A*

Q24: A 38-year-old patient presents with a soft, translucent swelling on the front edge of the sternocleidomastoid muscle. The swelling is non-tender and has not been associated with any infection. It is diagnosed as a branchial cyst. Which of the following is false regarding the given diagnosis? (Q849622)

A. Typical location is the meeting of upper and middle thirds of sternocleidomastoid.

B. It has an onset in late adulthood.

C. Cancerous lymph nodes may have to be ruled out.



D. Complete removal is done, ideally when not infected.

Correct Answer: B. It has an onset in late adulthood.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Branchial cysts typically present in early or middle adulthood. Branchial Cysts: Definition: Fluid-filled cysts from remnants of the second branchial cleft. Lined with squamous epithelium. Filled with thick, cloudy fluid. Appearance & Location: Typical Location: Front edge of the sternocleidomastoid muscle (where upper and middle thirds meet). (Option A) Onset: Early or middle adulthood. (Option B) Appearance: Soft, sometimes translucent swelling. Complications: Infection: May cause redness, tenderness, and difficulty in distinguishing from other neck masses. Age Consideration: In individuals over 35, rule out cancerous lymph nodes (Option C) before surgical removal. Treatment: Preferred Treatment: Complete removal, ideally when not infected. (Option D) Surgical Considerations: Cyst located above hypoglossal and glossopharyngeal nerves, but beneath the posterior belly of the digastric muscle. The spinal accessory nerve must also be identified to avoid damage.

@Neet_pg_bot

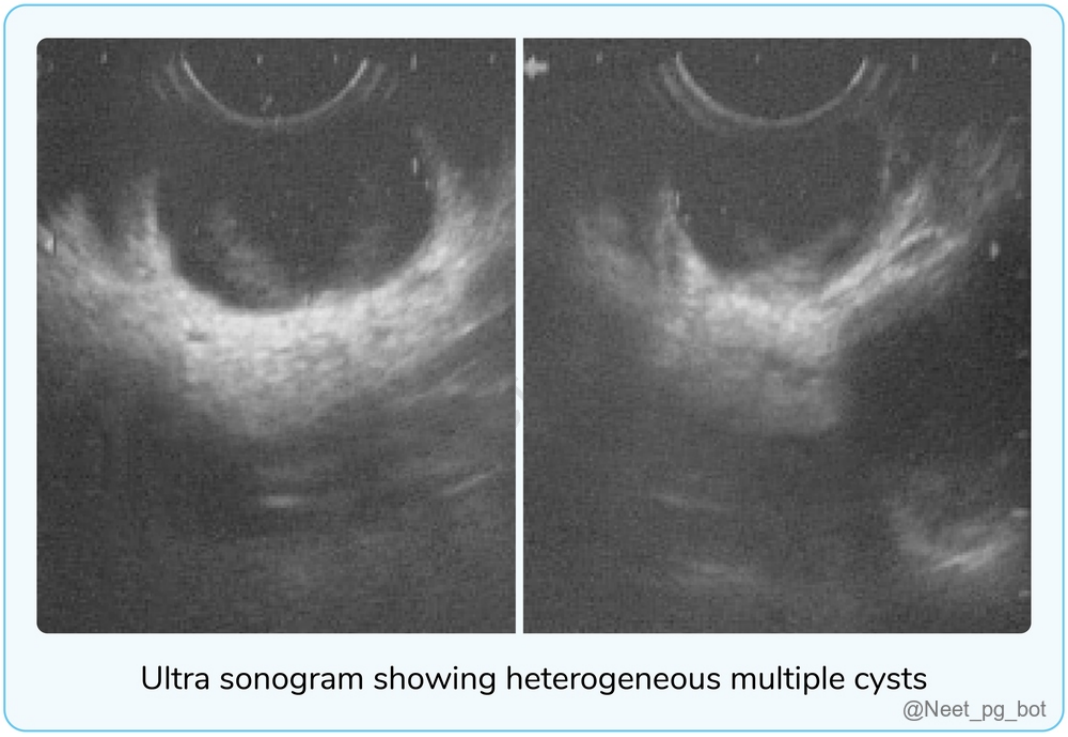
Q25: An infant presents with a translucent swelling in the neck that has been expanding over time as shown in the image below The swelling is filled with clear lymph and increases in size when the infant coughs.. Which of the following is false regarding the given condition? (Q849621)

A. Common locations include the cheek, axilla, groin, and mediastinum.

B. It has an unpredictable growth pattern.

C. It is incompressible and cystic in nature.

D. Injection of sclerosing agents can be given to reduce size.



Correct Answer: C. It is incompressible and cystic in nature.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The child is most likely suffering from Cystic hygroma , which is soft, partially compressible swelling filled with clear lymph. Features of Cystic Hygromas: Definition : Lymphatic malformations in neonates or infants. Appearance : Soft, partially compressible (Option C) swellings filled with clear lymph. Size Variation : May increase in size when the child cries or coughs. Common Locations : Neck (most common), face, submandibular region, tongue, floor of the mouth, cheek, axilla, groin, mediastinum . (Option A) Distinguishing Characteristics : Translucence. Behavior and Complications: Behavior : Unpredictable (Option B) ; can expand rapidly. Complications : Respiratory difficulties (may require aspiration or tracheostomy). Risk of infection. Treatment: Preferred Treatment : Early complete surgical excision. Alternative Treatment : Injection of sclerosing agents to reduce size. (Option D) Challenges : Complete resolution can be difficult due to its multicystic nature.

Ultra sonogram showing heterogeneous multiple cysts

Q1: What is the definition of the Miami criteria regarding intraoperative parathyroid hormone (PTH) measurement among the options listed below? (Q854934)

A. Quarter fall in 5 min

B. Quarter fall in 10 min

C. Half fall in 5 min

D. Half fall in 10 min

Correct Answer: D. Half fall in 10 min

Explanation: The Miami criteria are used in intraoperative parathyroid hormone (PTH) monitoring during parathyroidectomy. It states that a "half fall in PTH within 10 minutes after the removal of the suspected parathyroid adenoma indicates that the surgery has been successful" in curing the patient’s hyperparathyroidism. If PTH levels do not decrease after parathyroid surgery, it indicates that the cause of hyperparathyroidism may not have been fully addressed. Further investigation, reoperation, or imaging may be required to identify additional hyperfunctioning glands or exclude other potential causes.

NIH Link Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 879.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 28-year-old female presents with a bluish translucent extravasation cystic sublingual swelling . The swelling is accompanied by visible veins over the swelling and is transilluminant . What is the most likely diagnosis? (Q820193)

A. Thyroglossal cyst

B. Dermoid cyst

C. Ranula

D. Sublingual tumour

Correct Answer: C. Ranula

Explanation: Correct option C - Ranula: Ranula is a cyst that forms within the floor of the mouth, often beneath the tongue. It is caused by the obstruction of a salivary gland duct. It appears bluish-translucent due to the accumulation of saliva within the cyst. There are visible veins over it due to increased pressure on the surrounding blood vessels. It is a transilluminant swelling. Incorrect options: Option A - Thyroglossal cyst: Thyroglossal cysts are congenital fluid-filled swellings that form along the path where the thyroid gland migrates during fetal development. They appear in the midline of the neck, above the hyoid bone. They neither present as bluish-translucent cystic sublingual swellings nor do they involve the sublingual area. Option B - Dermoid cyst: Dermoid cysts are benign tumors that contain a variety of tissues, including skin, hair, and sometimes even teeth. They are typically present at birth and slowly grow over time. Dermoid cysts are not located in the sublingual area and do not usually cause visible veins overlying the area. Option D - Sublingual tumor : This refers to a tumor or growth occurring in the sublingual area.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 6-year-old child presents with a swelling in the subhyoid region of the neck that moves with deglutition and protrusion of the tongue. What is the recommended treatment for this patient? (Q820236)

A. Total thyroidectomy

B. Ramstedt's operation

C. Hemi-thyroidectomy

D. Sistrunk's operation

Correct Answer: D. Sistrunk's operation

Explanation: Correct Option D - Sistrunk's operation: The given features in the question stem lead to the diagnosis of Thyroglossal duct cyst. Sistrunk's operation is a surgical procedure used to treat a thyroglossal duct cyst. Thyroglossal duct cyst is a developmental anomaly resulting from the persistence of the thyroglossal duct. This cyst can present as a swelling in the subhyoid region of the neck that moves with swallowing and tongue protrusion. Sistrunk's operation involves removing the cyst, along with a portion of the hyoid bone and the central portion of the body of the hyoid bone. This procedure helps prevent recurrence and ensures complete removal of the cyst. Incorrect Options: Option A - Total thyroidectomy: This option is not appropriate for the given scenario. Total thyroidectomy involves the complete removal of the thyroid gland, which is not indicated for a swelling in the subhyoid region of the neck that moves with swallowing and tongue protrusion. Additionally, total thyroidectomy is not a suitable approach for a pediatric patient without proper indications. Option B - Ramstedt's operation: Ramstedt's operation, also known as pyloromyotomy, is a surgical procedure performed to treat pyloric stenosis, which is a condition affecting the stomach's outlet. This option is not relevant to the given scenario of a swelling in the subhyoid region of the neck. Option C - Hemi-thyroidectomy: Hemi-thyroidectomy involves the removal of half of the thyroid gland. This option is also not appropriate for the situation described. The subhyoid swelling is not related to the thyroid gland and its removal would not address the issue.

References:

PREPLADDER notes

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 45-year-old female patient undergoes a routine thyroid examination, during which a palpable thyroid nodule is discovered. Fine-needle aspiration cytology confirms the presence of papillary thyroid cancer. All of the following statements are true regarding papillary thyroid cancer Except: (Q820244)

A. It often presents with cervical lymph node metastases.

B. It is the most common type of thyroid cancer.

C. It arises from parafollicular C-cells

D. It is TSH dependent

Correct Answer: C. It arises from parafollicular C-cells

Explanation: Correct Option C - It arises from parafollicular C-cells: Papillary thyroid cancer arises from follicular cells of the thyroid gland, not from parafollicular C-cells. Parafollicular C-cells, also known as parathyroid cells or clear cells, are responsible for producing calcitonin, a hormone that regulates calcium levels in the body. Medullary thyroid cancer, a different type of thyroid cancer, arises from parafollicular C-cells. Incorrect Options: Option A - It often presents with cervical lymph node metastases: Papillary thyroid cancer commonly spreads to nearby lymph nodes in the neck. This is a characteristic feature of this type of thyroid cancer. Option B - It is the most common type of thyroid cancer: Papillary thyroid cancer is indeed the most common type of thyroid cancer,

accounting for approximately 70-80% of all cases. Option D - It is TSH dependent: Papillary thyroid cancer is generally considered to be TSH (thyroid-stimulating hormone) dependent. TSH, which is produced by the pituitary gland, stimulates the thyroid gland to produce thyroid hormones. Elevated TSH levels can contribute to the growth and function of papillary thyroid cancer cells. This is why TSH suppression therapy (using medications to lower TSH levels) is often part of the treatment plan for papillary thyroid cancer.

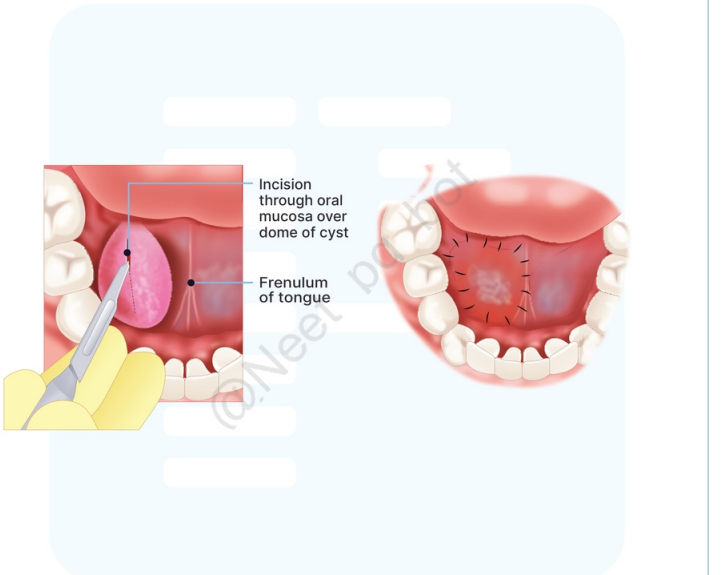
@Neet_pg_bot

Q5: A patient presents with swelling in the floor of the mouth. Upon examination, the swelling appears as shown in the image. What is the most likely diagnosis? (Q854776)

A. Cystic hygroma

B. Ranula

C. Dermoid



D. Branchial cyst

Correct Answer: B. Ranula

Explanation: The most likely diagnosis is Ranula, a specific type of mucus retention cyst that develops on the floor of the mouth, typically caused by blockage or rupture of the ducts of the sublingual or submandibular glands. This leads to mucus accumulation and the formation of a cystic swelling. Ranula Definition Ranulas are a type of extravasation mucocele caused by the rupture of the main duct or obstructed acini of the sublingual gland. They appear as bluish swellings on the floor of the mouth and resemble the belly of a frog. {{caption_text}} Location Commonly found in the anterior floor of the mouth. When it extends through the mylohyoid muscle, it presents as a submental swelling known as a "plunging ranula." Symptoms Typically soft, fluctuant, and painless unless infected. Diagnosis Confirmed through Magnetic Resonance Imaging (MRI) Ultrasound Aspiration of thick, sticky saliva differentiates it from a lymphangioma. Treatment Removal of the sublingual gland is preferred. Incision, drainage, and marsupialisation have low success rates. Although marsupialisation is often adequate, it has a higher recurrence rate compared to sublingual gland excision. OK-432 injection Botulinum toxin injections Incorrect Options: Cystic hygroma (Option A) is a congenital abnormality of the lymphatic system, usually presenting as a soft, cystic swelling in the neck area. It is not typically found on the floor of the mouth. Dermoid (Option C) cysts are developmental cysts that contain various tissues, such as skin, hair follicles, and sebaceous glands. While they can occur on the floor of the mouth, they are not exclusive to this region. Branchial cysts (Option D) are congenital cysts that form from remnants of the branchial apparatus. They are primarily found in the neck area and are not commonly seen on the floor of the mouth.

@Neet_pg_bot

Q6: A 23-year-old male patient presents with a swelling in the midline of his neck that shifts when he swallows or sticks out his tongue. What is the probable diagnosis? (Q855273)

A. Brachial cyst

B. Thyroglossal cyst

C. Plunging ranula

D. Dermoid cyst

Correct Answer: B. Thyroglossal cyst

Explanation: A thyroglossal cyst is a midline neck swelling that typically moves with swallowing or protrusion of the tongue. It results from incomplete closure of the thyroglossal duct, which is an embryological remnant. The cyst often lies in close proximity to the hyoid bone and can be felt to shift with movement of the tongue or swallowing. Thyroglossal Cyst: It is a congenital neck mass resulting from the persistence of the thyroglossal duct, an embryological structure. It can also be present in adulthood. The cyst represents a remnant of this duct and can be found anywhere along the midline from the base of the tongue to the thyroid isthmus. Most Common Site: Subhyoid (can also be seen on the floor of the mouth, Suprahyoid, near thyroid cartilage and foramen caecum) Treatment: Sistrunk Procedure: Complete surgical excision of the cyst and its tract up to the base of the tongue and a portion of the hyoid bone to prevent recurrence. Incision and drainage are never done as they lead to the formation of a Thyroglossal fistula. (It also forms if an inflamed cyst ruptures.)—Always Acquired. Brachial cyst (Option A): A brachial cyst, or branchial cleft cyst, generally appears as a lump along the anterior border of the sternocleidomastoid muscle, not in the midline of the neck. Plunging ranula (Option C) is a mucous cyst found in the floor of the mouth, typically located laterally rather than in the midline, and it usually doesn't shift with swallowing or tongue protrusion. Dermoid cyst (Option D) , a type of teratoma, is often present at birth and can appear in the midline of the neck. However, these cysts typically do not move with swallowing or tongue protrusion.

@Neet_pg_bot

Q7: A 32-year-old man with a history of chronic tobacco chewing presents with a painless white patch in the gingivobuccal sulcus that has persisted for the past 7 months. The lesion is non-scrapable and there is no restriction of mouth opening. What is the most appropriate next step in management? (Q857858)

A. Local excision and biopsy

B. Advise cessation of tobacco and observe

C. Intralesional steroid injections

D. Sclerotherapy

Correct Answer: A. Local excision and biopsy

Explanation: A persistent, non-scrapable white lesion of the oral mucosa in a chronic tobacco chewer is most suggestive of oral leukoplakia , a premalignant condition . Any oral white lesion persisting for more than 2 weeks , especially in individuals with tobacco exposure, requires histopathological evaluation to assess for epithelial dysplasia or early squamous cell carcinoma . Therefore, biopsy is mandatory and represents the most appropriate next step in management. Option B. Advise cessation of tobacco and observe: Tobacco cessation is important but cannot replace biopsy in a persistent lesion. Option C. Intralesional steroid injections: Used in inflammatory or fibrotic conditions like oral submucous fibrosis, not leukoplakia . Option D. Sclerotherapy of the lesion: Reserved for vascular lesions; no role in premalignant oral lesions .

@Neet_pg_bot

Q8: The false statement about cystic masses of the neck is: (Q857144)

A. Type 3 branchial fistula has its internal orifice on cricopharynxgeus

B. Cystic hygroma is filled with clear lymph

C. Thyroglossal cyst moves upwards on swallowing, and tongue protrusion

D. Fluctuation is positive in branchial cyst

Correct Answer: A. Type 3 branchial fistula has its internal orifice on cricopharynxgeus

Explanation: A branchial fistula can appear on one side or both sides and likely indicates a persistent second branchial cleft. The opening is typically found in the lower part of the neck near the front edge of the sternocleidomastoid muscle externally and internally; it's situated behind the tonsil on the front aspect of the posterior faucial pillar. In Type III cases, the passage runs between the internal and external carotid arteries, possibly reaching the pharynx's lateral wall or the base of the skull. Cystic hygroma is filled with clear lymph (Option B): Cystic hygroma lymphangioma is a birth defect with a large fluid-filled sac around the head and neck. The cyst comprises lymphatic tissues and white blood cells. Thyroglossal cyst moves upwards on swallowing and tongue protrusion (Option C): Thyroglossal duct cysts move upwards on swallowing and notably with tongue protrusion but this may occur with other midline cysts. Fluctuation is positive in branchial cyst (Option D): Branchial cyst is a fluctuant swelling that may transilluminate and is usually soft at its early stages, which makes it difficult to palpate.

@Neet_pg_bot

Q9: Which of the following structures is most likely to be injured, leading to lower lip paralysis in a 30-year-old teacher who underwent parotidectomy? (Q856747)

A. Temporal branch of the facial nerve

B. Cervical branch of facial nerve

C. Parotid duct

D. Mandibular branch of facial nerve

Correct Answer: D. Mandibular branch of facial nerve

Explanation: Weakness of the left lower lip after parotid surgery suggests injury to the mandibular branch of the facial nerve. The facial nerve is responsible for motor innervation to the muscles of facial expression. It is more commonly at risk during parotid gland surgeries Complications of Parotidectomy: Complication Description Temporary Facial Palsy Mostly the lower branches of the facial nerve - the marginal mandibular nerve. Most patients recover over time. Infection Rare, as parotidectomy is a clean procedure. Aseptic precautions and timely drain removal reduce the risk. Hematoma Formation Uncommon. Careful intraoperative hemostasis can prevent it. Larger hematomas may indicate a bleeding disorder and require management. Sialocele Formation Occurs if the main ductal system is exposed. Preventable with subcapsular dissection. Treatment: Anticholinergics, aspiration, and pressure dressings. Retromandibular area hollowing Can occur post-surgery Reduced by placing autologous fat grafts during the surgery. Frey’s Syndrome Also known as gustatory sweating; Caused by the cross-innervation of sweat glands by regenerating nerve fibres of the auriculotemporal nerve. For mild cases : Give antiperspirants;

Severe cases: Botulinum toxin injections or tympanic neurectomy. Permanent Facial Nerve Weakness D/t transection of the facial nerve during the surgery. Facial Numbness Permanent numbness of the earlobe, D/t transection of the great auricular nerve during the surgery. Temporal branch of the facial nerve (Option A) controls the upper face (e.g., forehead and eyelid), so injury here would not affect the lower lip . Cervical branch of the facial nerve (Option B) innervates the platysma muscle, which primarily affects neck and lower face movement but would also cause some degree of neck weakness and not just isolated lower lip weakness . Parotid duct (Option C) damage can affect the saliva flow but does not result in weakness of the lower lip .

@Neet_pg_bot

Q10: Which part of cranial fossa is injured in Raccoon eyes? (Q820177)

A. Anterior cranial fossa

B. Middle cranial fossa

C. Posterior cranial fossa

D. Bone aponeurotic layer

Correct Answer: A. Anterior cranial fossa

Explanation: Correct option B - Anterior cranial fossa Raccoon eyes, also known as periorbital ecchymosis , is a classic clinical sign of a basilar skull fracture , specifically involving the anterior cranial fossa . The bruising occurs when blood from a fracture (often involving the orbital plate of the frontal bone or the cribriform plate of the ethmoid) tracks forward into the loose subcutaneous tissue around the orbits. A key diagnostic feature is that the ecchymosis typically spares the tarsal plate , as the palpebral fascia prevents blood from crossing into the eyelid itself. Middl e cranial fossa (Option A): Typically associated with Battle's sign (post-auricular/mastoid ecchymosis), hemotympanum, and CSF otorrhea. Posterior cranial fossa (Option C): It usually involves injuries near the foramen magnum or occipital bone. B one aponeurotic layer (Option D): While a subgaleal hematoma (bleeding between the periosteum and the aponeurosis) can cause swelling, it is not the primary anatomical site of the fracture causing "Raccoon eyes."

@Neet_pg_bot

Q11: Which statement regarding retrosternal goitre is accurate? (Q855029)

A. Operated in all patients regardless of symptoms

B. Sternal incision is always required to operate

C. It receives blood supply from the thoracodorsal artery

D. Most of the retrosternal goitres can be removed by a neck incision

Correct Answer: D. Most of the retrosternal goitres can be removed by a neck incision

Explanation: Surgical approach decisions for retrosternal goitre depend on the size , location , and associated symptoms , and while some may require a sternotomy, most can be removed through a neck incision alone. Retrosternal goitre Definition A thyroid gland enlargement that extends into the mediastinum behind the Sternum Types Primary: Ectopic thyroid tissue in the mediastinum (10%) Secondary: Starts from neck and extends retrosternally (90%) Clinical Features Neck Swelling with Compression Symptoms: Difficulty breathing (tracheal compression) and swallowing (esophageal compression). Pemberton Sign: Facial flushing and increased difficulty breathing when raising the arms due to thoracic inlet compression. Diagnosis Physical examination: Limited palpation of the lower border of the thyroid swelling. Imaging: Computed Tomography (CT) Scan of the Neck and Chest is IOC to assess the extent of mediastinal involvement and to evaluate compression of surrounding structures. Management Primary / Recurrent / Large Malignant Retrosternal Goiter - Median Sternotomy (Option B ruled out) Secondary Retrosternal Goiter - Cervical / Neck Incision Operated in all patients regardless of symptoms (Option A): Surgical resection is the preferred standard for managing symptomatic retrosternal goitres and some asymptomatic cases. However, a "watchful waiting" approach may be appropriate for selected asymptomatic patients, especially with the development of alternative treatments. It receives blood supply from the thoracodorsal artery (Option C): blood supply to a retrosternal goitre primarily comes from the thyroid arteries, and the thoracodorsal artery mainly supplies the latissimus dorsi muscle, not the thyroid or retrosternal goitre.

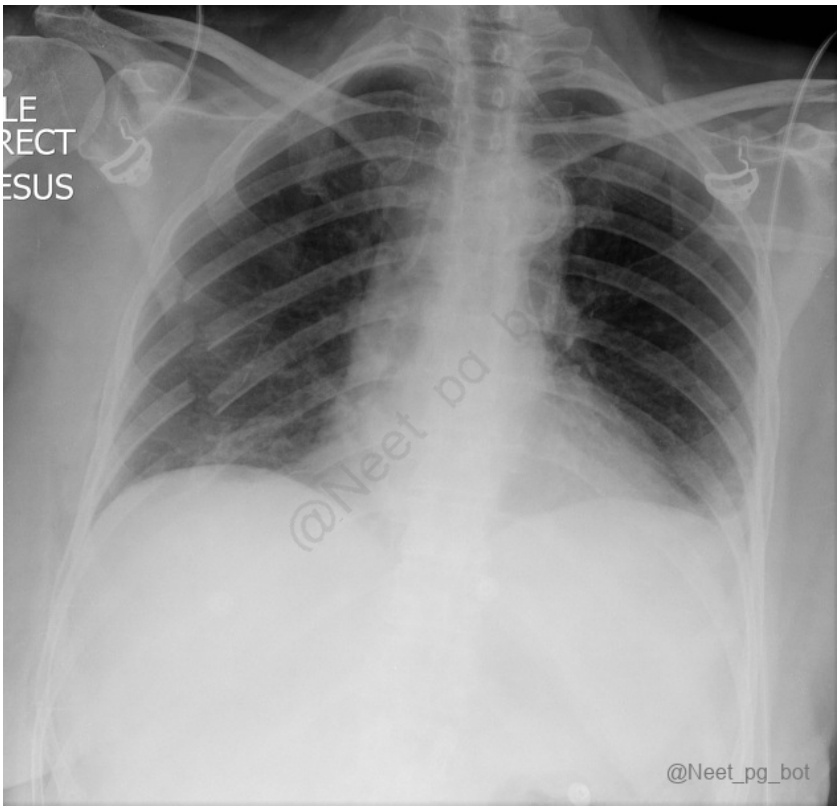
@Neet_pg_bot



Q12: A car driver was brought into the A & E following a RTA with complaints of breathlessness. On examination, his vitals are PR-112/min, BP-100/70, SpO2-90 %, and there is extensive bruising on his chest. What is the management of this patient? (Q859614)

A. Chest tube drainage

B. 24% oxygen

C. IPPV

D. Internal operative fixation of the fracture’s segments

Correct Answer: C. IPPV

Explanation: The given condition, along with the X-ray showing multiple rib fractures, is suggestive of a Flail chest, and the most appropriate intervention in this case is IPPV . Positive pressure ventilation is the appropriate initial management in such cases, as it helps to stabilise the flail segment by providing consistent internal pressure, reducing paradoxical movement, and improving oxygenation. Flail chest Definition It occurs when three or more consecutive ribs are fractured in at least two places , creating a flail segment that moves independently. It exhibits paradoxical chest movement (inwards during inhalation & outwards during exhalation) Management Ventilation Support: Oxygen supplementation and Analgesics- Initial management IPPV is the preferred TOC. Tracheostomy if support exceeds 10 days. Injury Management: Intercostal Tube Drainage : Removes air/fluids from the pleural space. Rib Fixation (Option D) : Stabilises the chest wall. Supportive Care: Blood Transfusions : For blood loss. IV Fluids : For hydration. Antibiotics : To prevent infection. Medications : Bronchodilators and steroids. Thoracotomy: Considered in severe cases Chest tube drainage (Option A) is used for pneumothorax or hemothorax, which may accompany the flail chest. However, without these complications, immediate airway management and stabilisation are more crucial, given the severity of the respiratory distress. 24% oxygen (Option B) is not sufficient for a patient in respiratory distress with a SpO2 of 90% . The primary management here should be focused on supporting ventilation and ensuring adequate oxygenation, which IPPV would achieve more effectively.

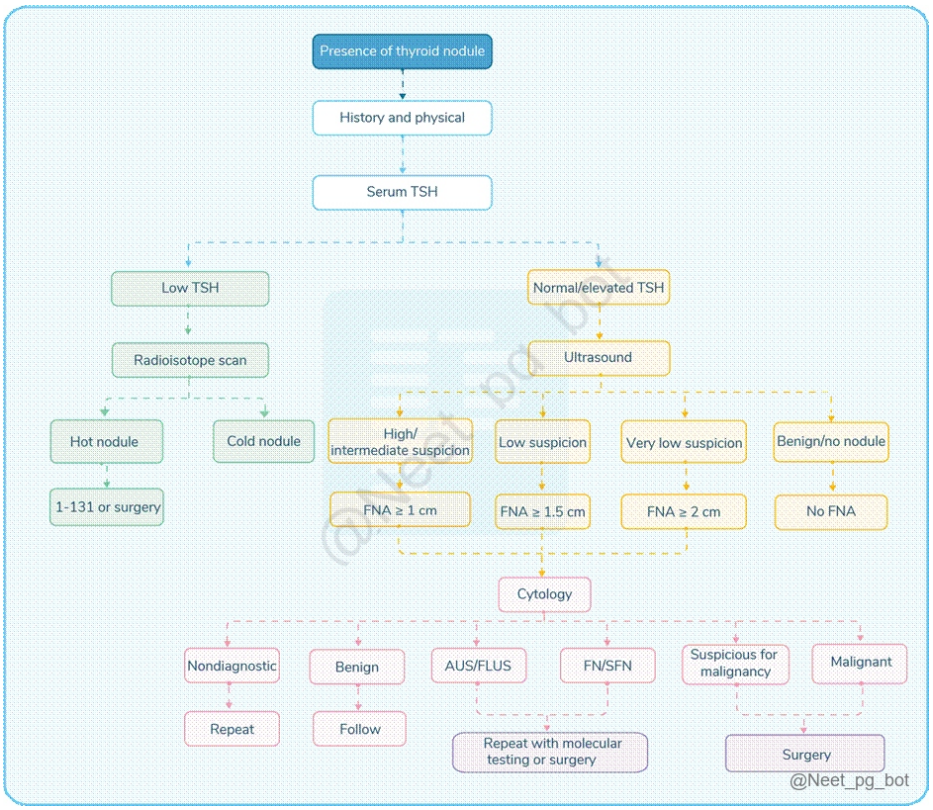
@Neet_pg_bot

Q13: Which of the following tests would a surgeon advise first in a patient with a large thyroid swelling? (Q859615)

A. Ultrasound of the neck



B. FNAC

C. Biopsy

D. Radioiodine uptake

Correct Answer: A. Ultrasound of the neck

Explanation: When a patient presents with a large thyroid swelling, the first step in evaluating the swelling is typically to perform an ultrasound of the neck . USG provides high resolution of the thyroid gland by well-characterizing parenchymal and nodular abnormalities. It provides valuable information about the size, characteristics, and composition of the swelling, and it also helps differentiate cystic and solid thyroid nodules. Ultrasound can guide further management, such as whether fine-needle aspiration cytology (FNAC) is necessary. {{caption_text}} FNAC (Option B) is a minimally invasive diagnostic procedure to evaluate abnormalities in various tissues, including thyroid nodules, but it is usually performed after imaging to assess the cytological details of the swelling. Biopsy (Option C) is generally not the first step in managing thyroid swelling. FNAC is typically preferred over a surgical biopsy for diagnostic purposes. A biopsy would be considered only if malignancy is strongly suspected and other tests (like FNAC) are inconclusive. Radioiodine uptake (Option D) is used to assess the functional status of the thyroid, but it is not the first step in evaluating a swelling. It is primarily used in cases where there are concerns about thyrotoxicosis or hyperthyroidism or in the context of thyroid nodules with known thyroid dysfunction.

@Neet_pg_bot

Q14: A 32-year-old patient who is a chronic alcoholic presents with oral ulcers and a burning sensation. A picture of the oral cavity is given below. What is the most likely diagnosis? (Q855770)

A. Leukoplakia

B. Erythroplakia

C. Submucosal fibrosis

D. Malakoplakia

Correct Answer: A. Leukoplakia

Explanation: Leukoplakia is a precancerous lesion that typically presents as white patches or plaques on the mucosal surfaces, often seen in the mouth, tongue, and gums. Leukoplakia Definition White patch on oral mucosa, defined clinically, excluding conditions like lichen planus, candidiasis, etc. Causes Smoking, tobacco chewing Alcohol abuse (especially with smoking) Chronic trauma (ill-fitting dentures, cheek bites) Associated with submucous fibrosis, hyperplastic candidiasis, Plummer-Vinson syndrome Common sites Buccal mucosa (most common in India) Oral commissures, floor of mouth, tongue, gingivobuccal sulcus, lip mucosa Age & Gender Men in their 40s are 2-3 times more affected than females. Clinical types Homogenous : Smooth or wrinkled white patch, lower malignancy risk Nodular (speckled) : White patches on an erythematous base, higher malignancy risk Erosive (erythroleukoplakia) : Interspersed with red patches, fissures, highest malignancy risk Malignant potential 1-17.5% risk, average 5% malignant transformation Higher risk in dysplastic lesions and certain locations Treatment Remove causative factors : Spontaneous regression in some cases. Biopsy : For lesions with high malignant potential. Surgical excision or laser/cryotherapy : For suspicious or small lesions Erythroplakia (Option B) is a bright red velvety plaque that cannot be characterised clinically or pathologically as any other disease. While it is a more dangerous condition (having a higher risk of transformation to oral cancer), and it can sometimes present with ulcers , it does not typically present with a burning sensation in the same way that leukoplakia might. Submucosal fibrosis (Option C) is a progressive fibrosis deep in the mucosa of the oral cavity. It causes trismus and ankylosing glossitis, not necessarily with oral ulcers as the primary complaints. Malakoplakia (Option D) is a rare inflammatory condition characterised by soft, yellowish plaques and is often found in immunocompromised individuals. It is more commonly seen in the genitourinary tract and is associated with chronic infections.

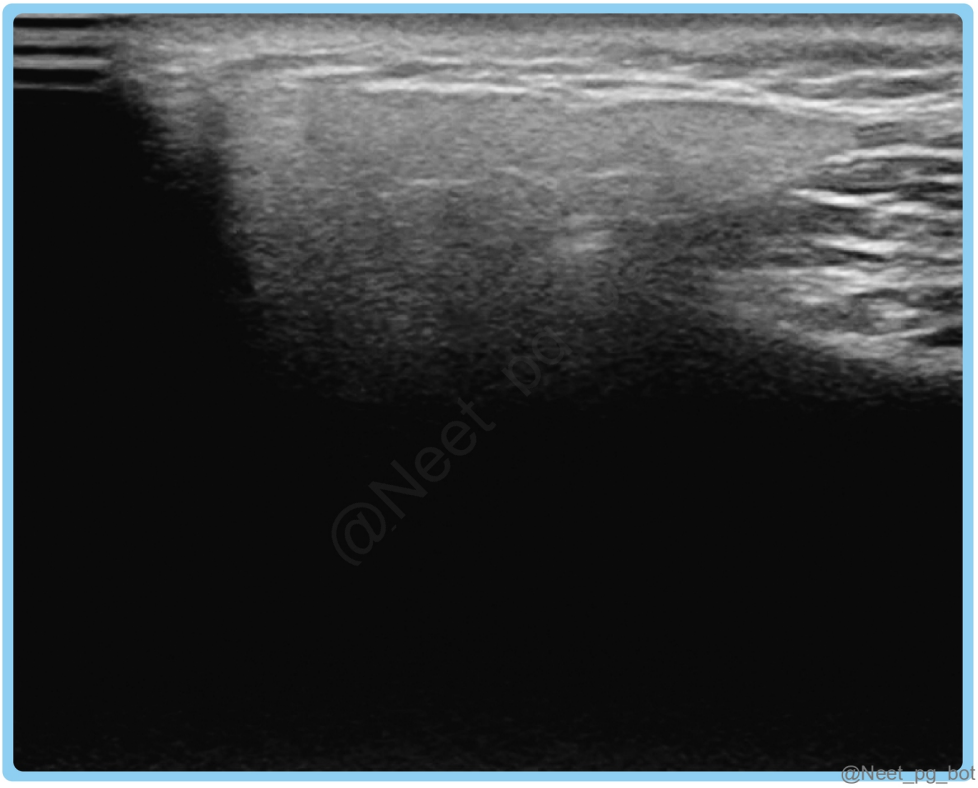
@Neet_pg_bot



Q15: A 45-year-old patient complained of pain in one side of the neck. She is afraid of eating food as it worsens the pain. Ultrasound imaging of the salivary glands is done and shown below. What is the most likely diagnosis? (Q855805)

A. Sialolithiasis

B. Foreign body

C. Osteoma of the floor of the mouth

D. Cervical lymphadenopathy

Correct Answer: A. Sialolithiasis

Explanation: Sialolithiasis refers to the formation of salivary stones (sialoliths) in the salivary glands , which commonly occur in the submandibular gland . Ultrasound imaging is one of the most common diagnostic tools for identifying sialoliths , as it can show hyperechoic areas indicative of salivary stones and their location in the gland. Sialolithiasis Definition Formation of salivary gland stones within the gland ducts Commonly Affected Age 30 to 60 years Commonly Affected Gland Submandibular gland (85%), due to its ascending duct course and the

mucinous, viscous saliva it produces, leads to stagnation and stone formation. Risk Factors Duct abnormalities Inflammation Increased calcium content in saliva Chronic dehydration Medications causing decreased salivary flow Clinical Features Cyclical postprandial swelling, dryness, asymmetrical gland enlargement, palpable stone, possible abscess formation. {{caption_text}} Submandibular Swelling Diagnostic Methods Conventional Radiographs : Initial diagnostic test, but may miss small stones. CT Scanning, USG, Magnetic Resonance Sialogram : More sensitive, especially for small stones. Sialography : Gold standard; involves dye injection for diagnosis and potential therapeutic use. Sialendoscopy : Direct visualization and removal of stones, safer than open surgery. {{caption_text}} CT- Wharton’s duct Sialolithiasis Treatment Options Small Distal Stones (<5 mm) : Endoscopic removal Large Distal Stones (>5 mm) : Duct slitting Impacted Stones : Transoral route Intraparenchymal Stones (5–7 mm) : Endoscopic extraction Large Stones (7-10 mm) : May require transoral slitting or external shock wave lithotripsy (ESWL) Hilar Stones : Endoscopic removal Gland Removal : Last resort if other treatments fail Foreign body (Option B) in the salivary ducts can also cause symptoms of pain and swelling , but these are typically associated with a history of trauma or foreign object ingestion. The pain may not specifically worsen with eating as it does in sialolithiasis , and ultrasound would typically show a foreign object rather than a stone . Osteoma of the floor of the mouth (Option C) is a benign bone tumour that can occur in the jaw or floor of the mouth , but it does not typically cause the sharp, intermittent pain associated with sialolithiasis . Additionally, ultrasound would not typically identify an osteoma as it is a bone . Cervical lymphadenopathy (Option D) refers to enlarged lymph nodes in the neck, often due to infections or malignancy. It usually presents with swelling and tenderness in the neck region. However, it does not cause pain when eating or pain localised to a specific salivary gland, which is characteristic of sialolithiasis.

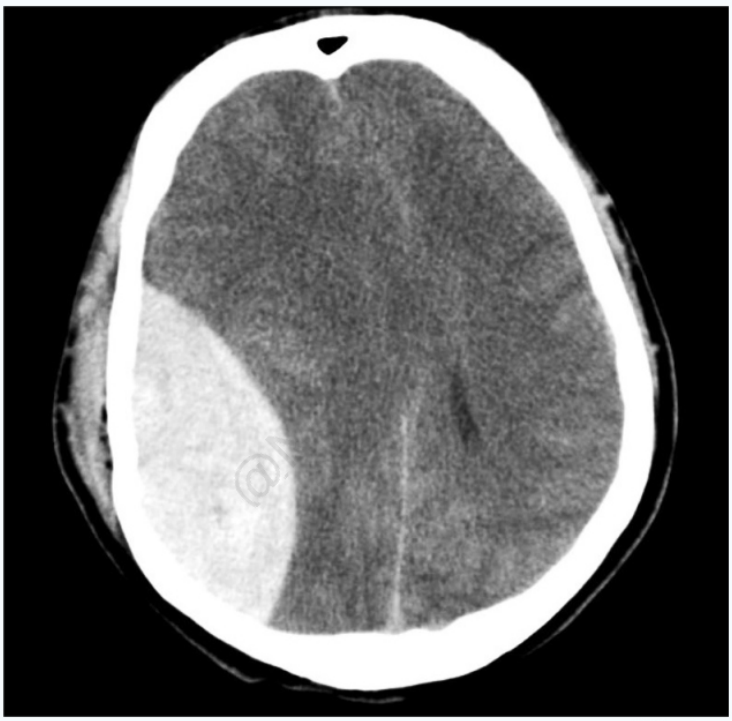
Bailey and Love's Short Practice of Surgery, 28th edition, Pages 836 - 838

↑ *Back to this question in Part A*

@Neet_pg_bot



Q16: A 30-year-old patient of RTA was brought to the emergency department. There was a history of vomiting. The patient was initially conscious and oriented, but after a few hours, he became drowsy and then progressed to stupor and coma. This sequence of lucid interval was followed by neurological deterioration. What is the preferred treatment option? (Q879144)

A. Wait for spontaneous resolution

B. Burr hole and evacuation

C. Craniotomy

D. Conservative management with IV mannitol

Correct Answer: C. Craniotomy

Explanation: The clinical history and CT imaging with a biconvex/lentiform hyperdense hematoma point towards the diagnosis of Epidural/Extradural hematoma (EDH), which is a neurosurgical emergency because it can rapidly expand due to arterial bleeding. Craniotomy is required when there is: Hematoma >30 mL Thickness >15 mm Midline shift >5 mm Neurological deterioration present Craniotomy allows complete evacuation of the EDH, ligation of the bleeding meningeal artery and decompression of the brain. Wait for spontaneous resolution (Option A): Never appropriate in acute EDH, because it can lead to herniation. Burr hole evacuation (Option B): Not effective for EDH since blood will be clotted and arterial, hence it requires craniotomy. Conservative management with IV mannitol (Option D): Temporary measure before surgery, not definitive management.

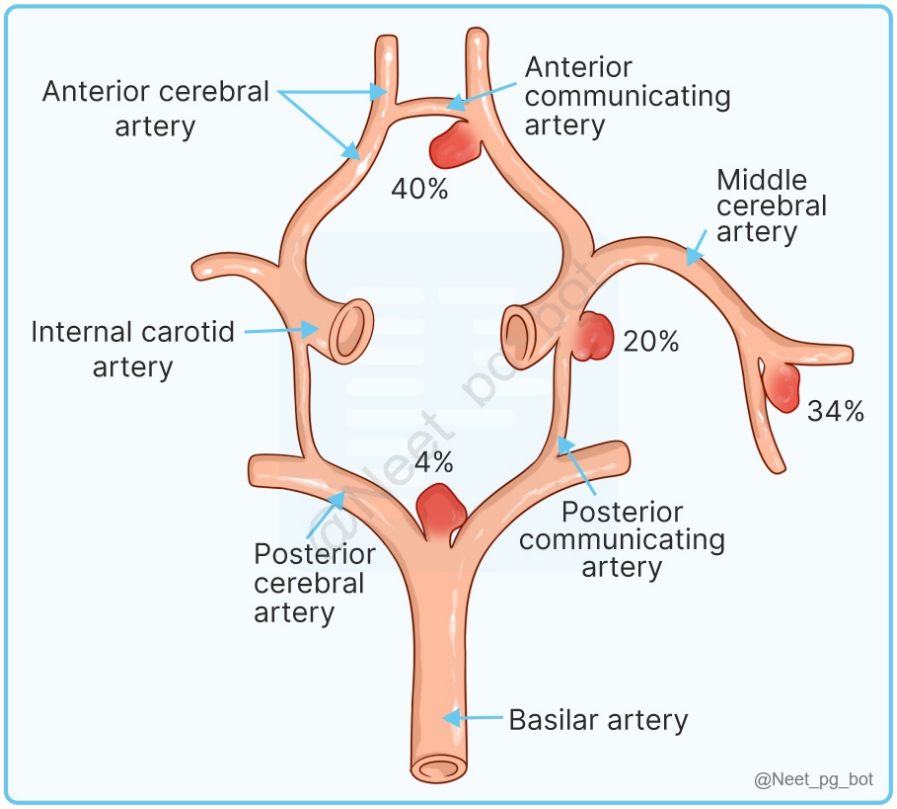
@Neet_pg_bot



Q17: What is the most common site of a Berry aneurysm in the circle of Willis? (Q879234)

A. Anterior cerebral artery

B. Middle cerebral artery

C. Basilar artery

D. Vertebral artery

Correct Answer: A. Anterior cerebral artery

Explanation: Correct Option A - Anterior cerebral artery: The most common site of a Berry (saccular) aneurysm is at the anterior communicating artery (AComA) near the junction of the anterior cerebral arteries (ACA) . Berry Aneurysm Common sites Anterior communicating artery – 40% (Option A) Posterior communicating artery – 34% Middle cerebral artery – 20% (Option B ruled out) Basilar artery – 4% (Option C ruled out) Genetic associations ADPKD Ehlers–Danlos type IV Marfan syndrome NF1 Risk factors Hypertension, smoking, coarctation of aorta, fibromuscular dysplasia

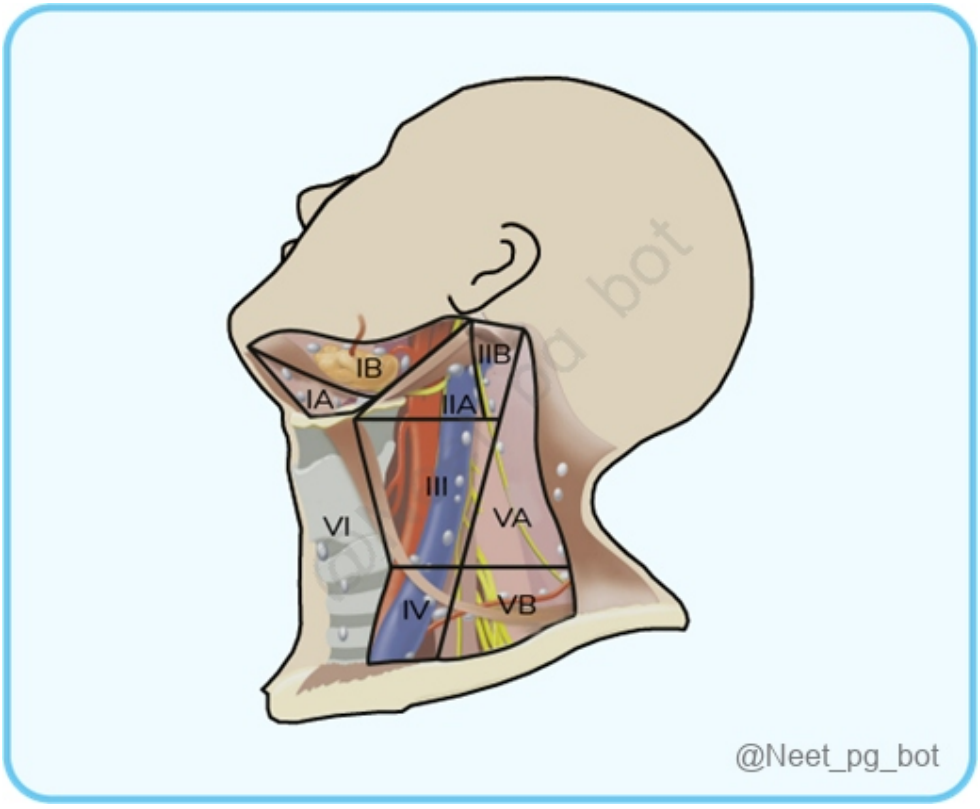
@Neet_pg_bot

Q18: In modified radical neck dissection, which of the following structures is NOT preserved? (Q860278)

A. Sternocleidomastoid muscle



B. Internal jugular vein

C. Spinal accessory nerve

D. Submandibular gland

Correct Answer: D. Submandibular gland

Explanation: In a modified radical neck dissection, the sternocleidomastoid muscle , internal jugular vein , and spinal accessory nerve are typically preserved. Types of Neck Dissections: Dissection LN removed Other structures removed/Preserved Radical Neck Dissection I - V CN XI, IJV, and SCM removed Modified Radical Neck Dissection (MRND) I I - V CN XI preserved MRND II I - V CN XI, IJV preserved MRND III I - V CN XI, IJV, SCM preserved Extended Neck Dissection I - V CN XI, IJV, SCM removed + one/more LN groups +/- Non lymphatic structures Selective Neck Dissections LN removed Primary site of cancer Supra-omohyoid I - III Oral cavity Extended Supra-omohyoid I - IV Oral cavity and oropharynx Postero-Lateral II - V Skin over the posterior scalp and upper neck Lateral II - IV Oropharynx, Hypopharynx, Larynx Anterior/ Central VI Thyroid/ Midline structures

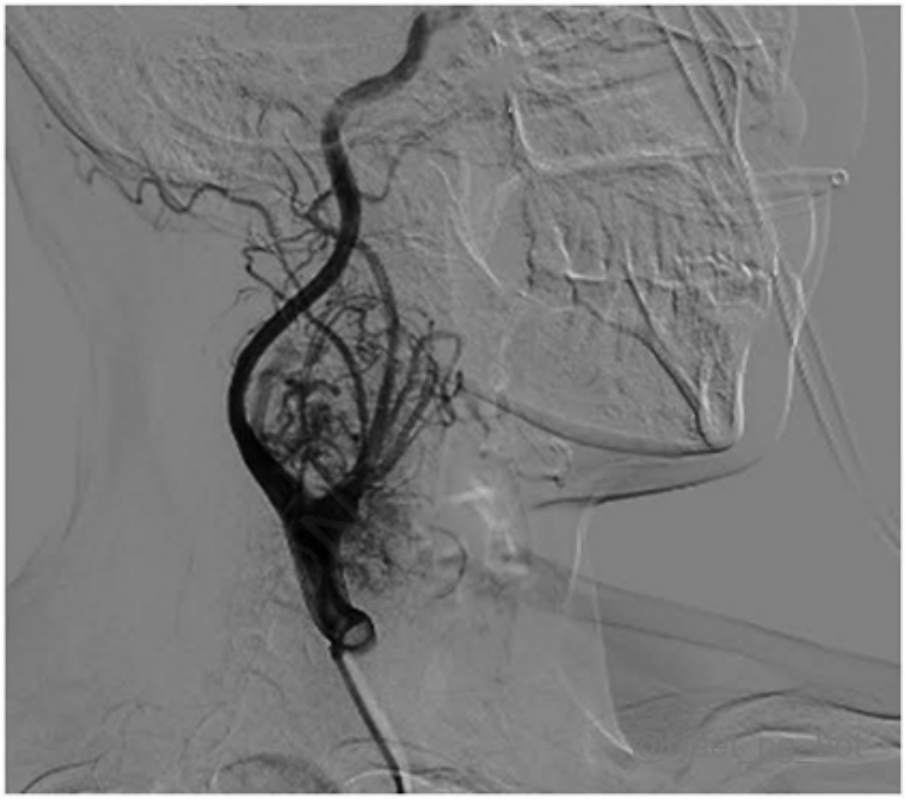
@Neet_pg_bot



Q19: History of pulsatile mass in the neck. Digital angiography image shown. Not filling on carotid compression. But refilling on releasing pressure. What is the diagnosis? (Q866454)

A. Carotid Aneurysm

B. Carotid Body tumour

C. AV fistula

D. Haemangioma

Correct Answer: B. Carotid Body tumour

Explanation: The image depicts Carotid body tumor, which is a highly vascular mass located at the carotid bifurcation. On digital subtraction angiography, the lyre sign (splaying of the internal and external carotid arteries) is seen. The characteristic finding in this question is tumour blush that disappears with carotid compression (loss of

arterial inflow) and reappears upon release - indicating that the tumour's vascularity depends on carotid blood flow. Carotid aneurysm (Option A): Would show persistent filling even with carotid compression if proximal to the aneurysm, and would not have the tumour blush pattern. AV fistula (Option C): Demonstrates early venous filling on angiography, not the filling–emptying–refilling pattern described here. Haemangioma (Option D): Typically a soft tissue vascular lesion, often cutaneous/subcutaneous, and not fed directly by carotid branches in this manner.

↑ *Back to this question in Part A*

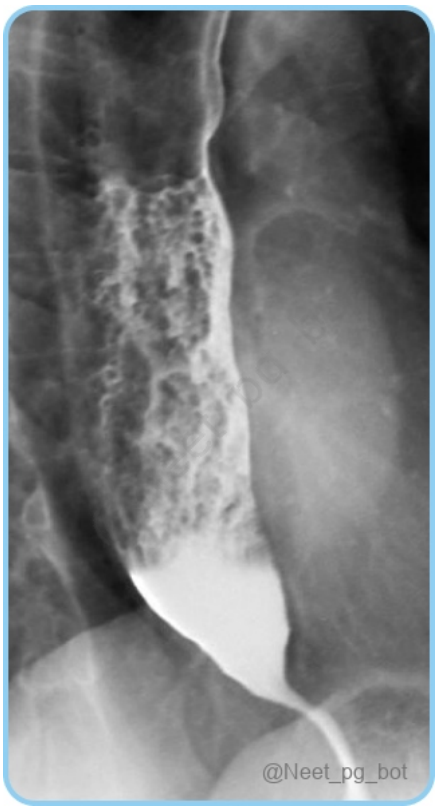
@Neet_pg_bot

Q20: An elderly male presents with foul-smelling breath and dysphagia. A barium swallow X-ray is provided. What is the most likely diagnosis? (Q853043)

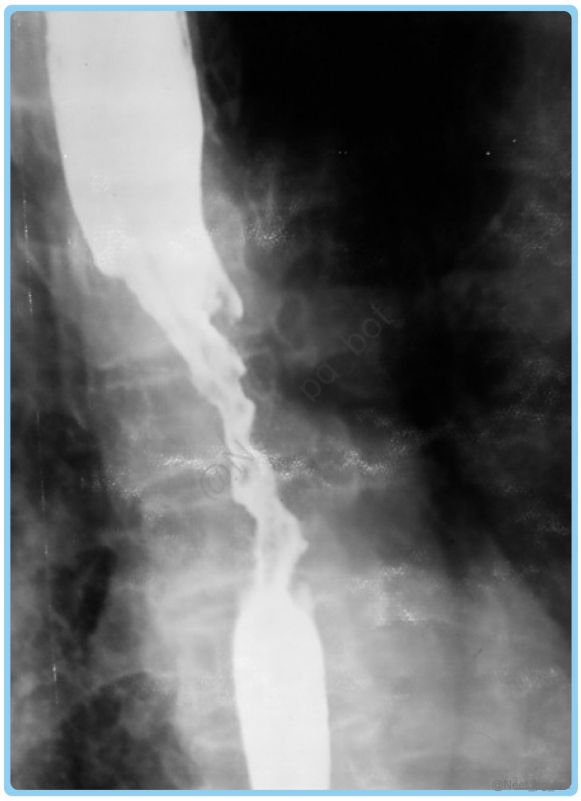
A. ■■■Tracheoesophageal fistula

B. Achalasia cardia

C. Carcinoma esophagus



D. Zenker's diverticulum



Correct Answer: D. Zenker's diverticulum

Explanation: The given barium swallow film shows a characteristic radiological finding known as a Pharyngeal pouch or Zenker's diverticulum , and the given symptoms also align with this diagnosis. It is an outpouching of the pharyngeal mucosa through a weak area in the posterior pharyngeal wall (Killian's dehiscence), which can trap food and cause bad breath. Zenker's diverticulum Clinical features: Dysphagia is the most prominent feature appears when the pouch gets filled with food and presses on the oesophagus. Gurgling sound is produced on swallowing. Regurgitation at night from undigested food causes cough and aspiration pneumonia. Halitosis (Chronic bad breathing) Malnourished due to dysphagia. Associated hiatus hernia Rarely can a coma develop in long-standing cases of pharyngeal pouches. Diagnosis: Barium swallow provides information regarding the size, location, and character of the mucosal lining. Endoscopy reveals fibrosis and pooling of food in the diverticulum. Treatment: Excision of the pouch and cricopharyngeal myotomy was done through a cervical approach. Dohlman’s procedure: The partition wall between the oesophagus and the pouch is exposed and divided by diathermy through a weerda scope. Endoscopic laser treatment: Partition wall between the oesophagus and the pouch is exposed and divided by CO2 laser using an endoscope. This procedure is known to have fewer recurrences and faster improvement in symptoms. Tracheoesophageal fistula (Option A) usually presents with cough, vomiting, difficulty in breathing , regurgitation and cyanosis. It is often seen in newborns or in patients with a history of oesophagal surgery or cancer. Achalasia cardia (Option B) is a disorder where the lower esophageal sphincter fails to relax properly, leading to dysphagia and regurgitation. Barium swallow shows dilated esophagus with a narrowing at the LES (Bird beak appearance/ Pencil tip appearance/ Rat tail appearance). Carcinoma esophagus (Option C) presents with narrowing or strictures in the esophagus due to tumour growth. Whereas a pharyngeal pouch (Zenker's diverticulum) is a protrusion from the pharynx

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 60 y/o male suddenly experiences an intense headache, described as the worst headache of his life, followed by vomiting and photophobia. O/E he has neck stiffness and a dilated pupil on the right side. A CT scan reveals bleeding in the subarachnoid space. Which of the following is the most common cause of this condition? (Q852704)

A. Hypertension

B. Intracranial aneurysm

C. Arteriovenous malformation (AVM)

D. Brain tumour

Correct Answer: B. Intracranial aneurysm

Explanation: The clinical scenario described is highly indicative of a subarachnoid haemorrhage (SAH), which is characterized by the sudden onset of a severe headache, vomiting, photophobia, neck stiffness, and neurological signs such as a dilated pupil. The most common cause of subarachnoid haemorrhage (SAH) is the rupture of an intracranial aneurysm , responsible for about 50% of cases. Subarachnoid Haemorrhage (SAH) Intracranial haemorrhage into the subarachnoid space, typically originating from the basal cisterns. It may occur spontaneously or following trauma (Trauma > Spontaneous) Causes of spontaneous SAH: Intracranial aneurysms: The most common cause Hypertension: Contributing to the formation and rupture of aneurysms. Arteriovenous (A-V) malformations Blood dyscrasias Anticoagulant drugs: Increasing the risk of bleeding. Brain tumours (malignant): Causing vessel erosion or rupture. Clinical Features: Sudden onset: Severe headache with vomiting. Raised intracranial pressure : Signs like photophobia and neck stiffness. Focal neurological deficits: Hemiplegia, dysphasia. Eye changes: Ptosis, dilated pupil, abnormal eye movements. Sudden loss of consciousness Rebleeding risk: Occurs in 40% of patients within 6-8 weeks, often fatal. Investigations: Imaging: CT scan: Primary imaging modality. Angiography: Carotid and vertebral angiogram to identify aneurysms or vascular malformations. Lumbar puncture: Performed to differentiate from meningitis ; done cautiously due to risk of coning. Management: Surgical interventions: Clipping or wrapping of aneurysm. Craniotomy: Followed by necessary procedures. Ligation of the common carotid artery: Risk of hemiplegia. Therapeutic embolization : To block abnormal blood vessels. Excision of vascular malformations.

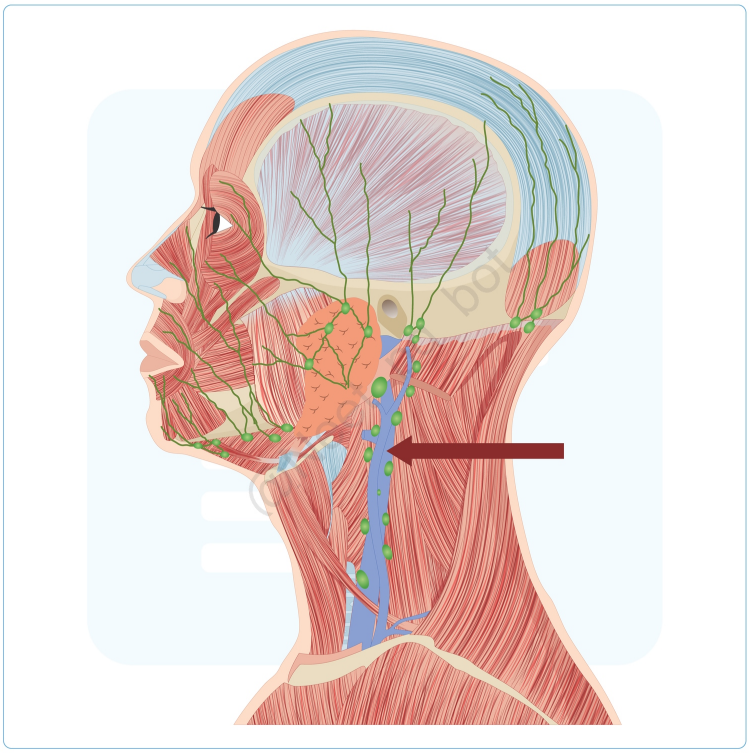
@Neet_pg_bot

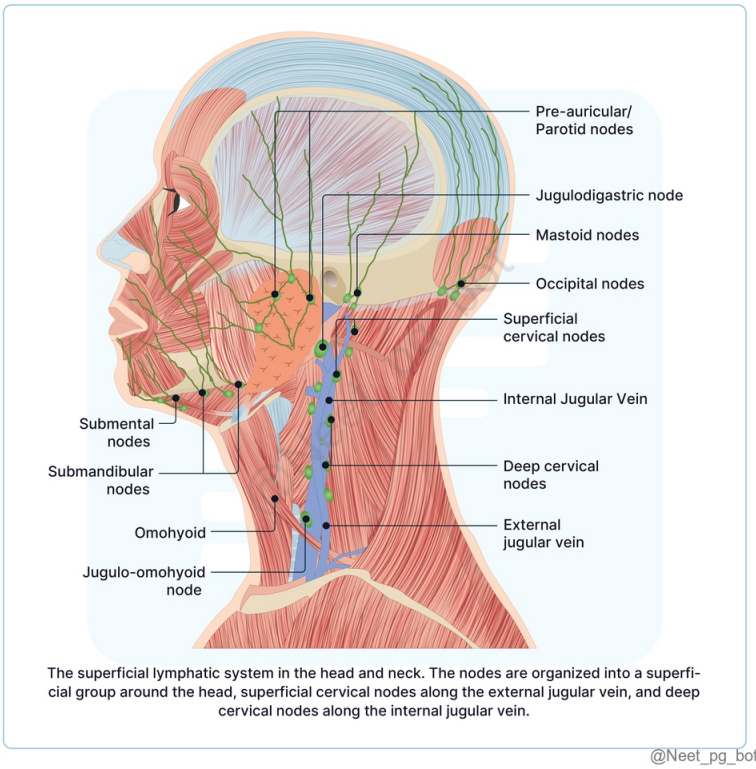


Q22: Identify the level of lymph nodes indicated in the marked region of the neck in the given anatomical image. (Q852717)

A. Level II

B. Level Ia

C. Level Ib



D. Level IV

Correct Answer: A. Level II

Explanation: The marked lymph nodes are located along the upper part of the internal jugular vein , extending from the skull base to the hyoid bone . Level II lymph nodes include the jugulodigastric nodes , commonly involved in head and neck malignancies . They are subdivided into: Level IIa: Medial to the sternocleidomastoid (SCM) muscle . Level IIb: Posterior to the SCM muscle . Cervical Lymph Node Levels Level Anatomical Location Key Features Level I Submental & submandibular Divided into Ia (midline) & Ib (lateral) Level II Upper internal jugular nodes Jugulodigastric region (common in nasopharyngeal CA) Level III Mid-jugular region

Between the hyoid & cricoid Level IV Lower jugular nodes Between the cricoid & clavicle Level V Posterior triangle Spinal accessory nodes Level Ia (Option B): Incorrect because these are submental nodes located in the midline under the chin. Level Ib (Option C): Incorrect because these are submandibular nodes located between the mandible and submental region . Level IV (Option D): Incorrect because these nodes are inferior to the cricoid cartilage , closer to the supraclavicular region .

The superficial lymphatic system in the head and neck. The nodes are organized into a superficial group around the head, superficial cervical nodes along the external jugular vein, and deep cervical nodes along the internal jugular vein.

@Neet_pg_bot

Q23: Which of the following is an indication for adjuvant radiotherapy in oral malignancy after resection and modified radical neck dissection (MRND)? (Q844310)

A. Extranodal extension

B. Multiple lymph node metastasis

C. T3 tumor

D. Close margin

Correct Answer: A. Extranodal extension

Explanation: Extranodal extension (ENE) is the strongest and most definitive indication for adjuvant radiotherapy after resection and modified radical neck dissection (MRND) in oral cavity squamous cell carcinoma. ENE signifies that tumor has penetrated beyond the lymph node capsule into surrounding soft tissues, which is associated with a markedly increased risk of locoregional recurrence and poor survival. Because of this high-risk biology, ENE typically requires post-operative chemoradiotherapy , making it the most important criterion among the options. Multiple lymph node metastasis (Option B): Multiple positive nodes (especially ≥2–3) are a recognized indication for adjuvant radiotherapy due to increased recurrence risk. However, the risk is not as severe as extranodal extension , making ENE the better single answer. T3 tumor (Option C): A T3 primary tumor is an intermediate-to-high-risk feature and often warrants postoperative radiotherapy to improve local control. But it is not as definitive or high-risk as ENE , so it is not the best choice. Close margin (Option D): Margins <5 mm are commonly treated with adjuvant radiotherapy, as they suggest potential microscopic residual disease. Still, this indication is less critical compared with extranodal extension, which carries the highest risk of recurrence.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 829

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: In the evaluation of squamous cell carcinoma (SCC) of the lip, which biopsy technique is considered most appropriate for obtaining a representative tissue sample for histopathological diagnosis? (Q844291)

A. Superficial shave biopsy of the tumor surface

B. Complete excision of the lesion

C. Incisional biopsy including both tumor and adjacent normal tissue

D. Punch biopsy limited to the ulcerated surface

Correct Answer: C. Incisional biopsy including both tumor and adjacent normal tissue

Explanation: For suspected malignancies of the lip, the goal is to obtain an adequate depth and margin of tissue for accurate histopathological evaluation. An incisional biopsy that includes both tumor tissue and a small portion of adjacent clinically normal mucosa allows assessment of the transition zone and tumor invasion depth. It avoids unnecessary full excision before staging and planning treatment. It is considered the standard technique when the lesion is too large for excision or when diagnosis must be confirmed before definitive therapy. Incorrect Options: Option A) Superficial shave biopsy : Too superficial; risks missing depth of invasion, which is crucial for SCC prognosis. Option B) Complete excision of the lesion : Not preferred initially unless the lesion is very small (<1

cm) and clinically clearly resectable; unnecessary for larger or ill-defined SCC. Option D) Punch biopsy limited to the ulcerated surface : Inadequate; samples only the superficial ulcer, missing deeper invasive margins and leading to false-negative or incomplete diagnosis.

References:

SRB's Manual of Surgery, 6th Edition, Page 376

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: A 65-year-old smoker presents with ulcerative lesions on his lower lip for the past year. On examination, there is a palpable ipsilateral submental lymph node approximately 5x5 cm. A biopsy from the lesion is suggestive of squamous cell carcinoma. What is the next step in management? (Q860454)

A. Radiotherapy

B. Combined chemoradiotherapy

C. Resection with primary closure alone

D. Resection of primary lesion with lip reconstruction and MRND

Correct Answer: D. Resection of primary lesion with lip reconstruction and MRND

Explanation: Resection of the primary lesion with lip reconstruction is necessary for the treatment of primary cancer, and given the presence of a palpable lymph node (suggesting potential nodal metastasis), modified radical neck dissection (MRND) is indicated to address any possible regional nodal spread. TNM Staging of Carcinoma lip: T Stage Tis: Carcinoma in situ T1 : Tumor ≤2 cm and ≤5 mm depth of invasion T2 : Tumor ≤2 cm and >5 mm but ≤10 mm depth, OR Tumor >2 cm but ≤4 cm and ≤10 mm depth T3 : Tumor >4 cm OR any tumor >10 mm depth of invasion T4 : Invasion of adjacent structures N Stage: N0: No regional lymph node metastasis N1-N3 : Based on number, size, and laterality of involved nodes M Stage: M0: No distant metastasis M1: Distant metastasis Management of Carcinoma lip: Early Stage (T1-T2N0) Wide local excision with 1 cm margins Consider elective neck dissection for tumours>2 cm or >4 mm in depth Reconstruction: Primary closure, local flaps, or skin grafts Advanced Stage (T3-T4 or N+) Wide local excision with ≥1 cm margins Neck dissection (comprehensive or selective based on nodal status) Complex reconstruction (local/regional flaps, free tissue transfer) Adjuvant radiotherapy or chemoradiotherapy based on pathological findings Reconstruction Options Wedge excision and primary closure (for small lesions) Local flaps: Abbe-Estlander, Karapandzic, nasolabial Regional flaps: Forehead, cervicofacial Free tissue transfer: Radial forearm free flap, anterolateral thigh flap Management of the Neck Elective neck dissection for high-risk tumours (>2 cm, >4 mm depth) Therapeutic neck dissection for clinically positive nodes Levels typically addressed: I-III for N0 neck, I-V for N+ neck Radiotherapy Adjuvant: For positive margins, perineural invasion, multiple positive nodes Definitive: For patients unfit for surgery or refusing surgery Brachytherapy: Can be considered for select early-stage lesions Chemotherapy Not routinely used in early-stage disease It may be combined with radiotherapy in locally advanced cases Follow-up and Surveillance Regular follow-up visits: Every 1-3 months for the first year, then gradually decreasing frequency

@Neet_pg_bot

Q26: A patient arrives at the emergency department following severe maxillofacial trauma sustained in a road traffic accident. The airway is compromised, and immediate intervention is required. What is the most appropriate immediate management? (Q860234)

A. Tracheostomy

B. Orotracheal intubation

C. Cricothyroidotomy

D. Bag mask with jaw thrust

Correct Answer: C. Cricothyroidotomy

Explanation: Cricothyroidotomy is the most appropriate immediate management when oro- or nasotracheal intubation is not feasible due to severe maxillofacial trauma. It provides an emergency surgical airway when other methods fail. Emergency Assessment and Management of Maxillofacial Trauma: Initial Assessment: Airway, Breathing, Circulation (ABC): Prioritize airway management following ATLS guidelines. Remove visible airway obstructions and apply direct pressure to bleeding points. Midface Bleeding: In conscious patients, position them forward or in the recovery position to prevent blood from obstructing the airway. Caution with suspected spinal injury. Maxillofacial Skeleton Damage: In cases of maxilla detachment or bilateral mandibular fractures, airway compromise is common due to tongue displacement and soft tissue edema. Airway Management: Endotracheal Intubation: Prepare for intubation, needle cricothyroidotomy, or surgical airway if intubation is difficult. Relieving Airway Compromise: Disimpact the maxilla and pull the tongue forward using a suture or towel clip. Ensure high-volume suction to clear blood and debris. Hemorrhage Management: Severe Bleeding: Control hemorrhage from large lacerations or penetrating injuries with direct pressure, nasal packs, or Foley catheters. Airway Protection: If swelling threatens the airway, consider endotracheal intubation or surgical airway. Head and Orbital Injury Assessment: Head Injury: A CT scan should be performed to rule out intracranial injuries, especially in intoxicated patients. Orbital Damage: Orbital fractures may lead to vision loss if untreated. Retrobulbar hemorrhage can cause optic nerve compression, leading to blindness. Tracheostomy (Option A) although definitive, it is a time-consuming surgical procedure and not ideal in an emergency . Used when airway control is required for long-term ventilation or when the situation allows for a controlled surgical setting . Bag-mask ventilation with jaw thrust (Option D) is not suitable for this patient due to the extensive facial trauma, which compromises the airway and makes this method ineffective. Endotracheal intubation (Option B) would be attempted first, but in cases where maxillofacial trauma precludes this, other options like cricothyroidotomy are prioritized.

@Neet_pg_bot

Q27: A child presented with the following findings and is planned to undergo surgery, which muscle will be repaired during surgery? (Q865320)

A. Orbicularis oris

B. Orbicularis oculi

C. Zygomaticus major

D. Levator alae nasi

Correct Answer: A. Orbicularis oris

Explanation: The image shows a child with a Cleft lip , a congenital anomaly resulting from the failure of fusion of facial processes during embryological development. Cleft lip and/or palate is the most common congenital abnormality affecting the orofacial region. The ultimate goal of cleft lip repair is to restore the sphincter function of the orbicularis oris muscle and obtain a cosmetically favourable outcome for the developing child. Management of cleft lip: Surgical principles: Cleft lip repair reconnects the muscles around the oral sphincter. Surgical techniques: Millard rotation advancement technique(most widely used) Le Mesurier's Thompson Tennison-Randall Orbicularis oculi (Option B) is a part of the anterior lamella in the eyelid; it encircles the eye and is involved in eyelid closure. It is not related to the lip. Zygomaticus major (Option C) is a facial muscle responsible for smiling and other facial expressions involving drawing the corner of the mouth upwards and outwards. It originates from the zygomatic bone and inserts into the angle of the mouth. Levator alae nasi (Option D) is a facial muscle that originates from the frontal process of the maxilla. It inserts into the skin of the ala of the nose and the upper lip. Its primary function is to elevate the upper lip and dilate the nostrils.

@Neet_pg_bot

Q28: Which among the following is the most common parotid gland tumour? (Q860295)

A. Pleomorphic adenoma

B. Warthin’s tumor

C. Adenoid cystic carcinoma

D. Mucoepidermoid carcinoma

Correct Answer: A. Pleomorphic adenoma

Explanation: Pleomorphic adenoma is the most common benign tumor of the parotid gland, accounting for about 60-70% of all parotid gland tumors. It is typically slow-growing and presents as a painless swelling. Warthin’s tumor (Option B) is the second most common benign tumor of the parotid gland. Adenoid cystic carcinoma (Option C) and mucoepidermoid carcinoma (Option D) are malignant tumors, but they are less common than pleomorphic adenomas. Pleomorphic Adenoma: Clinical Presentation : Painless, well-defined, solitary, mobile masses. Commonly located in the parotid glands (>80% of cases). It can also occur in the submandibular gland and hard palate. Sudden growth of facial nerve palsy may suggest malignant transformation (rare). {{caption_text}} Imaging : USG: Well-lobulated, hypoechoic lesions with possible calcifications. CT: Provides detailed anatomical imaging along with the extent of the tumour. MRI: Helps differentiate between benign and malignant tumours Fine-Needle Aspiration Cytology (FNAC) : Differentiates between inflammatory conditions and tumour- high sensitivity and specificity Histopathology : Gross Examination: Tumours are well-circumscribed, nodular, and firm, with a white to tan cut surface. May show cartilaginous areas; large tumours may exhibit degeneration or cystic changes. Microscopy: A mixture of epithelial, myoepithelial, and stromal components. Possible malignant changes: Ductal atypia, diffuse fibrosis, or necrosis Treatment: Surgical Excision of the tumour along with a cuff of normal tissue. Enucleation is not recommended due to the risk of capsular breach, tumour spillage, and recurrence. Salivary gland tumors The most common benign tumour Pleomorphic adenoma The most common benign tumour of infants and young children Hemangioma The most common malignan t tumour Mucoepidermoid carcinoma The most common malignant tumour in children and young adults Mucoepidermoid carcinoma The most common malignant tumour of Minor salivary glands Adenoid cystic carcinoma

@Neet_pg_bot

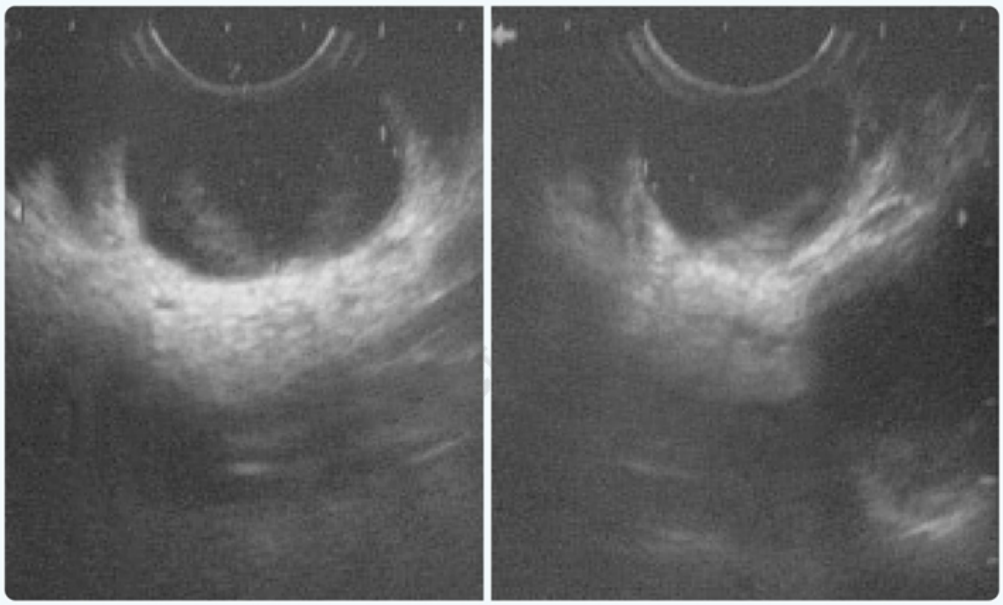
Q29: What is the most likely diagnosis for a young patient under 5 years of age presenting with a painless, soft, fluctuating mass on the lateral side of the neck? (Q860298)

A. Thyroglossal cyst

B. Cystic hygroma

C. Cervical lymphadenopathy

D. Ranula



Correct Answer: B. Cystic hygroma

Explanation: The child is most likely suffering from Cystic hygroma , which is soft, partially compressible swelling filled with clear lymph. Features of Cystic Hygromas: Definition : Lymphatic malformations in neonates or infants. Appearance : Soft, partially compressible swellings filled with clear lymph. (Option C) Size Variation : May increase in size when the child cries or coughs. Common Locations : Neck (most common), face, submandibular region, tongue, floor of the mouth, cheek, axilla, groin, mediastinum . Distinguishing Characteristics : Translucence. Behavior and Complications: Behavior : Unpredictable; can expand rapidly. Complications : Respiratory difficulties (may require aspiration or tracheostomy). Risk of infection. Treatment: Preferred Treatment : Early complete surgical excision. Alternative Treatment : Injection of sclerosing agents to reduce size. Challenges : Complete resolution can be difficult due to its multicystic nature. {{caption_text}} {{caption_text}} {{caption_text}} Incorrect Options: Thyroglossal cysts (Option A) are usually present in the midline of the neck and may be associated with swallowing or tongue movements. Cervical lymphadenopathy (Option C) typically involves lymph nodes and is often tender or associated with infection. Ranula (Option D) is a type of mucous retention cyst in the floor of the mouth and would not present as a lateral neck mass.

@Neet_pg_bot

Q30: What is the condition depicted in the given image, and what is the next investigation required for management? (Q860313)

A. Erythroplakia and biopsy

B. Erythroplakia and observation

C. Leukoplakia and biopsy

D. Leukoplakia and observation

Correct Answer: A. Erythroplakia and biopsy

Explanation: The condition here is erythroplakia. Erythroplakia is a red, velvety lesion that is often highly suspicious for malignancy, and biopsy is indicated to rule out cancer. Erythroplakia is a bright red velvety plaque that cannot be characterized clinically or pathologically as any other disease. Has a higher malignant potential than leukoplakia. Types : Homogenous Speckled Granular Erythroplakia interspersed with leukoplakia Management : Biopsy for diagnosis Surgical excision Strict follow-up {{caption_text}} {{caption_text}} Leukoplakia is defined as a white patch or plaque that cannot be rubbed off, and cannot be characterized clinically or pathologically as any other disease. It is a premalignant lesion and is painless/non-tender . {{caption_text}} Types : Homogenous Nodular Speckled Hairy: Associated with EBV. It is not actually hairy but appears so due to the corrugation caused by severe hyperkeratosis and acanthosis. Common in AIDS patients. Management : Biopsy to rule out carcinoma and confirm diagnosis. Stop smoking/ alcohol/ betel quid. Excision, skin grafting if needed. Regular follow-up. Isotretinoin, tocopherol, and beta-carotene. CO 2 laser.

@Neet_pg_bot

Q31: Match the following features seen due to compression of the following structures in the case of thyroid swelling: Structure Features 1. Trachea a. Hoarseness 2. Esophagus b. Horner syndrome 3. Sympathetic chain c. Dyspnea 4. Recurrent laryngeal nerve d. Dysphagia (Q857298)

A. 1-c, 2-d, 3-b, 4-a

B. 1-d, 2-c, 3-a, 4-b

C. 1-a, 2-d, 3-b, 4-c

D. 1-c, 2-a, 3-d, 4-b

Correct Answer: A. 1-c, 2-d, 3-b, 4-a

Explanation: Structure Compressed Feature Trachea Dyspnea Esophagus Dysphagia Sympathetic chain Horner syndrome Recurrent laryngeal nerve Hoarseness Compression of the trachea can cause difficulty breathing (dyspnea) because it obstructs the airflow. If the oesophagus is compressed, it can cause difficulty swallowing (dysphagia) due to obstruction, making it hard for food or liquid to pass down the throat. The sympathetic chain, if compressed, can lead to Horner syndrome, which presents as ptosis (drooping eyelid), miosis (constricted pupil), anhidrosis (lack of sweating), and enophthalmos (sunken eyeball) on the affected side. Compression of the recurrent laryngeal nerve can cause hoarseness (changes in the voice or voice weakness) because this nerve controls the muscles of the vocal cords, and its dysfunction affects vocalisation.

Q33: A 25-year-old patient had a RTA and was brought to the emergency room with bradycardia and a high BP. The GCS of this patient is < 8. What should be the immediate management in this patient? (Q820119)

A. Urgent CT head

B. Intubate and IPPV

C. Thrombolysis

D. Normal saline infusion

Correct Answer: B. Intubate and IPPV

Explanation: of correct answer.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q34: What is the Intubation of choice in a Maxillofacial trauma patient? (Q820169)

A. Tracheostomy

B. Laryngeal mask airway

C. Orotracheal intubation

D. Mask ventilation

Correct Answer: A. Tracheostomy

Explanation: Correct Option A - Tracheostomy: Tracheostomy involves creating a surgical airway directly into the trachea through the neck. While it provides a secure airway, it's generally not the initial choice for managing airways in maxillofacial trauma patients unless there are specific indications, such as severe facial fractures that prevent other methods of intubation. Tracheostomy is considered a more invasive procedure and is usually reserved for situations where other methods are not feasible or have failed. Incorrect Options : Option B - Laryngeal Mask Airway (LMA): Laryngeal mask airway is a supraglottic airway device that is less invasive than tracheostomy. It sits in the pharynx and seals around the laryngeal inlet, allowing positive pressure ventilation. However, in cases of significant maxillofacial trauma, proper placement and effective ventilation might be compromised due to anatomical disruptions and bleeding. Option C - Orotracheal Intubation: Orotracheal intubation involves passing an endotracheal tube through the mouth into the trachea. It provides a secure airway and is often the preferred choice for managing maxillofacial trauma patients, as it bypasses the potential obstacles created by facial fractures, allowing effective ventilation and protection of the airway. Option D - Mask Ventilation: Mask ventilation involves using a bag-mask device to manually deliver positive pressure ventilation to a patient. While it might be used temporarily in situations where intubation is difficult, it's not the intubation method itself. In maxillofacial trauma, mask ventilation can be challenging due to disrupted facial anatomy and potential difficulty in achieving a proper seal.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q35: A 50-year-old male chronic smoker came to OPD with cough, dyspnea, and difficulty swallowing . A palpable lump was present in the neck. Which of the following are smokers most likely to develop? (Q793891)

A. Adenocarcinoma

B. Squamous cell carcinoma

C. Large cell carcinoma

D. Adenoid cystic carcinoma

Correct Answer: B. Squamous cell carcinoma

Explanation: Correct Option B - Squamous cell carcinoma: In this case, a palpable lump in the neck suggests the possibility of head and neck cancer, which is strongly associated with smoking. Squamous cell carcinoma is the most common type of head and neck cancer. It arises from the squamous cells that line the mucosal surfaces of the head and neck, including the mouth, throat, and larynx. Risk factors include smoking, heavy alcohol consumption, and infection with certain types of human papillomavirus (HPV). Incorrect Options: Option A - Adenocarcinoma: Adenocarcinoma is another type of cancer that can occur in the head and neck, but it is less common than squamous cell carcinoma. It arises from the glandular cells that produce mucus and is often associated with tobacco use and exposure to certain chemicals. Option C - Large cell carcinoma: Large cell carcinoma is a type of lung cancer, not head and neck cancer, that accounts for about 10-15% of all lung cancers. It is characterized by large, abnormal cells that grow and divide uncontrollably. Option D - Adenoid cystic carcinoma: Adenoid cystic carcinoma is a rare type of cancer that can occur in several areas of the body, including the head and neck. It arises from the secretory cells that line certain glands, such as the salivary glands. It is not strongly associated with smoking.

Q25 (p. 1387)					

Q1: A 62-year-old male patient is having complaints of loss of vision in the form of a curtain coming down in front of the right eye. He has a history of 2 episodes of strokes, after which he has left-sided sensory and motor loss limited to the face and neck. Which of the following blood vessels might be stenosed in this case? (Q849435)

A. Left vertebral artery

B. Carotid artery

C. First part of the left subclavian artery

D. Superior mesenteric vein

Correct Answer: B. Carotid artery

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The condition is diagnosed as Carotid artery stenosis , having clinical features of face and neck paralysis along with Amaurosis fugax (loss of vision in the form of a curtain coming down in front of the eye). Carotid artery stenosis Carotid artery stenosis may cause TIAs (Transient Ischemic Attacks), which are short-lived mini strokes and are often recurrent, causing unilateral motor or sensory loss in the arm, leg or face. They are caused by the distal embolisation of platelet thrombi that form on the atheromatous plaque and enter the cerebral circulation. They are considered as a warning of impending major stroke. Duplex scan is done for assessment. Indications for Endarterectomy: Stenosis of more than or equal to 50% Ipsilateral amaurosis fugax or monocular blindness Contralateral facial paralysis or paresthesia Arm/leg paresthesia Hemianopia Dysphasia Sensory loss or visual inattention or neglect. Amaurosis fugax is the temporary loss of vision due decreased blood supply to the retina to blockage of arteries. It is presented as a feeling of a curtain coming down in front of the eyes.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 1008

↑ *Back to this question in Part A*

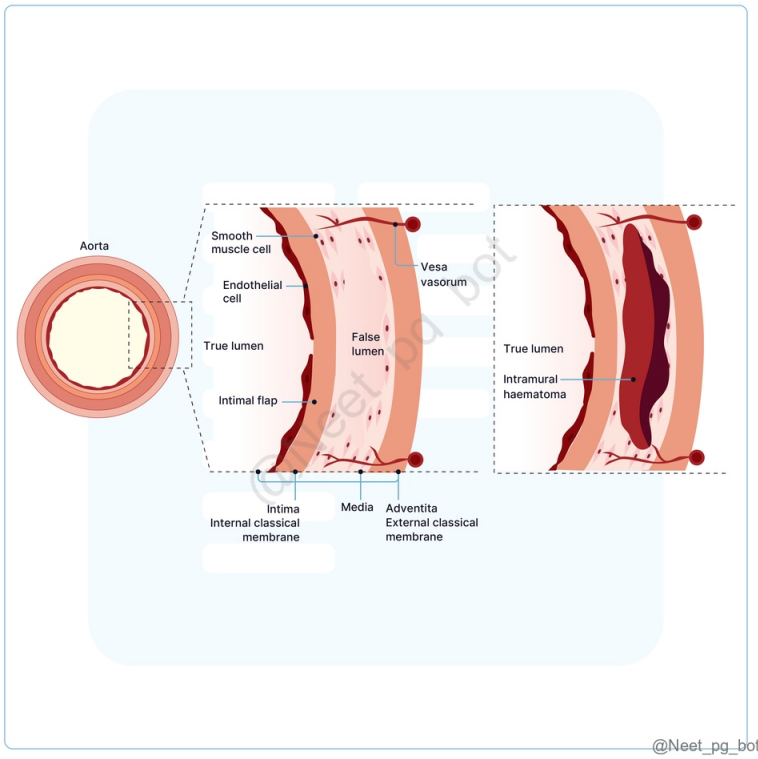
@Neet_pg_bot

Q2: A 67-year-old male was having complaints of sudden onset of severe chest pain, which was radiating to his back, and suddenly, he went unconscious. He was chronically hypertensive, a drug defaulter, and was having weakness, dizziness and dyspnea for 1 day. His current BP is 90/50 mm Hg, and his Heart Rate is 140 bpm. What is the best investigation of choice in this condition? (Q849415)

A. CT Angiography

B. Aortography

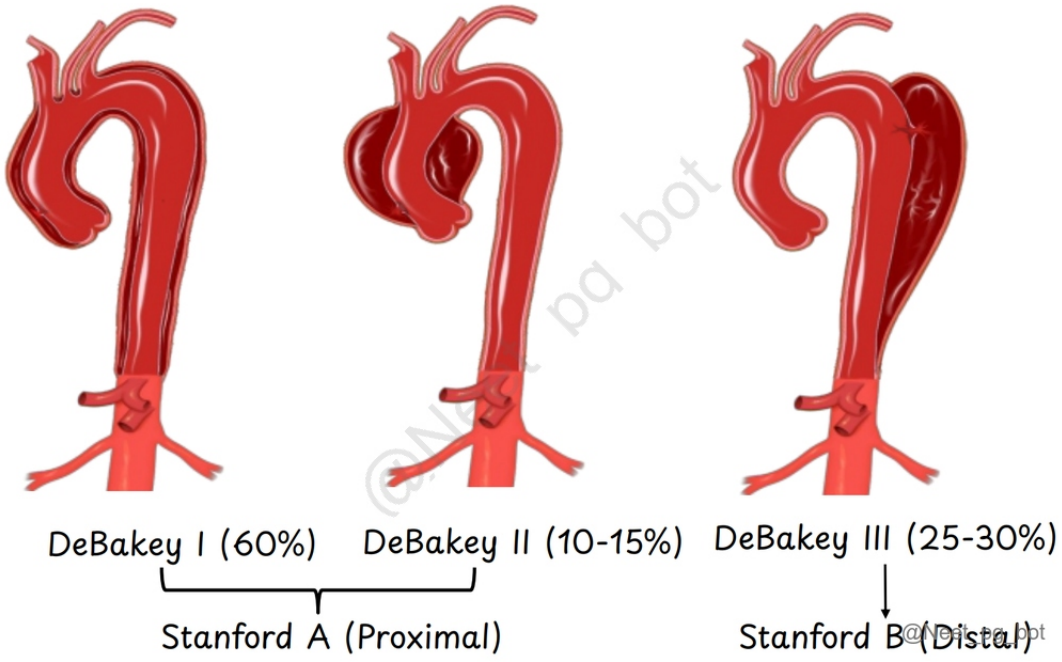
C. Trans Esophageal Echocardiography



D. Chest x-ray

Correct Answer: C. Trans Esophageal Echocardiography

■ *Listen (English)*



■ *Listen (Hindi)*

Explanation: The above given scenario is an unstable case of Aortic dissection, and the investigation of choice is TEE (Trans Esophageal Echocardiography). Aortic Dissection It occurs when a defect or a flap occurs in the aorta, resulting in blood tracking into aortic tissues, splitting the medial layer, and creating a false lumen. Clinical features: Sudden onset of severe, tearing chest, radiating to the interscapular region Renal pain and renal failure Paraplegia Syncope Weakness Hypotension or shock Investigations: If the patient is stable, CT angiography is the standard investigation of choice. (Option A) In the case of unstable patients (SBP<100 mm of HG, HR>100 bpm), the preferred investigation of choice will be TEE (TransEsophageal Echocardiography) MRI can also be done if CT is unequivocal. Chest x-ray (Option D) reveals widening of the mediastinum along with left-sided pleural effusion. TEE of an aortic dissection within the descending part Classification: DeBakey Classification (Based on the pattern of dissection) Type I Both ascending and descending aorta are involved Type II Only the ascending aorta is involved Type III Only the descending aorta is involved Stanford Classification (Based on whether the ascending aorta is involved in aortic dissection) Type A Only the ascending aorta or both ascending and descending aorta is involved. (It includes both Type I and Type II of DeBakey's classification) Type B Only the descending aorta is involved. (It includes Type III of DeBakey's classification) Aortography (Option B) is the investigation of choice for chronic mesenteric ischemia.

Aorta
Smooth muscle cell
Endothelial cell
True lumen
Intimal flap
False lumen
Vesa vasorum
True lumen
Intramural haematoma
Intima
Internal classical membrane
Media
Adventita

Q3: Which of the following signs is seen in Arteriovenous fistula? (Q849404)

A. Murphy's sign

B. Brudzinski's sign

C. Hegar's sign

D. Nicoladoni's sign

Correct Answer: D. Nicoladoni's sign

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Nicoladoni's / Branham's sign is observed in AVF: \ On pressing the artery proximal to the fistula, there is a decrease in the size of the pulsatile mass, disappearance of palpable thrill and decrease in heart rate. Arteriovenous Fistula (AVF) AVF is a communication between an artery and a vein that may be either congenital or acquired (trauma or surgical). Structurally, they are arterialised (become dilated, tortuous and thick-walled). Physiologically, there is an increase in venous return (as blood starts flowing from arteries to veins, which causes

an increase in cardiac output, which in turn results in an increase in systolic BP, leading to cardiac failure. On examination, there is a presence of pulsatile swelling, a thrill and auscultation reveals machinery murmur (buzzing continuous murmur) Murphy's sign (Option A): Pain during inspiration while palpating the right subcostal area is termed Murphy's sign. It is seen in acute cholecystitis. Brudzinski's sign (Option B): In meningitis, neck stiffness causes a patient's hips and knees to flex when the neck is flexed; this is Brudzinski's sign. Hegar's sign (Option C): Softening of the cervix in pregnancy is known as hegar's sign

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1023, 1024

↑ *Back to this question in Part A*

@Neet_pg_bot

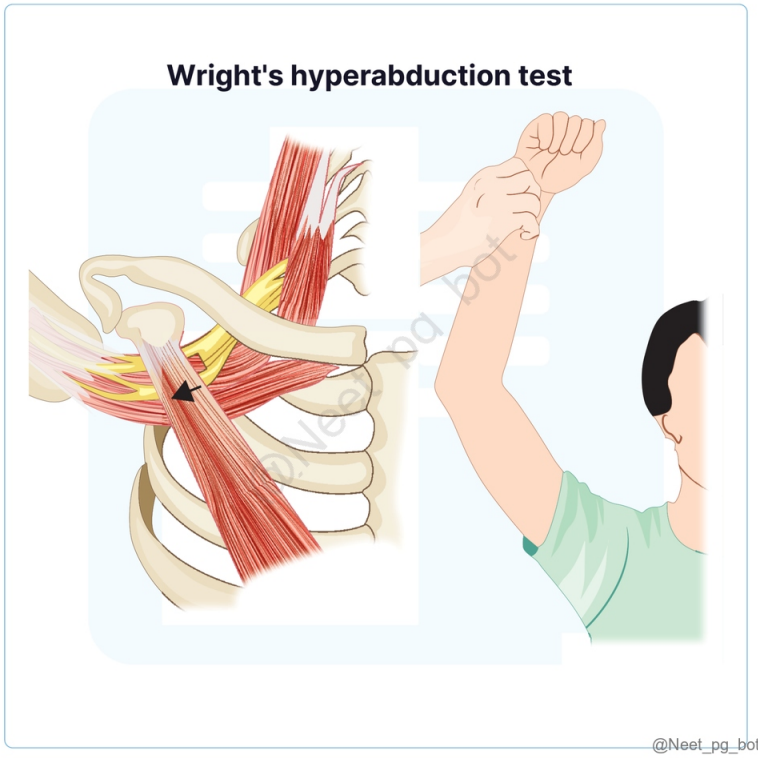
Q4: A 35-year-old female experiences numbness and tingling in her right arm, worsened by arm elevation. During examination, she abducts her arms to 90° with external rotation, flexes her elbows to 90°, and opens and closes her hands for 3 minutes, which reproduces her symptoms. Which test was most likely performed? (Q849407)

A. Adson's Test

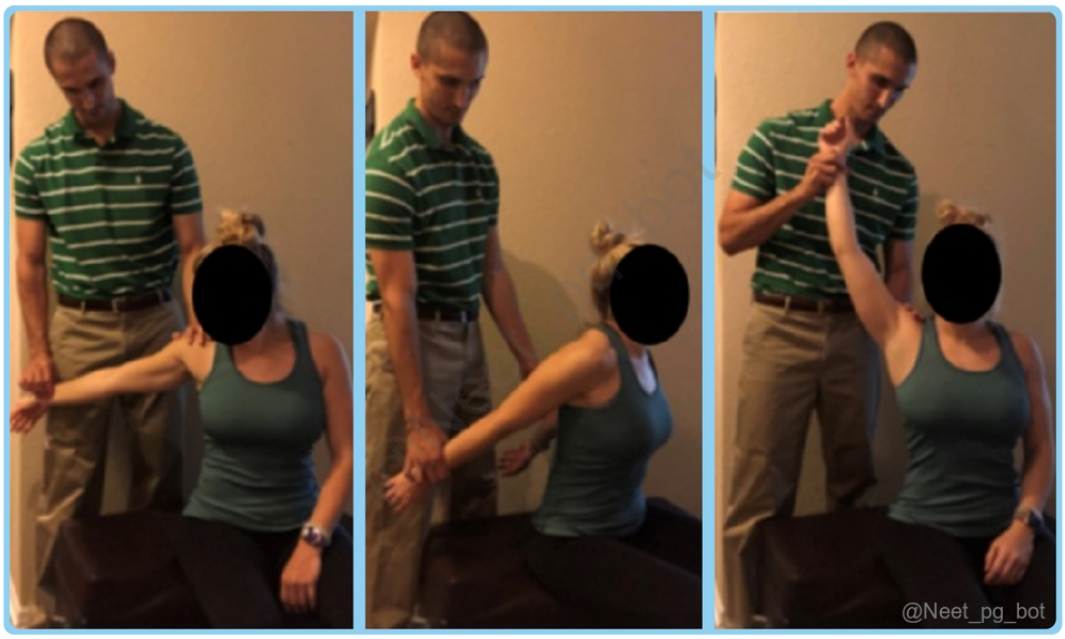
B. Roos Test

C. Wright's Test

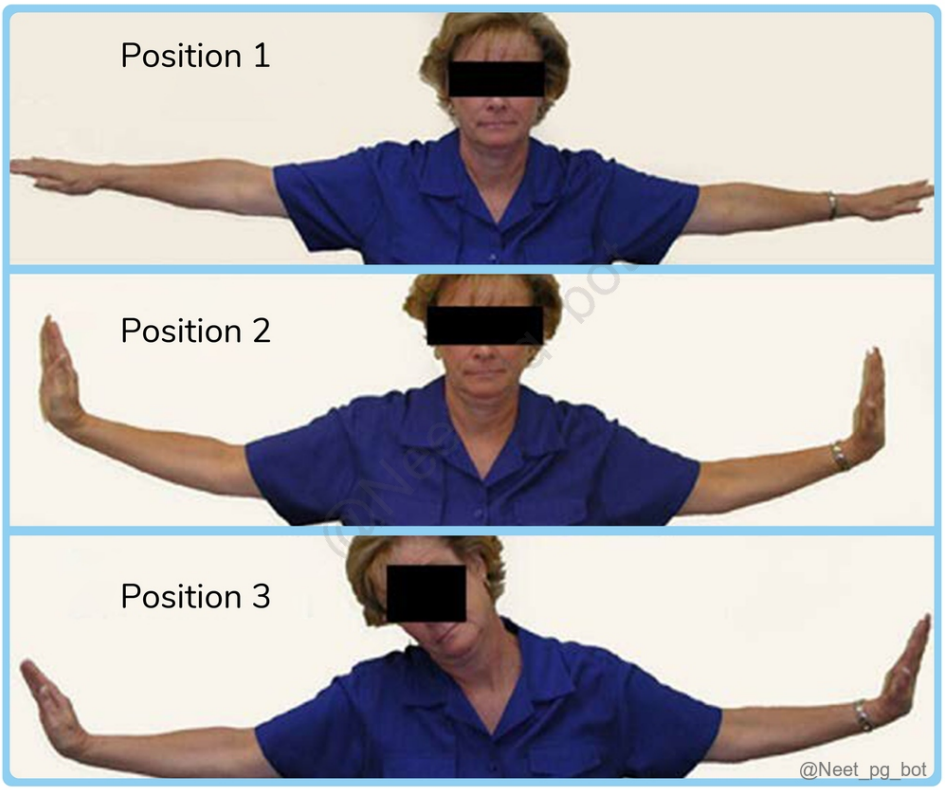
D. Elvey Test



Correct Answer: B. Roos Test



■ *Listen to Audio 1*



Explanation: The scenario describes the Roos test (also known as the Elevated Arm Stress Test), which is used to diagnose thoracic outlet syndrome (TOS). The test involves the patient abducting their arms to 90°, externally rotating them, flexing the elbows to 90°, and repeatedly opening and closing the hands for 3 minutes. Reproduction of symptoms like numbness or tingling during this test indicates a positive result, suggestive of TOS. Roos Test Common provocative diagnostic tests for Thoracic Outlet Syndrome (TOS): Test Maneuver Result Adson's Test (Option A) Arm abducted 30° and maximally extended. Patient extends neck, turns head toward the ipsilateral side, and inhales deeply. Decrease or absence of ipsilateral radial pulse. Elevated Arm Stress Test (EAST) / Roos Test (Option B) Arms in "surrender" position (abducted 90°, external rotation, elbows flexed 90°). The patient slowly opens and closes hands for 3 minutes. Pain, paresthesia, heaviness, or weakness precipitated. Upper Limb Tension Test (ULTT) / Elvey Test (Option D) Position 1: Arms abducted 90°, elbows flexed. Position 2: Active dorsiflexion of wrists. Position 3: Tilt head (ear to shoulder) in both directions. Symptoms in the ipsilateral arm (Position 1 & 2); Contralateral symptoms in Position 3. Wright's test (Option C) is a clinical sign in which the radial pulse weakens or disappears when the arm is abducted and externally rotated.

Adsons test is a physical examination maneuver used to detect vascular thoracic outlet syndrome (TOS) by assessing compression of the subclavian artery Elvey Test is a physical assessment used to evaluate the mobility and sensitivity of brachial plexus nerves in the arm, primarily to diagnose nerve compression, such as thoracic outlet syndrome

References:

https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6514035/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 23-year-old competitive swimmer presents with progressive weakness and tingling in his right hand. On examination, there is wasting of the small muscles of the hand and sensory loss in the medial side of the hand and forearm. Which of the following nerves is most likely compressed in this patient? (Q849406)

A. Median nerve (C5-T1

B. Ulnar nerve (C8-T1)

C. Radial nerve (C5-T1)

D. Axillary nerve (C5-C6)

Correct Answer: B. Ulnar nerve (C8-T1)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The most likely diagnosis is thoracic outlet syndrome (TOS), where the ulnar nerve (C8-T1) is commonly compressed and presents with muscle wasting in the hand and sensory loss in the medial hand and forearm. TOS often presents in athletes like swimmers, who frequently use overhead movements. The ulnar nerve is vulnerable in TOS because it passes through the thoracic outlet and can be compressed by anatomical structures such as a cervical rib or tight scalene muscles. Thoracic outlet syndrome: Category Details Predisposing Factors Cervical Rib, Cervical Hematoma (Trauma), Pancoast Tumor, Osteoarthritis, Long Transverse Process of C7 Clinical Manifestations Neurogenic TOS: Pain, numbness, and tingling due to nerve compression Arterial TOS: Pain, coldness, and paleness due to impaired arterial blood flow Venous TOS: Swelling, pain, and discolouration due to impaired venous return

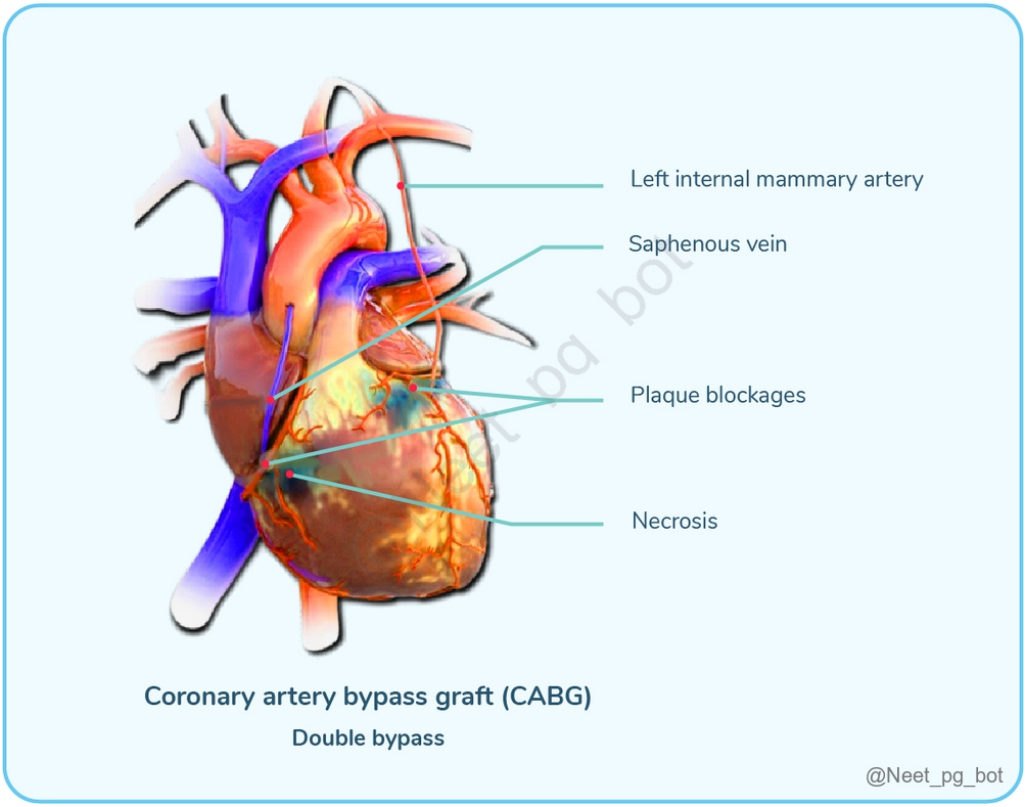
@Neet_pg_bot

Q6: Which of the following is the most preferred vascular graft for CABG? (Q849434)

A. Long saphenous vein

B. Dacron

C. Polyurethane



D. Left Internal Mammary Artery

Correct Answer: D. Left Internal Mammary Artery

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The most preferred vascular graft for CABG is LIMA (Left Internal Mammary Artery). Coronary Artery Bypass Graft (CABG) CABG is a procedure done by using a vascular graft for bypassing the blocked site of arteries and allowing the flow of blood to the heart muscles. Various types of grafts can be used as per need. For example, the most preferred graft for CABG is LIMA (Option D) , but the reversed long saphenous vein is more commonly used due to its extra length and it is easy to handle (Option A) . Dacron, polyurethane, and ePTFE (expanded polytetrafluoroethylene) are examples of synthetic vascular grafts. (Option B and C) .

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 946-953

↑ *Back to this question in Part A*

@Neet_pg_bot

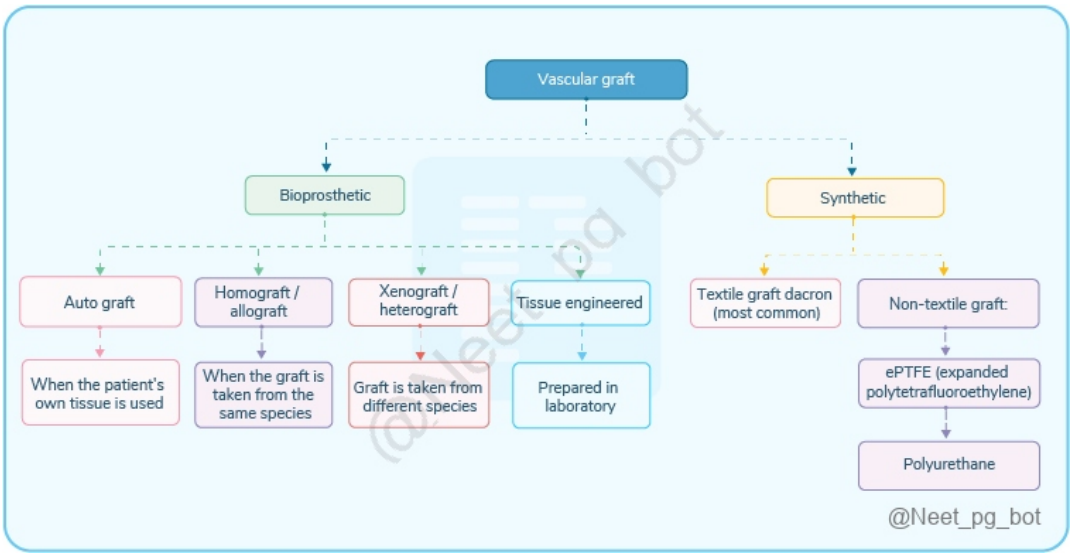
Q7: A 48-year-old male presents with retrosternal chest pain, which was radiation to the left arm and shoulder. He has a previous history of acute myocardial infarction.

CABG was advised, but the patient is insisting on using synthetic graft and wants to know more about it. Which of the following is the most preferred synthetic vascular graft for CABG? (Q849433)

A. Polyurethane

B. ePTFE

C. Dacron



D. Long saphenous vein

Correct Answer: C. Dacron

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The best synthetic type of vascular graft for CABG is Dacron. It is the most preferred vascular graft for supra-inguinal bypass surgery. Classification of Vascular grafts: Bioprosthetic grafts LIMA (Left Internal Mammary Artery): The most preferred vascular graft for CABG Long saphenous vein: Most commonly used in infra-inguinal surgeries due to small and medium-sized vessels (Option D) Synthetic grafts Dacron: Most commonly used synthetic graft in supra inguinal surgeries due to large vessels. (Option C) Polyurethane (Option A) ePTFE (expanded polytetrafluoroethylene) (Option B)

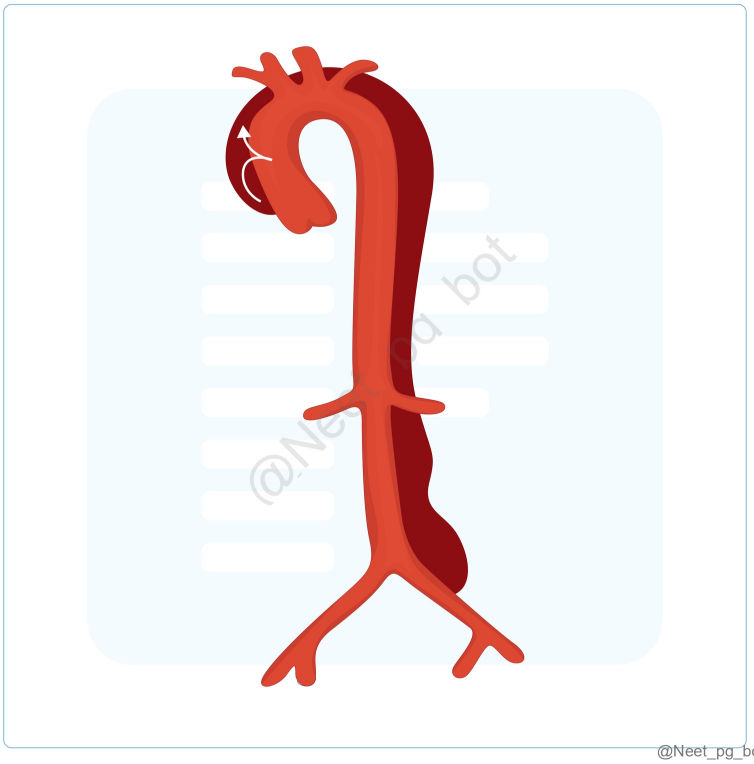
@Neet_pg_bot



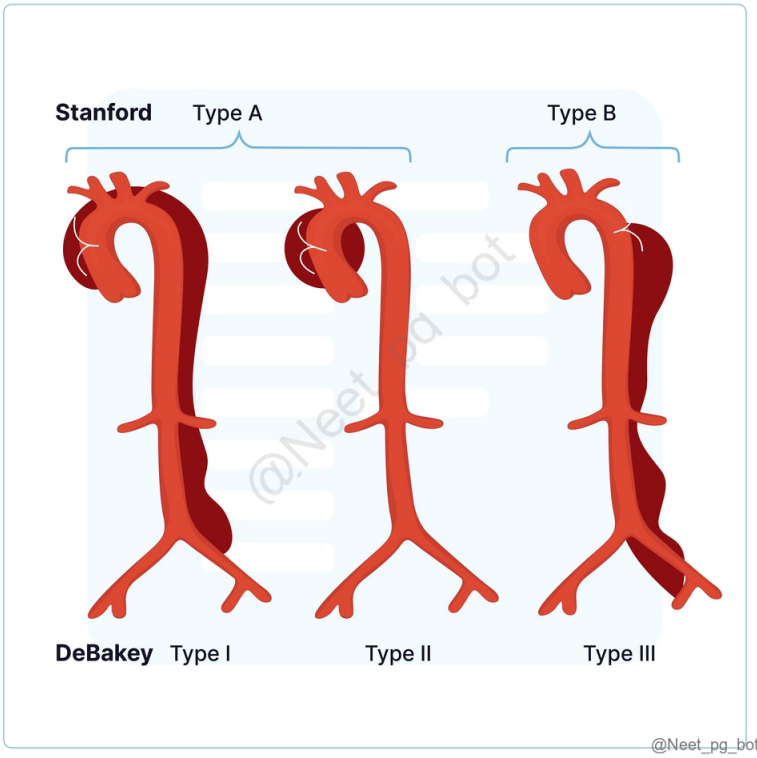
Q8: Based on the Stanford classification, which type of aortic dissection is shown below? (Q849418)

A. Type A

B. Type B

C. Type C

D. Type D



Correct Answer: A. Type A

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: According to the Stanford classification, the given image is classified as Type A aortic dissection. Aortic dissection occurs when a defect or a flap occurs in the aorta, resulting in blood tracking into aortic tissues, splitting the medial layer and creating a false lumen. There are 2 classifications, both of which are widely used for Aortic dissection. DeBakey Classification (Based on the pattern of dissection) Type I Both ascending and descending aorta are involved Type II Only the ascending aorta is involved Type III Only the descending aorta is involved Stanford Classification (Based on whether the ascending aorta is involved in aortic dissection) Type A Only the ascending aorta or both ascending and descending aorta is involved. (Option A) (It includes both Type I and Type II of DeBakey's classification) Type B Only the descending aorta is involved. (Option B) (It includes

Type III of DeBakey’s classification)

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 970, 971 Schwartz’s Principles of Surgery, 11th Edition, Page 876, 877

↑ *Back to this question in Part A*

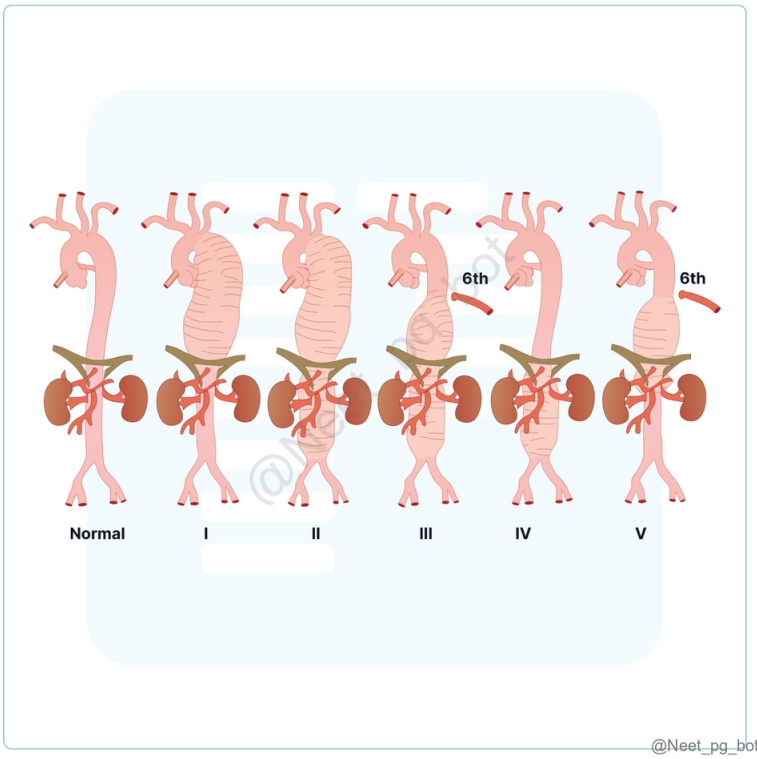
@Neet_pg_bot

Q9: A 72-year-old male with a history of hypertension and smoking presents with back pain, and imaging shows a thoracoabdominal aortic aneurysm starting at the sixth intercostal space and extending to just above the renal arteries. According to the Crawford classification, which type does this aneurysm correspond to? (Q849413)

A. Type I

B. Type II

C. Type III



D. Type V

Correct Answer: D. Type V

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Given the description, the patient is diagnosed with Type V thoracoabdominal aortic aneurysm Crawford's classification of thoracoabdominal aortic aneurysm: Type Involvement I Descending thoracic aorta to above renal arteries. II Descending thoracic aorta to below renal arteries. III From the sixth intercostal space to below renal arteries. IV The entire abdominal aorta from the twelfth intercostal space to the aortic bifurcation. V Portion of the thoracic aorta below the sixth intercostal space to above renal arteries.

References:

Sabiston’s Textbook of Surgery, 21 Edition, Page 1747, 1748

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 65-year-old male with a history of hypertension and smoking presents with an abdominal aortic aneurysm measuring 6.0 cm in diameter, detected during routine surveillance. Which of the following is the most appropriate next step in the management of this patient? (Q849412)

A. Regular ultrasound surveillance every 6 months

B. Begin beta-blocker therapy

C. Endovascular aneurysm repair

D. Lifestyle modifications and smoking cessation

Correct Answer: C. Endovascular aneurysm repair

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Abdominal Aortic Aneurysm : For an abdominal aortic aneurysm (AAA) that has reached 6.0 cm in diameter, surgical intervention is generally recommended due to the high risk of rupture. Endovascular aneurysm repair (EVAR) is a minimally invasive surgical approach that is often preferred for eligible patients, given its lower complication rates compared to open surgery. Surveillance is appropriate for smaller aneurysms, and medical management, including blood pressure control and lifestyle modifications, is essential but not sufficient alone for an aneurysm of this size. Management of Abdominal Aortic Aneurysm (AAA): Aspect Details Surveillance Small AAAs (3.0–3.9 cm): Monitor every 2–3 years using ultrasound. Medium AAAs (4.0–5.4 cm): Monitor every 6–12 months with ultrasound. Large AAAs (≥5.5 cm): Surgical intervention recommended; if not, frequent imaging and clinical review. Medical Management Risk Factor Modification : Smoking Cessation Blood Pressure Control Cholesterol Management: Statins recommended. Surgical Intervention I ndications for Surgery: Aneurysm Diameter ≥ 5.5 cm (High risk of rupture) Rapid Growth: >0.5 cm increase in six months. Symptomatic AAAs : Consider surgery. Surgical Options : Open Surgical Repair: Using a Dacron graft which is durable and has higher morbidity. Endovascular Aneurysm Repair (EVAR): Less invasive, requires long-term surveillance for complications.

Sabiston’s Textbook of Surgery, 21 Edition, Pages 1747-1751

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 45-year-old male with a history of bacterial endocarditis presents with sudden onset of severe headache, nausea, and vomiting. A CT scan of the head is shown below. Which of the following is the most likely cause of the haemorrhage in this patient? (Q849411)

A. Ruptured berry aneurysm

B. Traumatic brain injury

C. Hypertensive intracerebral haemorrhage

D. Ruptured mycotic aneurysm

Correct Answer: D. Ruptured mycotic aneurysm

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In this clinical scenario, the patient has a history of bacterial endocarditis, which significantly raises the likelihood of developing mycotic aneurysms. These aneurysms often occur in cerebral arteries due to septic emboli from the heart lodging in the vessel walls, leading to infection and weakening of the artery. This condition can result in a subarachnoid hemorrhage if the aneurysm ruptures . Causes of mycotic aneurysm: Bacterial infection (e.g., Staphylococcus, Streptococcus, Salmonella) Fungal infection (e.g., Candida, Aspergillus) Septicemia or endocarditis Other options: Option A : Ruptured berry (saccular) aneurysm — Typically presents with non-traumatic subarachnoid haemorrhage (thunderclap headache, blood in the basal cisterns on CT). There is no specific association with acute bacterial endocarditis or septic emboli causing saccular aneurysms. Option B: Traumatic brain injury — Requires history of significant head trauma; the stem gives an infective cardiac source and sudden spontaneous haemorrhage without trauma, making this unlikely. Option C: Hypertensive intracerebral haemorrhage — Usually occurs in deep brain structures (basal ganglia, thalamus, pons, cerebellum) in long-standing poorly controlled hypertension. While hypertensive bleeds can present acutely, the important history of infective endocarditis strongly favors an infective (mycotic) cause.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 1014 Sabiston’s Textbook of Surgery, 21 Edition, Page 1748

↑ *Back to this question in Part A*

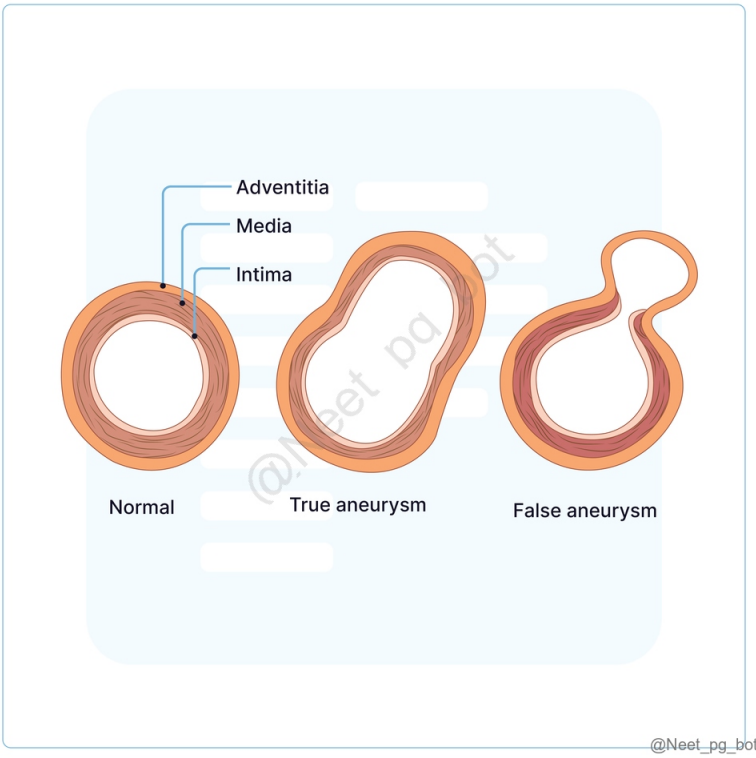
@Neet_pg_bot

Q12: A 58-year-old male presents with a pulsatile mass in the right groin following recent arterial catheterisation. Doppler ultrasound reveals an aneurysm. Which characteristic best describes this type of aneurysm? (Q849410)

A. Involves all three arterial wall layers

B. Fusiform dilation of the artery.

C. Wall composed of fibrous tissue only



D. Commonly caused by atherosclerosis

Correct Answer: C. Wall composed of fibrous tissue only

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: With the given history, the patient has developed a Pseudoaneurysm post catheterisation. Aspect True Aneurysm False (Pseudoaneurysm) Aneurysm Definition Involves all three layers of the arterial wall. Involves only a layer of fibrous tissue outside the vessel. (Option A ruled out) Wall Structure Intima, media, and adventitia are involved. Only fibrous tissue surrounds the breach. Morphology Fusiform or saccular. Typically spherical or ovoid. (Option B ruled out) Aetiology Atherosclerosis, genetic conditions. Trauma, surgery, or arterial puncture. (Option D ruled out) Clinical Features May be asymptomatic until complications arise. Often presents with a pulsatile mass or pain. Common Locations Large arteries (e.g., aorta, iliac). Peripheral arteries (e.g., femoral, popliteal). Diagnosis Detected by ultrasound, CT, and MRI. Detected by ultrasound or angiography. Management Surgical repair or endovascular techniques. Repair or percutaneous methods (e.g., thrombin injection).

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1005, 1017-1024

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 65-year-old male with a history of atrial fibrillation presents to the emergency department with sudden, severe abdominal pain that is disproportionate to physical examination findings. He also reports vomiting and the passage of blood in his stool. Given his history and clinical presentation, which artery is most likely involved in this patient's condition? (Q849409)

A. Superior Mesenteric Vein

B. Superior Mesenteric Artery

C. Inferior Mesenteric Artery

D. Inferior Mesenteric Vein

Correct Answer: B. Superior Mesenteric Artery

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Given the patient’s presentation, the diagnosis is Acute mesenteric ischemia and the most common artery involved is Superior mesenteric artery (SMA), which supplies a large portion of the small intestine and part of the colon. Occlusion of the SMA is the most common cause of acute mesenteric ischemia, leading to sudden, severe abdominal pain, particularly in patients with atrial fibrillation. Acute Mesenteric Ischemia (AMI): Aspects Description Definition Sudden reduction in blood supply to the intestines, leading to ischemia and potential necrosis. Commonly involves the Superior mesenteric artery (SMA). Clinical Features Pain: Severe, sudden-onset abdominal pain disproportionate to physical findings. Others: Nausea, vomiting, diarrhea, bloody stools, shock. Risk Factors Cardiovascular: Atrial fibrillation, recent MI, heart failure. Vascular: Atherosclerosis, vasculitis. Others: Hypercoagulable states. Radiological Features CT Angiography: Preferred diagnostic tool; reveals SMA occlusion, String of sausage sign , bowel wall thickening, pneumatosis intestinalis, portal venous gas. Management Initial: IV fluids, broad-spectrum antibiotics, pain control. Definitive: Anticoagulation (e.g., IV heparin), surgical embolectomy, bowel resection. Vasodilators (e.g., papaverine) can be used intra-arterially to relieve vasospasm.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 1312, 1313

↑ *Back to this question in Part A*

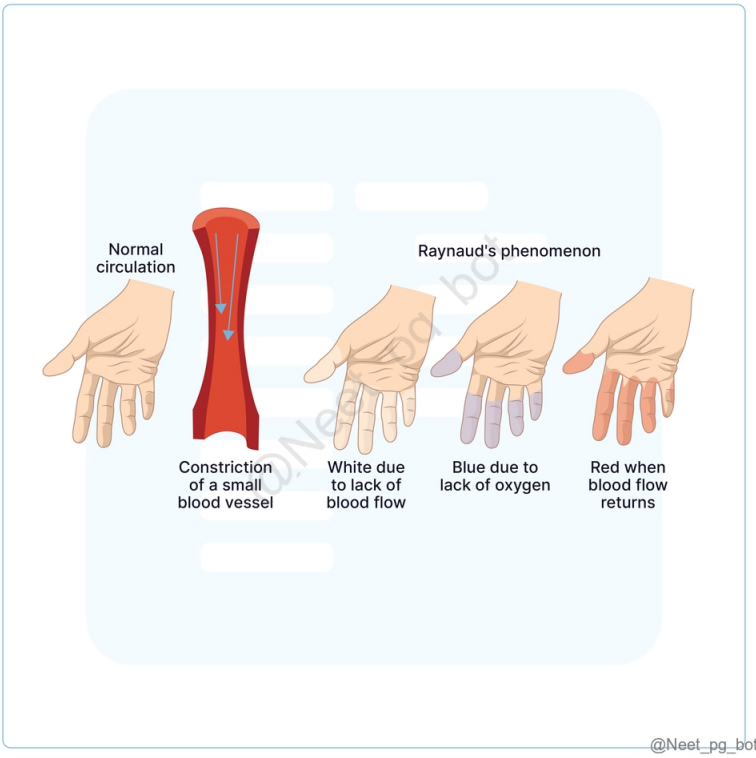
@Neet_pg_bot

Q14: A 24-year-old woman presents with episodic colour changes in her fingers triggered by cold temperatures and stress. The episodes follow a characteristic sequence. What is the correct sequence of events in the skin colour changes seen in the Raynaud phenomenon? (Q849408)

A. Rubor → Cyanosis → Pallor

B. Cyanosis → Pallor → Rubor

C. Pallor → Cyanosis → Rubor



D. Rubor → Pallor → Cyanosis

Correct Answer: C. Pallor → Cyanosis → Rubor

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Sequence of events in Raynaud's phenomenon: Pallor : The initial phase where the skin becomes pale or white due to reduced blood flow and vasospasm. Cyanosis : Followed by a blue or purple colour due to continued reduced blood flow and lack of oxygen. Rubor : The final phase is where the skin turns red as blood flow returns and the area warms up.

Ganong’s Review of Medical Physiology, 26th Edition, Page 260

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 58-year-old male presents to the emergency department with a sudden onset of severe pain in his left leg. The leg appears pale and feels cold to the touch, and the patient is unable to move or feel his toes. On examination, no pulses are detectable below the knee. What is the most likely diagnosis? (Q849347)

A. Deep vein thrombosis

B. Acute limb ischemia

C. Chronic venous insufficiency

D. Cellulitis

Correct Answer: B. Acute limb ischemia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient’s symptoms strongly suggest Acute limb ischemia , a serious condition caused by a sudden blockage of blood flow to the limb. It is typically recognised by the "5 P's": Pain : Intense, sudden pain in the affected limb. (most common symptom) Pallor: The limb appears pale due to reduced blood flow. Pulselessness: The absence of a pulse beyond the site of the blockage. Paresthesia: Numbness or tingling in the limb. Paralysis: The inability to move the limb due to muscle weakness. Prompt recognition and treatment are essential to restore blood flow and prevent permanent damage to the limb. Deep Vein Thrombosis (DVT) (Option A): DVT typically presents with swelling, pain, and redness in the affected leg, but it does not usually cause the leg to be pale and cold or result in a loss of pulses. The loss of pulses and coldness are more indicative of arterial rather than venous issues. Chronic Venous Insufficiency (Option C): Chronic venous insufficiency generally causes symptoms such as swelling, varicose veins, and skin changes over time. It does not typically present with sudden onset severe pain, pallor, coldness, or loss of pulses. Cellulitis (Option D): Cellulitis usually presents with redness, warmth, swelling, and tenderness of the skin. It typically does not cause loss of pulses, coldness, or the inability to move or feel the toes, which are more consistent with ischemic conditions rather than infection.

Schwartz’s Principles of Surgery, 11th Edition, Page 954

↑ *Back to this question in Part A*

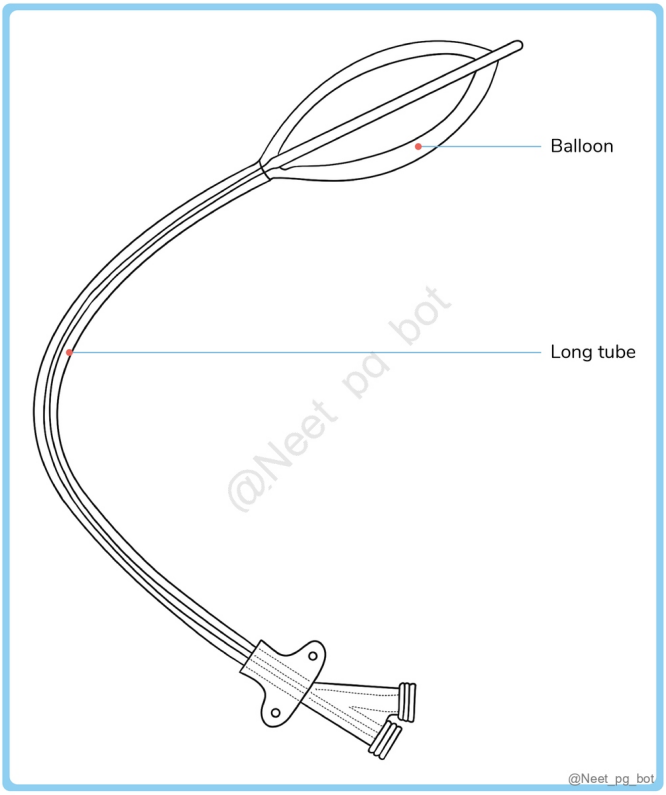
@Neet_pg_bot

Q16: A 65-year-old male presents with a sudden onset of severe pain in his left leg, which has become cold and pale. On examination, there is an absence of distal pulses. Imaging reveals a large saddle embolus at the aortic bifurcation. What is the most appropriate catheter to use for embolectomy in this case? (Q849405)

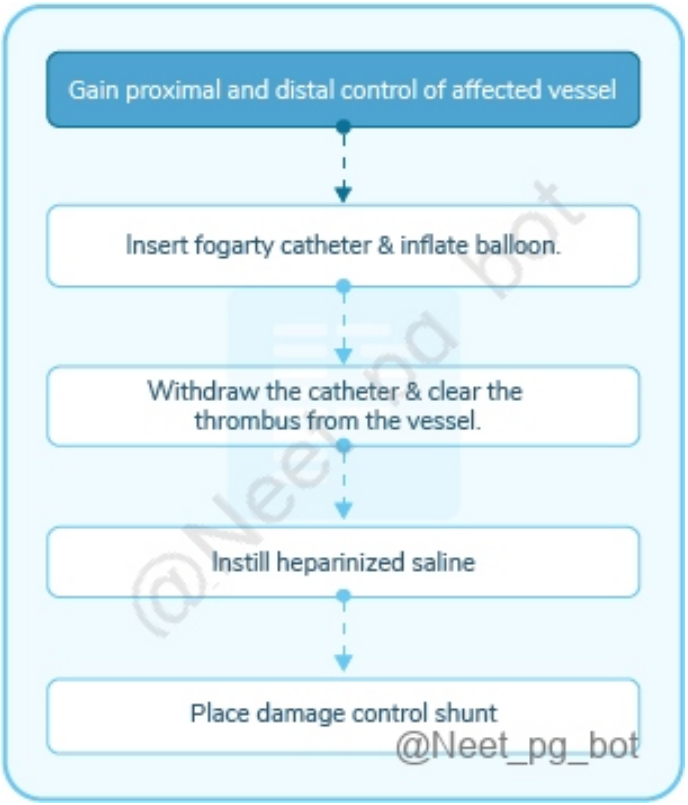
A. Seldinger catheter

B. Swan-Ganz catheter

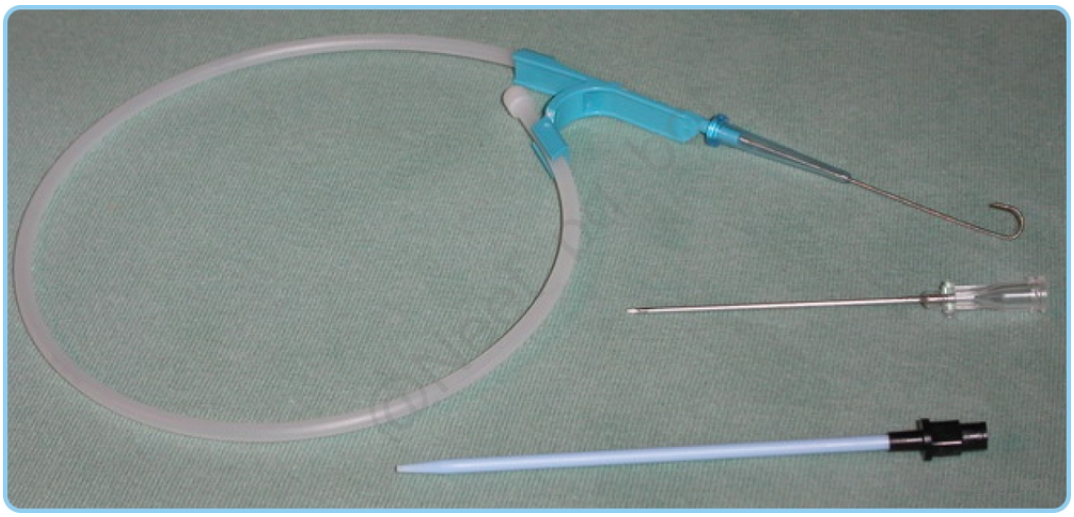
C. Fogarty catheter



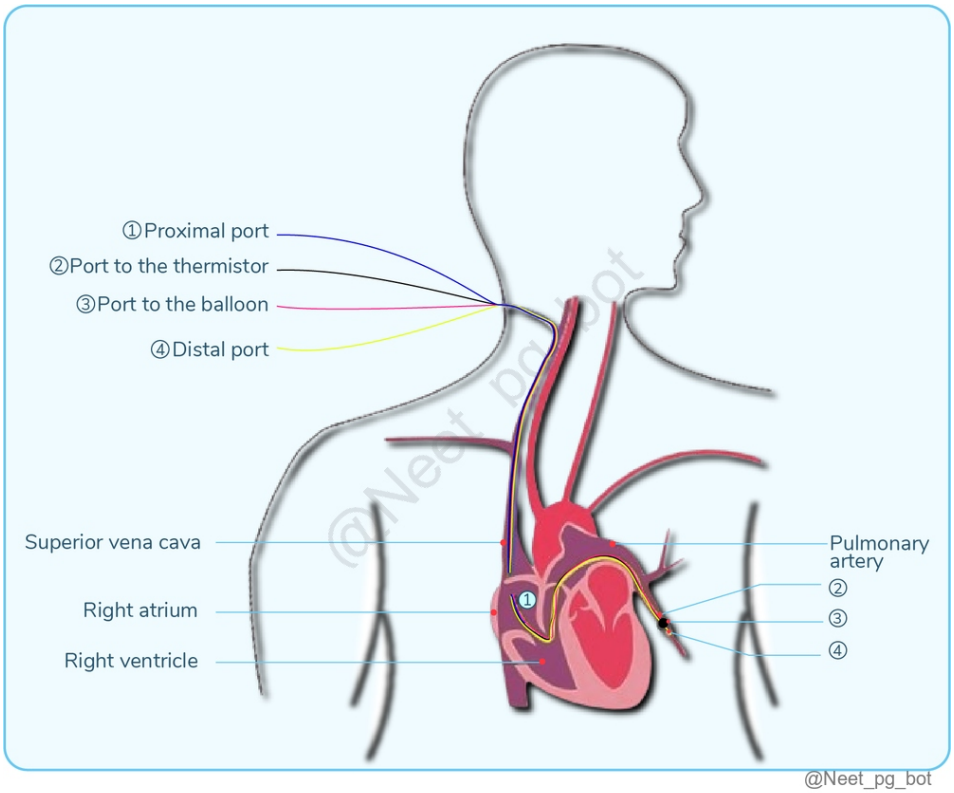
D. Tenckhoff catheter



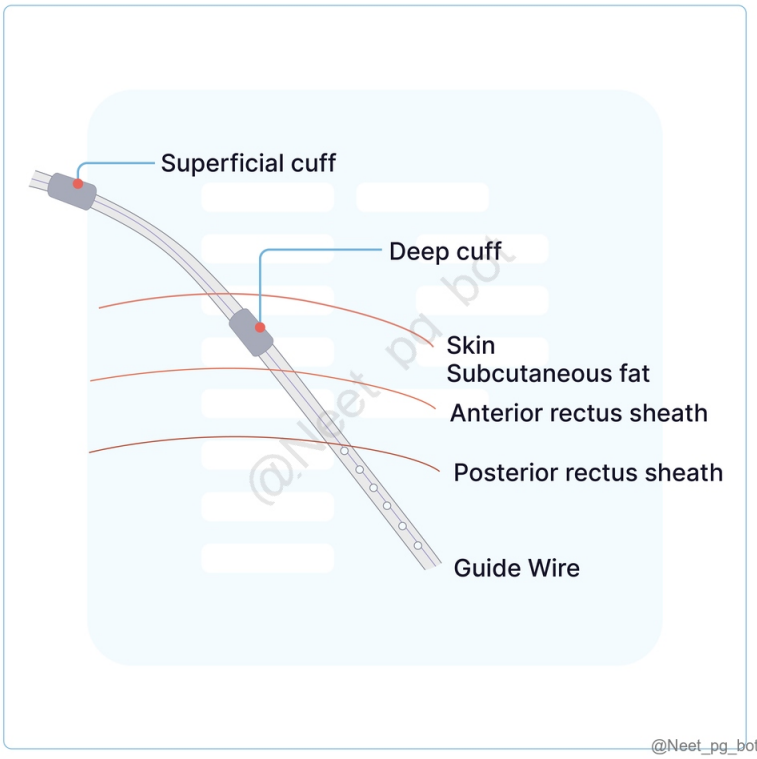
Correct Answer: C. Fogarty catheter



■ *Listen (English)*



■ *Listen (Hindi)*



Explanation: Fogarty catheter – Specifically designed for embolectomy or thrombectomy. Embolectomy using Fogarty catheter: Seldinger catheter (Option A) is used for guiding wires in vascular procedures but not for embolectomy. Swan-Ganz catheter (Option B) is primarily used for measuring pulmonary artery pressures and cardiac output, not for embolectomy. Tenckhoff catheter (Option D) is typically used in peritoneal dialysis and is not applicable in vascular procedures like embolectomy.

Balloon
Long tube
@Neet_pg_bot

Gain proximal and distal control of affected vessel
Insert fogarty catheter & inflate balloon.
Withdraw the catheter & clear the thrombus from the vessel.
Instill heparinized saline
Place damage control shunt
@Neet_pg_bot

①Proximal port
②Port to the thermistor
③Port to the balloon
④Distal port
Superior vena cava
Right atrium
Right ventricle
Pulmonary artery
②

Sabiston's Textbook of Surgery, 21st Edition, Page 1800

↑ *Back to this question in Part A*

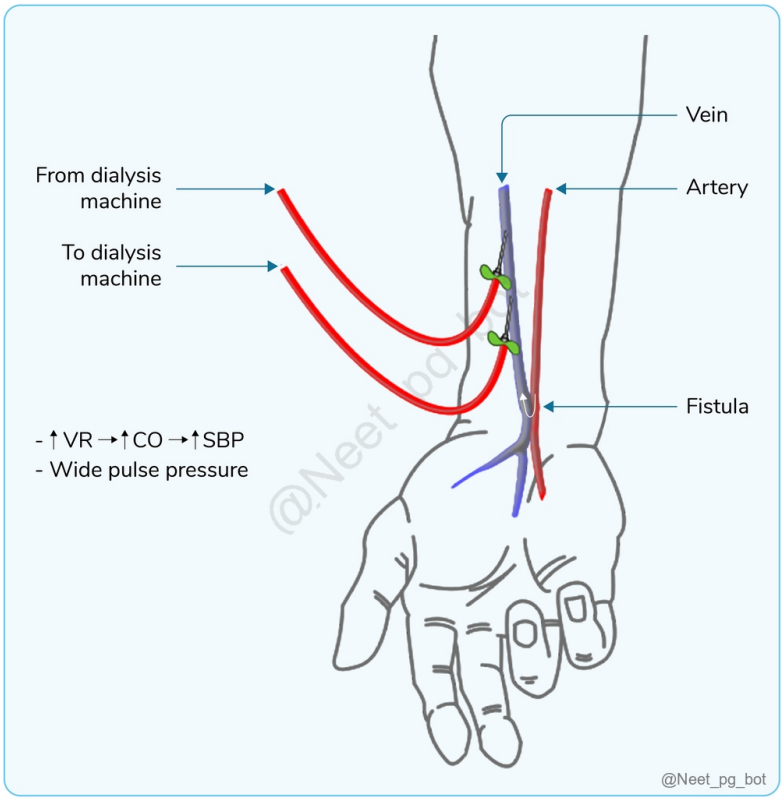
@Neet_pg_bot

Q17: A 60-year-old male with end-stage renal disease is scheduled for the creation of a surgically created arteriovenous (AV) fistula to facilitate long-term hemodialysis. Which of the following is the most commonly used type of AV fistula for this purpose? (Q849401)

A. Cimino-Brescia fistula

B. Blalock-Taussig shunt

C. Snuff box fistula



D. Axillary-axillary loop graf

Correct Answer: A. Cimino-Brescia fistula

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Cimino-Brescia fistula is the most commonly used AV fistula for hemodialysis access. It involves connecting the radial artery to the cephalic vein at the wrist, creating a durable and reliable access point for hemodialysis. Surgically created Arterio-Venous fistula : It is a connection made between an artery and a vein, typically in the arm, and is most commonly used for patients with end-stage renal disease who require hemodialysis. Examples of Surgically created fistulas are: Brescia-Cimino fistula: It is created between the Radial artery and the Cephalic vein. Snuff Box fistula: It is created between the Posterior branch of the radial artery and Cephalic vein (Option C) Feinberg fistula: It is created between the Radial artery and the Basilic vein.

SRB's Manual of Surgery, 6th Edition, Page 33

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 46-year-old male presents with intense pain in his left leg along with the following lesion. Which of the following is the most probable diagnosis? (Q849399)

A. Neuropathic ulcer

B. Venous ulcer

C. Arterial ulcer

D. Pressure ulcer

Correct Answer: C. Arterial ulcer

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The most probable diagnosis of the given ulcer is Arterial ulcer. It occurs due to severe arterial insufficiency of digital and medium sized arteries leading to ischemia and tissue death in the region. They may present as painful erosions, located between the toes, dorsum of feet, on the shin and around malleoli. Characteristic features of arterial ulcers: Punched-out edges are seen It is intensely painful Distal pulses are not palpable Thin, shiny skin is seen Loss of hair in the area Brittle nails are seen Venous ulcer (Option B) Arterial ulcer (Option C) Neuropathic ulcer (Option A) Pressure ulcer (Option D) Site Gaiter's area (area between malleolus and calf) At distal ends of limbs, such as toes, feet and legs. Over toe joints, under the heel, over malleoli, under the metatarsal head, etc Seen over pressure points, most common are ischium, greater trochanter, sacrum, hee, malleolus, occiput, etc Appearance Vertically oval with a sloping edge and will not penetrate deep fascia. Punched-out edges are seen in this type of ulcer. Ulcers can be associated with gangrene and abscesses; osteomyelitis can be seen here. Punched out ulcer with bone as a base. Cause Caused by ambulatory chronic venous hypertension due to varicose veins. This occurs due to severe arterial insufficiency of digital and medium-sized arteries, leading to ischemia and tissue death in the region. It is caused due to repeated trauma and ischemia due to microangiopathy in diabetic patients . It is tissue necrosis and ulceration due to prolonged pressure on any part of the body. Characteristics It is initially painful, then chronically becomes painless. It heals on rest and treatment but reforms again. It is intensely painful, distal pulses are not palpable, associated with shiny skin, brittle nails and loss of hair over the region. Also known as diabetic ulcer since it is seen in diabetic patients. It is common in bedridden patients with head injuries, neurological deficits, and comatose and stroke-ridden patients.

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 998, 999

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A 35-year-old male with a 12-year history of smoking presents with severe rest pain and discoloration of the left lower limb's digits as shown below. He has experienced worsening pain in this limb for the past 2 days, following 3 months of discomfort. What is the appropriate management for this condition? (Q849394)

A. Lumbar sympathectomy

B. Abstinence from smoking

C. Amputation

D. Vasodilators

Correct Answer: C. Amputation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient presents with advanced peripheral arterial disease , most likely Buerger’s disease (Thromboangiitis obliterans) , as suggested by: History of chronic smoking Rest pain in the limb Black discoloration of the toes (indicating dry gangrene) Progressive worsening of symptoms over months The blackened digits in the image represent non-viable tissue , which is: Irreversible A source of pain At risk of infection Amputation is required at this stage to: Remove gangrenous tissue Prevent secondary infection Relieve intractable rest pain

References:

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 1024

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A 56-year-old male presents with sudden pain and numbness in his right lower limb for 1 day. On examination, the limb is cold and pale and exhibits loss of sensory and mild motor functions. Doppler studies reveal only venous signals. What grade of Rutherford's classification is this case? (Q849393)

A. Grade I

B. Grade IIA

C. Grade IIB

D. Grade III

Correct Answer: C. Grade IIB

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The above clinical scenario is a case of Acute Limb Ischemia (ALI) with Grade IIB of Rutherford's classification. Rutherford's classification of acute limb ischemia: Grade Category Sensory loss Motor deficit Arterial doppler signals Venous doppler signals Prognosis I (Option A) Viable none none Audible Audible No immediate threat IIA (Option B) Marginally Threatened None or minimal (toes) none Inaudible Audible Salvageable if promptly treated IIB (Option C) Immediately threatened More than toes Mild/moderate Inaudible Audible Salvageable with immediate revascularisation III (Option D) Irreversible Profound or insensate Paralyzed Inaudible Inaudible Limb is irreversibly damaged, major tissue loss, and amputation.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1012

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 38-year-old chronic smoker presents with lower limb pain during walking for 2 weeks. Examination reveals an ankle-to-brachial systolic pressure ratio of 0.7. What is the correct interpretation of this finding? (Q849392)

A. Critical limb ischemia

B. Intermittent claudication

C. Normal index

D. Calcified vessels

Correct Answer: B. Intermittent claudication

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: ABPI is measured supine by checking the systolic blood pressure in both upper and lower limbs (brachial, posterior tibial, and dorsalis pedis arteries). The higher value from each limb is used to calculate the ABPI. ABPI (Ankle brachial pressure index) or ABI (Ankle brachial index) here is 0.7 which indicates intermittent claudication in Buerger's disease. ABI / ABPI = Systolic BP in the Ankle/ Systolic BP in the arm Value Interpretation 0.1 - 0.4 Critical limb ischemia (Option A) 0.5 - 0.9 Intermittent claudication (Option B) 1.0 - 1.2 Normal (Option C) > 1.2 Calcified vessels (seen in patients with DM, End stage renal disease) (Option D)

References:

Sabiston’s Textbook of Surgery, 21st Edition, Page 1773

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: What is the most specific investigation of choice for peripheral arterial disease? (Q849391)

A. Ankle-Brachial Index

B. Duplex ultrasonography

C. CT angiography

D. Magnetic Resonance Angiography

Correct Answer: C. CT angiography

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: CT angiography is considered the most specific investigation of choice due to: High resolution: High-resolution imaging of the entire vascular tree from the abdominal aorta to the foot arteries in a single examination. 3D reconstruction: Providing 3D reconstructions is crucial for intervention planning. Calcification detection: Accurate detection and quantification of arterial calcification. Less invasive: Less invasive than conventional angiography while maintaining detailed imaging. Characteristic radiological findings in peripheral arterial disease include: Disease confinement to distal circulation. Segmental occlusions with "skip" lesions. Extensive collateralization, notably "corkscrew" collaterals .

References:

Schwartz’s Principles of Surgery, 11th Edition, Page 974

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A 65-year-old man presents with pain in his right calf that occurs after walking 200 meters and is relieved by rest. The pain does not occur when he is at rest or when he walks shorter distances. Based on Boyd's classification of intermittent claudication, which grade best describes this patient's condition? (Q849390)

A. Grade 0

B. Grade I

C. Grade II

D. Grade III

Correct Answer: C. Grade II

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's pain occurs after walking 200 meters and is relieved by rest, which corresponds to Grade II claudication. Boyd's classification of intermittent claudication : Grade Description Grade 0: Asymptomatic (Option A ruled out) No symptoms of claudication, even with exercise Grade I: Mild claudication (Option B ruled out) Able to walk more than 200 meters (about 650 feet) before onset of symptoms Grade II: Moderate claudication (option C) Able to walk between 50 and 200 meters (about 160 to 650 feet) before onset of symptoms Grade III: Severe claudication (Option D ruled out) Able to walk less than 50 meters (about 160 feet) before onset of symptoms Grade IV: Ischemic rest pain Pain occurs at rest or with minimal exertion

References:

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 998, 999

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: A 40-year-old male presents with pain in his hands and feet, which worsens with cold exposure. He has a history of heavy smoking. On examination, he has ulcers on his fingers and toes. Angiography reveals "corkscrew" collaterals and segmental occlusions. Which of the following conditions is most likely in this patient? (Q849389)

A. Systemic sclerosis

B. Thromboangiitis obliterans

C. Atherosclerosis

D. Frostbite

Correct Answer: B. Thromboangiitis obliterans

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's age, heavy smoking history, and angiographic findings with "corkscrew" collaterals strongly indicate Buerger's Disease (Thromboangiitis obliterans). This condition involves inflammatory thrombosis affecting small and medium-sized vessels, primarily in the extremities. It presents with pain, ulcers, and claudication in both upper and lower limbs, often leading to gangrene if untreated. Smoking cessation is crucial for management, as it is the most important modifiable risk factor. Angiography shows "corkscrew" collaterals

References:

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 1024 Schwartz’s Principles of Surgery, 11th Edition, Page 974

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: A 72-year-old man presents with a sudden onset of severe pain, numbness, and coldness in his left leg. On examination, the left leg appears pale, and no pulse is palpable below the femoral artery. What is the most probable cause of this acute peripheral arterial occlusion? (Q849388)

A. Atherosclerosis

B. Buerger's disease

C. Fibromuscular dysplasia

D. Arterial dissection

Correct Answer: A. Atherosclerosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient shows classic features of acute limb ischemia- sudden severe pain, pallor, pulselessness, numbness, and coldness. In elderly patients, the most common cause of acute arterial occlusion is acute thrombosis superimposed on chronic atherosclerotic disease. Atherosclerotic plaques narrow the artery and predispose it to sudden clot formation, leading to complete occlusion. This mechanism is far more common, making atherosclerosis the most probable cause in this clinical scenario. Incorrect Options: Option B) Buerger's disease : Seen in young male smokers (20–40 years), affects small and medium vessels - rare in elderly. Option C) Fibromuscular dysplasia : Occurs in young to middle-aged women, commonly affecting renal and carotid arteries. Option D) Arterial dissection : More typical in the aorta or carotid arteries; peripheral arterial dissection causing acute limb ischemia in an elderly man is uncommon compared with atherosclerotic thrombosis.

Q25 (p. 1430)	*Q26 (p. 1430)*				

Q1: A 62-year-old male presents with left leg swelling and pain for 5 days and has a positive D-dimer test. Duplex ultrasonography confirms an extensive DVT involving the left popliteal and femoral veins. Which of the following is the most appropriate initial management strategy? (Q849439)

A. Unfractionated heparin followed by warfarin

B. LMWH followed by oral anticoagulant

C. Catheter-directed thrombolysis

D. IVC filter placement

Correct Answer: B. LMWH followed by oral anticoagulant

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Treatment of DVT: Anticoagulation: For initial management of acute DVT without contraindications to anticoagulation, the current recommended approach is to start with LMWH and transition to an oral anticoagulant. This approach has several advantages: LMWH provides rapid anticoagulation without the need for monitoring. Oral anticoagulants have shown non-inferiority or superiority to warfarin in large clinical trials. They have a better safety profile and do not require regular INR monitoring. This regimen allows for outpatient management in many cases, reducing hospitalization rates. Investigation of DVT: Venous Doppler with Duplex scanning Non-invasive; detects thrombus by impaired blood flow and inability to compress veins. Presence of echogenic material completely filling the lumen of vein Absence of compressibility Absence of blood flow Venogram Accurate for detecting and locating thrombus and differentiating occlusive and non-occlusive thrombus but less commonly used due to invasiveness. Impedance Plethysmography Measures changes in venous volume and flow using a cuff. Less useful for calf DVT and previous thrombosis. Fibrin and Fibrinogen Assays Measures fibrin degradation products, including D-dimer. D-dimer has a high negative predictive value. Radioactive Fibrinogen Study Uses radiolabeled fibrinogen to detect thrombus. Less commonly used. Magnetic Resonance Venous Imaging (MRVI) Non-invasive; Useful for imaging iliac veins and IVC. Management of DVT : Initial

Anticoagulation Subcutaneous LMWH: Rapidly anticoagulate confirmed DVT cases. Intravenous Unfractionated Heparin: For patients with significant renal impairment. Fondaparinux or Bivalirudin: Alternatives for those with heparin sensitivity or heparin-induced thrombocytopenia. Transition to Oral Anticoagulation Duration: At least 3 months or longer based on risk factors or recurrence. Novel anticoagulants (NOACs): Rivaroxaban, Apixaban (factor Xa inhibitors), Dabigatran (direct thrombin inhibitor). Vitamin K Antagonists: Warfarin (alternative to NOACs). Monitoring Anticoagulation Heparin: Activated partial thromboplastin time (APTT). Warfarin: INR maintained between 2.0 to 3.0. For Patients with contraindications to Anticoagulation Temporary IVC Filter (Option D): Consider if bleeding risk prevents anticoagulation or to prevent pulmonary embolism. It does not treat the existing thrombus and is associated with long-term complications. Endovascular Surgery Thrombus removal, lysis, and stenting. Beneficial in selected patients, especially those with iliofemoral thrombosis, to reduce risk of chronic post-thrombotic syndrome. Unfractionated heparin followed by warfarin (Option A) was the traditional approach, but it has largely been superseded by LMWH and DOACs due to the need for hospitalization, frequent aPTT monitoring for unfractionated heparin, and long-term INR monitoring for warfarin. Catheter-directed thrombolysis (Option C) is generally reserved for massive iliofemoral DVT with severe symptoms or limb-threatening situations. It carries a higher risk of bleeding and is not first-line therapy for most DVT cases.

@Neet_pg_bot

Q2: An infant presents with a large, rapidly growing vascular malformation, along with severe thrombocytopenia and microangiopathic hemolytic anemia. What is the most likely diagnosis? (Q849459)

A. Klippel-Trénaunay Syndrome

B. Kasabach-Merritt Syndrome

C. Sturge-Weber Syndrome

D. Capillary Hemangioma

Correct Answer: B. Kasabach-Merritt Syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Syndromes associated with AV Malformation: Klippel-Trénaunay syndrome Kasabach-Merritt Syndrome (KMS) A mesodermal abnormality characterized by: Cutaneous nevus, Persistent vestigial veins with varicose veins, Soft-tissue and bone hypertrophy. Segments of deep veins are hypoplastic or aplastic. Possible obstruction of lymphatics. Treatment: Conservative management with compression stockings. Removal of large superficial varicose veins done only if deep veins are patent. A life-threatening coagulopathy of infancy characterized by: Thrombocytopenia Microangiopathic hemolytic anemia Consumptive coagulopathy. Rapidly growing vascular tumor Treatment: Mainly supportive care Embolization: Possible if a single feeding vessel is present. Medical Therapies: Steroids,vincristine and sirolimus. Capillary hemangioma: Sturge-Weber Syndrome (Option C) is characterized by facial nevus or port wine stain and neurological symptoms like contralateral hemiparesis, focal seizures and/or intellectual disability. It is not associated with severe thrombocytopenia and microangiopathic hemolytic anemia. Capillary Hemangioma (Option D) is the commonest birthmark seen on the head and neck. Majority occurs as a consequence of intravascular thrombosis, fibrosis, and mast cell infiltration and resolve spontaneously. It is not associated with severe thrombocytopenia and microangiopathic hemolytic anemia.

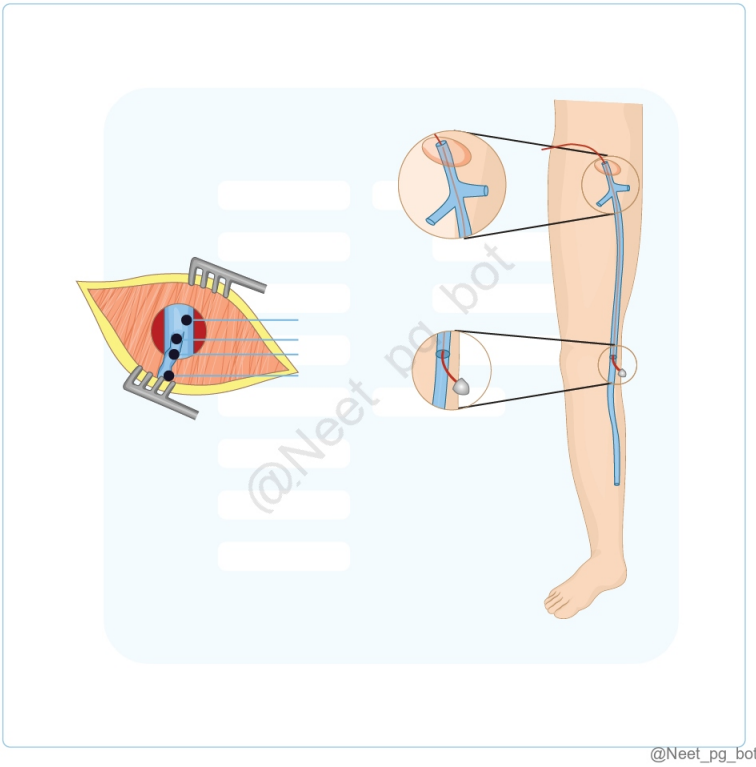
@Neet_pg_bot

Q3: A 50-year-old man presents with prominent varicose veins on his medial thigh and calf. Upon examination, incompetence of the great saphenous vein (GSV) is identified. The surgeon is considering the appropriate surgical intervention. What is the primary indication for performing Saphenofemoral Junction Ligation and GSV Stripping? (Q849455)

A. Varicose veins on the posterolateral calf due to small saphenous vein incompetence

B. Incompetence of the great saphenous vein with varicose veins on the medial thigh and calf

C. Varicose veins on the anterior thigh due to incompetent perforator veins



D. Small varicose veins unsuitable for endovenous ablation

Correct Answer: B. Incompetence of the great saphenous vein with varicose veins on the medial thigh and calf

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Incompetence of the great saphenous vein with varicose veins on the medial thigh and calf: Saphenofemoral Junction Ligation and GSV Stripping are indicated primarily for varicose veins resulting from GSV incompetence, particularly when these veins are located on the medial thigh and calf. Open Surgery Procedure Saphenofemoral Junction Ligation and Great Saphenous Vein Stripping Indication: Used for varicose veins in the medial thigh and calf due to great saphenous vein (GSV) incompetence. Procedure: An incision is made in the groin to access the saphenofemoral junction where the GSV meets the femoral vein. Tributaries of the GSV are ligated. Stripping: The GSV is tied off at the junction, and a device is inserted into the GSV and pulled out through an incision near the knee, stripping the vein as it is removed. Saphenopopliteal Junction Ligation and Small Saphenous Vein Stripping Indication: Used for varicose veins on the posterolateral calf due to small saphenous vein (SSV) incompetence. Procedure: An incision is made to access and ligate the saphenopopliteal junction where the SSV joins the popliteal vein. Stripping: Similar to the GSV procedure, the surgeon either strips the vein using a device or resects the proximal portion of the vein.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 55-year-old male with chronic venous insufficiency presents with a venous ulcer on his lower leg. He has a history of prolonged standing at work and reports aching and heaviness in his legs. What is correct regarding compression therapy in this patient? (Q849453)

A. Class 1 compression hosiery exerts 18-24 mmHg of pressure

B. Compression bandaging typically exerts less pressure than compression hosiery

C. Compression bandaging should be avoided in patients with a history of venous ulcers

D. Compression therapy is most effective when it exerts a graduated pressure to promote venous return

Correct Answer: D. Compression therapy is most effective when it exerts a graduated pressure to promote venous return

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Compression therapy works by exerting graduated external pressure on the legs, which helps promote blood flow back to the heart and reduces venous hypertension. This is particularly important in conditions like varicose veins where venous return is compromised. Compression Therapy in Varicose Veins Mechanism: Graduated external pressure promotes venous return. Reduces venous pressure, especially in a standing position. Types of Compression: Compression Hosiery: Knee-length or thigh-length garments. Indications: Varicose Veins: Alleviates symptoms; first-line therapy. Post-Intervention: Used after varicose vein treatments. Minimizes complications, promotes healing, and prevents recurrence. Long-term Prevention: Lifelong Class 2 stockings are recommended Categories based on pressure levels: Class Pressure (mmHg) Class 1 14–17 (Option A) Class 2 18–24 Class 3 25–35 Compression Bandaging: Multi-layered approach for desired pressure. Compression bandaging applies more pressure than hosiery (Option B) and is more often used in cases like venous ulcers or more severe conditions. Indications: Venous Ulcers (Option C): Essential for ulcers from venous insufficiency; use 35–40 mmHg pressure. Mixed Ulcers: Caution with arterial disease; use 30 mmHg if ABPI 0.5–0.8. Severe Arterial Compromise: Revascularization advised before bandaging if ABPI < 0.5 or ankle pressure < 60 mmHg.

@Neet_pg_bot

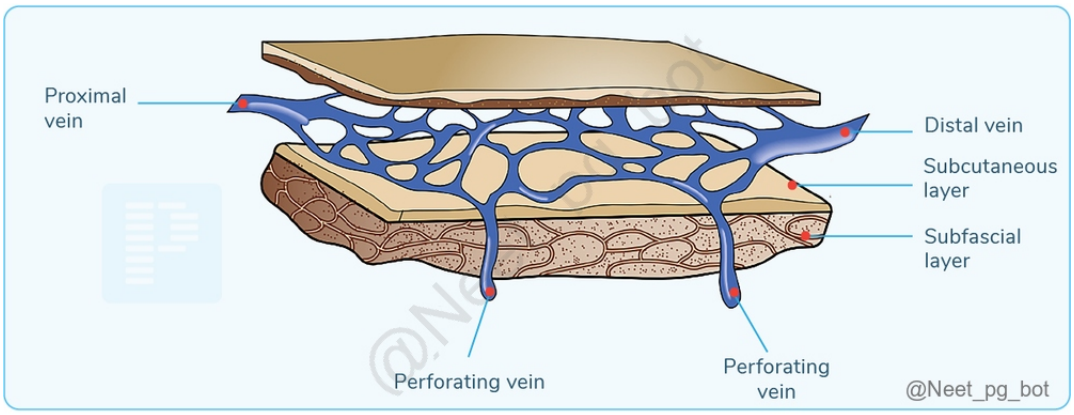
Q5: Which of the following statements about the pathophysiology of varicose veins is incorrect? (Q849447)

A. Defects in the walls or valves of the veins lead to retrograde blood flow.

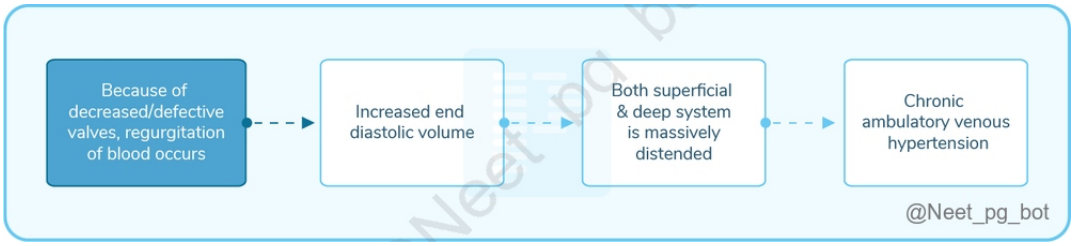
B. Inflammatory changes in walls lead to dilatation, elongation and valvular dysfunction.

C. The veins have a low end-diastolic volume.

D. Chronic ambulatory venous hypertension develops.



Correct Answer: C. The veins have a low end-diastolic volume.



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The pathophysiology of varicose veins includes the development of an increased end-diastolic volume. Pathophysiology of varicose veins: An anatomic or dynamic cause leads to damage of the valvular

system. Inflammatory changes affect the walls of the valves as well. This leads to the retrograde blood flow (Option A) and pooling of blood. This causes an increase in the end-diastolic volume in the veins. The superficial (visible) and deep venous systems are affected by this, which causes their dilatation (varicosity), elongation (Option B) , and even leads to secondary valvular dysfunction. This causes an increased ambulatory venous hypertension (Option D). This is responsible for the complications of varicose veins. Decreased amounts of elastin and an imbalance between collagen I and III suggest that the loss of the venous wall intimal architecture leads to dilation, tortuosity, and the formation of varicose veins . Dilation of superficial venous tributaries caused by increased transmission of pressure by the perforating veins: Pathophysiology:

@Neet_pg_bot

Q6: A patient comes to the surgery OPD complaining of small swellings and a wound on his right lower leg. On clinical evaluation, he is found to have hyperpigmentation in his right leg around the ankle and lower third of the leg. He also has a healed venous ulcer and is symptomatic. According to the CEAP classification, what is the clinical stage of the disease in this case? (Q849449)

A. C5a

B. C5s

C. C3r

D. C6

Correct Answer: B. C5s

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: According to the CEAP classification, the healed venous ulcer belongs to the C5 group, and since the patient is symptomatic, it can be classified as C5s. The CEAP (Clinical- Etiology- Anatomy- Pathology) classification for chronic venous disorders: Feature Classification For clinical classification: No signs of venous disease C0 Telangiectasia (<1 mm) or reticular veins (1–3 mm) C1 Varicose veins (>3 mm) C2 Edema C3 Pigmentation or eczema C4a LDS or atrophic blanche C4b Corona phlebectatica C4c Healed venous ulcer C5 Active venous ulcer C6 Clinical class can be further characterised as symptomatic (s), asymptomatic (a) or recurrent following previous successful treatment or healing (r), e.g. C2a, C2s, C6r. For etiological classification: Congenital Ec Primary Ep Secondary (post-thrombotic) Es No venous cause identified En For anatomical classification: Superficial veins As Perforator veins Ap Deep veins Ad No venous location identified An For anatomical classification: Reflux Pr Obstruction Po Reflux and obstruction Pr,o No venous pathophysiology identified Pn Pigmentation/Eczema LDS Atrophic blanche Corona phlebectatica

@Neet_pg_bot

Q7: A 50-year-old woman with inflammatory bowel disease presents with a painful ulcer on her leg. The ulcer has a necrotic edge and a purulent base, with significant surrounding erythema. What type of ulcer is most consistent with this presentation? (Q849461)

A. Neurotrophic ulcer

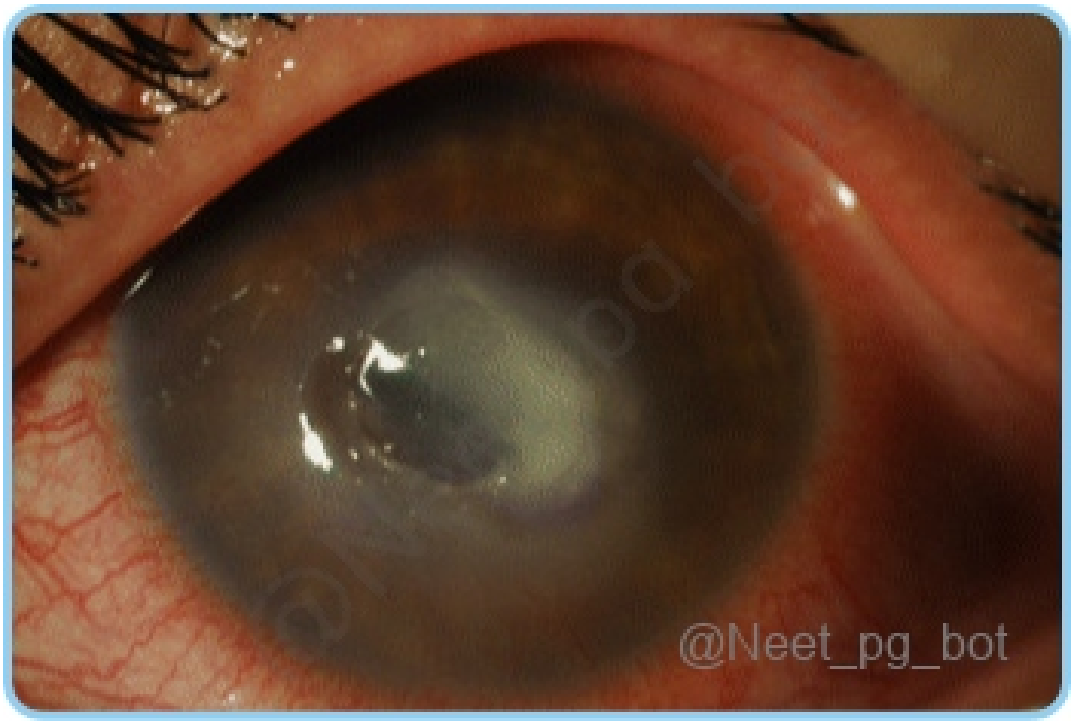
B. Pyoderma gangrenosum

C. Venous ulcer

D. Arterial ulcer

Correct Answer: B. Pyoderma gangrenosum

■ *Listen (English)*



■ *Listen (Hindi)*

Explanation: The clinical scenario here points to pyoderma gangrenosum that is a lower limb ulcer associated with IBS. Types of Lower Limb Ulcers: Type History Location Pain Lesion Characteristics Associated Findings

Ischemic/ arterial (Option D) Smoking, Intermittent claudications Distal, on dorsum of foot or toes, over bony prominences Severe, particularly at night; relieved by dependency Irregular edge; poor granulation tissue, dry necrotic base; round or punched-out with sharp demarcation; no surrounding inflammation Trophic changes of chronic ischemia, pale, hair loss, atrophic skin, cool feet; absence of pulses, prolonged capillary refill; ankle brachial index (ABI) <0.5; dependent rubor, elevation pallor Venous (Option C) Varicose veins, DVT, trauma, surgery, multiple pregnancies; aching/ swelling worse at end of day, relieved with elevation Lower third of leg (gaiter area); between malleolus and lower calf, majority at medial malleolus Mild; relieved by elevation Shallow, irregular/shaggy shape; granulating base; flat or steep elevation margins; fibrinous material at ulcer bed with moderate to heavy exudate; surrounding inflammation present Lipodermatofibrosis/ lipodermatosclerosis, pigmentation, edema, atrophie blanche; telangiectasia; normal capillary refill time, normal ankle brachial index (ABI) Neurotrophic (Option A) Numbness, paresthesias, burning, loss sensation in foot, Diabetes mellitus Under calluses or pressure points (e.g., plantar aspect of first or fifth MTP joint) None Punched-out, with deep sinus, variable depth partial thickness to severe involving tendon, fascia, joint capsule, or bone; surrounding inflammation present Demonstrable neuropathy, may be associated with underlying osteomyelitis Vasculitis History of primary or secondary connective tissue disease Pretibial and dorsum of foot but not always geographically limited Extremely painful Multiple, punched-out, inflamed indurated base (pathergy phenomenon); surrounding inflammation present; surrounding skin shows reticulate vascular pattern Fat necrosis/chronic panniculitis on pathology Hypertensive (local infarct) Normal pulses Lateral malleoli Severe Black necrosis; surrounding inflammation present Aka Martorell's ulcer; seen in patients with prolonged/ suboptimal controlled hypertension Pyoderma Gangrenosum (Option B) Unknown pathogenesis Develops in sites of previous trauma, around scars, donor sites used for grafting Severe Non-infective ulceration with purulent base ; well-defined, bluish, undermined borders; surrounding erythema; deep necrotic ulcer; surrounding inflammation present Seen with inflammatory bowel disease , immunodeficient states, myeloma, leukemia, Behcet's syndrome

@Neet_pg_bot

Q8: A 62-year-old man has a chronic ulcer on his leg from a burn injury sustained 12 years ago. Recently, the ulcer has developed indurated, painless, raised edges and surrounding fibrosis. What is the most likely diagnosis? (Q849460)

A. Venous ulcer

B. Pressure ulcer

C. Marjolin's ulcer

D. Actinic keratosis

Correct Answer: C. Marjolin's ulcer

■ *Listen to Audio 1*

Explanation: A Marjolin ulcer is a type of skin cancer that develops in areas of chronically damaged skin, such as old scars, burns, or non-healing wounds. It most commonly presents as squamous cell carcinoma Venous ulcers (Option A): Commonly located around and above the medial malleoli due to numerous perforators. Ulcer is large,

with a gently sloping edge and granulation tissue, nonhealing, tender, and recurrent, often with secondary infections. The surrounding skin often exhibits thickening, inflammation, induration, pigmentation (hemosiderosis), and fibrosis . Pressure ulcers (Option B) are the most common complication in bedridden patients or those with spinal cord injuries over bony prominences due to prolonged pressure. Marjolin's ulcer refers to a malignant transformation arising from burn scars or chronic non-healing wounds, such as pressure ulcers, over many years. Actinic Keratosis (Option D) are precancerous lesions that can lead to squamous cell carcinoma (SCC). Ill-marginated, erythematous, scaling, and rough papules or patches, often with signs of solar damage (atrophy, uneven pigmentation, telangiectasias).

@Neet_pg_bot

Q9: A 64-year-old woman is scheduled for the great saphenous vein (GSV) stripping to treat her varicose veins. What is the most likely nerve injury she might experience post-operatively? (Q849458)

A. Sural nerve

B. Common peroneal nerve

C. Saphenous nerve

D. Tibial nerve

Correct Answer: C. Saphenous nerve

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The most likely nerve to be injured during GSV varicose vein surgery is the saphenous nerve. Complications of Varicose vein surgery: Wound infections: Most common complication, reduced by prophylactic antibiotics. Recurrent Varicose Veins(10-20%): Small saphenous vein surgery>>Great saphenous vein surgery Nerve injury: Most common serious complication. Saphenous nerve injury (Option C) (7%): Occurs following great saphenous vein (GSV) stripping to the knee. Sural nerve injury (Option A) (20%): Occurs following small saphenous vein (SSV) surgery. Common peroneal nerve injury (Option B) (4%): Occurs following small saphenous vein (SSV) surgery. Venous thromboembolic complications (0.5%): Deep vein thrombosis(DVT) Thrombophlebitis Hematoma, ecchymosis, local hyperpigmentation Lymphocele Tibial nerve (Option D) is less commonly affected as it descends along the back of the thigh and popliteal fossa to the distal border of the popliteus and is not closely associated with the surgical area of the great saphenous vein (GSV).

@Neet_pg_bot

Q10: A patient with chronic venous insufficiency presents with symptomatic varicose veins. The physician decides to use foam sclerotherapy, specifically the Tessari technique, to treat the affected veins. What is the typical ratio of sclerosant to air used in the Tessari technique for creating the foam? (Q849457)

A. 1:1

B. 1:2

C. 1:3

D. 1:6

Correct Answer: C. 1:3

- *Listen (English)*
- *Listen (Hindi)*

Explanation: In the Tessari technique, the typical ratio of sclerosant to air is 1:3. This ratio is used to create a stable foam with a larger surface area, which improves contact with the vein walls during sclerotherapy. Sclerotherapy A sclerosing agent, typically sodium tetradecyl sulphate , is injected into the affected vein. This agent damages the vein lining, causing it to collapse and eventually be absorbed by the body. To enhance the effectiveness of the sclerosant, it is mixed with air to create a foam . This foam allows for greater contact with the vein wall and displaces blood that could inactivate the sclerosant Indications: Telangiectasias, reticular veins, and small, nonaxial varicose veins (<6 mm) visible in chronic venous disease; suitable for patients with persistent symptoms despite medical management. Aspect Tessari Technique Sclerosants Indications and Contraindications Foam Preparation Two syringes: one with sclerosant, one with air/gas (CO2) Connected via multi-way stopcock. Sclerosant to air ratio is usually 1:3 or 1:4 Repeated plunger action to create foam STS: Synthetic sodium salt with anesthetic properties Polidocanol: Synthetic polyethylene glycol, also an anesthetic. Effective for telangiectasias, reticular veins HTS: 23% hypertonic saline, osmotic agent Candidates: Asymptomatic patients and those with controlled recent or recurrent venous bleeding may undergo sclerotherapy without additional diagnostics. Contraindications: Avoid sclerotherapy during acute venous thrombosis or pregnancy. Risks : Microembolism risk Vessel Size: Suitable for veins up to 6 mm in diameter, including small, nonaxial varicose veins, reticular veins, and telangiectasias. Injection Technique Downstream injection from larger to smaller veins. Controlled foam volume to displace blood. Advantages Minimally invasive, enhanced efficacy, safety profile. Reduced volume requirement due to foam. STS: Rapid clearance in blood, effective for larger veins. Polidocanol: Decreased risk of thrombosis, suitable for smaller veins. Tessari technique

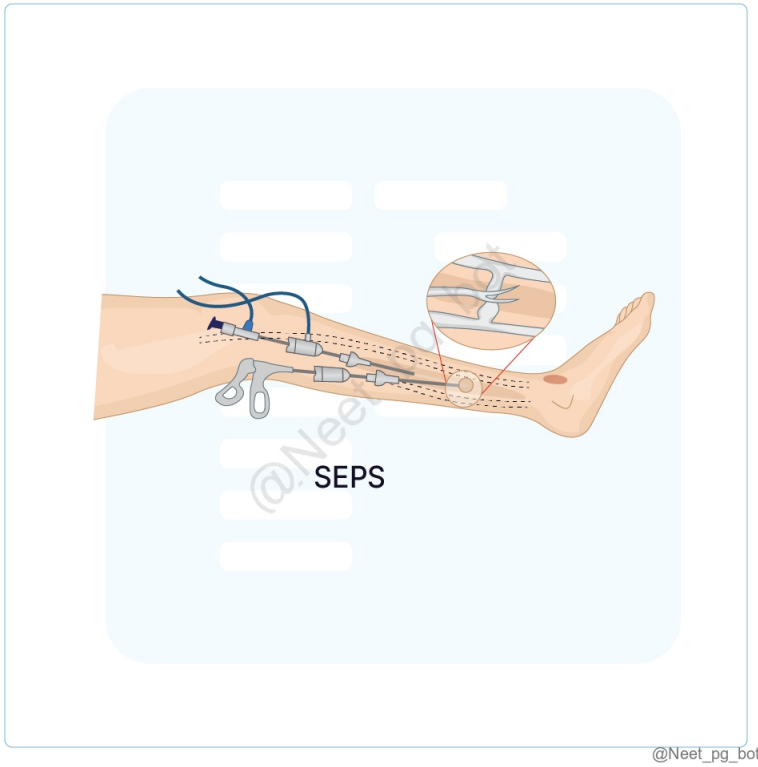
@Neet_pg_bot

Q11: Which of the following statements best describes the difference between Dodd and Cockett surgeries? (Q849456)

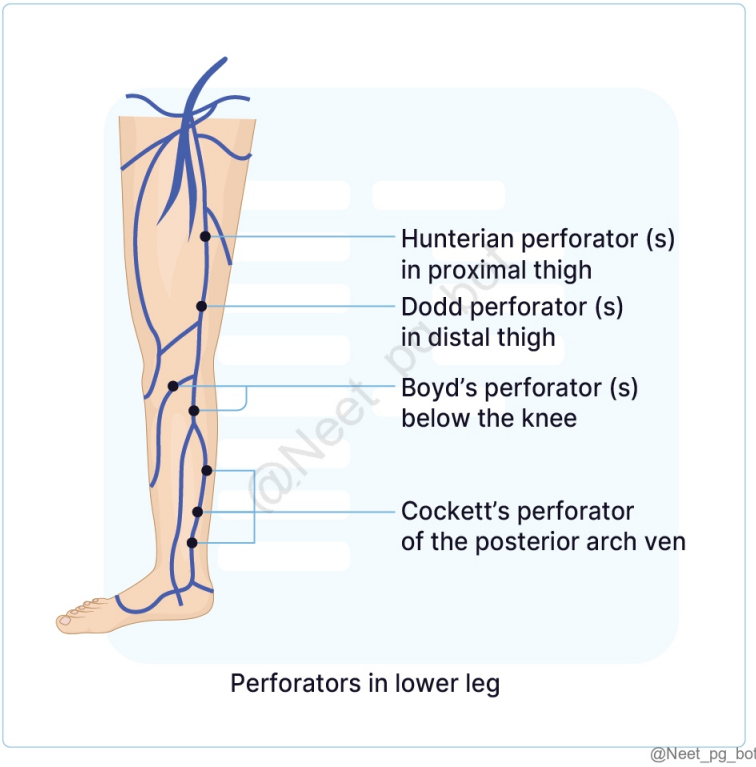
A. Dodd: ligation in the thigh; Cockett: ligation in the lower leg

B. Dodd: open surgery; Cockett: endoscopic

C. Dodd: targets superficial veins; Cockett: targets deep veins



D. Dodd: higher risk of nerve injury; Cockett: lower risk



Correct Answer: A. Dodd: ligation in the thigh; Cockett: ligation in the lower leg

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Dodd surgery targets perforator veins in the thigh. Cockett surgery focuses on perforator veins in the lower leg. Surgery for Perforator incompetence Surgery Purpose Technique Advantages Current Relevance SEPS (Subfascial Endoscopic Perforator Vein Surgery) Treats chronic venous insufficiency by targeting incompetent perforator veins. Minimally invasive; uses an endoscope to access and clip/divide perforator veins. Less pain, shorter recovery, fewer complications. Preferred over open surgery; effective in preventing venous ulcers. Dodd Surgery Addresses incompetent perforator veins in the thigh. Open surgery ; incision made to ligate or divide thigh perforator veins (Dodd perforators). Direct access to perforator veins. Less common due to SEPS; historically significant. Cockett Surgery Targets incompetent perforator veins in the lower leg. Open surgery ; incision over the lower leg to ligate perforator veins near the medial malleolus (Cockett perforators). Direct access to lower leg perforator veins. Less common due to SEPS; historically significant.

↑ *Back to this question in Part A*

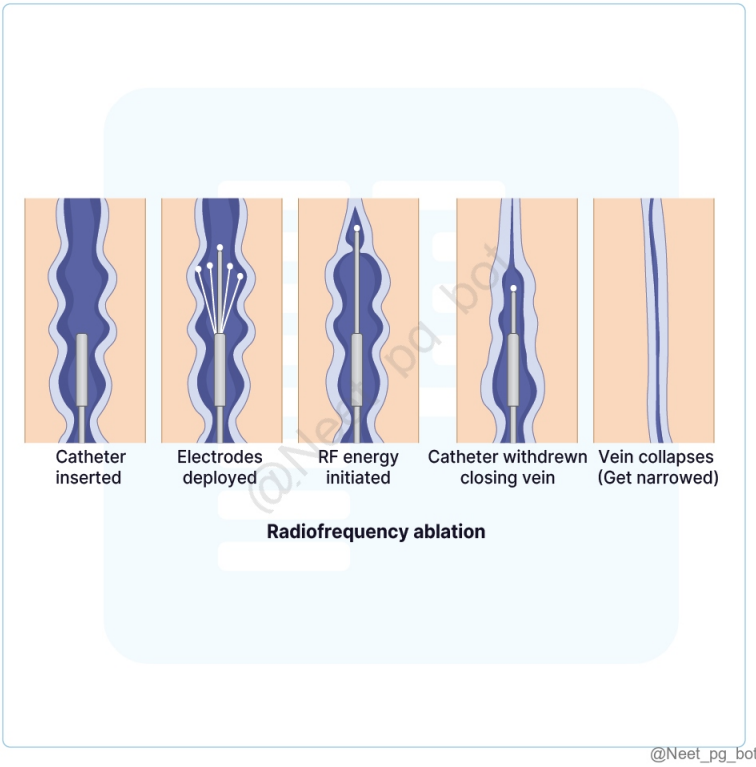
@Neet_pg_bot

Q12: A 45-year-old woman presents with symptomatic varicose veins. She is interested in learning about the available treatment options and their benefits. Her primary concern is to minimize recovery time and reduce post-operative pain. Which of the following surgical approaches is most appropriate for this patient? (Q849454)

A. Saphenofemoral ligation and great saphenous stripping

B. Saphenopopliteal junction ligation and small saphenous stripping

C. Endovenous laser ablation (EVLA)



D. Phlebectomy as a standalone procedure

Correct Answer: C. Endovenous laser ablation (EVLA)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Endovenous laser ablation (EVLA): EVLA is a minimally invasive procedure associated with faster recovery , less pain , and bruising compared to open surgery. It is the preferred option for patients seeking a quicker return to normal activities. Aspect Endovenous Laser Ablation (EVLA) Radiofrequency Ablation (RFA) Procedure Overview Minimally invasive, uses laser energy to close incompetent veins. Gold standard and has largely replaced surgical ligation and stripping. Minimally invasive, uses radiofrequency energy to close veins Indications Treats incompetent truncal veins, often used for varicose veins Treats incompetent truncal veins, similar to EVLA Advantages High efficacy (>95% closure rate) Cost-effective Versatile (treats large and small veins) Effective for tortuous veins Standard fibers treat perforator veins High efficacy (>95% closure rate) Standardized treatment cycles Potentially reduced post-procedural pain and bruising Simplified procedural setup without laser safety protocols Applications Varicose veins Venous ulcer treatment, when combined with compression therapy Varicose veins Key Differences Laser energy used for vein ablation Requires laser safety protocols Radiofrequency energy used for vein ablation Automated energy delivery simplifies the procedure Saphenofemoral ligation and great saphenous stripping (Option A) : An open surgical procedure with longer recovery and more post-operative pain, making it less ideal for patients wanting minimal downtime. Saphenopopliteal junction ligation and small saphenous stripping (Option B) : Another open surgery, associated with increased recovery time and discomfort post-operatively. Phlebectomy as a standalone procedure (Option D) : Involves small incisions to remove veins directly, but can cause more pain and extended recovery compared to minimally invasive options.

Bailey and Love’s Short Practice of Surgery, 28th Edition, Page 1033-1035

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 45-year-old male presents with chronic leg pain, swelling, and visible varicose veins. A duplex ultrasound is performed to assess venous function. Which of the following statements is TRUE regarding interpreting the duplex scan in this patient? (Q849452)

A. The duplex scan should be performed with the patient in a supine position

B. A reflux time of less than 500 milliseconds is clinically significant

C. Presence of perforator vein with a diameter >3.5 mm is significant

D. The duplex scan is primarily used to locate perforating veins

Correct Answer: C. Presence of perforator vein with a diameter >3.5 mm is significant

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Duplex imaging is the preferred modality for assessing venous insufficiency. A significant finding in duplex imaging is a perforator vein with a diameter greater than 3.5 mm and a reflux time of 500 milliseconds or longer, which indicates significant perforator reflux. This finding helps guide the management of varicose veins and associated symptoms. The duplex scan should NOT be performed with the patient in a supine position (Option A) to evaluate reflux. In the supine position, valves may remain open without any flow, leading to an erroneous assessment. The correct method is to perform the scan with the patient standing or in a markedly trunk-elevated position to assess valve function and reflux accurately. A reflux time of 500 milliseconds or longer (Option B) is considered clinically significant, not <500 milliseconds. This threshold helps differentiate normal venous function from pathological reflux, which can contribute to varicose vein formation and chronic venous insufficiency. The duplex scan is not primarily used to locate perforating veins (Option D) . Instead, it is used to assess venous reflux in both superficial and deep veins , identifying incompetent valves and evaluating the overall function of the venous system. While perforator veins can be visualized, the scan’s main purpose is to determine the presence and extent of reflux. Parameter Significance Position during Scan Standing or trunk-elevated (NOT supine) Reflux Time (≥ 500 ms) Indicative of significant reflux Perforator Vein Diameter (> 3.5 mm) Suggestive of significant perforator reflux Primary Use of Duplex Scan Assess venous reflux, NOT locating perforators

Sabiston Textbook of Surgery, 21st Edition, Page 1817, 1818

↑ *Back to this question in Part A*

@Neet_pg_bot

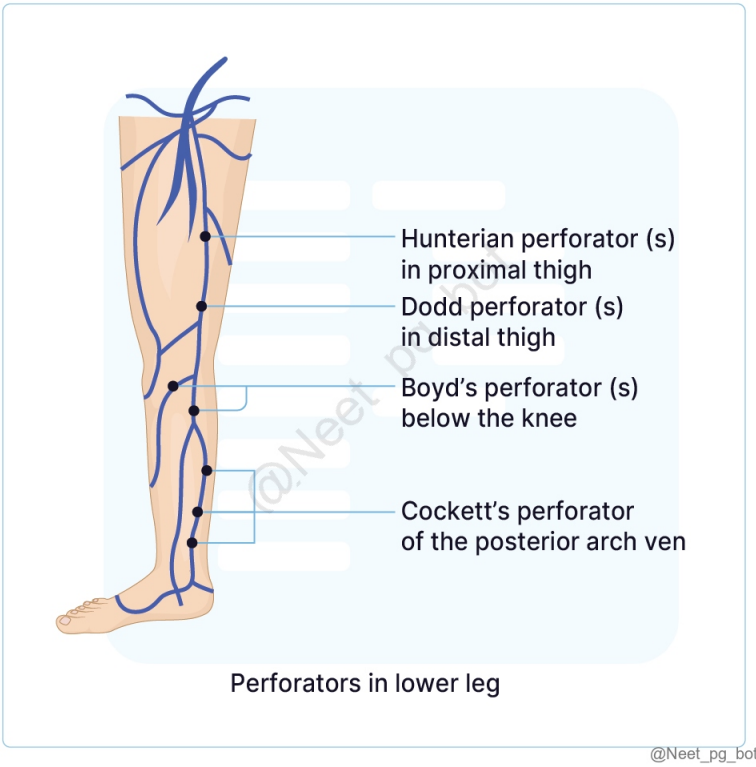
Q14: The following test was conducted in the clinic for a patient suffering from varicose veins. On releasing only tourniquet 3, the filling of blood was observed. What does this signify? (Q849451)

A. Hunterian’s perforator incompetence

B. Boyd’s perforator incompetence

C. Dodd’s perforator incompetence

D. Cockett’s perforator incompetence



Correct Answer: D. Cockett’s perforator incompetence

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The test being done here is a multiple/three-tourniquet test. On releasing tourniquet 3, the filling of blood signifies Cockett’s perforator incompetence (ankle perforators). Multiple tourniquet test: This test is done to locate the exact perforator that is incompetent. Procedure: The patient is asked to lie in the supine position, and the limb is elevated to empty the veins. Multiple tourniquets are tied just below the locations of the perforators (one below the saphenofemoral junction, one above the knee and one below the knee), and the patient is asked to stand. The tourniquets are removed one by one from below upwards, checking each segment of the leg for filling of blood. Once the tourniquet is removed and the segment drained by a perforator shows filling, it depicts the

respective perforator incompetence (Proximal thigh- Hunterian perforator, distal thigh- Dodd's perforator, below knee- Boyd's perforator, ankle perforators- Cockett's perforators).

Perforators in lower leg

@Neet_pg_bot

References:

SRB's Manual of Surgery, 6th Edition, Page 224

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A patient with varicose veins is being examined in the surgical OPD. The Brodie-Trendelenburg I test is done for the patient, and the surgeon notices that blood is filling from above. What does this signify? (Q849450)

A. Valvular incompetence

B. Perforator incompetence

C. Sapheno-femoral incompetence

D. Presence of DVT

Correct Answer: C. Sapheno-femoral incompetence

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Brodie-Trendelenburg test/ Trendelenburg I test is done to determine the patency of the saphenofemoral junction and hence shows a saphenofemoral incompetence if filling from above is seen. Procedure: Patient is asked to lie in the supine position. The leg is elevated, the vein is emptied by “milking,” and a tourniquet is tied just below the saphenofemoral junction. Patient is asked to stand up quickly. The tourniquet is released. Observation: When there is rapid filling of blood from above, this signifies sapheno-femoral incompetence. Valvular incompetence (Option A) is determined by the Schwartz test . It involves tapping the lower end of the saphenous vein and feeling the impulse at the saphenofemoral junction in a standing position. This confirms the long, continuous column of blood in the vein due to valvular incompetence. Perforator incompetence (Option B) is determined by the Trendelenburg test II, which is similar to test I in that the patient is asked to stand up after the same steps. However, here, the tourniquet is not released, and the filling of blood from below signifies perforator incompetence. Presence of DVT (Option D) is determined by Perthe’s test, in which the patient is asked to walk around or exercise with an elastic bandage wrapped around the legs. The development of severe cramp-like pain in the calf determines DVT.

SRB’s Manual of Surgery, 6th Edition, Page 223, 224.

Pratt

↑ *Back to this question in Part A*

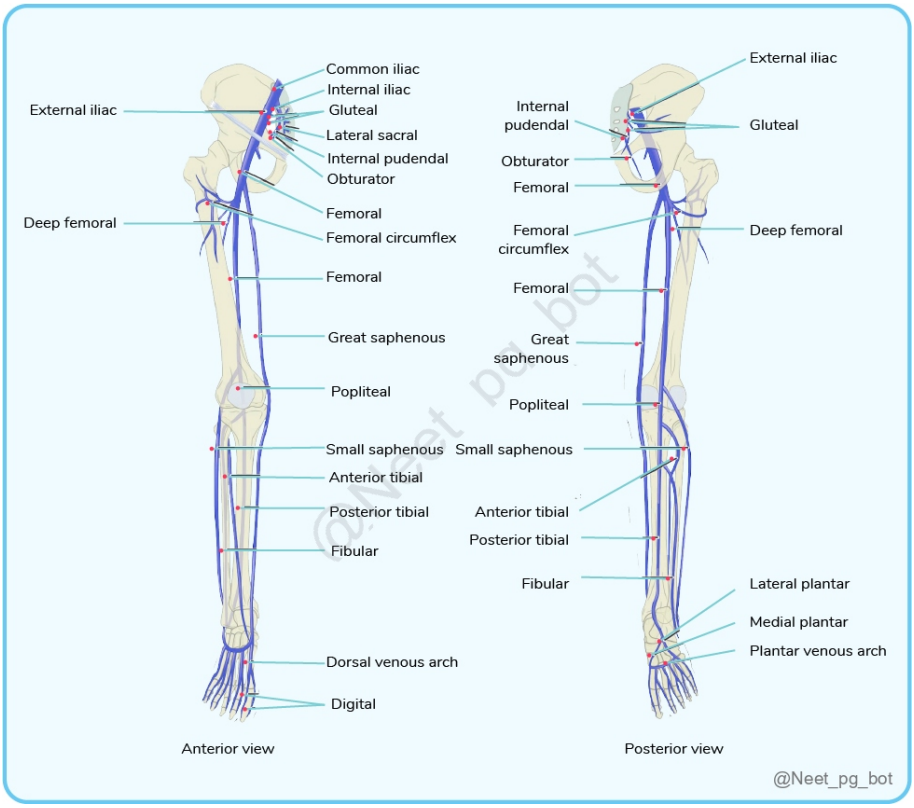
@Neet_pg_bot

Q16: A 45-year-old man presents with left leg swelling and pain for 3 days. Duplex ultrasonography reveals a thrombus in the popliteal vein. Which of the following veins is most likely to be involved next in the progression of this DVT? (Q849436)

A. Great saphenous vein

B. Common femoral vein

C. Posterior tibial vein



D. External iliac vein

Correct Answer: B. Common femoral vein

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The common femoral vein is the most likely to be involved next in the progression of this deep vein thrombosis. DVT typically propagates proximally, from the calf veins through the popliteal vein and into the femoral vein . The common femoral vein is the next major deep vein in the anatomical sequence above the popliteal vein. Most DVTs (about 90%) start in the calf veins, particularly in the soleal sinuses. From there, they can propagate proximally through the popliteal and femoral veins. Anatomy of Deep Veins in Lower Limb: Foot and ankle: Deep veins accompany the dorsalis pedis and posterior tibial arteries. Calf: Three pairs of deep veins - anterior tibial, posterior tibial (Option C) , and peroneal veins. These join to form the popliteal vein behind the knee. Thigh: The popliteal vein becomes the femoral vein as it passes through the adductor canal. The great saphenous vein (a superficial vein), and the deep femoral vein drain into the femoral vein in the femoral triangle when it becomes known as the common femoral vein. Pelvis: The common femoral vein becomes the external iliac vein (Option D) , which joins with the internal iliac vein to form the common iliac vein. Abdomen: The left and right common iliac veins join to form the inferior vena cava which goes on to the right atrium. The great saphenous vein (Option A) is a superficial vein, not part of the deep venous system. DVT primarily affects the deep veins and is less likely to involve superficial veins.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1025, 1043

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: After noticing small swellings over his legs, a 60-year-old man comes to the surgical OPD. He is a tailor by occupation and works long hours. He explains that he experiences a heaviness and aching in the legs after a long day of work but is relieved once he elevates his legs and rests. Which of the following is not a more severe sign of this disease? (Q849448)

A. Thrombophlebitis

B. Lipodermatosclerosis

C. Ulceration

D. Pedal edema

Correct Answer: D. Pedal edema

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The clinical scenario here points to the diagnosis of varicose veins . Pedal edema is commonly seen and is not a severe sign of this disease. Clinical features of varicose veins: Unsightly appearance of tortuous veins Dull aching pain in the legs Heaviness of legs Early fatigue of the legs Pedal edema (Option D) Signs: Pruritis, telangiectasis, reticular veins, varicose veins, positive cough impulse at the saphenofemoral junction. These symptoms worsen with prolonged standing and sitting and relieve on limb elevation and rest. Varicose veins: Telangiectasias and reticular veins: More severe symptoms/ complications include: Thrombophlebitis (Option A) Hyperpigmentation (due to hemosiderrin deposits) Lipodermatosclerosis (Option B) associated with eczema Ulceration (loss of epithelium) (Option C) Bleeding from attenuated vein clusters Venous neuropathy Lipodermatosclerosis, atrophic blanche and brawny edema: Hyperpigmentation and eczema:

Schwartz Principles of Surgery, 11th Edition, Page 996

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 50-year-old woman presents with visible, dilated veins on both legs. She has a history of two pregnancies and works as a retail clerk. On examination, the dilated veins are most prominent along the posterior aspect of her calves. Which of the following describes the classification of her varicose veins based on the involved venous system? (Q849446)

A. Great Saphenous Vein System

B. Small Saphenous Vein System

C. Non-saphenous veins

D. Perforator veins

Correct Answer: B. Small Saphenous Vein System

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given anatomical description is characteristic of the Small Saphenous Vein (SSV) system as it runs at the posterior aspect of the calf . The risk factors in the above scenario suggest that this is likely a case of primary varicose veins , as opposed to secondary varicose veins that underlying conditions like deep venous thrombosis or syndromes like Klippel-Trenaunay would cause. Risk factors for varicose veins: Age: Incidence increases with age Gender: M/c in females Obesity Pregnancy and multiparity Prolonged standing or sitting Family history Previous deep vein thrombosis Hormonal factors (e.g., oral contraceptives, hormone replacement therapy) Classification based on involved veins: Great Saphenous Vein (GSV) system (Option A) typically involves the medial aspect of the leg and thigh. Small Saphenous Vein (SSV) system (Option B) involves the posterior aspect of the calf. Non-saphenous veins (Option C) include the lateral venous system. Perforator veins (Option D) connect superficial and deep veins. Classification based on cause: Primary varicose veins: These occur due to intrinsic venous wall or valvular weakness without any identifiable underlying cause. Secondary varicose veins: These develop due to an underlying condition, such as: Deep venous thrombosis (post-thrombotic syndrome) Arteriovenous fistula Klippel-Trenaunay syndrome May-Thurner syndrome

↑ *Back to this question in Part A*

@Neet_pg_bot

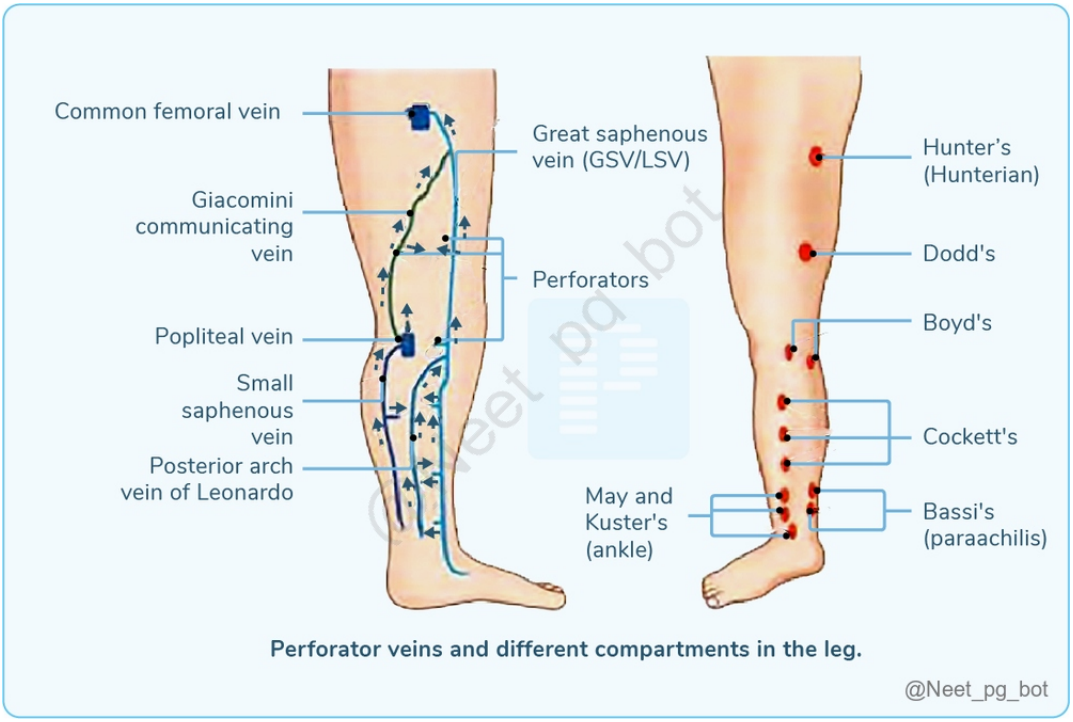
Q19: A 55-year-old woman presents with varicose veins in her left leg. On examination, you notice dilated, tortuous veins along the posterior aspect of her calf

and lateral thigh. To accurately map the incompetent veins for potential treatment, which of the following describes the most likely location of the Boyd perforator vein? (Q849445)

A. Medial ankle, posterior to the medial malleolus

B. Medial calf, approximately 10 cm above the medial malleolus

C. Lateral calf, at the junction of the middle and lower thirds



D. Medial knee, approximately 10 cm below the knee joint line

Correct Answer: D. Medial knee, approximately 10 cm below the knee joint line

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Boyd perforator vein , also known as the upper paratibial perforator , is typically located on the medial aspect of the leg, approximately 10 cm below the knee joint line. This perforator connects the great saphenous vein or its tributaries to the deep veins of the leg, specifically the posterior tibial veins. Superficial veins: Great Saphenous Vein (GSV): Originates from the medial marginal vein of the foot, ascends along the medial aspect of the leg and thigh, and drains into the common femoral vein at the saphenofemoral junction. Small Saphenous Vein (SSV): Begins at the lateral aspect of the foot, ascends posteriorly along the calf, and typically drains into the popliteal vein at the saphenopopliteal junction which then becomes the femoral vein. Perforator veins: Perforators connect the superficial and deep venous systems, allowing blood to flow from superficial to deep veins. Key perforators include: Ankle perforators: Cockett perforators (posterior tibial perforators): Three perforators located along the medial ankle and distal calf. May and Kusters perforators Calf perforators: Boyd perforator: Located approximately 10 cm below the knee joint on the medial aspect of the leg, connects the great saphenous and superficial femoral veins. Sherman perforator: Located in the mid-calf region. Thigh perforators: Dodd perforator: Located in the middle third of the medial thigh. Hunterian perforator: Located in the upper thigh, connecting the GSV to the femoral vein. Lateral perforators: Lateral calf perforators: Less clinically significant, connecting the lateral venous system to deep veins. The medial ankle, posterior to the medial malleolus, describes the Cockett perforators (Option A) , a group of three perforators located in the distal third of the leg. The medial calf, approximately 10 cm above the medial malleolus, is more consistent with the position of the middle Cockett perforator (Option B) , not the Boyd perforator. The lateral calf, at the junction of the middle and lower thirds location (Option C), does not correspond to any major named perforator vein. The lateral aspect of the calf contains smaller, less clinically significant perforators.

Perforator veins and different compartments in the leg.

Sabiston Textbook of Surgery, 21st Edition, Page 1814

www.researchgate.net/figure/Location-of-the-perforating-veins-on-the-front-and-inner-sides-of-the-calf-Blue_fig15_278656090#:~:text=The%20medial%20ankle%20perforating%20veins,the%20great%20saphenous%20vein%20territory.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A 55-year-old woman presents with recurrent episodes of tender, erythematous cord-like swellings along different superficial veins of her lower extremities over the past 3 months. Which of the following is most likely to be associated with this presentation? (Q849444)

A. Recent childbirth

B. Thromboangiitis obliterans

C. Pancreatic malignancy

D. Polycythemia vera

Correct Answer: C. Pancreatic malignancy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient presents with symptoms of recurrent superficial thrombophlebitis, possibly migratory (thrombophlebitis migrans) . The recurrent nature and lack of obvious predisposing factors raise concern for an underlying systemic condition, particularly malignancy. Trousseau identified the association of migratory thrombophlebitis and malignant disease, involving the tail of the pancreas. This association, known as Trousseau's syndrome , is a classic presentation of occult pancreatic malignancy. While recent childbirth (Option A) is a risk factor for thrombophlebitis, it's not relevant in this case, given the patient's age and the recurrent nature of the symptoms over three months. Thromboangiitis obliterans (Buerger's disease) (Option B) typically affects young male smokers and involves both arteries and veins. It's less likely in this scenario compared to malignancy. Polycythemia vera (Option D) can be associated with thrombophlebitis, but the recurrent and migratory nature of the symptoms in this case is more suggestive of malignancy, particularly pancreatic cancer.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1046

STP

↑ *Back to this question in Part A*

@Neet_pg_bot

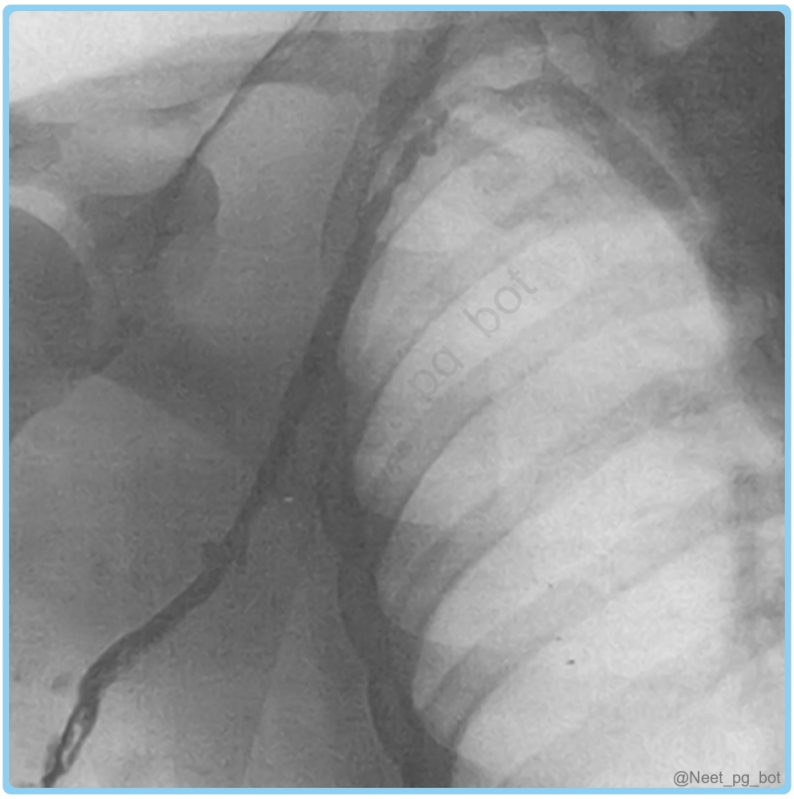
Q21: A 20-year-old competitive swimmer presents with a 2-day history of left arm pain, swelling, and mild discoloration after intense training. Duplex ultrasound shows a thrombus in the left subclavian vein. What is the most likely diagnosis? (Q849443)

A. Thoracic outlet syndrome

B. Paget-Schrotter syndrome

C. Raynaud's phenomenon

D. Lymphedema



Correct Answer: B. Paget-Schrotter syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient is experiencing Paget-Schrotter syndrome, which is an effort induced thrombosis due to subclavian vein compression. Often seen in young athletes with repetitive upper extremity motion (e.g., swimming). Thoracic outlet syndrome (Option A) can lead to Paget-Schrotter syndrome but is incorrect because the ultrasound confirmed the presence of a thrombus. Raynaud's phenomenon (Option C) causes episodic color

changes in the fingers or toes in response to cold or stress, not with a thrombus in the subclavian vein. Lymphedema (Option D) results from impaired lymphatic drainage and usually develops gradually. It is less likely to occur suddenly after exercise.

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1047 Sabiston’s Textbook of Surgery, 21st Edition, Page 1830

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: A 30-year-old woman is in the post-operative ward after a cesarean section. She had no complications and gave birth to a healthy baby. Which of the following is a prophylactic step she needs to be advised to prevent deep vein thrombosis? (Q849442)

A. Early mobilization along with compression stockings

B. Low molecular weight heparin

C. Low-dose unfractionated heparin

D. Fondaparinux

Correct Answer: A. Early mobilization along with compression stockings

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The case scenario here is of an abdominopelvic surgery that needs early mobilization with compression stockings as a prophylaxis for preventing DVT. In the above scenario, the risk factor for DVT is pregnancy and immediate postpartum, along with having undergone an abdominopelvic surgery which only needs mechanical methods of prophylaxis rather than pharmacological. Risk groups for deep vein thrombosis: Older age groups (>40 yrs) Hospitalized and immobilized patients Pregnancy and the recently postpartum state Those on hormonal replacement therapy Women on oral contraceptive pills Major surgery Long haul travellers (>6hrs) With conditions like: Past venous thromboembolism Malignancies Nephrotic syndrome Varicose veins Antiphospholipid syndrome Myeloproliferative disorders Polycythemia Obesity Level of risk Suggested thromboprophylaxis options Very low-risk General or abdominopelvic surgery No specific thromboprophylaxis Early ambulation along with compression stockings (Option A) Low risk General or abdominopelvic surgery Mechanical prophylaxis Early ambulation and mechanical device (compression stockings) Moderate risk General or abdominopelvic surgery LMWH (at recommended doses) (Option B) LDUH (Option C) or mechanical prophylaxis High bleeding risk Mechanical prophylaxis Early ambulation and mechanical device(compression stockings High risk General or abdominopelvic surgery LMWH (at recommended doses), fondaparinux (Option D) , and mechanical prophylaxis High bleeding risk General or abdominopelvic surgery for cancer Mechanical thromboprophylaxis Extended-duration LMWH (4 weeks)

References:

Sabiston's Textbook of Surgery, 21st Edition, Page 1829 Schwartz Principles of surgery, 11th Edition, Page 984, 985

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A patient came with complaints of discoloration of his left leg as shown in the image. He has a history of deep vein thrombosis and has been inconsistent on medication. What is the possible diagnosis here? (Q849441)

A. Venous gangrene

B. Venous ulcer

C. Atrophic blanche

D. Post-thrombotic leg

Correct Answer: D. Post-thrombotic leg

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The scenario here points to a post-thrombotic leg due to the history of previous DVT and non-compliance to oral anticoagulants Post-thrombotic syndrome: Post-thrombotic syndrome (PTS), also called postphlebitic syndrome and venous stress disorder is a medical condition that may occur as a long-term complication of deep vein thrombosis (DVT). Chronic venous insufficiency patients may have superficial vein incompetence with or without perforator incompetence or having previous DVT with complete obliteration or partial recanalisation with incompetence. Develop in 20% to 50% of patients after DVT. Symptoms: Leg pain Sensation of leg heaviness, pulling or fatigue Limb swelling Signs: Leg edema Redness Dusky cyanosis Perimalleolar or more extensive telangiectasia New varicose vein Stasis hyperpigmentation Lipodermatosclerosis Leg ulcer Venous gangrene (Option A): Presents with blackish discoloration, blebs and edema. Venous ulcer (Option B): Long saphenous vein perforator incompetence is often associated with venous ulcers, typically on the medial aspect of the ankle, and is often seen in long-standing varicose veins. Atrophic blanche (Option C): It is localized white atrophic skin surrounded by hyperpigmentation and dilated capillaries associated with varicose veins.

↑ *Back to this question in Part A*

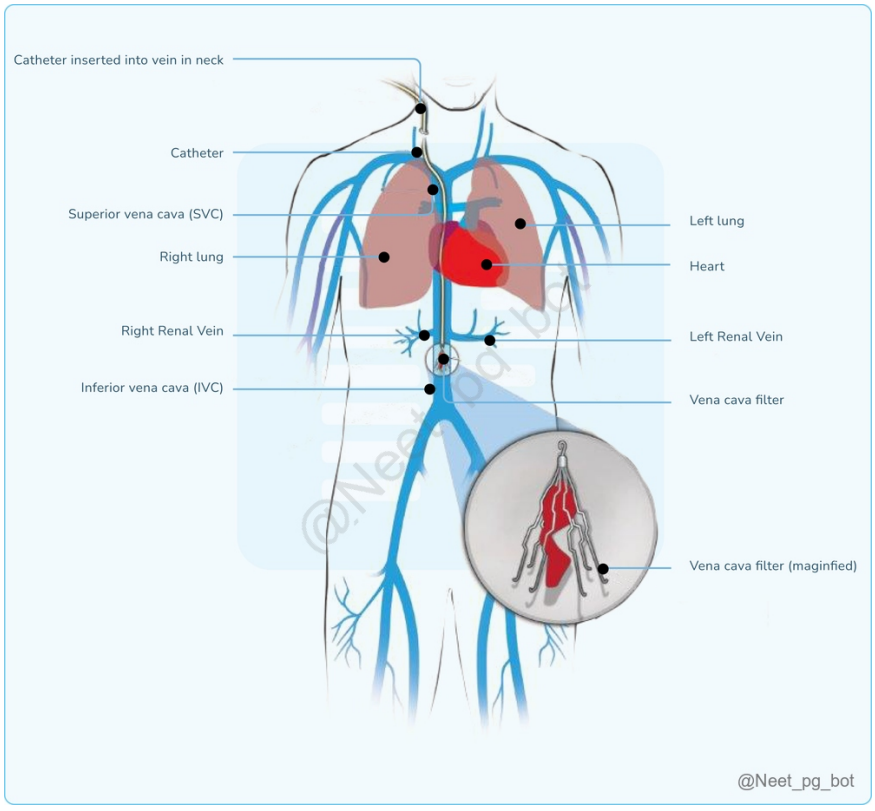
@Neet_pg_bot

Q24: A 45-year-old man with metastatic colorectal cancer is diagnosed with an acute DVT of the left leg. He had an episode of upper GI bleed 2 days ago. His lab results show a platelet count of 40,000/μL and an INR of 1.8. Which of the following is the most appropriate management strategy for preventing pulmonary embolism in this patient? (Q849440)

A. Start anticoagulation with LMWH

B. Place a permanent IVC filter

C. Place a retrievable IVC filter



D. Start anticoagulation with UFH

Correct Answer: C. Place a retrievable IVC filter

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In this case, the patient has an acute DVT with a high risk of progression to pulmonary embolism. However, he also has significant contraindications to anticoagulation: Thrombocytopenia (platelet count 40,000/µL) and Coagulopathy (INR 1.8). These factors make anticoagulation extremely high-risk. In such scenarios, where there is an acute proximal DVT and a contraindication to anticoagulation, placement of an IVC filter is indicated . The choice of a retrievable filter allows for potential removal once the contraindications to anticoagulation resolve. Reassessment in 3 months is appropriate to evaluate if the filter can be safely removed and anticoagulation initiated. Start anticoagulation with LMWH (Option A) is incorrect due to the high bleeding risk associated with the patient's active GI bleeding, thrombocytopenia, and coagulopathy. Place a permanent IVC filter (Option B): While an IVC filter is indicated, a permanent filter is not the best choice. Retrievable filters are preferred when possible, as they allow for removal once anticoagulation becomes feasible, reducing long-term complications associated with permanent filters. Start anticoagulation with UFH (Option D): Even anticoagulation with unfractionated heparin carries a significant risk of exacerbating the patient's bleeding complications.

Sabiston Textbook of Surgery, 21st Edition, Page 1830, 1831

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: A 45-year-old man with a history of colorectal cancer underwent surgery 3 weeks ago and is now presenting with complaints of left leg swelling and pain for 3 days. His left calf is 4 cm larger than the right. Using Wells' criteria for DVT, what is his pre-test probability score and risk category? (Q849438)

A. 2 points; Moderate risk

B. 5 points; High risk

C. 3 points; Moderate risk

D. 4 points; High risk

Correct Answer: D. 4 points; High risk

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Wells' criteria for Deep Vein Thrombosis is a clinical prediction rule used to estimate the pretest probability for DVT. It helps clinicians determine the need for further diagnostic testing. The patient scores 4 points (Option C) on the Wells' criteria, placing them in the high-risk category. Malignancy (Including treatment done within past 6 month) (1 point) Recently bedridden for >3 days or major surgery within last 4 weeks (1 point) Calf swelling > 3 cm compared to the other leg (1 point) Entire leg swollen (1 point) This scoring system, when combined with D-dimer testing, helps in the diagnostic algorithm for DVT, potentially reducing unnecessary imaging studies in low-risk patients. Well’s criteria for detecting DVT: Variable Score Active cancer (patient either receiving treatment for cancer within the previous 6 months or currently receiving palliative treatment) 1 Paralysis, paresis, or recent cast immobilization of the lower extremities 1 Recently bedridden for ≥ 3 days, or major surgery within the previous 12 weeks requiring general or regional anesthesia 1 Localized tenderness along the distribution of the deep venous system 1 Entire leg swelling 1 Calf swelling at least 3 cm larger than that on the asymptomatic side (measured 10 cm below tibial tuberosity) 1 Pitting edema confined to the symptomatic leg 1 Collateral superficial veins (non-varicose) 1 Previously documented deep vein thrombosis 1 Alternative diagnosis more likely than DVT -2 Low probability (5%) of DVT: score –2 to 0 Moderate probability (17%) of DVT: score 1 or 2 High probability (17–53%) of DVT: score >2

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1044, 1045

↑ *Back to this question in Part A*

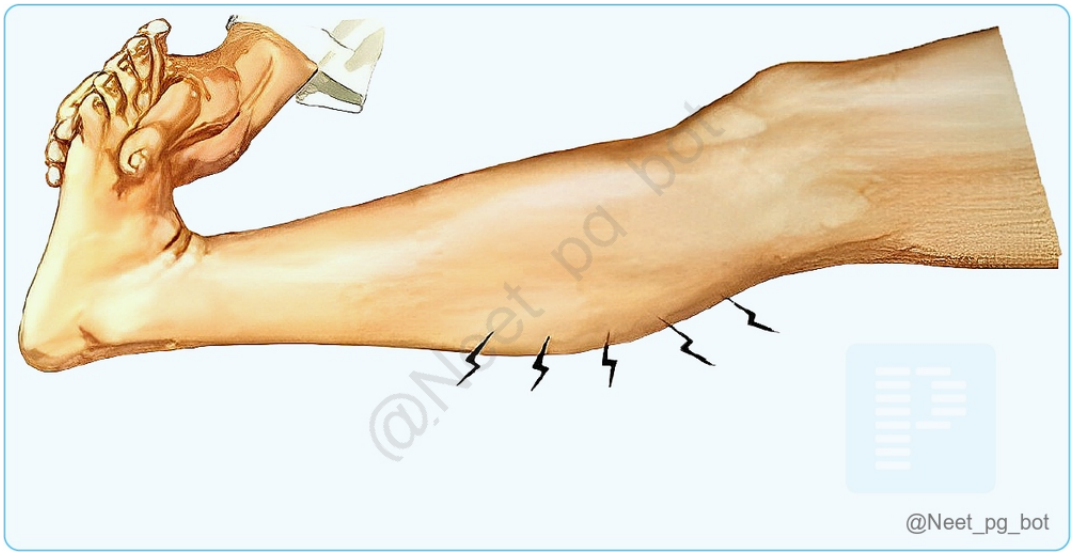
@Neet_pg_bot

Q26: A 52-year-old male presents with a swollen, painful left calf that developed over the past two days. He reports no history of trauma, surgery, or prolonged immobility. Physical examination reveals a warm, erythematous, and tender left calf. Which of the following clinical features is most specific for diagnosing deep vein thrombosis? (Q849437)

A. Calf pain on dorsiflexion of the foot

B. Asymmetrical calf swelling

C. Pain that worsens with leg elevation



D. Localized tenderness along the course of the deep veins

Correct Answer: D. Localized tenderness along the course of the deep veins

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Localized tenderness along the course of the deep veins is one of the most specific clinical signs of DVT. This symptom occurs due to a thrombus within the deep veins, which triggers pain when pressure is applied along the affected vein. Clinical Feature Significance 1. Localized tenderness Specific for DVT; indicates inflammation along the vein. 2. Asymmetrical calf swelling Common but not specific to DVT. 3. Erythema and warmth Suggestive of inflammation or thrombosis. 4. Pain in the affected limb Can occur with or without movement; can indicate venous obstruction. 5. Dilated superficial veins May indicate compensatory circulation due to deep venous obstruction. 6. Homans' sign Non-specific; Passive forceful dorsiflexion of the foot with extended knee will cause tenderness in the calf. 7. Mose’s sign Painful response to gentle squeezing of the lower calf from side-to-side. 8. Neuhof's Sign Thickening and deep tenderness in the calf muscles upon palpation. 9. Phlegmasia Alba Dolens DVT of the femoral vein causes painful congestion and edema of the leg with lymphangitis, which further increases edema (white leg). 10. Phlegmasia Caerulea Dolens Extensive DVT in iliac and pelvic veins leading to a blue leg with possible venous gangrene or infarction. Pratt's sign : Applying pressure to the calf muscle; if it feels tense and causes pain, it may indicate acute deep vein thrombosis (DVT). Calf pain on dorsiflexion of the foot (Option A): Homans' sign is the pain or Resistance of the calf muscles to forcible dorsiflexion of the foot. It has been traditionally associated with DVT but is not specific and should not be routinely elicited due to its lack of reliability. Asymmetrical calf swelling (Option B) is a common feature of DVT but is not specific. It can be present in other conditions, such as lymphedema or muscular injuries. Pain that worsens with leg elevation (Option C) is more indicative of arterial insufficiency . In DVT, the pain may worsen with dependency due to increased venous pressure.

Q1: A 40-year-old female presents with persistent swelling in her lower legs. Upon physical examination, the swelling is noted to be non-pitting, and the patient has no signs of irreversible skin changes. What is the most appropriate Brunner's classification grade for her condition? (Q849351)

A. Subclinical/latent

B. Grade I

C. Grade II

D. Grade III

Correct Answer: C. Grade II

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient with non-pitting edema with no signs of irreversible skin changes belongs to Grade II of the Brunner’s classification. Brunner’s clinical classification of lymphedema: Grades Clinical Features Subclinical/Latent Excess interstitial fluid. Histological abnormality in lymphatics & lymph nodes. No clinically apparent lymphedema. I Pitting edema. II Non-pitting edema. III Edema with irreversible skin changes.

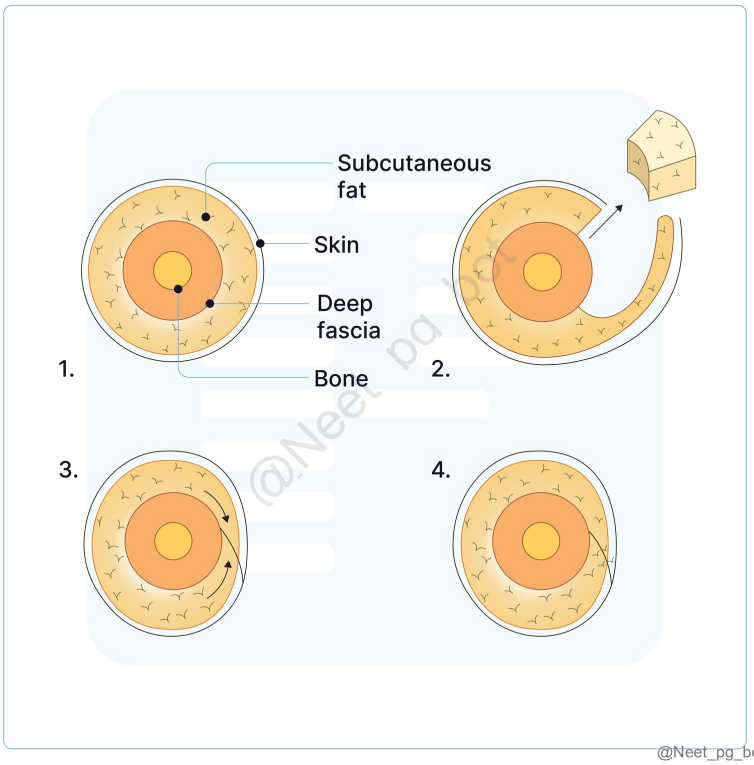
@Neet_pg_bot

Q2: A 60-year-old female with severe lymphedema of the lower limb, not responding to conservative therapies. Due to persistent swelling and functional impairment, she



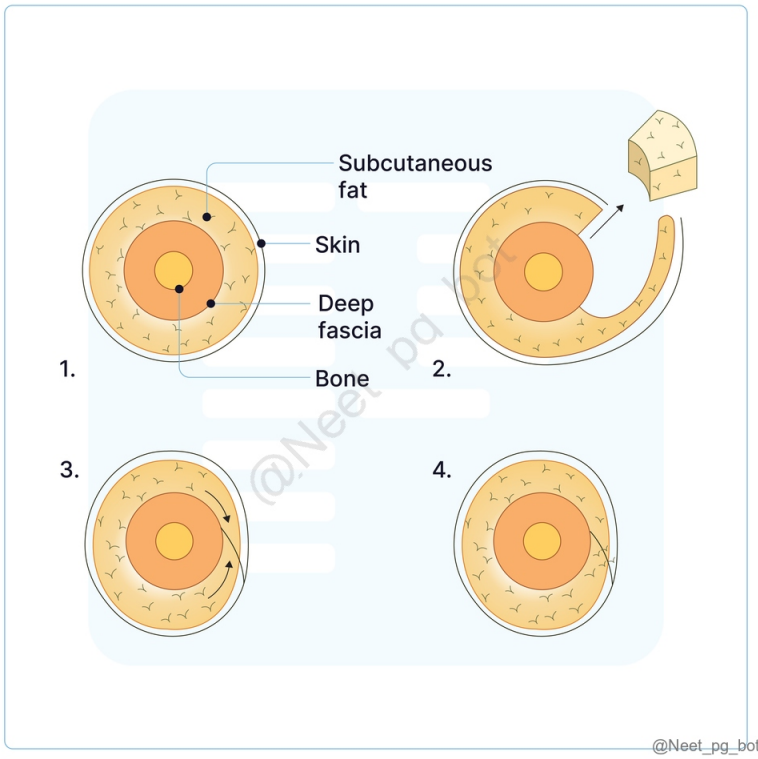
undergoes surgical intervention. An image of the surgical procedure is shown below. What is the procedure known as? (Q849354)

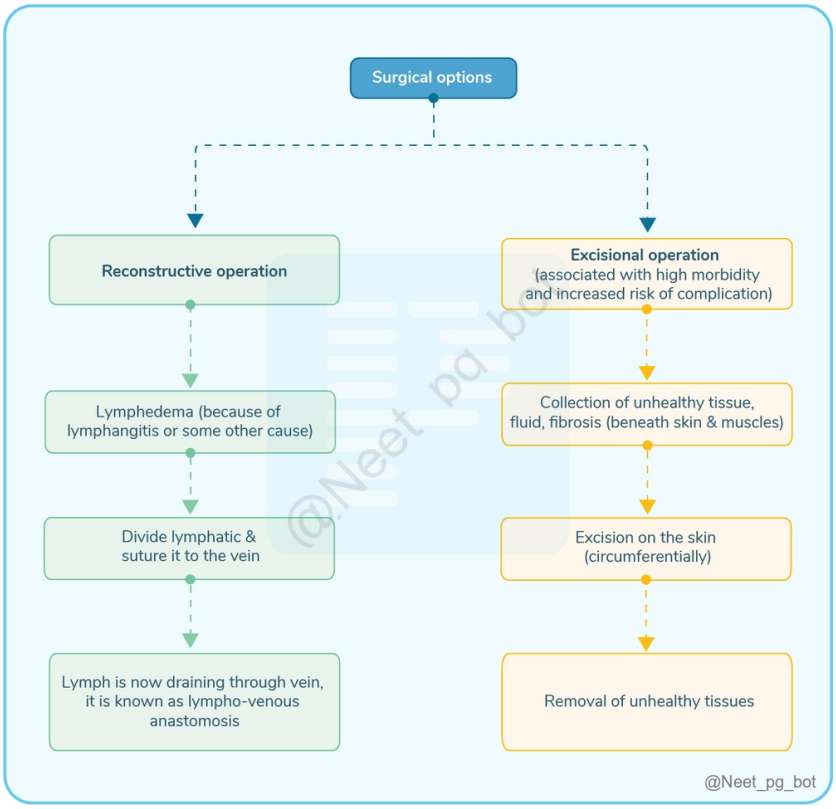
A. Thompson Procedure

B. Charles Procedure

C. Nielubowicz Operation

D. Kinmonth procedure





Correct Answer: A. Thompson Procedure

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Thompson procedure is a type of excisional operative procedure that involves removing unhealthy tissues. Lymphedematous tissue is removed beneath the skin flaps. The epidermis and part of the dermis from one of these skin flaps are carefully shaved off with a Humby's knife. This shaved tissue is placed under the opposite flap, positioned deep beneath the deep fascia, similar to a Swiss roll. Charles Procedure Radical excision of all skin + subcutaneous tissue → STSG Used only in end-stage elephantiasis Much more destructive than Thompson Nielubowicz Operation Lymphatic–venous anastomosis A microvascular bypass procedure No large flap or excision 4. Kinmonth Procedure Lymph node transplantation (e.g., inguinal → axilla) No flap tunneling

SRB's Manual of Surgery, 6th edition, Pages 246, 247, 248

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A patient with breast carcinoma after 11 years of Modified radical mastectomy and radiotherapy, now presents with pain, skin nodules and worsening of swelling of left arm as shown in the image below. What is the most probable diagnosis? (Q849356)

A. Lymphangiosarcoma

B. Venous thrombosis

C. Cellulitis

D. Lymphedema

Correct Answer: A. Lymphangiosarcoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Lymphangiosarcoma is seen in chronic long-standing lymphedema following mastectomy (more than 10 years). They present as single/multiple bluish-red skin and subcutaneous nodules. They can ulcerate and bleed. Treatment: Neoadjuvant chemoradiation followed by surgical excision with or without amputation.

References:

Sabiston Textbook of Surgery, 21st edition, Pages 746, 832

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A patient with chronic lymphedema is being evaluated for surgical management. Which of the following is not a reduction procedure for lymphedema? (Q889676)

A. Liposuction

B. Charles' procedure

C. Homans' procedure

D. Lymphatic–venous shunt

Correct Answer: D. Lymphatic–venous shunt

Explanation: Lymphatic–venous shunt is a physiologic/reconstructive procedure , not a reduction procedure. Reduction procedures (remove excess tissue): Liposuction (Option A) : Suction-assisted removal of adipose tissue; minimally invasive. Charles' procedure (Option B) : Radical excision of skin/subcutaneous tissue down to deep fascia; covered with skin grafts. Homans' procedure (Option C) : Elevation of skin flaps to excise subcutaneous tissue, followed by primary closure.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 35-year-old man presents to the emergency department with a rapidly spreading reddish streak on his left arm, accompanied by fever and swollen axillary lymph nodes. He reports sustaining a small cut on his hand two days ago while gardening. Physical examination reveals a tender, warm, erythematous streak extending from the hand to the upper arm, with blanching on pressure. What is the next best step in the management of this patient? (Q849348)

A. Immediate surgical incision and drainage of the affected area

B. Oral antihistamines and topical corticosteroids

C. Limb elevation and initiation of intravenous antibiotics like penicillin or cloxacillin

D. Watchful waiting for 48 hours before initiating any treatment

Correct Answer: C. Limb elevation and initiation of intravenous antibiotics like penicillin or cloxacillin

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The rapidly spreading reddish streak on the arm, accompanied by fever and swollen regional (axillary) lymph nodes, are classic signs of acute lymphangitis. The recent history of a small cut while gardening provides a likely entry point for the causative organisms. The treatment primarily involves administration of broad-spectrum antibiotics (e.g. penicillin, cloxacillin) & elevation and rest of affected limb. Acute Lymphangitis Definition Acute nonsuppurative infection and spreading inflammation of lymphatics of skin and subcutaneous tissues Causative Organisms • Beta-hemolytic streptococci • Staphylococci • Clostridial organisms (less common) Risk Factors • Small trauma or skin break • In endemic areas: Wuchereria bancrofti (transmitted by Culex mosquito) Clinical Features • Streaky redness which is spreading (typical) • Pain • Fever • Palpable tender regional lymph nodes • Blanching on pressure • Fever, tachycardia (features of toxemia) Complications • Abscess formation • Toxaemia, septicemia • Chronic lymphangitis leading to acquired lymphoedema Investigations • Complete blood count • Renal and liver function tests • Blood culture Management • Broad-spectrum antibiotics (e.g. penicillin, cloxacillin) • Elevation and rest of affected limb • Glycerine magnesium sulphate dressing • Management of toxemia or septicemia if present {{caption_text}}

References:

SRB’s Manual of Surgery, 6th Edition, Pages 37, 38

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A patient with chronic lymphedema is advised decongestive lymphatic therapy (DLT). Which of the following is not a component of decongestive lymphatic therapy? (Q889675)

A. Manual lymphatic drainage

B. Compression therapy

C. Regular diuretic therapy

D. Limb elevation

Correct Answer: C. Regular diuretic therapy

Explanation: Decongestive Lymphatic Therapy (DLT) improves lymphatic drainage and promotes collateral pathways. Diuretics are not part of DLT because they offer no long-term benefit in lymphedema and should be avoided. Components: Limb elevation (Option D) Manual lymphatic drainage (MLD) (Option A) : Proximal massage to direct lymph flow Compression therapy (Option B) : Multilayer bandaging/garments, intermittent pneumatic compression. Exercise Skin care Genital edema: scrotal support if needed

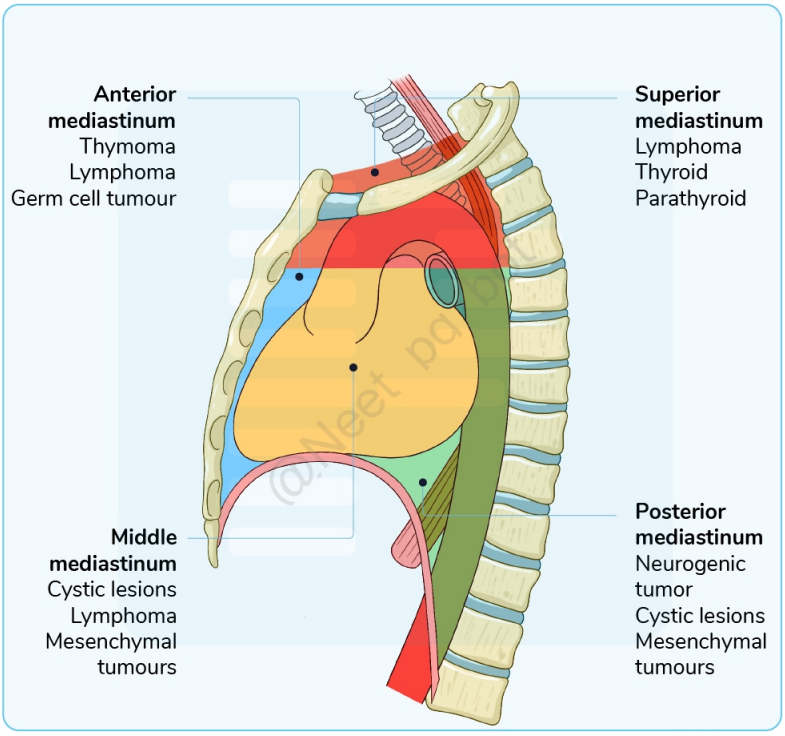
@Neet_pg_bot

Q7: What is the most common site of mediastinal lymphoma? (Q889673)

A. Anterior mediastinum



B. Middle mediastinum

C. Posterior mediastinum

D. Superior mediastinum

Correct Answer: A. Anterior mediastinum

Explanation: The anterior mediastinum is the most common site for several major "T" masses, including: Thymoma Teratoma Thyroid (retrosternal goitre) Terrible Lymphoma.

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 992

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 60-year-old woman has had chronic lower-limb lymphedema for 15 years following cancer surgery. She presents for routine follow-up. Which of the following is not a complication of chronic lymphedema? (Q889672)

A. Recurrent cellulitis

B. Stewart-Treves Syndrome

C. Fibrosis

D. Venous ulcer

Correct Answer: D. Venous ulcer

Explanation: Venous ulcers are primarily a complication of venous insufficiency , not lymphedema. Complications of Lymphedema: Recurrent Cellulitis/Erysipelas (Option A) : Protein-rich fluid acts as a medium for bacterial growth, leading to frequent skin infections. Lymphangitis: Repeated inflammation further destroys remaining lymphatic channels. Dermatophytosis: Fungal infections like tinea pedis occur due to impaired local immunity. Progressive Fibrosis (Option C) : Chronic inflammation causes tissue to harden and become non-pitting. Skin Remodelling: Results in hyperkeratosis, acanthosis (thickening), and wart-like papillomatosis. Lymphostatic Elephantiasis: The terminal stage involving extreme limb deformity and deep skin folds. Stewart-Treves Syndrome (Option B) : A rare, highly lethal angiosarcoma arising in long-standing lymphedema (typically >10 years).

@Neet_pg_bot

Q9: Direct contrast lymphangiography is planned in a patient with a suspected lymphatic abnormality. Which of the following statements regarding this procedure is true? (Q889670)

A. It is a noninvasive imaging technique requiring no anaesthesia

B. Contrast is injected rapidly into a peripheral vein

C. Cannulation is usually performed on lymphatic vessels at the dorsum of the foot

D. It is commonly used as a routine diagnostic test for lymphedema

Correct Answer: C. Cannulation is usually performed on lymphatic vessels at the dorsum of the foot

Explanation: Direct contrast lymphangiography is an invasive procedure that provides the finest anatomical detail of the lymphatic system. Superficial lymphatic vessels on the dorsum of the foot are cannulated- slow injection of oil-based contrast (ethiodized oil). Complications: Lymphatic vessel damage & allergic reactions Pulmonary embolism (if contrast enters the venous system via lymphovenous anastomoses)

References:

Sabiston Textbook of Surgery, 21st Edition, Page 1837

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A newborn is noted to have bilateral, non-pitting swelling of the feet and lower legs present since birth, as shown in the image. Examination shows thickened skin and prominent veins over the dorsum of the feet. The child's father has similar leg swelling. There is no history of surgery, infection, or trauma. Which of the following statements regarding this condition is true? (Q889667)

A. It is most commonly caused by filarial infection

B. It is inherited in an autosomal recessive pattern

C. It is associated with mutations in the FLT4 (VEGFR-3) gene

D. The lymphedema typically resolves spontaneously with age

Correct Answer: C. It is associated with mutations in the FLT4 (VEGFR-3) gene

Explanation: The scenario describes Milroy's disease. A genetic primary lymphedema presenting with congenital or early-onset lower-limb swelling due to impaired lymphatic drainage. Swelling: Present at birth or soon after, usually bilateral lower-limb lymphedema (often feet), may be asymmetric. Gene: Pathogenic variants in FLT4 (VEGFR-3) , affecting lymphatic vessel development. Autosomal dominant (Option B) with variable expression and reduced penetrance. Other signs: Prominent veins below knees, upslanting toenails, hydrocele in males, papillomatosis. Filarial infection (Option A) : This is the most common cause of secondary lymphedema worldwide, but it is an acquired parasitic infection, not a congenital genetic condition present from birth. Spontaneous resolution (Option D): Lymphedema is a progressive and usually irreversible condition. Without management, it typically worsens through stages of fibrosis rather than resolving.

@Neet_pg_bot

Q11: A 52-year-old woman with a history of pelvic surgery and radiotherapy presents with long-standing swelling of the left leg.The clinical appearance is shown. Which grade of lymphedema does this most likely represent? (Q889664)

A. Grade 0

B. Grade I

C. Grade II

D. Grade III

Correct Answer: D. Grade III

Explanation: The patient's presentation of a grossly enlarged limb with hyperkeratosis , thickened skin , and deep skin folds matches the advanced tissue injury and fibrosis characteristic of the third stage. Grading of Lymphedema: Stage Key Features 0 Lymphatic fibrosis occurs, but there is no clinical evidence of edema. I Protein-rich fluid accumulation results in soft pitting edema. II Local inflammation and deposition of connective and adipose tissue result in non-pitting, spongy edema that does not reduce with elevation. III Recurrent infections and severe subcutaneous fibrosis lead to irreversible edema and skin changes of lymphostatic elephantiasis.

@Neet_pg_bot

Q12: Identify the given condition and choose among the following: {{caption_text}} (Q849357)

A. Stewart - Treves syndrome

B. Lymphedema

C. Cystic hygroma

D. Marjolin’s ulcer

Correct Answer: A. Stewart - Treves syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This image shows lymphedema with bluish-red skin with subcutaneous nodules which suggests a diagnosis of Stewart - Treves syndrome. It occurs in a patient with breast carcinoma after about 10 years of MRM and radiotherapy, if the patient has severe lymphedema and is left untreated. Clinically presented as bluish-red skin with subcutaneous nodules that ulcerate and bleed (Option A) .

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 4-month-old baby is brought to the hospital with complaints of swelling in the neck as given in the image and diagnosed as cystic hygroma. Which of the following is

true regarding the condition? {{caption_text}} (Q849355)

A. Swelling presents after the age of 1 year

B. It is a benign tumor

C. Laser excision is the treatment of choice

D. The size remains constant throughout the life

Correct Answer: B. It is a benign tumor

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Cystic hygroma is a type of cavernous lymphangioma. Lymphangioma is the lymphatic analog of hemangioma of blood vessels. They are congenital benign tumors of the lymphatic system (Option A) . They are isolated cystic masses of lymphatic tissue that can produce lymph. Over time the tumor enlarges due to the accumulation of lymph within the cyst (Option D) . Treatment includes surgical excision of the tumor (Option C) .

Sabiston Textbook of Surgery, 21st edition, Pages 746,747

↑ *Back to this question in Part A*

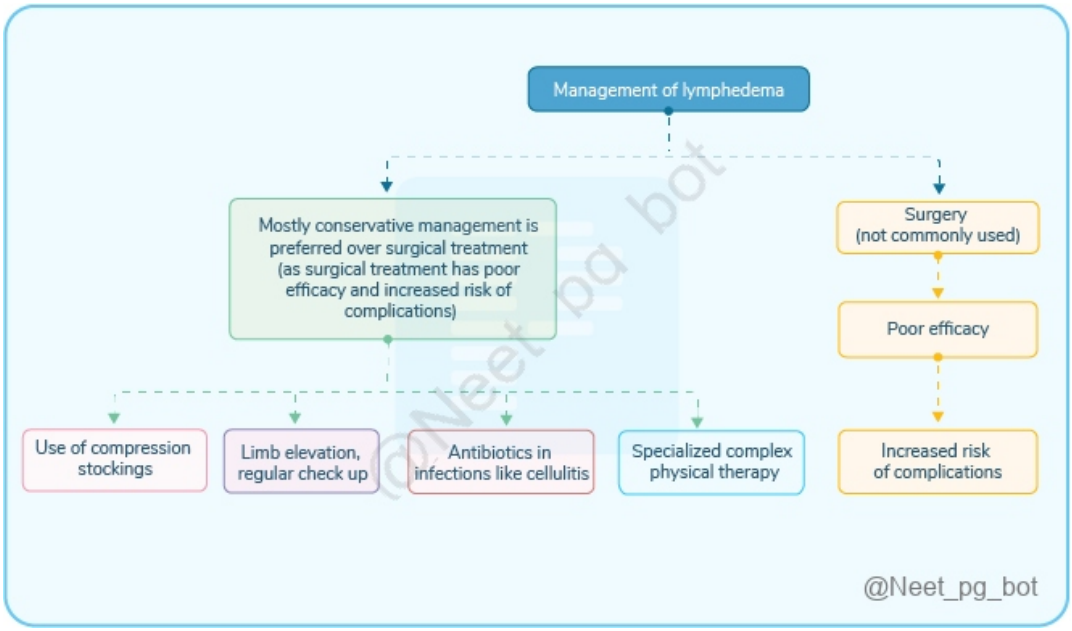
@Neet_pg_bot

Q14: Which of the following is the least preferred treatment option for early management of lymphedema? (Q849353)

A. Use of compression stockings

B. Limb elevation, regular check-up

C. Specialized complex physical therapy



D. Nielubowicz procedure

Correct Answer: D. Nielubowicz procedure

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Conservative management is the most commonly preferred treatment for lymphedema. (Option A, B & C) Surgical procedures (eg. Nielubowicz procedure) are only done in severe chronic lymphedema due to poor efficacy and complications (Option D) .

References:

www.cancer.gov/about-cancer/treatment/side-effects/lymphedema#how-is-lymphedema-treated

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 55-year-old male with chronic leg swelling presents with difficulty pinching the skin over the dorsum of his foot. What is this sign known as? {{caption_text}} (Q849352)

A. Buffalo hump

B. Square toes

C. Stemmer's sign

D. Merkel's sign

Correct Answer: C. Stemmer's sign

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The sign of inability to pinch a fold of skin at the root of the second toe suggesting lymphedema is known as Stemmer’s sign. Clinical features of Lymphedema: Buffalo hump: Refers to a fat pad that develops on the dorsum of foot, often associated with conditions like Cushing’s syndrome or prolonged use of corticosteroids. It is not related to skin pinching or lymphedema (Option A) . {{caption_text}} Square toes : The toes appear square-shaped due to prolonged confinement in tight footwear (Option B) . {{caption_text}} Stemmer's sign : Skin over the dorsum of the foot cannot be pinched because of subcutaneous fibrosis (Option C) . {{caption_text}}

@Neet_pg_bot

Q16: A 25-year-old female presents with swelling in her right calf and foot, which has gradually worsened over the past few years. She reports that the swelling started in her teenage years and has become more pronounced with time. What is the diagnosis in this patient? (Q849350)

A. Congenital lymphedema

B. Lymphedema praecox

C. Lymphedema tarda

D. None of the above

Correct Answer: B. Lymphedema praecox

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The above clinical scenario is a case of Lymphedema praecox , a type of primary lymphedema. Types of primary lymphedema: Congenital Lymphedema (Option A) Lymphedema Praecox (Option B) Lymphedema Tarda (Option C) Age: Seen in < 1 year of age Present at birth. Lower limb, genitalia, and face are involved. Usually B/L and multiple limbs are involved. Familial version of congenital lymphedema – known as Milroy's disease. M/C type of primary lymphedema (>90% of cases). Age: 1 to 35 years . M/C seen in females . Usually unilateral . Involves calf and foot Familial version of lymphedema praecox - known as Meig's disease. Age: Usually seen in > 35 years age group It is a rare disease.

@Neet_pg_bot

Q17: A 55-year-old woman presents with chronic swelling of her left arm. She has a history of breast cancer treatment 2 years ago. Which of the following is the most common iatrogenic cause of lymphedema in this patient's scenario? (Q849349)

A. Radiotherapy

B. Lymph node dissection

C. Chemotherapy

D. Biologic Targeted Therapy

Correct Answer: B. Lymph node dissection

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical presentation indicates secondary lymphedema due to axillary lymph node dissection, which is the most common iatrogenic cause of secondary lymphoedema. Secondary Lymphedema Filariasis MC overall cause of lymphedema worldwide MC secondary cause of lymphedema Lymphoedema due to Lymphatic obstruction Surgery Axillary block dissection- MC cause of secondary lymphedema in the USA MC iatrogenic cause of secondary lymphedem Inguinal block dissection Lymphedema due to Lymphatic disruption Infections Tuberculosis Syphilis Fungal and Bacterial infections Other causes: Trauma Malignancy Radiotherapy

Q1: Which of the following paraneoplastic syndromes is NOT commonly associated with small cell lung carcinoma (SCLC)? (Q849541)

A. Syndrome of Inappropriate Antidiuretic Hormone (SIADH)

B. Eaton-Lambert Syndrome

C. Hypercalcemia

D. Cushing's Syndrome

Correct Answer: C. Hypercalcemia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypercalcemia is more commonly associated with squamous cell carcinoma (SCC) of the lung rather than small cell lung carcinoma (SCLC). It usually results from the ectopic production of parathyroid hormone-related protein (PTHrP) . Lung Cancer Type Paraneoplastic Syndromes Small Cell Lung Cancer (SCLC) Hyponatremia (SIADH) (Option A) Ectopic ACTH Production (Cushing-like syndrome) (Option D) Eaton-Lambert Syndrome (common) (Option B) Hypertrophic Osteoarthropathy Peripheral Neuropathy, Cerebellar Degeneration Thrombotic Events (occasionally) Adenocarcinoma Hypertrophic Osteoarthropathy (1-10% of cases) Neurological and Muscular Syndromes (rarely) Squamous Cell Carcinoma (SCC) Hypercalcemia (frequent due to PTHrP) Thrombotic Events (e.g., Trousseau’s syndrome) Peripheral and central neuropathies Common Across Lung Cancers Hematologic Syndromes (e.g., Thrombotic Events, Leukemoid reactions, Pure red cell aplasia) Neurological and Muscular Syndromes (e.g., Peripheral Neuropathy, Cerebellar Degeneration) Nonbacterial thrombotic (marantic) endocarditis (NBTE) Carcinoid syndrome Gynecomastia Acanthosis nigricans Erythema gyratum repens Nephrotic syndrome Hypouricemia

Schwartz Surgery. 11th edition. Pg. 681, 682

Harrison’s Principles of Internal Medicine. 21st edition. Pg. 599

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 3-year-old child presents with a history of choking followed by intermittent coughing and wheezing. The X-ray is as follows. What is the most appropriate investigation for diagnosis and intervention? (Q849521)

A. Chest X-ray

B. CT Scan

C. Rigid Bronchoscopy

D. Flexible Bronchoscopy

Correct Answer: C. Rigid Bronchoscopy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The X-ray shows a foreign body in the tracheobronchial tree. Tracheo-Bronchial Foreign Body Most Common Site: Right Main Bronchus (RMB): The wider calibre and vertical alignment make it the most frequent site for foreign body lodgment. Symptoms: Asymptomatic: Some cases may not present any symptoms. Wheezing: Due to airway narrowing, often accompanied by a persistent cough and signs of obstructive emphysema. Pyrexia (Fever) and Productive Cough: Indicative of pulmonary suppuration (infection). Investigations: Rigid Bronchoscopy: The gold standard for both diagnosis and removal of foreign bodies . It allows direct visualization and retrieval. It reaches up to the third-generation bronchioles and requires general anaesthesia, with ventilation facilitated by multiple holes in the scope. Flexible Bronchoscopy (Option D) is primarily used for diagnostics and deep lung biopsies, performed under local anaesthesia. While it can remove foreign bodies, rigid bronchoscopy is more effective, especially for larger objects and in pediatric cases. Complications: Lung Collapse (Atelectasis) Pneumonia Respiratory Failure Acute Respiratory Distress Syndrome (ARDS) Bleeding Infection Perforation Bronchospasm Chest X-ray (Option A) and CT Scan (Option B) are primarily diagnostic tools rather than therapeutic ones.

UTD_9_4_262_266.pdf (journalagent.com)

↑ *Back to this question in Part A*

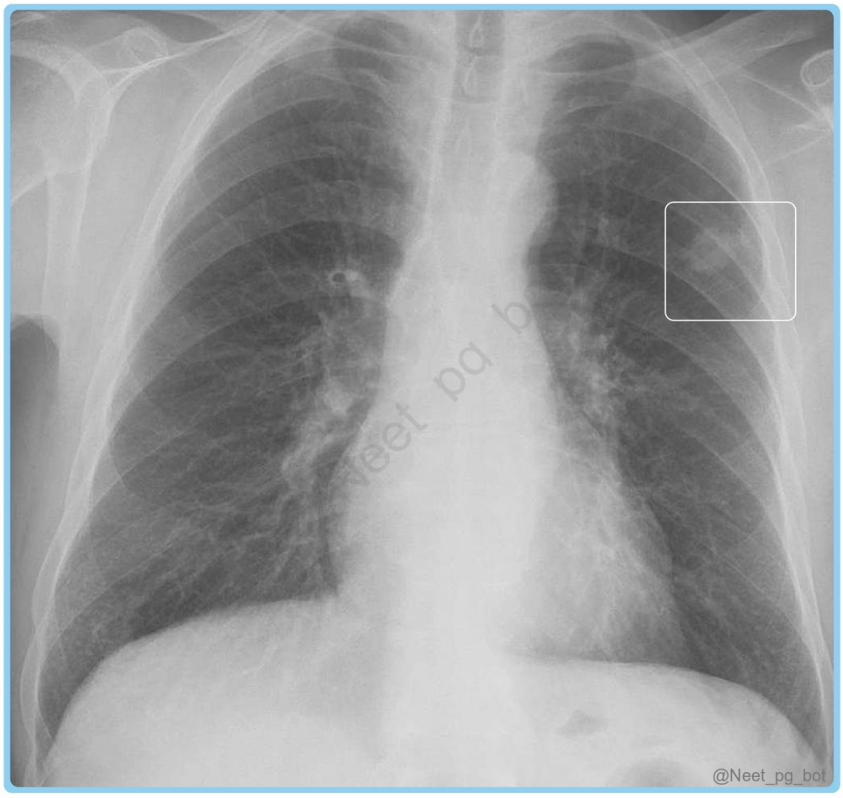
@Neet_pg_bot

Q3: A 55 y/o male with a persistent cough and occasional chest discomfort has a chest X-ray showing a 2.5 cm peripheral, sharply demarcated, lobulated mass with a “popcorn” appearance. No smoking history. What is the most likely diagnosis? (Q849522)

A. Pancoast Tumor

B. Pulmonary Hamartoma

C. Lung Abscess



D. Cystic Adenomatoid Malformation

Correct Answer: B. Pulmonary Hamartoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Pulmonary hamartomas are the most common benign lung tumours and are characterized by a peripheral, sharply demarcated, lobulated mass with a “popcorn” appearance on X-ray. They often consist of normal tissue elements like cartilage in an abnormal location and are commonly found in patients aged 40 to 60 years. PULMONARY HAMARTOMA Characteristics Most frequent benign tumour of the lung. Consist of normal tissue elements containing mesothelial and endothelial elements in an abnormal location; overgrowth of cartilage. Age & Sex 40 to 60 years. More common in males. Location Usually peripheral and slow-growing. Imaging Findings CXR shows a 2 to 3-cm mass that is sharply demarcated and lobulated; Usually not calcified “Popcorn” appearance is characteristic Treatment Excision of the lesion Related Conditions Cystic adenomatoid malformation (Option D) in infants may represent adenomatous hamartomas Pancoast tumours (Option A) are peripheral lung carcinomas at the lung apex that invade nearby structures like the brachial plexus and sympathetic chain. They typically cause severe upper chest/arm pain and weakness, which this patient does not have. Lung Abscess(Option C) often presents with acute or recurrent fever, cough with pleuritic pain, and hemoptysis with foul-smelling sputum. Chest X-ray typically reveals a localized opacity with smooth margins and fluid level. The “popcorn” appearance is not associated with abscesses.

Sabiston Textbook of Surgery, 21st edition, Pg.1619

Bailey and Love Surgery, 28th edition. Pg. 991

SRB Surgery 6th edition. Pg. 1112, 1104,1105,1112

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 45 y/o male with a 3-month history of cough, hemoptysis, and wheezing has a CXR showing a central mass obstructing the right bronchus. Biopsy reveals a low-grade malignant tumour diagnosed as bronchial adenoma. Which of the following is NOT a type of bronchial adenoma? (Q849528)

A. Adenoid Cystic Carcinoma

B. Carcinoid

C. Small Cell Carcinoma

D. Mucoepidermoid Carcinoma

Correct Answer: C. Small Cell Carcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Small cell carcinoma is a highly malignant and aggressive type of lung cancer, not considered a bronchial adenoma. It has a different origin and clinical behaviour compared to bronchial adenomas. BRONCHIAL ADENOMA Definition Tumours arising from bronchial epithelium or glands are less aggressive than typical lung cancers. Types Carcinoids (Option B) (85%): Low-grade, typical and atypical variants. Adenoid Cystic Carcinoma (ACC) (Option A): Slow-growing, 10% of adenomas. Mucous Gland Adenomas: Benign, arise from mucous glands. Mucoepidermoid Carcinomas (Option D): 1-5% of adenomas, varying malignancy. Symptoms Central Lesions: Dyspnea, stridor, wheezing, cough, hemoptysis, recurrent infections. Peripheral Lesions: Often asymptomatic, may be discovered incidentally. Diagnostic Tests Chest X-ray: Detects nodules or masses, central lesions best seen with an oblique view CT Scan: Assesses tumor size, location, lymph node spread Bronchoscopy: Visualizes airways, allows biopsy MRI: Used when CT is unclear Octreotide Nuclear Scan: Detects carcinoid tumors, metastasis sites CT-Guided Fine-Needle Aspiration: For peripheral nodules Treatment Surgical Resection: Main treatment Bronchoscopic Surgery: For small tumours; higher bleeding risk. Open Lung Surgery/VATS: Preferred for complete removal, maximal parenchymal preservation Laser Ablation: Not recommended as primary treatment, used for recurrent tumours. Prognosis The 5-year survival rate is 96% following complete surgical resection.

↑ *Back to this question in Part A*

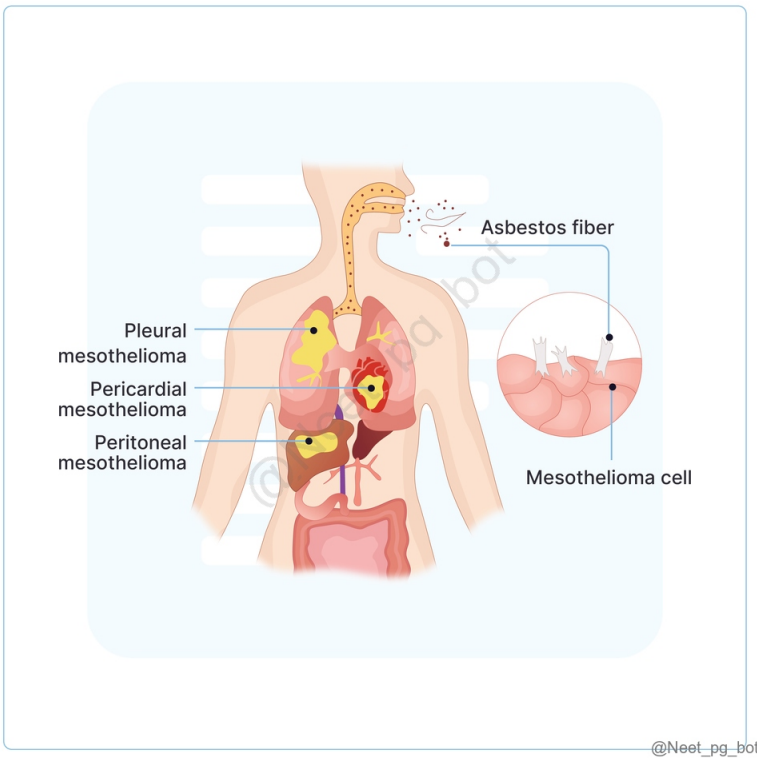
@Neet_pg_bot

Q5: A 65-y/o male, who worked for 30 years in shipbuilding, presents with a 6-month h/o progressive shortness of breath, chest pain, and significant weight loss. A CXR reveals a pleural effusion and a subsequent pleural biopsy confirms the diagnosis of malignant mesothelioma. Which subtype of malignant mesothelioma is most likely to be associated with a better prognosis in this patient? (Q849529)

A. Sarcomatoid subtype

B. Epithelial subtype

C. Mixed (biphasic) subtype



D. Both B and C

Correct Answer: B. Epithelial subtype

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Epithelial subtype is the most common and is associated with a better prognosis compared to other types. MALIGNANT MESOTHELIOMA About Highly aggressive malignancy originating from pleural mesothelial cells, strongly linked to asbestos. The most common primary pleural tumor. Latency Period 15–40 years after asbestos exposure. Risk Factors Male predominance (2:1); Most common after age 40. Asbestos exposure (occupational, familial): Commonly in industries like shipbuilding, brake pad manufacturing, and other asbestos-related manufacturing processes. Secondary Exposure : Family members of workers exposed their clothes and belongings. Types of Asbestos Serpentine fibres (less likely to cause mesothelioma) Amphibole fibres (higher risk, especially crocidolite). Histologic Subtypes Epithelial: Better prognosis Sarcomatoid (Option A): More aggressive Mixed (Option C): Combination of both; Aggressive Symptoms Dyspnea, chest pain, pleural effusion in over 90% of cases, weight loss, fever. Onset: Insidious, leading to late-stage diagnosis in most patients.

References:

Schwartz's Principles of Surgery, 11th edition, Pg. 743-744

Sabiston Textbook of Surgery, 21st edition, Pg. 1631-1632

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 65 y/o male with a 30-year history in brake pad manufacturing presents with dyspnea, chest discomfort, and cough. Imaging shows pleural thickening and nodules. Biopsy confirms early-stage malignant mesothelioma. Which IHC markers and treatments are most consistent with this diagnosis? (Q849534)

A. Positive CEA, negative vimentin, treated with radiation therapy alone

B. Negative CEA, positive vimentin, treated with Extended Pleurectomy and Decortication (EPD) combined with chemotherapy

C. Positive CEA, negative cytokeratins, treated with chemotherapy only

D. Negative vimentin, positive cytokeratins, treated with Extrapleural Pneumonectomy (EPP) alone

Correct Answer: B. Negative CEA, positive vimentin, treated with Extended Pleurectomy and Decortication (EPD) combined with chemotherapy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This IHC profile is consistent with malignant mesothelioma. The combination of EPD, a lung-preserving surgery, with chemotherapy is an appropriate and effective treatment approach, aiming to achieve complete macroscopic resection and improve survival. MALIGNANT MESOTHELIOMA About Highly aggressive malignancy originating from pleural mesothelial cells, strongly linked to asbestos. The most common primary pleural tumour. Diagnosis Imaging : CXR, CT, MRI, FDG-PET: Assess tumour invasion and metastasis ECG: Checks for cardiac involvement Biopsy : Pleural Biopsy: Via thoracoscopy, thoracentesis, or open techniques. Immunohistochemistry findings: Diagnosis Mesothelioma Adenocarcinoma Carcinoembryonic Antigen (CEA) Negative Positive Vimentin Positive Negative Low Molecular Weight Cytokines Positive Negative Electron Microscopy Long, sinuous villi Short, straight villi with fuzzy glycocalyx Staging : Based on tumour invasion (T), lymph node involvement (N), and metastasis (M). Treatment Multimodality Therapy: Early-stage: Surgery (EPP or EPD) with cisplatin-based chemotherapy and radiotherapy. Advanced Disease: Chemotherapy may extend survival but not cure. Palliative Care: Pleural catheters, pleurodesis. Surgical Options: Extrapleural Pneumonectomy (EPP): Complete lung resection; higher risk but more extensive. Extended Pleurectomy and Decortication (EPD): Lung-preserving, safer, preferred in many centres. Prognosis Median survival is 24–36 months depending on stage and treatment.

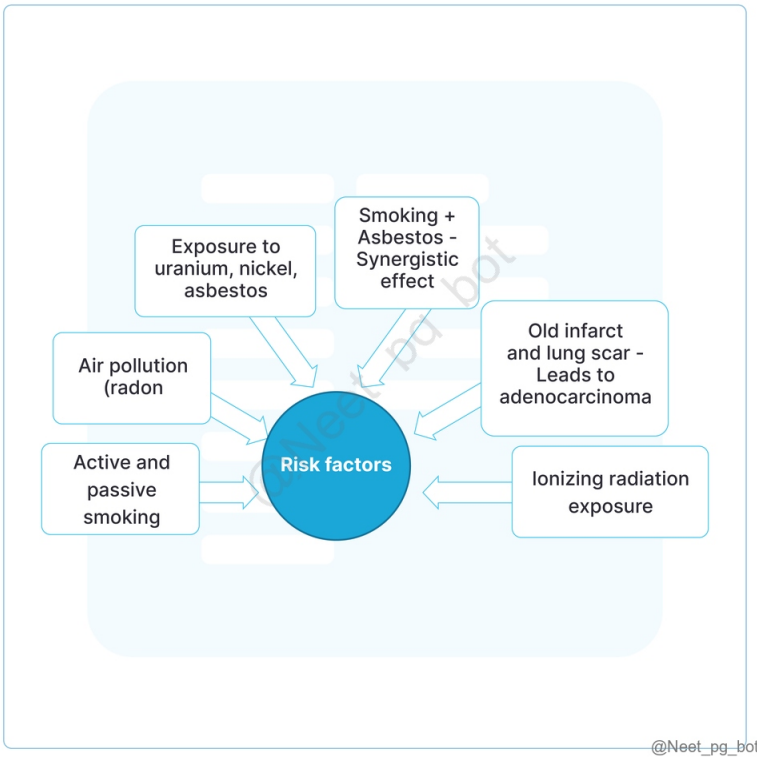
@Neet_pg_bot

Q7: What is the most common type of lung carcinoma? (Q849535)

A. Small cell lung carcinoma

B. Bronchogenic carcinoma

C. Adenocarcinoma



D. Squamous cell carcinoma

Correct Answer: C. Adenocarcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Adenocarcinoma is the most common histological type of lung cancer, particularly in non-smokers and women. It accounts for around 45% of all lung cancers It originates in the peripheral parts of the lungs and is a subtype of non-small cell lung carcinoma. While it is associated with various risk factors, including smoking, it also frequently occurs in non-smokers. \ Risk factors of Lung Cancer Small cell lung carcinoma (Option A) is a type of lung cancer that is more aggressive and often associated with smoking. However, it is not the most common type of lung neoplasm. Bronchogenic carcinoma (Option B) is a broad term used to describe any lung cancer originating in the bronchi or lung parenchyma. However, adenocarcinoma is the most common specific type of lung cancer. Squamous cell carcinoma (Option D) is also linked to smoking and occurs in the central parts of the lungs. While it is a common type of lung cancer, it is less prevalent than adenocarcinoma.

Sabiston Textbook of Surgery, 21st edition, Pg. 1594, 1595

Bailey and Love Surgery, 28th edition. Pg. 985

Types of lung cancer | Cancer Research UK

Lung Cancer - StatPearls - NCBI Bookshelf (nih.gov)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A 60-year-old male, with a 40-year history of smoking, presents with a persistent cough, hoarseness, and recent onset of facial swelling and distended neck veins. Imaging reveals a mass in the central region of the right lung. Based on the location and clinical features, what is the most likely diagnosis? (Q849538)

A. Adenocarcinoma

B. Squamous Cell Carcinoma (SCC)

C. Large Cell Carcinoma

D. Apical (Pancoast's) Tumor

Correct Answer: B. Squamous Cell Carcinoma (SCC)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Squamous Cell Carcinoma (SCC) is strongly associated with smoking and is commonly located centrally in the lungs. It can compress surrounding structures, leading to symptoms like hoarseness (due to recurrent laryngeal nerve involvement) and superior vena cava syndrome, making this the most likely diagnosis. Type of Lung Cancer Key Features Tumor Location Adenocarcinoma (Option A ruled out) Most common histologic type (45% of lung cancers). Early metastasis, CNS involvement, mucin production, glandular differentiation Peripheral Squamous Cell Carcinoma (SCC) Associated with smoking (90% of cases). Keratinization, intercellular bridges, central necrosis & cavitation. Central Large Cell Carcinoma (Option C ruled out) Highly aggressive Undifferentiated, lacks specific features. Slow-growing, but highly vascular. Peripheral Small Cell Neuroendocrine Tumors Highly aggressive Early metastasis to lymph node, Neuroendocrine origin Central Typical/Atypical Carcinoids Typical Carcinoids- Indolent growth Atypical Carcinoids- Aggressive growth Varies Apical (Pancoast's Tumors) (Option D ruled out) Invades brachial plexus Causes severe localized pain. Pancoast’s syndrome Apical (Upper Lung)

@Neet_pg_bot

Q9: What is the most common site of metastasis for lung cancer? (Q849539)

A. Liver

B. Brain

C. Adrenal Glands

D. Bone

Correct Answer: B. Brain

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Brain is the most common site of metastasis for lung cancer , with approximately 47% of patients with non-small cell lung cancer (NSCLC) showing brain involvement. This high prevalence is due to the vascular nature of the brain and the tendency of lung cancer cells to spread hematogenously. The most common site of metastasis in Ca lung is the brain Brain > bone > liver > adrenal glands > distant lymph nodes Ca lung is the most common primary for metastasis to: (Pneumonic- KEPABS) K– Kidney E– Esophagus P– Pancreas A– Adrenal B– Brain S– Skin The liver (Option A) is a common site for metastasis from various cancers, including lung cancer, but it is not the most frequent site for lung cancer metastasis. Studies indicate that liver metastases occur in about 22% of lung cancer cases. Adrenal Glands (Option C) metastasis is relatively common, occurring in about 15% of lung cancer cases. While significant, it ranks lower than brain metastases. Bone (Option D) metastases are also common in lung cancer, affecting around 36% of patients. However, they are still less prevalent than brain metastases.

Sabiston Textbook of Surgery, 21st edition, Pg. 1595

Non-small cell lung CA metastaes

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 65 y/o woman presents to the emergency with a sudden onset of shortness of breath, chest pain, and hypotension. She is diagnosed with a massive pulmonary embolism. Which of the following is the most appropriate initial treatment for this patient? (Q849520)

A. Inferior Vena Cava (IVC) Filter

B. Thrombolytic Therapy

C. Ventilator Support

D. Vitamin K Antagonists

Correct Answer: B. Thrombolytic Therapy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Thrombolytics are the treatment of choice for patients with massive PE who are experiencing severe circulatory compromise (e.g., hypotension, shock). These medications help break down the clot quickly, reducing the risk of further complications and improving blood flow. Eg. Streptokinasse- 6 lakh units can be given initially Management: Anticoagulants and observation. Patients with severe right heart strain and shortness of breath, following is the treatment: Fibrinolytics Radiologically guided catheter embolectomy Inferior Vena Cava (IVC) Filter (Option A): In the case of a massive PE with hemodynamic instability, the priority is to quickly restore blood flow using thrombolytics or mechanical embolectomy. IVC filters do not treat existing clots and are not the immediate choice for unstable patients. They are typically used for patients who have contraindications to anticoagulation therapy or for those with recurrent PEs despite adequate anticoagulation. Ventilator Support (Option C): While important for managing respiratory failure, ventilator support does not directly address the underlying cause of the embolism. Thrombolytics or surgical intervention is needed to treat the clot. Vitamin K Antagonists (Option D): Vitamin K antagonists are not used for the immediate treatment of a massive PE. Their effect is not rapid enough to be effective in the acute setting of a hemodynamically unstable patient.

@Neet_pg_bot

Q11: A 65 y/o male with a 35-pack-year smoking history presents with worsening dyspnea, cough, and weight loss. A CT shows a 6.5 cm right upper lobe mass invading the chest wall, with ipsilateral mediastinal lymph node involvement and liver metastasis as seen on the PET scan. What is the TNM stage of his lung cancer? (Q849543)

A. T2b, N1, M0

B. T3, N2, M1b

C. T4, N2, M1a

D. T3, N3, M1c

Correct Answer: B. T3, N2, M1b

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: T3 refers to a tumour>5 to ≤7 cm with chest wall invasion, N2 indicates ipsilateral mediastinal nodes, and M1b refers to a single extrathoracic metastasis. AJCC 8TH EDITION OF TNM STAGING OF LUNG CARCINOMA PRIMARY TUMOR (T) T1 T1a(mi) Minimally invasive carcinoma T1a ≤ 1 cm T1b 1 - 2 cm T1c 2 - 3 cm T2 Involvement of the main bronchus with the involvement of carina Involvement of visceral pleura Association with atelectasis or obstructive pneumonitis T2a 3 - ≤4 cm T2b 4 - ≤5 cm T3 > 5 - ≤7 cm OR Direct invasion of Chest wall, Phrenic nerve, Pericardium OR Satellite nodules in the same lobe T4 > 7 cm in greatest dimension OR Any tumour with invasion of the mediastinum, diaphragm, heart, great vessels, recurrent laryngeal nerve, carina, trachea, oesophagus, spine OR Separate tumours in different lobes of the ipsilateral lung. LYMPH NODE (N) N1 Ipsilateral peribronchial and/or hilar nodes and intrapulmonary nodes N2 Ipsilateral mediastinal and/or subcarinal nodes N3 Contralateral mediastinal or hilar; ipsilateral/contralateral scalene/supraclavicular DISTANT METASTASIS (M) M1 Distant metastasis M1a Tumor in contralateral lung or pleural/pericardial nodule/malignant effusion M1b Single extrathoracic metastasis, including single non-regional lymph node M1c Multiple extrathoracic metastases in one or more organs T2b, N1, M0 (Option A) : T2b refers to a tumour>4 to ≤5 cm without chest wall involvement, and N1 refers to ipsilateral peribronchial or hilar nodes, without distant metastasis. T4, N2, M1a (Option C) : T4 would indicate a tumour>7 cm or with extensive invasion, and M1a refers to a tumour spread within the thoracic cavity but not to distant organs. T3, N3, M1c (Option D) : N3 indicates contralateral lymph node involvement, and M1c refers to multiple extrathoracic metastases in one or more organs.

TNMC classification

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 65 y/o male with a confirmed diagnosis of stage IIIB non-small cell lung cancer (NSCLC) is being evaluated for treatment options. His disease is localized with significant mediastinal lymph node involvement, and he has a good performance status. Which of the following is the most appropriate initial treatment for this patient? (Q849544)

A. Surgical resection followed by adjuvant chemotherapy

B. Chemoradiation followed by maintenance immunotherapy

C. Systemic therapy with palliative radiation

D. Adjuvant chemotherapy alone

Correct Answer: B. Chemoradiation followed by maintenance immunotherapy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: For stage IIIB lung cancer, which involves significant mediastinal lymph node involvement but not distant metastasis, the standard treatment approach is combined chemoradiation. This is followed by maintenance immunotherapy to improve outcomes and manage residual disease. Treatment of CA lung Stage IA: Surgical resection only. No chemotherapy. Stage IB: Surgical resection Adjuvant chemotherapy if the tumour is greater than 4 cm. (Option A) Stage IIA & IIB: Surgery followed by adjuvant chemotherapy; lobectomy is preferred. Stage IIIA (minimal N2 involvement): Chemoradiation or surgery followed by adjuvant chemotherapy. Stage IIIB: Combined chemoradiation followed by maintenance immunotherapy for 1 year. Stage IV: Systemic therapy with palliative radiation (Option C) including targeted therapy or immunotherapy based on mutation status. Adjuvant chemotherapy alone (Option D) is typically used after surgical resection in earlier-stage NSCLC (e.g., stage I, II, or IIIA) to eliminate any remaining cancer cells. It is not appropriate as a standalone treatment for stage IIIB disease, where chemoradiation or combined modalities are more effective.

Sabiston textbook of Surgery 21st edition Pg 1596.

Treatment of CA lung

↑ *Back to this question in Part A*

@Neet_pg_bot

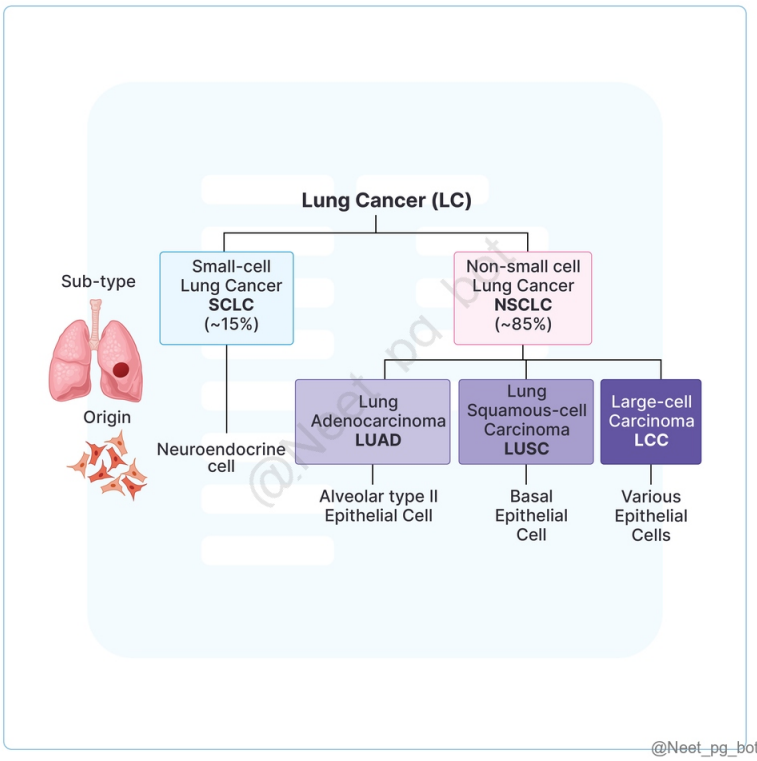
Q13: A 63-year-old man with a history of smoking presents with a central lung mass, weight loss, and a new diagnosis of squamous cell carcinoma (SCC). Which of the following is a common clinical presentation associated with squamous cell carcinoma of the lung due to its typical location? (Q849545)

A. Pleural effusion causing dyspnea

B. Hypercalcemia with renal stones

C. Superior vena cava syndrome

D. Horner's syndrome



Correct Answer: C. Superior vena cava syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Squamous cell carcinoma of the lung often presents with central tumors that can obstruct the superior vena cava, leading to superior vena cava syndrome. Superior vena cava syndrome (SVCS) is a condition caused by the obstruction of blood flow through the superior vena cava, leading to symptoms like facial swelling, distended neck veins, and upper body edema. Pleural effusion causing dyspnea (Option A): While pleural effusion can occur

in lung cancer, it is not specifically associated with SCC's typical central location as prominently as superior vena cava syndrome. Hypercalcemia with renal stones (Option B): Hypercalcemia can be seen in SCC due to paraneoplastic syndromes, but renal stones are not a specific or primary presentation related to the tumor's central location. Horner's syndrome (Option D) is more commonly associated with Pancoast tumors (a type of lung cancer affecting the apex of the lung), not the centrally located squamous cell carcinoma.

Lung cancer

Sabiston textbook of surgery, pg no 1595

Superior vena cava syndrome

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 62- y/o man with a history of heavy smoking is diagnosed with a central lung mass. He is also noted to have severe hypercalcemia and is receiving chemotherapy and radiation therapy. Which of the following statements is true? (Q849546)

A. SCLC is less aggressive than large cell carcinoma

B. Oat cells are seen in Large cell carcinoma

C. SCLC is strongly linked to smoking and can cause SIADH

D. Large cell carcinoma usually presents in central lung areas

Correct Answer: C. SCLC is strongly linked to smoking and can cause SIADH

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Small cell carcinoma is highly associated with smoking and often presents with paraneoplastic syndromes such as SIADH, Cushing syndrome, and Lambert-Eaton syndrome. Symptoms of paraneoplastic syndromes include muscle cramps, muscle weakness, elevation of calcium in the blood and clubbing, a change in the shape of the fingertips. Small cell carcinoma Large cell carcinoma Histology Small, oval-shaped cells, High nucleus-to-cytoplasm ratio, scant cytoplasm; often contains "oat cells" (Option B ruled out). Large cells with abundant cytoplasm, and prominent nucleoli. Growth Highly aggressive, rapid growth, early spread (Option A ruled out). Less aggressive than SCLC, but still fast-growing. Aetiology Strongly associated with smoking. Significantly associated with smoking Location Central lung areas Peripheral lung areas (Option D ruled out) Treatment Highly responsive to radiotherapy and chemotherapy. Moderate response to treatment often requires surgery. Prognosis Poor, due to early metastasis. Better than SCLC but still poor compared to other NSCLC types. Associated conditions Paraneoplastic syndromes, SIADH, Cushing's. (Option C) Rarely associated with paraneoplastic syndromes.

Small cell lung CA

Large cell lung CA

Schwartz 11th edition , Page 671,672

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 72 y/o woman presents with severe shoulder pain and noticeable ptosis. Imaging reveals a mass at the apex of the lung, involving the upper ribs and vertebrae. Horner's syndrome is observed. Which imaging modalities are most suitable for the evaluation of this condition? (Q849547)

A. Chest X-ray

B. Ultrasound

C. CT scan

D. MRI

Correct Answer: D. MRI

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Given the symptoms, a Pancoast tumor is suspected, which may invade soft tissues like the brachial plexus and sympathetic chain. MRI is ideal for assessing the involvement of these structures. Pancoast Tumor Also known as Superior Sulcus Tumor, is a rare peripheral lung carcinoma originating from the apex of the lung, accounting for 5% of lung cancers. Invades the brachial plexus, sympathetic chain, upper ribs, and vertebrae. Symptoms: Intractable upper chest and arm pain, arm weakness. Presentations: Pancoast's Syndrome: Lower brachial plexus palsy, Horner's syndrome, rib erosion, and apical shadow on imaging. Horner's Syndrome: Characterized by miosis, enophthalmos, anhidrosis, ptosis, and loss of spino-ciliary reflex. Investigations: Imaging: Chest X-ray, CT scan, MRI (preferred for visualizing brachial plexus and sympathetic chain involvement). Biopsy: Bronchoscopy with biopsy, CT-guided biopsy. Treatment: Surgery: Lobectomy or pneumonectomy. Radiotherapy Chemotherapy: Methotrexate. Chest X-ray (Option A) can detect a lung mass, but it is not detailed enough to fully evaluate the extent of the tumour or its involvement with surrounding structures. Ultrasound (Option B) is not suitable for evaluating lung masses or bony structures in the chest; it is better suited for soft tissue assessment and fluid-filled areas. CT scan (Option C) provides detailed imaging of the lung mass, including its relationship to the ribs, vertebrae, and surrounding structures, however, MRI would provide additional critical information regarding soft tissue and nerve involvement, which is why it might be considered more appropriate in this specific context.

@Neet_pg_bot

Q16: Which of the following statements regarding cardiac tumours is true? (Q849548)

A. Angiosarcomas are the most common benign primary cardiac tumours.

B. Nearly 90% of primary cardiac tumours are malignant.

C. Myxomas are the most common primary cardiac tumours in adults.

D. Cardiac myocytes have high proliferative activity, contributing to the formation of cardiac tumours.

Correct Answer: C. Myxomas are the most common primary cardiac tumours in adults.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Myxomas account for more than half of all primary cardiac tumours and are the most common type in adults. Cardiac Tumours Classification: Primary Tumours: Rare, divided into benign congenital, benign acquired, and malignant tumours. Metastatic Tumours: Secondary tumours spread to the heart from other body sites. Types of Cardiac Tumours Tumour Type Description Myxoma The most common primary cardiac tumour- accounts for over 50% of cases. Rhabdomyoma Most common in infants and children, often linked to tuberous sclerosis. Angiosarcoma (Option A) The most common malignant primary cardiac tumour. Incidence and Prognosis: Benign Tumors: Constitute nearly 90% of primary cardiac tumors. (Option B) Malignant Tumors: Rare, making up 10% of primary cardiac tumors; poor prognosis if metastases are present. Reasons for Rarity: Cardiac Myocytes: Terminally differentiated with tight cell cycle control, reducing the risk of tumour formation. (Option D) Low Proliferative Activity: Limited opportunities for the abnormalities in cell cycle kinetics that typically lead to tumours. Treatment and Research: Specialized Care: Referring patients to hospitals experienced in cardiac tumours can improve outcomes. Research Gap: Due to the extreme rarity of cardiac tumours, there is a lack of organized research on their aetiology and treatment.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 55 y/o female presents with symptoms of shortness of breath, occasional dizziness, and a recent episode of fever and weight loss. Imaging studies reveal a mass in the left atrium and is diagnosed with atrial myxoma. Which of the following is true? (Q849549)

A. The majority of atrial myxomas arise from the right atrium.

B. Atrial myxomas are more common in males, around 3rd decade of life.

C. Atrial myxomas can cause systemic emboli and obstruction of blood flow.

D. The genetic cause of atrial myxomas is always linked to an autosomal recessive pattern.

Correct Answer: C. Atrial myxomas can cause systemic emboli and obstruction of blood flow.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Atrial myxomas can lead to systemic emboli due to tumor fragments breaking off and obstructing blood flow, which can cause symptoms such as shortness of breath and dizziness. Atrial Myxoma Overview More common in females between 40 -60 years of age. (Option B) Embryology: Originate from multipotent mesenchymal cells with potential for neural and endothelial differentiation. Inheritance: Familial- 10 % - inked to autosomal dominant pattern (Option D) Sporadic - 90% Location: Left atrium (75%) > Right Atrium (25%) (Option A ruled out) > both atria & ventricles (5%) Characteristically found in the interatrial septum. Clinical features: Systemic embolization (since they lack a strong structure) - leads to neurologic deficit. Intracardiac obstruction- leading to mitral stenosis /valve obstruction symptoms Atrial myxomas, although rare, can lead to significant complications if not promptly diagnosed and treated.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: A 14 y/o boy presents with a chest wall deformity characterized by a protruding sternum, resulting in a convex appearance of the chest. The patient is otherwise asymptomatic, and his chest wall growth is nearing completion. Which of the following statements about the management of this condition is true? (Q849550)

A. The Nuss procedure is the preferred surgical approach.

B. Non-surgical bracing is effective in correcting pectus carinatum

C. The modified Ravitch procedure is exclusively used for treating the Pigeon chest.

D. Surgical intervention for pectus carinatum is typically recommended for cosmetic reasons.

Correct Answer: D. Surgical intervention for pectus carinatum is typically recommended for cosmetic reasons.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Surgical correction for pectus carinatum is usually performed in the late teens after chest wall growth has slowed, and it is often done for cosmetic reasons. Chest Wall Deformities: Pectus Excavatum and Pectus Carinatum Pectus Excavatum: Description: Depression of the sternum leading to a concave chest appearance. Surgical Approaches: Modified Ravitch Procedure: Removal of affected cartilage and repositioning of the sternum. Nuss Procedure (Option A): Minimally invasive insertion of a metal bar behind the sternum to reshape the chest, which is later removed. Pectus Carinatum (Pigeon Chest): Description: Elevated sternum resulting in a convex chest appearance. Clinical Features: Patients are almost always asymptomatic, hence, treatment is often offered for aesthetic purposes. Surgical Intervention: Modified Ravitch Procedure (Option C): Repositioning of the sternum and cartilage, so that the sternum can be flattened out. A similar to the approach for pectus excavatum. Done only after late teens- when no further growth of chest wall will happen. Non-Surgical Options: External Bracing (Option B): Used for younger patients whose chest wall growth is not completed yet, to correct deformity before growth slows.

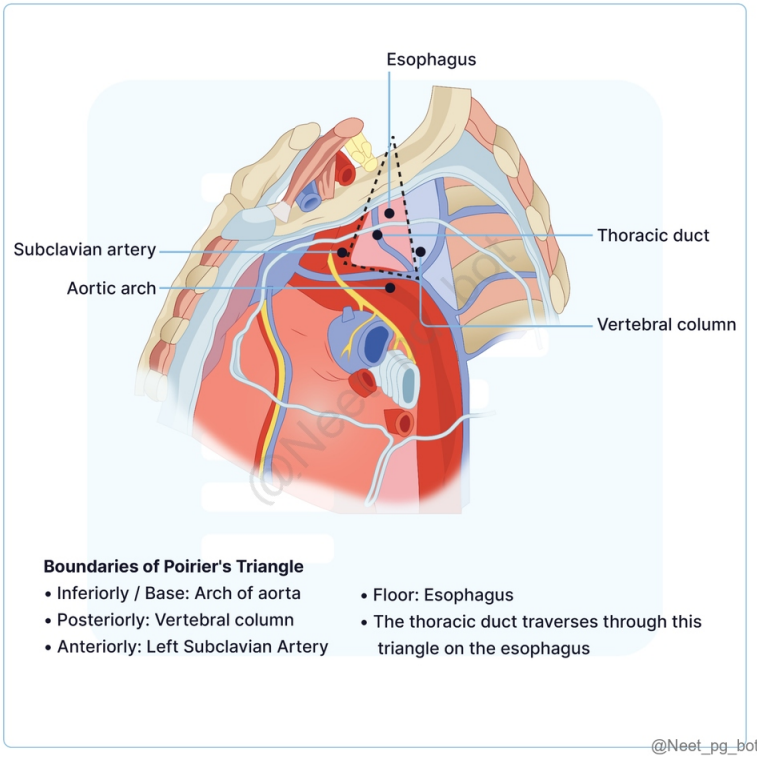
@Neet_pg_bot

Q19: The thoracic duct, the largest lymphatic vessel in the body, passes through the posterior mediastinum. Which of the following anatomical triangles is the key area used for locating and managing the thoracic duct? (Q849492)

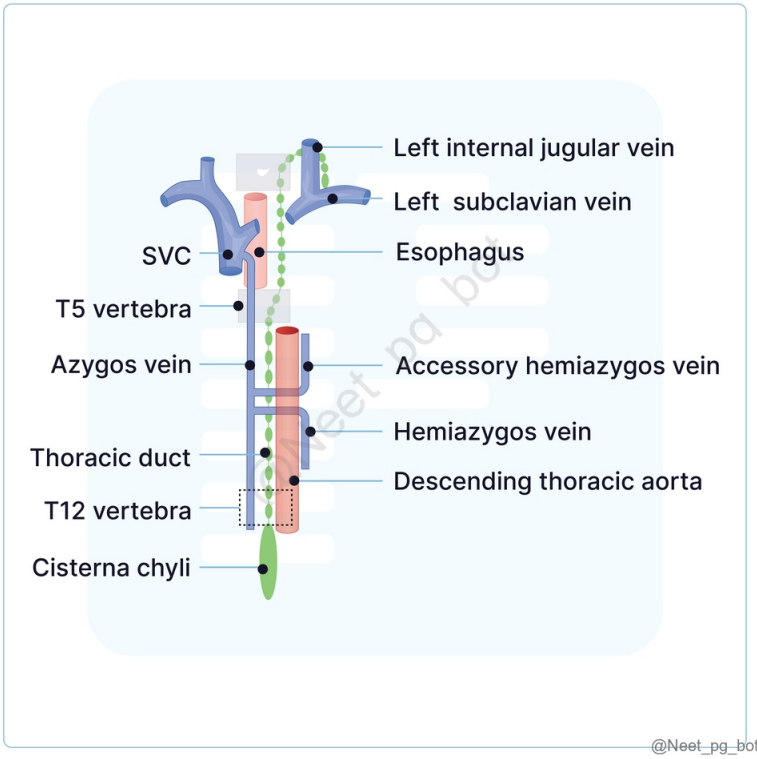
A. Simon's triangle

B. Lesgaft's triangle

C. The triangle of Petit



D. Poirier’s Triangle



Correct Answer: D. Poirier’s Triangle

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: By performing left posterolateral thoracotomy, the thoracic duct can be identified in a triangle known as Poirier's triangle THORACIC DUCT Simon's triangle (Option A) is defined by the recurrent laryngeal nerve on the anterior side, the common carotid artery on the posterior side, and the inferior thyroid artery forming the base. This triangle is significant because it helps in locating the recurrent laryngeal nerve. Lesgaft's triangle (Option B) or the superior lumbar triangle is bordered by the sacrospinalis muscle, the 12th rib, and the posterior edge of the internal oblique muscle. The triangle of Petit (Option C) or the inferior lumbar triangle is defined by the boundaries of the latissimus dorsi muscle, the external oblique muscle, and the iliac crest.

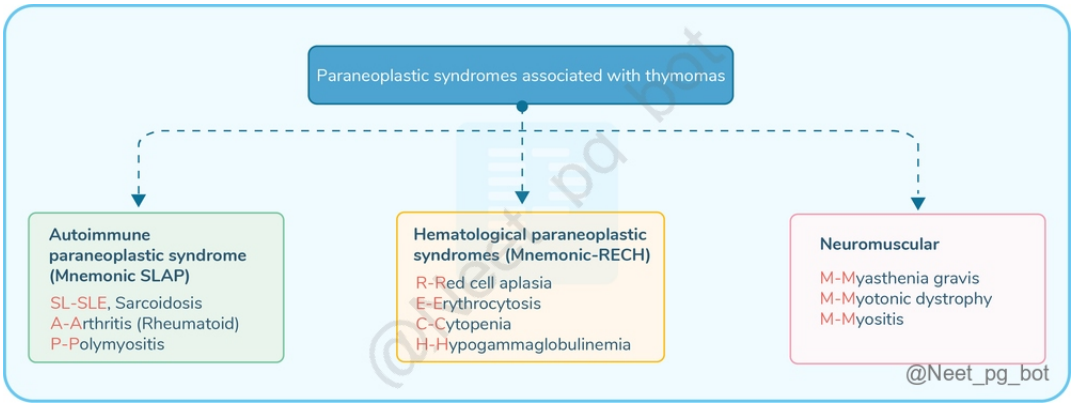
@Neet_pg_bot

Q20: A 48 y/o female presents with fluctuating muscle weakness, difficulty speaking, and drooping eyelids that worsen with physical activity. Imaging reveals a mass in the anterior mediastinum. Which of the following is the most likely paraneoplastic syndrome associated with her condition? (Q849463)

A. Lambert-Eaton myasthenic syndrome

B. Myasthenia gravis

C. Cushing syndrome



D. Syndrome of inappropriate antidiuretic hormone (SIADH)

Correct Answer: B. Myasthenia gravis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A mass in the anterior mediastinum is commonly associated with a thymoma . Thymomas are strongly associated with myasthenia gravis (MG). 50% of thymoma patients have MG. The symptoms of muscle weakness, dysarthria, and ptosis that worsen with activity are classic hallmarks of myasthenia gravis (MG). Lambert-Eaton myasthenic syndrome (Option A) is a paraneoplastic syndrome typically associated with small-cell lung cancer, not thymomas. It presents with proximal muscle weakness and autonomic dysfunction, but it is less common than myasthenia gravis in thymoma cases. Cushing syndrome (Option C) is usually associated with ectopic ACTH production from tumours like small-cell lung cancer or adrenal adenomas, not thymomas. Syndrome of inappropriate antidiuretic hormone (Option D) is another paraneoplastic syndrome more commonly linked with small cell lung cancer, leading to hyponatremia, rather than thymomas.

↑ *Back to this question in Part A*

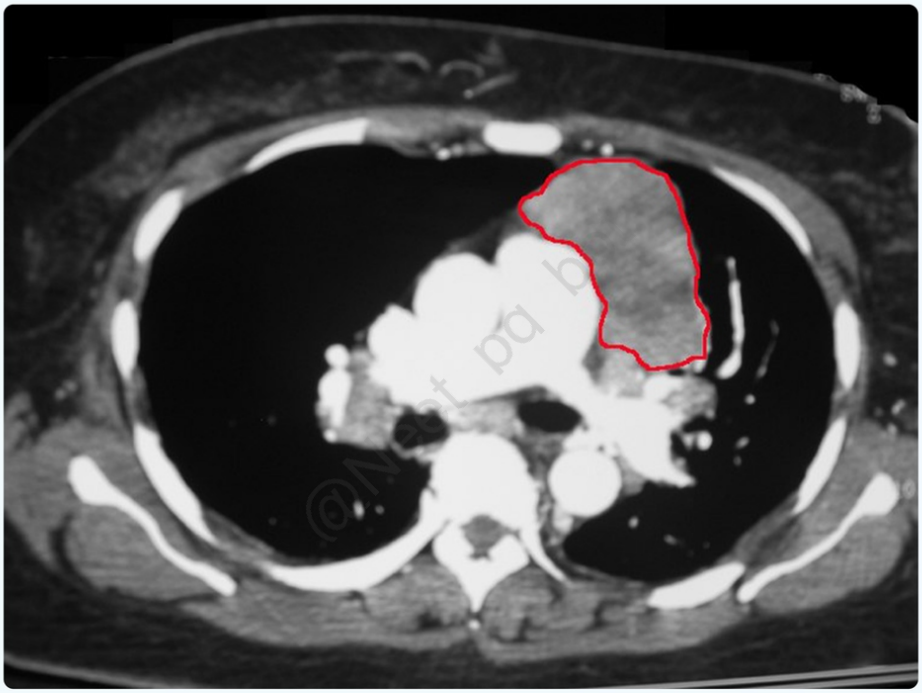
@Neet_pg_bot

Q21: A 55 y/o male presents with a persistent cough and dyspnea on exertion. A chest x-ray reveals an anterior mediastinal mass with tracheal deviation. What is the next best step in evaluating this patient for a potential thymoma? (Q849464)

A. Serum markers

B. Chest X-ray with lateral view

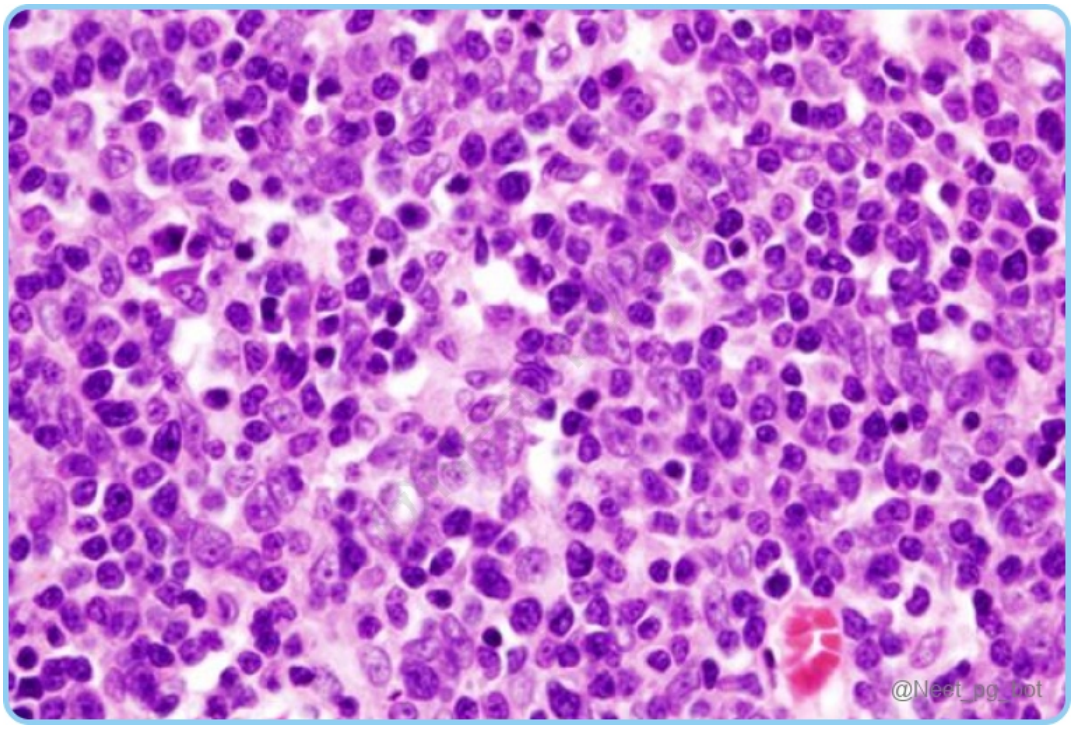
C. Contrast-enhanced CT scan



D. Pulmonary function tests (PFTs)

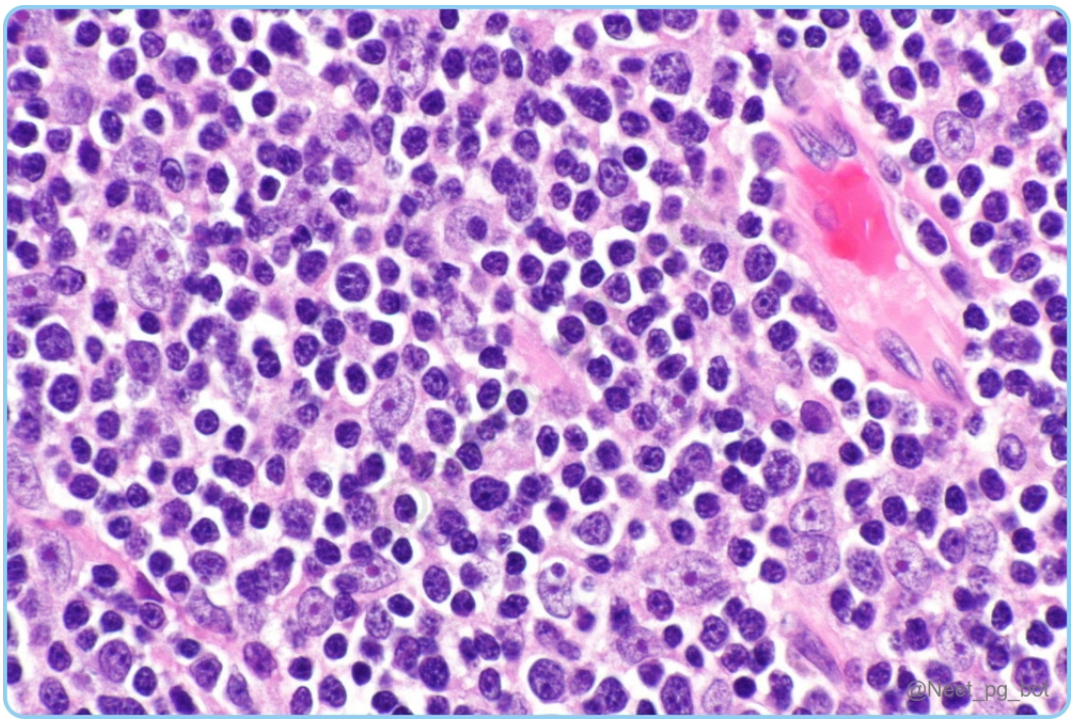
Correct Answer: C. Contrast-enhanced CT scan

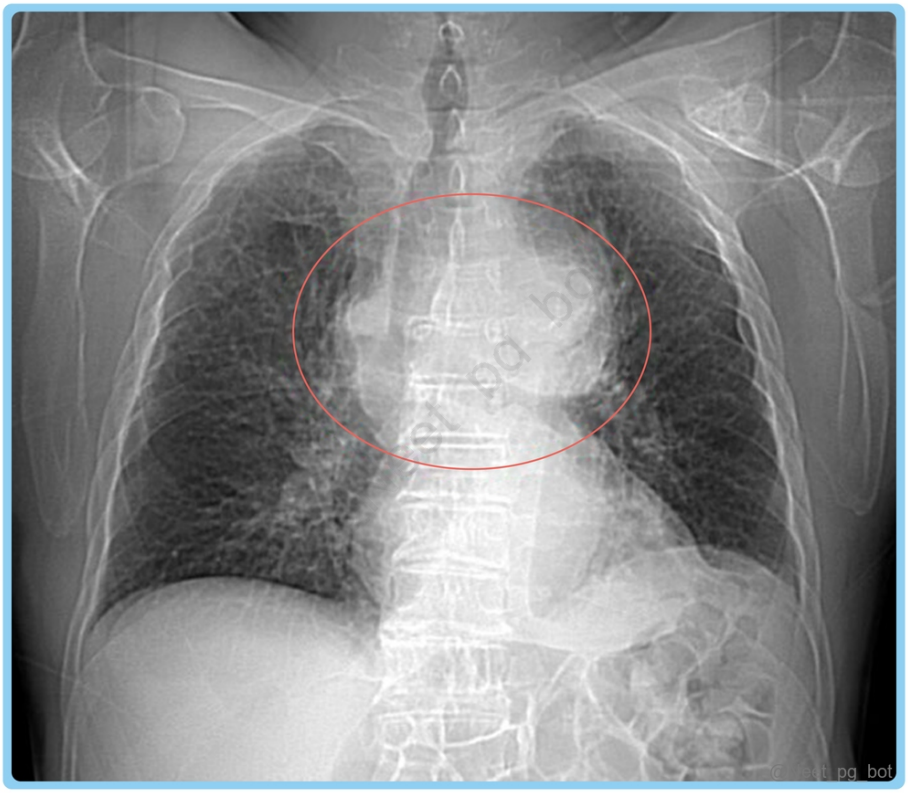
■ *Listen (English)*



■ *Listen (Hindi)*

Explanation: A contrast-enhanced CT scan is the next best step for evaluating a thymoma. It provides detailed imaging, assessing the tumour's relationship with surrounding structures and helping to determine the extent of the disease. Clinical features Mostly asymptomatic (small tumor), incidentally detected. It may compress the trachea (dyspnea), esophagus (dysphagia), recurrent laryngeal nerve (dysphonia or hoarseness of voice), and superior vena cava (superior vena cava syndrome). Investigations: CT scan: Investigation of choice Determine the extent of the disease. Histology (definitive diagnosis) Noninvasive thymomas: Medullary-type epithelial cells (elongated or spindle-shaped) or a mixture of medullary- and cortical-type epithelial cells (admixture of polygonal cortical-type epithelial cells and a denser infiltrate of thymocytes). Invasive thymoma: Cytologically benign but locally invasive. The epithelial cells are with abundant cytoplasm and rounded vesicular nuclei, mixed with numerous thymocytes. Cytokeratin (marker to distinguish thymoma from lymphoma, thymomas are positive for cytokeratin) Serum markers (Option A) are not typically used to evaluate an anterior mediastinal mass suspected to be a thymoma. They are generally used to differentiate between seminimatous & non-seminimatous germ cell tumours based on the AFP levels. Chest X-ray with a lateral view (Option B): While a lateral chest X-ray can help localize the mass within the mediastinum, it is not as informative as a CT scan. A lateral view could provide some additional information, but a CT scan is superior in detailing the characteristics and extent of the mass. Pulmonary function tests (Option D) are important in assessing lung function, particularly before surgery, but they do not provide specific information about the thymoma itself. They are useful in surgical planning rather than in the initial evaluation.





CT scan of thymoma

@Neet_pg_bot

@Neet_pg_bot

Bailey & Love's Short Practice of Surgery 28th Edition, Page 992.

Schwartz’s Principles of Surgery, 11th Edition, Page.727,731

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: A 63 y/o female is diagnosed with a Stage III thymoma and presents with symptoms of myasthenia gravis. The tumour appears to have invaded the superior vena cava and pericardium. What is the most appropriate treatment plan for this patient? (Q849465)

A. Complete surgical resection

B. Radiation therapy alone

C. Observation and periodic follow-up imaging

D. Chemotherapy as a primary treatment without surgery

Correct Answer: A. Complete surgical resection

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Complete surgical resection of the tumour is the most appropriate treatment plan for a Stage III thymoma with invasion into nearby structures. Surgical resection may include removing and r econstructing the involved structures, such as the pericardium and superior vena cava. For optimising patient care, a multidisciplinary approach with chemotherapy, neoadjuvant chemotherapy, radiotherapy and immunotherapy is usually undertaken after resection and reconstruction to prevent disease recurrence. The Masaoka-Koga system is based on surgical findings and describes the extent of tumour spread. It categorizes thymomas into stages I-IV, with higher stages indicating more extensive disease. Masaoka-Koga Staging System Stage I The tumour is completely encapsulated, meaning it is confined within the thymus gland and has not spread beyond its capsule. Stage II The tumour has spread beyond the capsule of the thymus. Microscopic or macroscopic invasion into the surrounding fatty tissue or mediastinal pleura. Stage III The tumour has spread to adjacent organs in the chest, such as the pericardium, the lungs, or the great vessels (aorta, vena cava, pulmonary artery). Stage IV The tumour has spread to distant sites in the body. Stage IVa : Spread to the pericardium or pleura Stage IVb : Spread to distant organs through the bloodstream or lymphatic system. Radiation therapy alone (Option B) is generally not sufficient for a Stage III thymoma, especially one that has invaded surrounding structures. It is typically used as an adjunctive treatment after surgery or as palliative therapy in inoperable cases. Observation and periodic follow-up imaging (Option C) is not an appropriate treatment strategy for a Stage III thymoma. This approach might be suitable for small, asymptomatic, and non-invasive thymomas, but not for advanced-stage tumors. Chemotherapy as a primary treatment without surgery (Option D): While chemotherapy can be used as a primary treatment for patients who are not candidates for surgery, this patient has no contraindications to surgery and would benefit from the curative option of surgical resection following chemotherapy.

Schwartz’s Principles of Surgery, 11th Edition, Pg.731

Sabiston Textbook of Surgery (21st Edition), Page 1635.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A 48 y/o man with a history of pulmonary TB presents with progressive shortness of breath, facial swelling, and difficulty swallowing. His chest X-ray shows an abnormal shadow in the mediastinum. A CT scan reveals extensive fibrotic tissue compressing the SVC and oesophagus. What is the most likely diagnosis? (Q849466)

A. Superior vena cava syndrome

B. Pulmonary embolism

C. Chronic fibrous mediastinitis

D. Thymoma

Correct Answer: C. Chronic fibrous mediastinitis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's history of pulmonary tuberculosis, along with imaging findings showing fibrosis and compression of the SVC and oesophagus, strongly suggest chronic fibrous mediastinitis. Chronic fibrous mediastinitis is a rare disorder characterized by extensive fibrotic tissue formation in the mediastinum. This fibrosis can compress vital mediastinal structures such as the SVC, oesophagus, trachea, and pulmonary arteries, leading to symptoms like shortness of breath, facial swelling, and dysphagia. The condition often follows a history of granulomatous infections such as tuberculosis or histoplasmosis, which provoke a chronic inflammatory response in the mediastinum. Superior vena cava syndrome (Option A): This is a condition where the SVC is obstructed, leading to symptoms like facial swelling and difficulty swallowing but there is no associated mediastinal fibrosis. It is not the primary diagnosis. Pulmonary embolism (Option B): This condition causes sudden shortness of breath and chest pain but does not typically cause facial swelling or difficulty swallowing. There is also no associated mediastinal fibrosis. Thymoma (Option D) is a tumour that occurs in the anterior mediastinum. It can cause compression of mediastinal structures but is less likely to be associated with a history of granulomatous infection and extensive fibrosis.

References:

Schwartz's Principles of Surgery, 11th Edition, Pg.736

↑ *Back to this question in Part A*

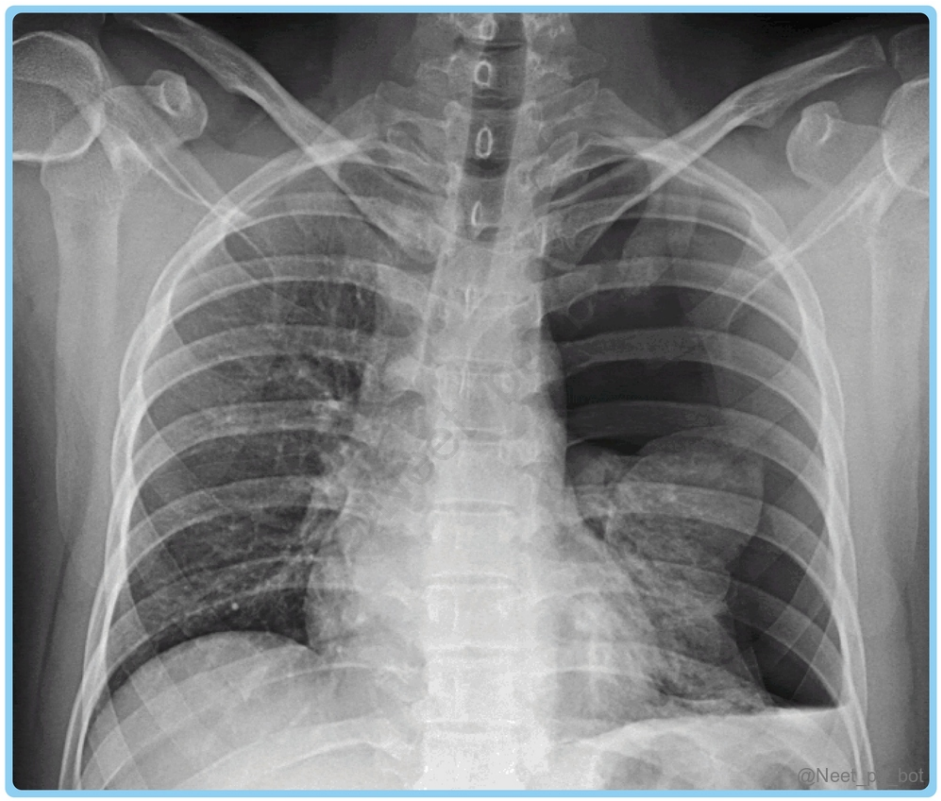
@Neet_pg_bot

Q24: A 72-year-old male with COPD presents with sudden severe shortness of breath and right-sided chest pain. On examination, he is cyanotic, in respiratory distress, and has diminished breath sounds on the right side. A CXR shows a large air collection in the right pleural space. What is the most likely diagnosis? (Q849474)

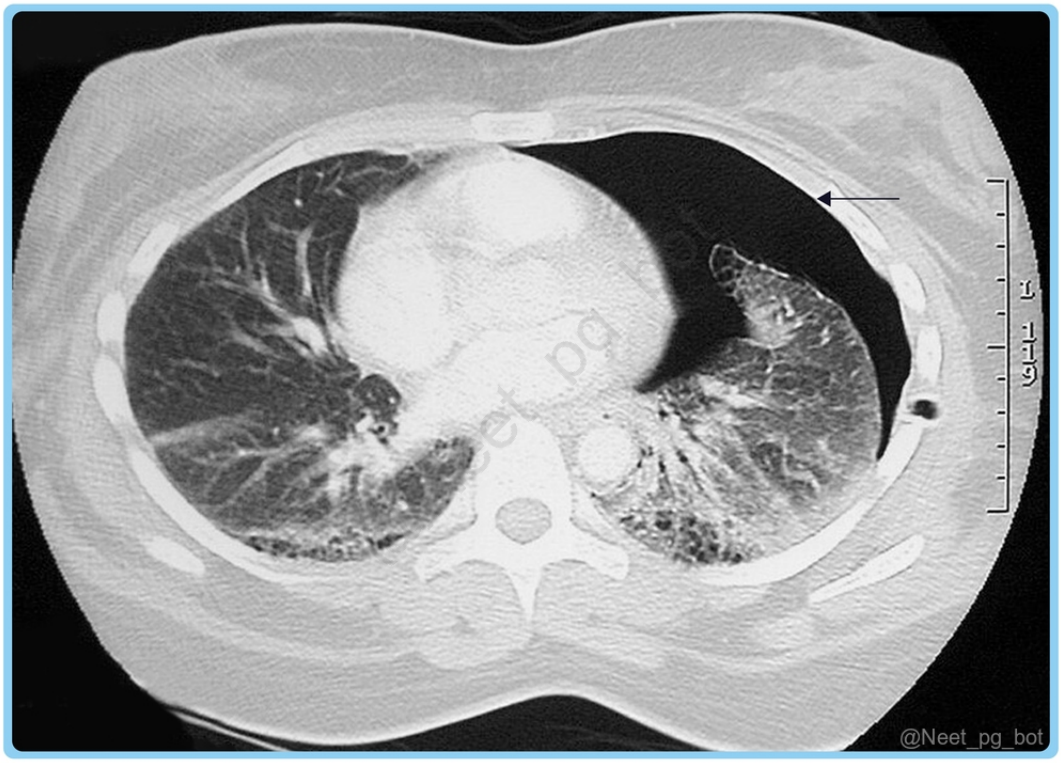
A. Primary Spontaneous Pneumothorax (PSP)

B. Secondary Spontaneous Pneumothorax (SSP)

C. Chylothorax



D. Hemothorax



Correct Answer: B. Secondary Spontaneous Pneumothorax (SSP)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: SSP is common in older adults with underlying lung diseases such as COPD. The patient's symptoms of severe shortness of breath, chest pain, and a history of COPD are classic for SSP. Aspect Primary Spontaneous Pneumothorax (PSP) Secondary Spontaneous Pneumothorax (SSP) About Occurs without underlying lung disease. (Option A) Typically affects young individuals (under 35 years) It arises from the rupture of small blebs or cysts on the lung surface, leading to air entering the pleural space. . Occurs in individuals with existing lung pathology. More common in older adults (typically over 45 years). Recurrence rates are higher compared to PSP, with up to 80% of patients experiencing additional episodes Risk Factors Male sex Tall and thin body type Smoking Family history of pneumothorax Chronic obstructive pulmonary disease (COPD) Cystic fibrosis Tuberculosis Lung cancer Other lung diseases (e.g., asthma, sarcoidosis) Clinical Features Sudden onset of chest pain Mild to moderate dyspnea Rarely life-threatening Severe dyspnea Hypoxemia and hypercapnia Chest pain Potential for acute respiratory failure Investigations Chest X-ray CT scan may be used for confirmation in some cases Chest X-ray CT scan for differential diagnosis, especially in emphysema cases Treatment Observation for small, asymptomatic cases. Needle aspiration for larger cases. Chest tube placement if aspiration fails. Surgical options (VATS, pleurodesis) for recurrent cases. Hospital admission for monitoring. Chest tube placement for large or symptomatic cases. Surgical intervention based on underlying disease. Chest X-ray of Pneumothorax CT of Pneumothorax Chylothorax (Option C): Chylothorax is caused by the accumulation of chyle (a milky fluid rich in triglycerides, chylomicrons, and white blood cells) in the pleural space due to disruption of the thoracic duct. It is associated with dyspnea and cough, but the pleural fluid is typically milky or clear. This patient’s presentation of sudden chest pain and respiratory distress with a history of COPD is more indicative of SSP rather than chylothorax. Hemothorax (Option D): Hemothorax refers to the presence of blood in the pleural cavity, often caused by trauma, surgery, tumours, or spontaneous bleeding. It presents with chest pain, signs of shock, and dullness on percussion. The patient’s history and the absence of trauma or surgery make SSP a more likely diagnosis in this case. Hemothorax would also typically present with signs of bleeding and shock, which are not described here.

@Neet_pg_bot

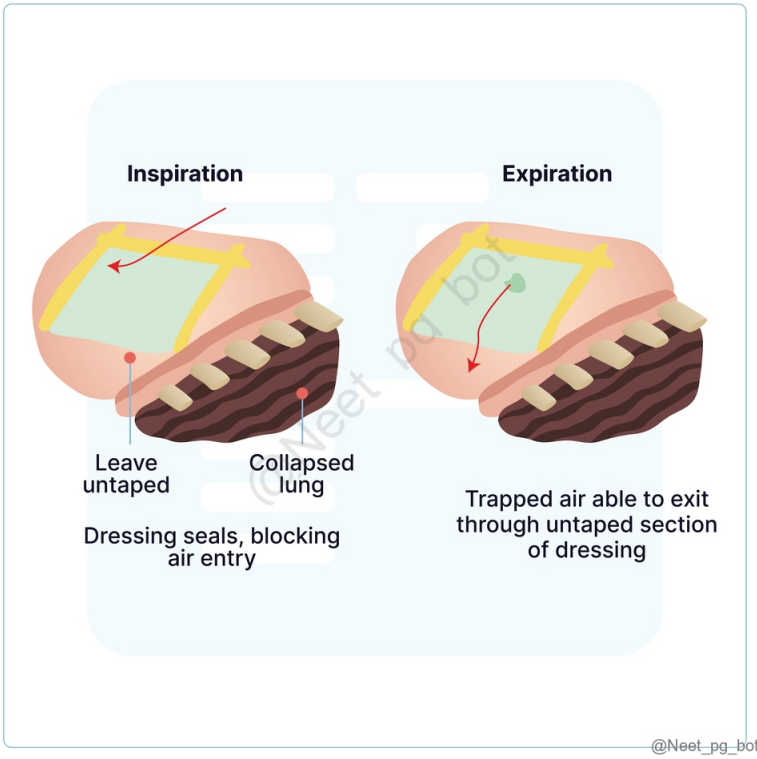
Q25: A 30-year-old male presents to the emergency department after a stabbing injury to the chest, having respiratory distress, 4 cm wound on the right side. On

examination, his breath sounds are decreased on the right side, and he shows signs of hypoxia. His vital signs are stable. What is the most appropriate first step in managing this patient? (Q849479)

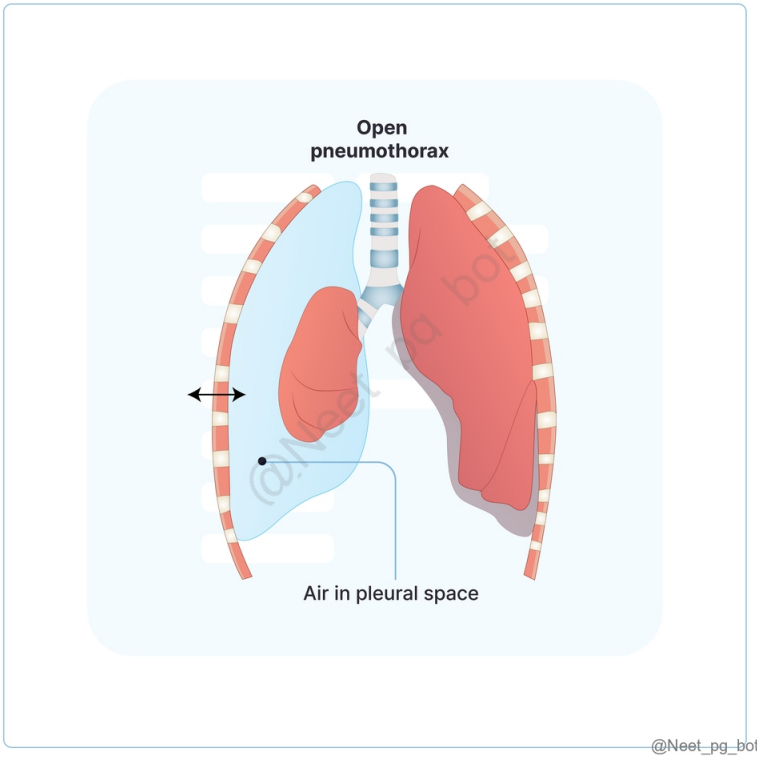
A. Perform needle thoracocentesis in the 2nd intercostal space, midclavicular line

B. Insert a chest tube immediately at the site of the injury

C. Apply a sterile occlusive dressing over the wound, taped on three sides



D. Obtain a chest X-ray to assess the injury and confirm the diagnosis



Correct Answer: C. Apply a sterile occlusive dressing over the wound, taped on three sides

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient’s history of trauma to the chest leading to an open wound of 4cm and clinical findings of absent breath sounds are characteristic of open pneumothorax. Applying a sterile occlusive dressing, taped on three sides, helps to seal the wound and prevent air from being drawn into the pleural space with each breath, which can help stabilize the patient and prevent progression to a tension pneumothorax. OPEN PNEUMOTHORAX Pathophysiology Large defect in the chest wall (>3 cm). Intrathoracic pressure = Atmospheric pressure. If the size of the defect > 2/3rds of the trachea’s diameter, the air is drawn through the wound rather than the trachea, leading to air accumulation in the hemithorax, hypoventilation, and hypoxia. Initial Management Seal the Defect with a sterile occlusive plastic dressing (e.g., OPSITE™) taped on three sides to create a flutter valve. Chest Tube Placement: Insert a chest tube as soon as possible at a site distant from the injury. Potential Complications Tension Pneumothorax if the defect creates a one-way valve effect. Perform needle thoracocentesis in the 2nd intercostal space, midclavicular line (Option A): Needle thoracocentesis is used for tension pneumothorax, not open pneumothorax. Insert a chest tube immediately at the site of the injury (Option B): While chest tube placement is crucial for managing pneumothorax and pleural effusion, it should be performed at a site remote from the injury. The immediate priority for an open pneumothorax is to seal the defect first to prevent further complications. Obtain a chest X-ray to assess the injury and confirm the diagnosis (Option D): Although a chest X-ray is helpful for diagnosis, the management of an open pneumothorax should not be delayed for imaging. Immediate sealing of the wound is critical to stabilize the patient and prevent further complications.

@Neet_pg_bot

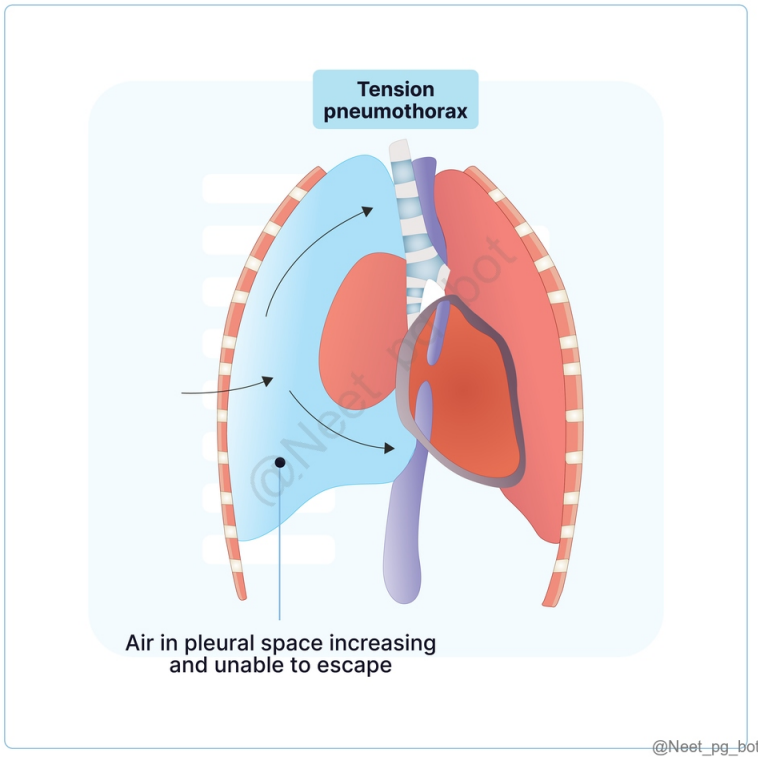
Q26: A 25-year-old male, after a motor vehicle accident, presents with severe respiratory distress, decreased breath sounds on the right, hyper-resonance, and tracheal deviation to the left. His BP is 85/55 mmHg, and jugular veins are distended. What is the most appropriate next step in management? (Q849480)

A. Order an urgent chest X-ray to confirm the diagnosis

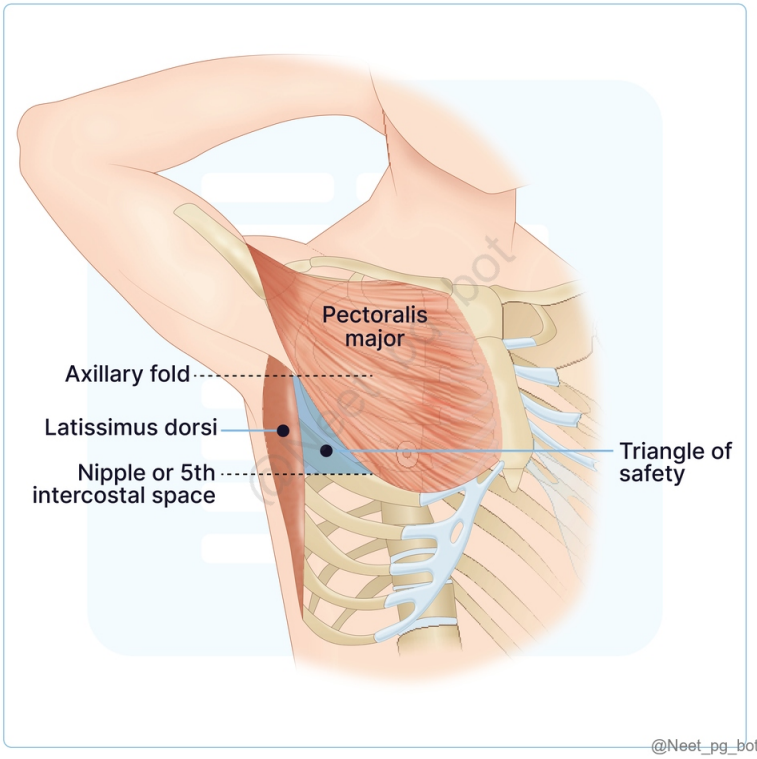
B. Perform an immediate needle thoracocentesis in the 5th intercostal space, in anterior axillary line

C. Insert a chest tube into the 5th intercostal space in the anterior axillary line

D. Perform a finger thoracostomy in the safe triangle



Correct Answer: B. Perform an immediate needle thoracocentesis in the 5th intercostal space, in anterior axillary line



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient presents with low blood pressure, distended jugular veins, and signs of tension pneumothorax, including severe respiratory distress, tracheal deviation, and hyper-resonance. This life-threatening condition requires immediate needle thoracocentesis to relieve the pressure. Once stable, a chest tube should be inserted. TENSION PNEUMOTHORAX Pathophysiology D/t ‘one-way valve’ air leaks from the lung or chest wall. Air is sucked into the thoracic cavity without any escape, collapsing and compressing the affected lung. The mediastinum shifts to the opposite side, reducing venous return and compressing the opposite lung, leading to decreased cardiac output and function. This can result in sudden death. Causes Penetrating Chest Trauma. Blunt Chest Trauma with parenchymal lung injury and persistent air leak. Iatrogenic Lung Injury (e.g., central venepuncture) Mechanical Positive-Pressure Ventilation. Clinical Features Tachypnea and Tachycardia Hyper-resonance and Decreased/Absent Breath Sounds Resonant Percussion with severe mediastinal/tracheal shift Cyanosis and Hypotension Chest Pain Distended Neck Veins Emergency Management Tension pneumothorax is a clinical diagnosis and treatment should never be delayed by waiting for radiological confirmation. Immediate Thoracocentesis (needle): Wide bore needle (typically a 20- or 22-gauge) in the 5nd intercostal space in the safety triangle. Decompression should be performed in the "safe triangle." Safe Triangle Boundaries : Posterior: Latissimus dorsi Anterior: Lateral border of the pectoralis major Inferior: A line drawn perpendicularly from the nipple to the back, just anterior to the mid-axillary line. In critical situations, a finger thoracostomy can be done in the same location. Nasal Oxygen for support. Intercostal Tube Placement (ICT) once stable and confirmed by chest X-ray. Additional Care Antibiotics and analgesics for treatment. Ventilator Support with IPPV in severe cases. Order an urgent chest X-ray to confirm the diagnosis (Option A): While a chest X-ray can confirm the diagnosis of tension pneumothorax, it should not delay immediate treatment. Tension pneumothorax is a clinical

diagnosis and requires urgent intervention without waiting for imaging confirmation. Insert a chest tube into the 5th intercostal space in the anterior axillary line (Option C): Chest tube insertion is an important step after initial decompression but is not the first intervention. Needle thoracocentesis is performed first to immediately relieve the pressure. Perform a finger thoracostomy in the safe triangle (Option D): A finger thoracostomy may be performed in extreme situations where other methods are not feasible or in a pre-hospital setting, but needle thoracocentesis is typically the preferred method in an emergency department setting.

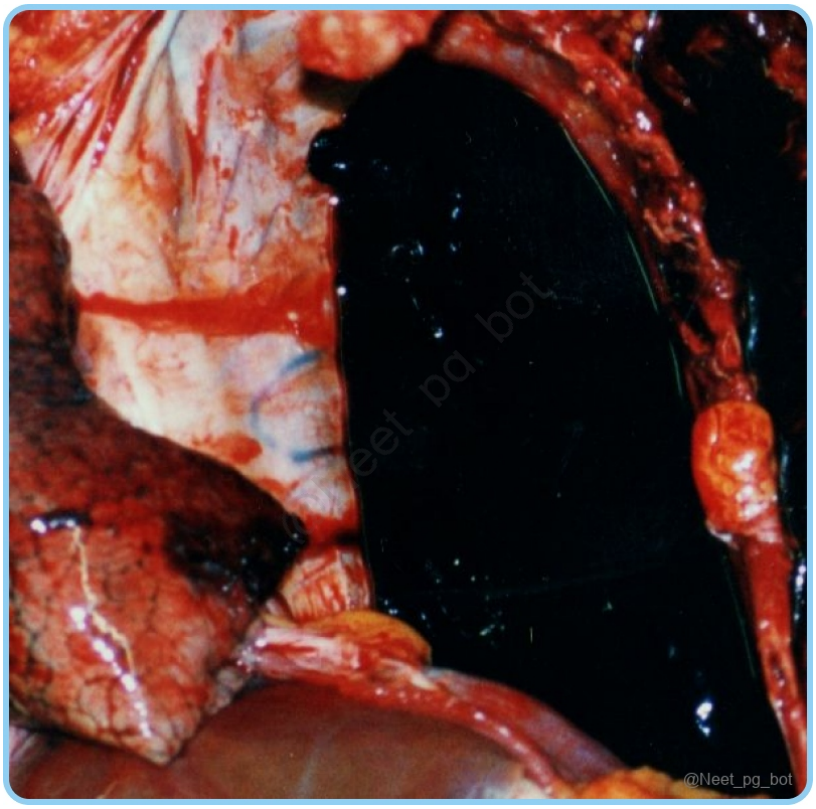
@Neet_pg_bot

Q27: A 70 y/o woman with lung cancer presents with sudden severe chest pain and shortness of breath, 3 weeks post-lobectomy. She is pale, tachypneic, with BP 85/50 mmHg and HR 120 bpm. Examination reveals right-sided dullness and diminished breath sounds. A CXR shows a large pleural effusion, and thoracentesis drains 1000ml of blood. What is the most appropriate next step in management? (Q849481)

A. Observation and follow-up with chest X-ray

B. Administration of antibiotics and bronchodilators only

C. Thoracotomy with evacuation and lung decortication



D. Intercostal chest tube (ICT) placement

Correct Answer: D. Intercostal chest tube (ICT) placement

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Given the significant blood in the pleural cavity (hemothorax) and the patient's hemodynamic instability, ICT placement is necessary to evacuate the blood, relieve pressure on the lung, and stabilize the patient before considering further surgical intervention if needed. HEMOTHORAX Definition The presence of blood in the pleural cavity, causes irritation, pain, and potential shock. Causes Trauma (e.g., rib fractures) Postoperative complications (e.g., lung, cardiac, esophageal surgeries) Tumours (lung, mediastinum, pleura) Leaking aneurysms Clinical Features Chest pain and tenderness Dyspnea Dullness on percussion Diminished breath sounds Signs of shock Investigations Chest X-ray Aspiration (pleural tap) Chest CT scan Treatment Intercostal chest tube (ICT) placement in the mid-axillary line in the 5th intercostal space. Antibiotics and bronchodilators Thoracotomy if persistent or large blood loss Criteria for Thoracotomy: >1.5 L blood lost in last 1 hour (or) >200cc/hour over next 2-4 hours Complications Infection and empyema Acute respiratory distress syndrome (ARDS) Observation and follow-up with chest X-ray (Option A): Observation is inappropriate in this case due to the large blood volume in the pleural cavity and the patient's hemodynamic instability. Immediate intervention is required to address the underlying issue. Administration of antibiotics and bronchodilators only (Option B): While antibiotics and bronchodilators may be necessary adjuncts to prevent infection and improve lung function, they are not sufficient for the initial management of a large hemothorax. Thoracotomy with evacuation and lung decortication (Option C): Thoracotomy is usually reserved for cases where there is initial chest tube output of 1500 ml of blood or persistent bleeding (over 200-300 mL/hr) or clotted hemothorax that cannot be managed with chest tube drainage alone. Although this might be considered later, the initial step should be ICT placement.

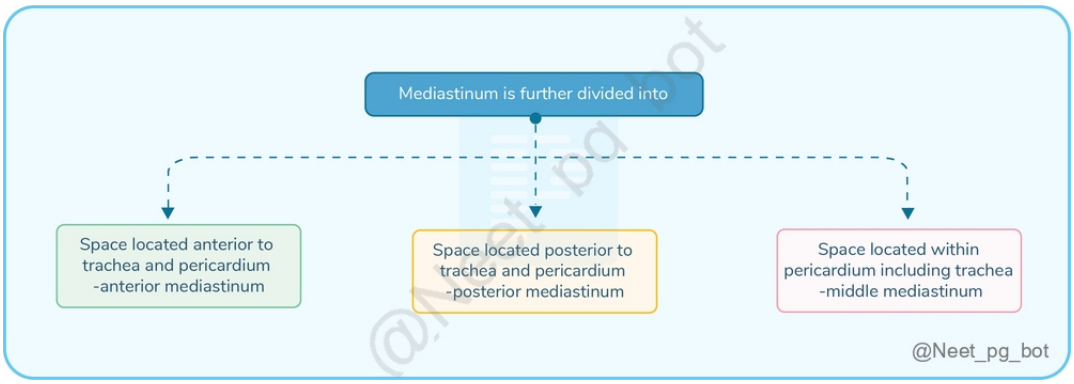
@Neet_pg_bot

Q28: Which of the following is least likely to be found in the posterior mediastinum? (Q849462)

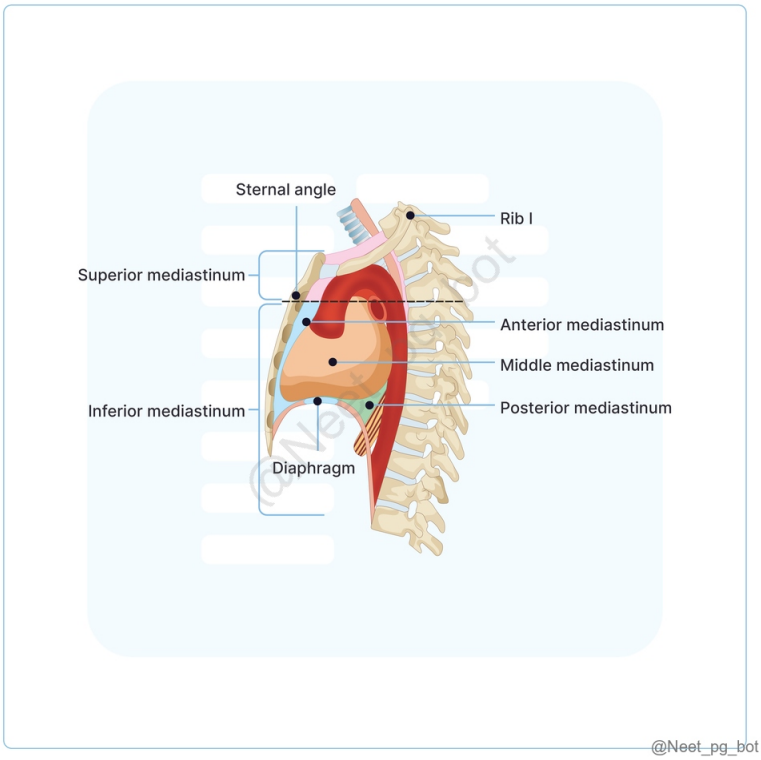
A. Neurofibroma

B. Thymoma

C. Ganglioneuroma



D. Aneurysm of descending aorta



Correct Answer: B. Thymoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Thymomas are primarily located in the anterior mediastinum , making them unlikely to be found in the posterior mediastinum. Neurofibroma (Option A) is the most common type of neurogenic tumor in the posterior mediastinum, accounting for a significant percentage of cases. Ganglioneuroma (Option C) is a neurogenic tumor typically found in the posterior mediastinum. Aneurysm of descending aorta (Option D): This vascular mass can be found in the posterior mediastinum, where the descending aorta is located. Tumors of mediastinum Anterior mediastinum Middle mediastinum Posterior mediastinum Thymomas Thymic carcinomas Thymic cyst Germ cell tumors Lymphomas Parathyroid adenomas Carcinoid tumor Fibroma Lymphomas Tumors of the heart and great vessels Tumors of the trachea, mainstem bronchi, and oesophagus Aortic pathologies such as aortic aneurysm, abscess, or dissection. Pericardial cysts Bronchogenic cysts Neuroenteric cyst Mesothelial cyst Pheochromocytoma Neurilemomas (schwannomas) Neurofibromas Ganglioneuromas Ganglioneuroblastomas Neuroblastomas Pheochromocytomas The mediastinum is the central area within the chest, between the thoracic inlet superiorly and the diaphragm inferiorly. Laterally, it is bordered by the parietal pleura, while the sternum marks its anterior boundary and the vertebral column is its posterior limit.

@Neet_pg_bot

Q29: A 45 y/o male presents with chest pain and dyspnea one week after undergoing oesophagal surgery. A pleural tap reveals milky white fluid with high triglyceride levels. Which of the following is the most appropriate next step in the management of this patient? (Q849493)

A. Oral antibiotics

B. Thoracic duct ligation via thoracoscopy

C. Oral diet with medium-chain triglycerides

D. Immediate pleurodesis with talc

Correct Answer: C. Oral diet with medium-chain triglycerides

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Oral diet with medium-chain triglycerides (option C) is the appropriate first-line management for postoperative chylothorax . MCTs are absorbed directly into the portal venous system, bypassing the lymphatic channels, and thus reduce the chyle leak. Initial conservative treatment includes: MCT-based oral diet or NPO with TPN Chest tube drainage Somatostatin or octreotide Monitoring of output volume Management of chylothorax: Initial Treatment: Intercostal tube (ICT) drainage, oral diet with medium-chain triglycerides, and total parenteral nutrition (TPN) to bypass the lymphatic system. Done before surgical repair via thoracoscopy Antibiotics: Administered to treat the underlying cause. Oral antibiotics (Option A): is incorrect because there is no evidence of infection or empyema. Antibiotics are not routinely used in sterile chylous effusion. Thoracic duct ligation via thoracoscopy (Option B): is incorrect at this stage. It is a second-line intervention , reserved for persistent high-output leaks (>1,000 mL/day for 5–7 days) or failure of conservative treatment. Immediate pleurodesis with talc (Option D): is incorrect because pleurodesis is considered only in refractory or inoperable cases , not as a first-line treatment.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q30: A 35 y/o male presents with milky urine and abdominal pain after a fatty meal. He reports weight loss and frequent urinary infections. Urinalysis shows chyluria. What is the most likely underlying cause of chyluria in this patient? (Q849494)

A. Renal stone disease

B. Filarial infection

C. Tuberculosis

D. Diabetes mellitus

Correct Answer: B. Filarial infection

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Filarial infection is the most common cause of chyluria, as it can obstruct intestinal lymphatics, leading to lymph leakage into the urine. Chyluria Passage of milky white chylous urine, aggravated after fatty meals. Causes: Most Common: Filarial infections (2% of cases). Other Causes: Tumors, tuberculosis, malaria, and ascariasis infestation. Mechanism: Obstruction of intestinal lymphatic vessels leads to high lymphatic pressure, causing lymph to enter the renal lymphatics, or rupture of intestinal lymphatics into the renal pelvis/ureter, forming a lympho-urinary fistula. Clinical Features: Symptoms mimic bacterial or tuberculous pyuria and may include urinary infections and protein loss. Possible presentation of colic due to lymph clots in the urinary system. Diagnostic Tools: Urine study, culture, intravenous urogram (IVU), lymphangiography, and abdominal ultrasound. Management: Dietary changes (low-fat, protein-rich diet). Antibiotics and diethylcarbamazine (DEC). Increase oral fluid intake. Surgical options include ligation of dilated lymphatics or sclerosing lymph vessels. Renal stone disease (Option A): While renal stones can cause urinary symptoms, they do not typically lead to chyluria or milky white urine. Tuberculosis (Option C): Although tuberculosis can cause urinary symptoms, it is not the most common cause of chyluria compared to filarial infections & also the history is not pointing towards TB. Diabetes mellitus (Option D) can lead to various urinary symptoms but is not associated with the development of chyluria.

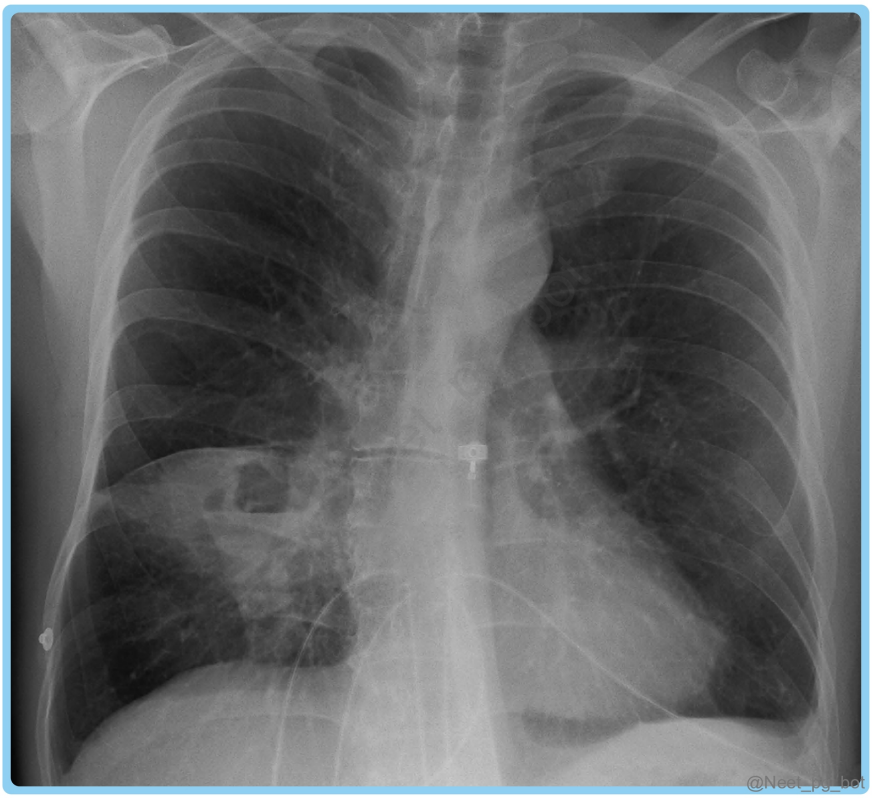
↑ *Back to this question in Part A*

@Neet_pg_bot



Q31: A 60 y/o male presents with fever, cough, and foul-smelling sputum. A chest X-ray reveals a localized opacity in the apical lower lobe. Sputum culture shows the presence of anaerobic bacteria. Which of the following is the most likely cause? (Q849495)

A. Aspiration of oropharyngeal secretions

B. Hematogenous spread from endocarditis

C. Direct extension from pneumonia

D. Bronchial obstruction due to lung cancer

Correct Answer: A. Aspiration of oropharyngeal secretions

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The X-ray shows a lung abscess. Aspiration is the most common cause of lung abscesses , particularly in the apical lower lobe, and is frequently associated with anaerobic bacteria from the oral cavity. Lung Abscess Localized suppuration in the lung is characterized by tissue necrosis Aetiology: Infectious: Pneumonia due to Streptococcus, Pneumococcus, Haemophilus, Staphylococcus, anaerobic bacteria, etc. Chronic upper respiratory infections (e.g., sinusitis, tonsillitis, dental infections). Mechanical: Bronchial obstruction due to tumours or foreign bodies. Other Causes: Septicaemia and aspiration, commonly lead to lung abscess in the apical lower lobe. Sites of Infection: Apical Lower Lobe: Most frequently involved in aspiration-related lung abscesses. Posterior Segments: Can be affected due to gravity when aspiration occurs. Upper Lobes: May be involved in cases of tuberculosis or certain types of pneumonia. Routes of Infection: Aspiration: Inhalation of oropharyngeal or gastrointestinal secretions, often leading to anaerobic infections from the oral cavity. Hematogenous Spread: From e.g., endocarditis or septicemia Direct Extension: Localized infections in adjacent structures (e.g., pneumonia, empyema) can extend into lung tissue. Hematogenous spread from endocarditis (Option B) : While it can cause lung abscesses, it is less common than aspiration in the context of anaerobic infections and would typically present with multiple abscesses rather than a localized opacity. Direct extension from pneumonia (Option C) can cause lung abscesses, but in this case, the specific presence of anaerobic bacteria and the apical location suggest aspiration as the more likely cause. Bronchial obstruction due to lung cancer (Option D) is a possible

cause of infection and abscess formation, but the presence of anaerobic bacteria and the patient's age make aspiration a more plausible cause, especially in the context of a localized opacity in the lung.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q32: A 58 y/o male with a history of chronic kidney disease presents to the clinic with shortness of breath and chest discomfort. A chest X-ray shows a pleural effusion on the right side. Analysis of the pleural fluid reveals the following: Pleural fluid protein to serum protein ratio: 0.7 Pleural fluid lactate dehydrogenase (LDH) to serum LDH ratio: 0.65 Pleural fluid LDH level: 300 U/L (serum LDH upper limit of normal is 200 U/L) Based on these findings and Light’s criteria, which of the following is the most likely cause of this patient's pleural effusion? (Q849496)

A. Congestive heart failure

B. Lung cancer

C. Nephrotic syndrome

D. Cirrhosis

Correct Answer: B. Lung cancer

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The high protein and LDH ratios, along with the elevated LDH level, are consistent with a pleural effusion due to exudative cause. Lung cancer is a common cause of exudative pleural effusions, which meet Light’s criteria for exudates. Transudative effusions result from an imbalance in hydrostatic or oncotic pressure, leading to protein-poor, clear or straw-coloured fluid. Exudative effusions stem from inflammation or increased capillary permeability, producing protein-rich, often turbid, bloody, or purulent fluid. Light's criteria for exudative effusions Pleural fluid protein to serum protein ratio > 0.5 Pleural fluid LDH to serum LDH ratio > 0.6 Pleural fluid LDH level > 2/3 of the upper limit of normal for serum LDH Causes of Pleural Effusion Transudative Exudative Congestive heart failure Cirrhosis Nephrotic syndrome Superior vena cava obstruction Pulmonary embolism Sarcoidosis Hypoalbuminemia Fluid retention/overload Lobar collapse Meigs syndrome Malignant: Lung cancer Lymphoma Mesothelioma Metastatic cancers Infectious: Bacterial pneumonia/empyema

Tuberculosis Fungal infections Viral infections Parasitic infections Collagen Vascular Disease-related: Rheumatoid arthritis Wegener granulomatosis Systemic lupus erythematosus Churg-Strauss syndrome Abdominal/Gastrointestinal disease-related: Esophageal perforation Subphrenic abscess Pancreatitis/pancreatic pseudocyst Meigs syndrome Other Causes: Pulmonary embolism with infarction Coronary artery bypass grafting Radiation/trauma Dressler syndrome Asbestosis After lung transplantation After bone marrow transplantation Drug-induced Uremia Congestive heart failure (Option A): Typically associated with transudative effusions, which are low in protein and LDH. This patient's pleural fluid analysis suggests an exudative effusion, making this option less likely. Nephrotic syndrome (Option C): Usually causes transudative effusions due to low protein levels. This effusion has a higher protein content, making this option unlikely. Cirrhosis (Option D): Also commonly leads to transudative effusions due to low oncotic pressure from hypoalbuminemia. The characteristics of this effusion align more with an exudative process.

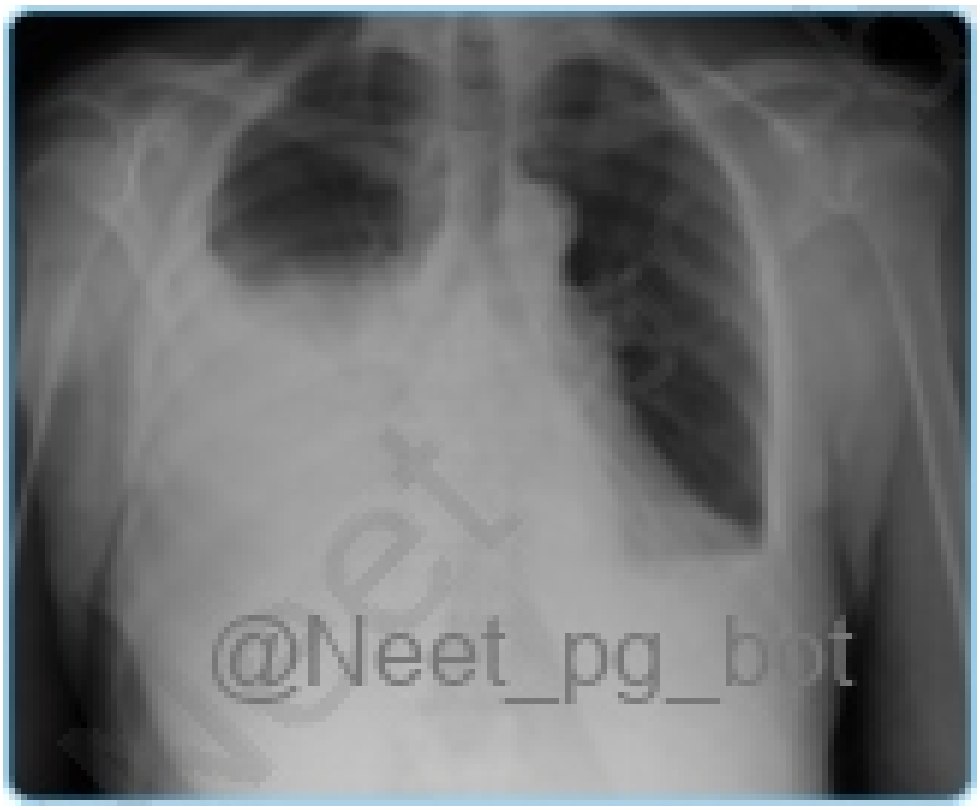
Schwartz's Principles of Surgery, 11th Edition, Pg.738,739

↑ *Back to this question in Part A*

@Neet_pg_bot

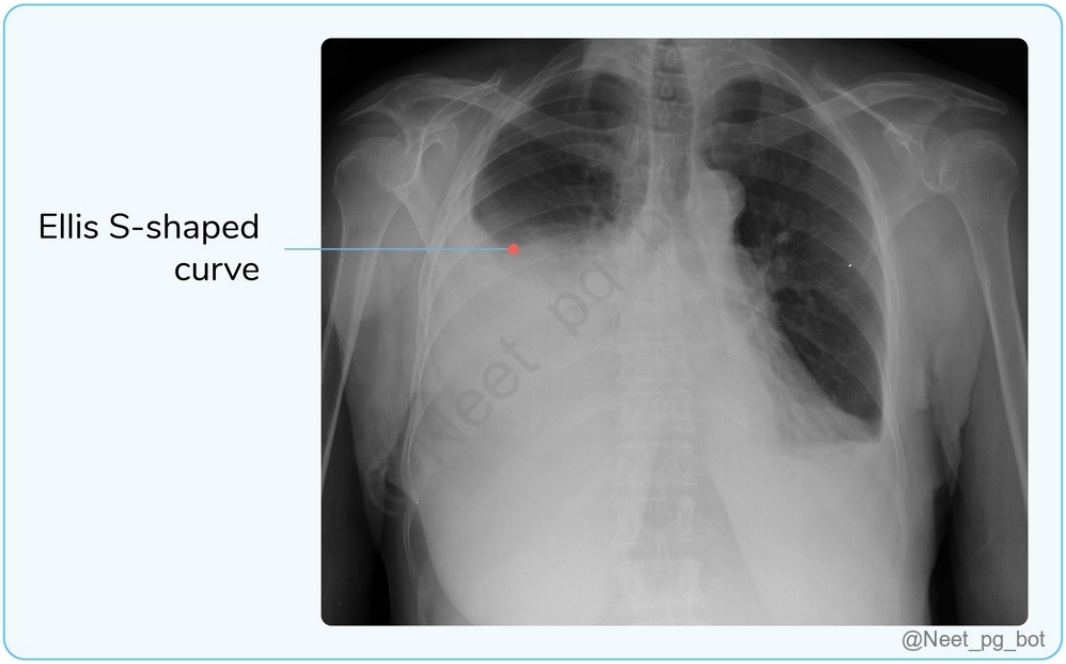


Q33: A 72 y/o male with h/o COPD presents with progressive shortness of breath and chest pain. The chest X-ray findings are shown below. Thoracentesis is performed, and analysis of the pleural fluid reveals high protein & LDH levels. Which of the following is the next best step in managing this patient? (Q849497)

A. Initiate diuretic therapy

B. Perform a pleural biopsy

C. Insert a chest tube for drainage



D. Administer antibiotics

Correct Answer: C. Insert a chest tube for drainage

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The Chest X-ray shows massive amounts of fluid in the right lung and a characteristic Ellis S-shaped curve. Based on investigatory findings & the Light's criteria, this patient is having exudative pleural effusion. Inserting a chest tube is the most appropriate next step for this patient, as it directly addresses the symptoms of dyspnea and chest pain by removing the excess fluid. The high protein content and elevated LDH levels indicate an exudative effusion, likely caused by inflammation or malignancy, which needs to be drained. The Ellis S-shaped curve on the chest X-ray further supports the presence of a large effusion that is causing significant lung compression. By draining the fluid, the patient's respiratory symptoms can be alleviated, and further diagnostic testing can be performed if needed. Initiate diuretic therapy (Option A): Diuretics are typically used to manage pleural effusions associated with heart failure or fluid overload. However, given the evidence of a large effusion and the elevated protein and LDH levels, indicating an exudative process, diuretics alone would not be sufficient. Perform a pleural biopsy (Option B): Although a pleural biopsy might be indicated if malignancy is suspected, the immediate concern is to relieve the patient's symptoms by draining the effusion. A biopsy can be considered later if needed. Administer antibiotics (Option D): Antibiotics are necessary if there is evidence of an infectious process, such as pneumonia. However, there is no indication of infection, making antibiotics an inappropriate first step.

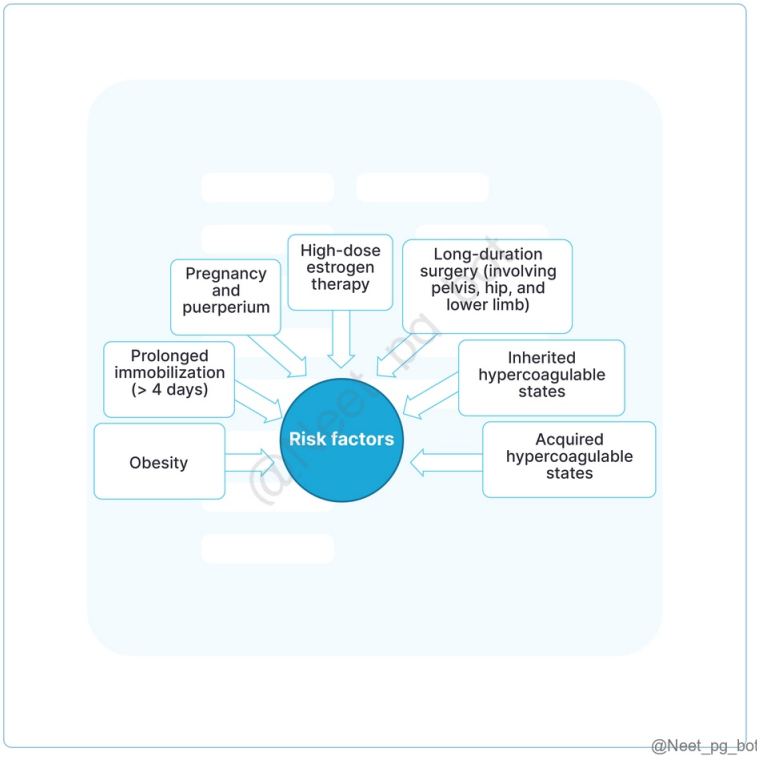
@Neet_pg_bot

Q34: A 50 y/o male patient has been hospitalized following a hip replacement surgery for the past 6 days. He has a history of obesity and smoking. On the sixth day, he suddenly develops shortness of breath, and chest pain, and coughs up blood. Which of the following is the most likely contributing factor to his current condition? (Q849518)

A. Prolonged immobility

B. Dehydration

C. High blood pressure



D. Recent blood transfusion

Correct Answer: A. Prolonged immobility

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's prolonged bed rest following hip replacement surgery is the most likely contributing factor to his condition. The patient’s symptoms of sudden dyspnea, chest pain & hemoptysis following prolonged immobilization give rise to the suspicion of a pulmonary embolism. Immobility → DVT → Pulmonary embolism → Clot lodges in pulmonary artery & blocks blood flow to a portion of the lung → Dyspnea & chest pain. Risk factors (for PE): Dehydration (Option B): While dehydration could potentially contribute to clot formation, the primary risk factor in this scenario is the prolonged immobility associated with postoperative bed rest, making it a more significant factor for developing a pulmonary embolism. High blood pressure (Option C) is not directly associated with an increased risk of pulmonary embolism. The patient’s symptoms and recent surgery-related immobility are more indicative of a thromboembolic event rather than issues related to hypertension. Recent blood transfusion (Option D): Although blood transfusions can have various complications, they are not commonly associated with an increased risk of pulmonary embolism. The key risk factor here is the patient’s prolonged immobility after hip surgery.

Sabiston Textbook of Surgery, 21st edition, Pg.1827

↑ *Back to this question in Part A*

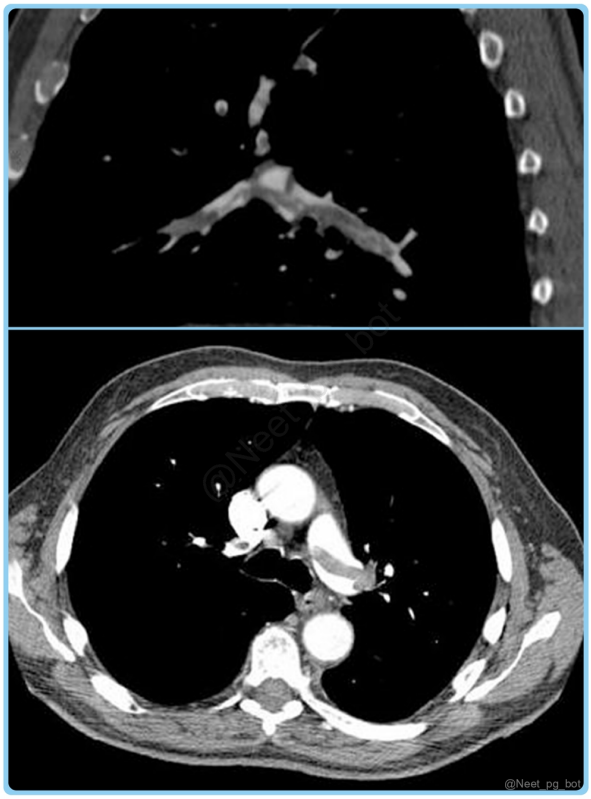
@Neet_pg_bot

Q35: Which of the following is the most commonly used gold standard investigation for diagnosing pulmonary embolism in a clinical setting? (Q849519)

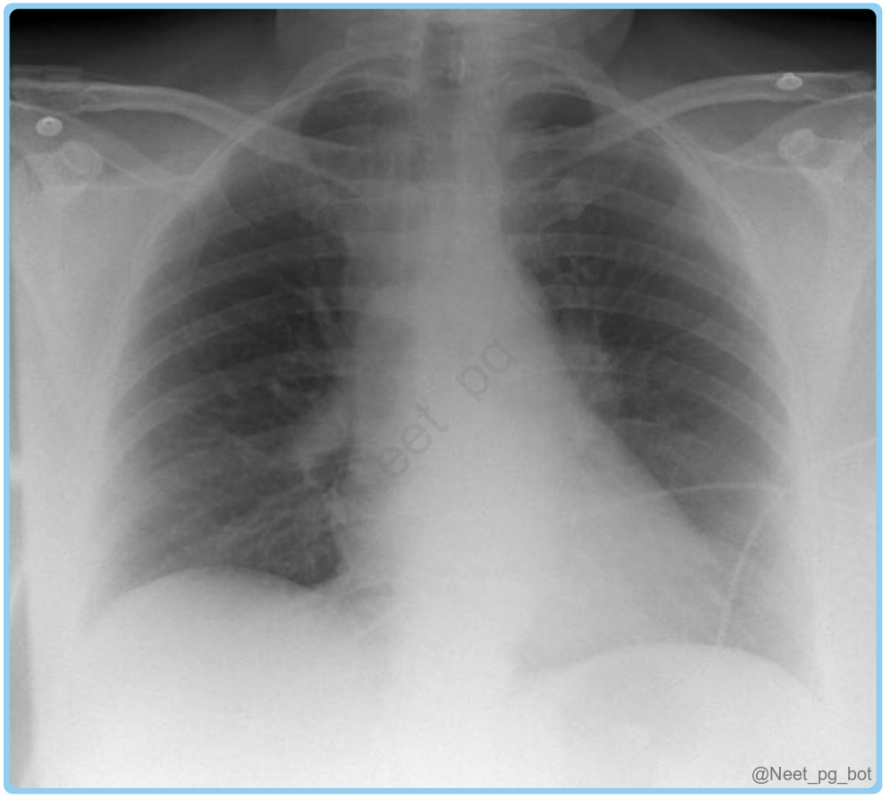
A. Doppler Ultrasound

B. Chest X-ray

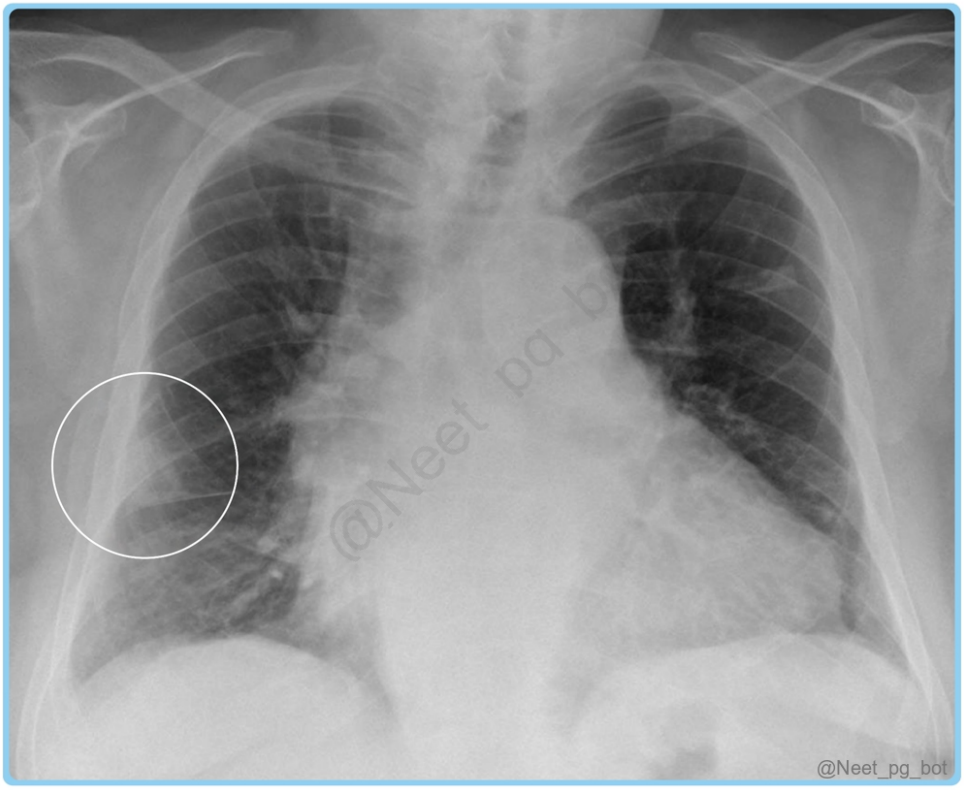
C. Ventilation-Perfusion (V/Q) Lung Scan



D. CT Pulmonary Angiography (CTPA)



Correct Answer: D. CT Pulmonary Angiography (CTPA)



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: CTPA is widely accepted as the gold standard investigation for diagnosing pulmonary embolism due to its high accuracy, speed, and ability to provide comprehensive diagnostic information. It is the preferred test in most clinical scenarios when PE is suspected. Investigations: Multidetector CT (MDCT): Investigation of choice (best investigation) CTPA (CT pulmonary angiography): Gold standard CT pulmonary angiography shows the presence of a saddle embolus and substantial thrombus burden in the lobar branches of both main pulmonary arteries. ECG findings: Sinus tachycardia (Most specific finding) S1Q3T3 (most specific finding) Doppler Ultrasound (Option A) is primarily used to assess the risk of PE by looking for DVT in the legs but does not serve as a direct diagnostic tool for PE. Therefore, it is not considered the gold standard for diagnosing pulmonary embolism. Chest X-ray (Option B): While useful for ruling out other conditions, a chest X-ray cannot directly identify a pulmonary embolism. Findings suggestive of PE, such as the Westermark sign or Hampton's hump, are rare and not always conclusive. The Westermark sign is characterized by a focal area of hyperlucency on chest radiographs, caused by oligemia distal to a pulmonary artery obstruction, often indicating a pulmonary embolism. Hampton’s hump is seen as a wedge-shaped opacity on the radiograph, typically located at the lung periphery, suggesting pulmonary infarction. Ventilation-Perfusion (V/Q) Lung Scan (Option C): Despite being a valuable diagnostic tool, the V/Q scan is less specific and sensitive compared to CT pulmonary angiography. Its results often need confirmation by additional testing. Modified Well’s Criteria It is a scoring system to determine the likelihood of PE and thromboembolic events. Features Score Symptoms and signs of DVT 3 PE more likely than an alternate diagnosis 3 Heart rate >100 bpm 1.5 Recent immobilization or surgery (<4 weeks) 1.5 Previous PE or DVT 1.5 Hemoptysis 1 Active Cancer 1 Score: >4 - PE likely ; </= 4 - PE unlikely

Q1: In a 35-year-old individual with a history of chronic smoking who is experiencing bluish discoloration of the toes and intermittent claudication, what would be the most suitable investigation to conduct next? (Q856763)

A. CT Angiography

B. MR Angiography

C. Digital subtraction angiography

D. Duplex scan

Correct Answer: D. Duplex scan

Explanation: The most appropriate investigation to confirm the diagnosis and assess the severity of the arterial occlusion in the lower limbs is a Duplex scan. The given case with chronic smoking, bluish toes, and intermittent claudication is suggestive of peripheral arterial disease (PAD), commonly linked to atherosclerosis in smokers. Duplex Doppler ultrasound (DUS) combines B-mode ultrasound for imaging vessels and Doppler ultrasound to assess blood flow, providing an accurate, cost-effective, and non-invasive alternative to angiography for detecting vascular issues. It is useful for initial evaluation but may have limitations in visualising deeper arteries. CT Angiography (Option A) is considered more specific and detailed imaging, and it's not the first-line investigation for peripheral arterial disease (PAD). It is usually considered when other non-invasive tests (like duplex scans) are inconclusive or when a more detailed assessment is required. MR Angiography (Option B) is similar to CT

angiography, which provides detailed vascular imaging but is not the initial choice. It's generally used when other methods are not feasible or are contraindicated. Digital subtraction angiography (Option C) is an invasive procedure that involves the injection of contrast dye into the blood vessels followed by X-ray imaging. It is generally reserved for cases where other imaging modalities have not provided sufficient information or when endovascular intervention (such as angioplasty) is planned.

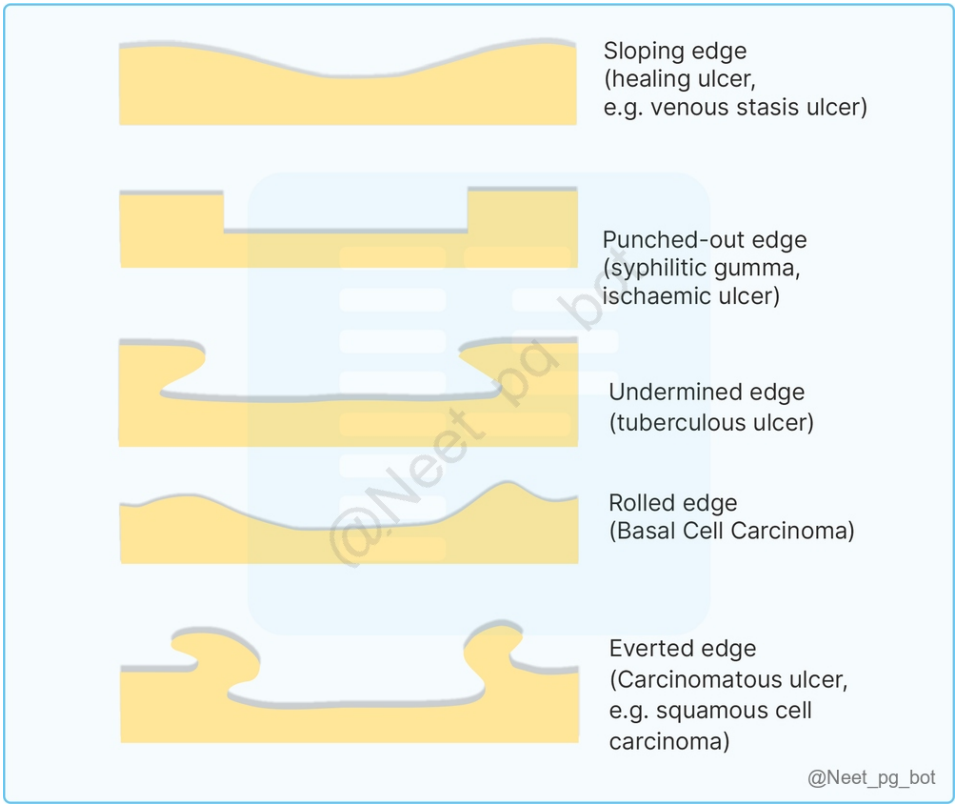
@Neet_pg_bot

Q2: Identify the type of ulcer? (Q866906)

A. Arterial Ulcer

B. Venous ulcer



C. Diabetic ulcer

D. Neuropathic

Correct Answer: B. Venous ulcer

Explanation: An ulcer in the gaiter area (medial aspect of the lower leg, above the ankle) is most commonly due to chronic venous insufficiency . These ulcers are typically shallow, have irregular margins, and are associated with skin changes like hyperpigmentation, lipodermatosclerosis, and edema. The type of ulcer edges seen in various clinical conditions is listed in the table below: Type of edges Clinical conditions Details Sloping edge Healing ulcer Varicose ulcer Inner part: Red (healthy granulation tissue) Middle part: Blue (epithelial proliferation) Outer part: White (scar/fibrous tissue) Undermined edge Tubercular ulcers Disease process advances in the deeper plane (subcutaneous tissue) whereas (skin) epidermis proliferates inwards Punched out edge Arterial / Ischemic ulcers Gummatous (syphilitic) ulcer Trophic ulcer Due to endarteritis Raised and beaded edge Rolled out / Pearly white edge Rodent ulcer- Basal cell carcinoma Beads are due to proliferating active cells Pearly white in appearance Everted edge / Rolled out edge Squamous cell carcinoma Due to the spill of proliferating malignant tissue over the normal skin Arterial ulcer (Option A): Usually found on toes, dorsum of foot, or pressure points; have “punched-out” edges, very painful, and are associated with diminished pulses. Diabetic ulcer (Option C): Typically over pressure points of the foot (metatarsal heads, heel) due to neuropathy; often painless. Neuropathic ulcer (Option D): Similar to diabetic ulcers but specifically due to peripheral neuropathy from any cause; usually over pressure-bearing areas.

@Neet_pg_bot

Q3: A 50-year-old diabetic man presents with a progressive increase in pain in his calf. He now prefers to sleep in a seated position by hanging his leg to alleviate pain.Pain is more in the distal part like toes and feet. It gets aggravated with movements and pressure. The pain is increased in lying down and elevation of foot; it may be reduced on hanging the foot down. Which of the following is the most likely cause? (Q793482)

A. Rest pain

B. Sciatica

C. Neurological claudication

D. Venous claudication

Correct Answer: A. Rest pain

Explanation: Correct option : Option a: The most likely cause of the patient's symptoms, based on the provided information, is rest pain. Rest pain It is continuous aching in calf or feet and toes or in the region even at rest depending on site of obstruction. It is a ‘ cry of dying nerves’ due to ischemia of the somatic nerves. It signifies severe decompensated ischemia. Pain gets aggravated by elevation and is relieved in dependent position of the limb Pain is more in the distal part like toes and feet. It gets aggravated with movements and pressure. Rest pain is increased in lying down and elevation of foot; it may be reduced on hanging the foot down. Incorrect Choices: Option b: Sciatica is a condition that causes pain, numbness, or weakness in the lower back, buttocks, and legs due to compression or irritation of the sciatic nerve. However, the patient's symptoms of worsening pain with walking and relief by hanging the leg are inconsistent with sciatica. Option c: Neurogenic claudication is another possible cause of the patient's symptoms, which occurs due to spinal stenosis or nerve root compression, causing pain, numbness, and weakness in the lower back, buttocks, and legs. However, the patient's symptoms of worsening pain with walking and relief by hanging the leg are not typical of neurogenic claudication. Option d: Venous claudication is caused by chronic venous insufficiency, leading to decreased blood flow and oxygen supply to the affected tissues. However, the patient's symptoms of worsening pain with walking and relief by hanging the leg are not typical of venous claudication.

@Neet_pg_bot

Q4: Which of the following findings is likely to be seen in this patient? (Q855695)

A. Decreased posterior tibial & dorasalis pedis pulsations

B. Loss of sensation over the foot

C. Positive tredelenberg sign

D. Pain on compression of the calf

Correct Answer: B. Loss of sensation over the foot

Explanation: The given image depicts a neurotrophic (diabetic) ulcer, where the loss of sensation in the foot is typically observed. Clinical features of different ulcers are as follows: Venous ulcer Arterial ulcer Neurotrophic ulcer Pressure ulcer Site Gaiter's area (area between malleolus and calf) At distal ends of limbs, such as toes, feet and legs. Over toe joints, under the heel, over malleoli, under the metatarsal head, etc Seen over pressure points, most common are ischium, greater trochanter, sacrum, hee, malleolus, occiput, etc Appearance Vertically oval with a sloping edge and will not penetrate deep fascia. Punched-out edges are seen in this type of ulcer. Ulcers can be associated with gangrene and abscesses; osteomyelitis can be seen here. Punched out ulcer with bone as a base. Cause Caused by ambulatory chronic venous hypertension due to varicose veins. This occurs due to severe arterial insufficiency of digital and medium-sized arteries, leading to ischemia and tissue death in the region. It is caused due to repeated trauma and ischemia due to microangiopathy in diabetic patients . It is tissue necrosis and ulceration due to prolonged pressure on any part of the body. Characteristics It is initially painful, then chronically becomes painless. It heals on rest and treatment but reforms again. It is intensely painful, and distal pulses are not palpable, and associated with shiny skin, brittle nails and loss of hair over the region. Numbness Paresthesias Burning or loss of sensation in the foot Diabetes mellitus (also known as diabetic ulcer) It is common in bedridden patients with head injuries, neurological deficits, and comatose and stroke-ridden patients. Decreased posterior tibial & dorsalis pedis pulsations (Option A) suggest a vascular problem, such as peripheral artery disease, which affects blood flow to the feet. Neurotrophic ulcers are caused by nerve damage, not vascular issues. Positive Trendelenburg sign (Option C) is a sign of hip or pelvic injury, indicating weakness in the gluteus medius muscle. It is unrelated to neurotrophic ulcers, which affect the feet due to nerve damage. Pain on compression of cthe alf (Option D) is typically associated with compartment syndrome or deep vein thrombosis (DVT), which involves swelling or clot formation in the legs. Neurotrophic ulcers are linked to sensory loss from nerve damage, not pain from calf compression.

@Neet_pg_bot

Q5: A 32-year-old male chronic smoker presents with pain in the fingers for a few months. On examination, gangrenous ulcers were present in the fingers, as shown below. Investigation showed blood glucose and lipid profile within normal limits. Which of the following is the most likely diagnosis? (Q857126)

A. Buerger's disease

B. Diabetic ulcers

C. Acute paronychia

D. Raynaud's phenomenon

Correct Answer: A. Buerger’s disease

Explanation: Buerger’s Disease (Thromboangitis Obliterans) Feature Details Definition Non-atherosclerotic, segmental inflammatory vasculitis affecting small & medium-sized arteries and veins. Etiology Strong association with tobacco use (smoking or chewing). Exact cause unknown (likely immune-mediated). Epidemiology Young males (20–45 years), most commonly smokers. More common in Middle East, South Asia. Pathophysiology Inflammation leads to thrombosis and vascular occlusion. Sparing of proximal arteries (unlike atherosclerosis). Segmental involvement (skip lesions). Clinical Features Claudication, rest pain (foot, hands). Raynaud’s phenomenon (vasospasm causing colour changes in fingers/toes). Ulcers & gangrene (especially in fingers/toes). Migratory superficial thrombophlebitis (inflamed veins). Diagnosis Clinical diagnosis (no specific lab tests). Doppler & Angiography → Corkscrew collateral vessels (pathognomonic). Exclusion of other causes (diabetes, atherosclerosis, vasculitis). Management Complete smoking cessation (most important). Vasodilators (e.g., calcium channel blockers for Raynaud’s). Antiplatelets & anticoagulants (limited benefit). Pain management (NSAIDs, opioids if needed). Amputation (for non-healing ulcers or gangrene). Prognosis Poor if smoking continues but stabilises with smoking cessation. Diabetic ulcers (Option B) Occurs more commonly among patients(both males and females) with diabetes. It is seen more commonly in the foot. Acute paronychia (Option C) This is the most common infection of the hand. It is often caused by careless nail trimming or picking the skin around the nail fold. The pus is trapped beside the nail. Raynaud’s phenomenon (Option D) This phenomenon causes the blood vessels in the extremities to narrow, and it restricts the blood flow. This usually affects the fingers and toes.

@Neet_pg_bot

Q6: What is the probable medical condition for an 80-year-old male who experienced pain and swelling in the calf muscle on the right side after being immobilized due to a fracture in the right inter-trochanteric region? (Q857130)

A. Chronic osteomyelitis

B. Deep vein thrombosis

C. Compartment syndrome

D. Arterial claudication

Correct Answer: B. Deep vein thrombosis

Explanation: The scenario of a patient being immobilised and exhibiting symptoms such as calf swelling and pain strongly indicate the likelihood of DVT. Deep vein thrombosis (DVT) occurs when a blood clot forms in a deep vein, typically in the lower leg, thigh, or pelvis. Symptoms may include pain, swelling, and tenderness in the calf or thigh, along with warm and red skin. Virchow's Triad components - endothelial injury, stasis, and hypercoagulable state - increase the risk of DVT. Chronic osteomyelitis (Option A) The intraosseous blood vessels thrombose, and bone infarcts. Pus lifts the periosteum. To treat osteomyelitis, all dead tissue needs to be removed. If a fracture exists, it needs to be stabilized. Compartment syndrome (Option C) A compartment syndrome develops at any time during the first 48 hours after the accident or surgery. The patient usually complains of severe pain with some numbness in the foot. The foot may be cold still with pulses. Arterial claudication (Option D) Claudication is usually a symptom of peripheral artery disease, in which the arteries that supply blood, usually the legs, are narrowed.

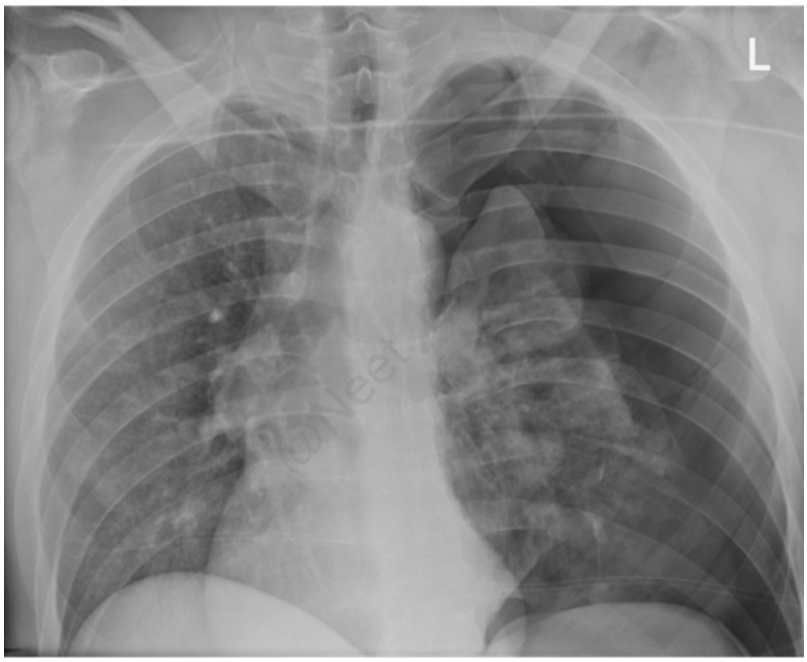
↑ *Back to this question in Part A*

@Neet_pg_bot



Q7: A 25-year-old male patient involved in a road traffic accident was managed upon arrival at the emergency room, with a respiratory rate of 25 breaths per minute and a blood pressure of 80/45mmHg, and exhibiting hyper-resonance on the left side of the chest, what is the appropriate action based on the findings from the chest x-ray? (Q857456)

A. Wide bore needle insertion in the 2nd ICS

B. Wide bore needle insertion in the 5th ICS followed by an intercostal drain in the 5th ICS

C. Aspiration of the pleural fluid

D. No intervention needed

@Neet_pg_bot

Correct Answer: B. Wide bore needle insertion in the 5th ICS followed by an intercostal drain in the 5th ICS

Explanation: The patient shows signs of tension pneumothorax: hypotension, tachypnea, and unilateral hyper-resonance. Immediate decompression is required in adults at the 5th ICS, anterior axillary line. This is followed by definitive intercostal chest drain (ICD) insertion in the triangle of safety. Delay in intervention can lead to cardiovascular collapse and death. Incorrect Options: Option A) Widebore needle in 2nd ICS: Traditional site; less preferred in adults due to higher failure rates. Option C) Aspiration of pleural fluid: Used for simple pleural effusion, not tension pneumothorax. Option D) No intervention: Incorrect; patient is hemodynamically unstable and requires urgent decompression.

Bailey and Love Short Practice of Surgery, 28th Edition, Page 374

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: A patient underwent surgery, for which she was immobilised. Patient started complaining of leg pain on the 5th postoperative day. On examination , Homan’s sign is positive. What is the most probable diagnosis? (Q857539)

A. Deep Venous thrombosis

B. Urinary sepsis

C. Peripheral vascular disease

D. Lymphangitis

Correct Answer: A. Deep Venous thrombosis

Explanation: Based on the information provided, the most probable diagnosis for the patient experiencing leg pain on the 5th postoperative day with a positive Homan's sign is Deep Venous Thrombosis (DVT). Homan's sign refers to calf pain elicited by dorsiflexion of the foot, and it is often associated with DVT. DVT is a condition in which a blood clot forms in a deep vein, commonly in the lower extremities. Immobilization following surgery is a known risk factor for the development of DVT. Other risk factors include a history of DVT, obesity, smoking, and certain medical conditions. Urinary sepsis (Option B) Urinary sepsis typically presents with symptoms such as fever, urinary urgency, and dysuria (painful urination), rather than leg pain. Peripheral vascular disease (Option C) Peripheral vascular disease refers to conditions that affect blood flow to the extremities and may cause pain or cramping during physical activity, but it is less likely to be related to the immobilization following surgery. Lymphangitis (Option D) Lymphangitis refers to the inflammation of lymphatic vessels, which can cause red streaks on the skin and swollen lymph nodes but is less likely to be associated with leg pain in this context. Clinical features of DVT : Clinical Feature Significance Localized tenderness Specific for DVT; indicates inflammation along the vein. Asymmetrical calf swelling Common but not specific to DVT. Erythema and warmth Suggestive of inflammation or thrombosis. Pain in the affected limb Can occur with or without movement; can indicate venous obstruction. Dilated superficial veins May indicate compensatory circulation due to deep venous obstruction. Homans' sign Non-specific; Passive forceful dorsiflexion of the foot with extended knee will cause tenderness in the calf. Mose’s sign Painful response to gentle squeezing of the lower calf from side-to-side. Neuhof's Sign Thickening and deep tenderness in the calf muscles upon palpation. Phlegmasia Alba Dolens DVT of the femoral vein causes painful congestion and edema of the leg with lymphangitis, which further increases edema (white leg). Phlegmasia Caerulea Dolens Extensive DVT in iliac and pelvic veins leading to a blue leg with possible venous gangrene or infarction.

@Neet_pg_bot

Q9: How is empyema thoracis treated? (Q857541)

A. Antibiotics alone

B. Chest tube drainage and antibiotics

C. ICD alone

D. Wait and watch

Correct Answer: B. Chest tube drainage and antibiotics

Explanation: Intercostal Chest Drainage (ICD) + IV Antibiotics is the standard treatment. Chest tube (ICD) removes pus, while broad-spectrum antibiotics (e.g., ceftriaxone + metronidazole or piperacillin-tazobactam) control infection.\ If loculated collections persist, intrapleural fibrinolytics (streptokinase, urokinase) may be needed . Antibiotics alone (Option A) Antibiotics are necessary but not sufficient because pus in the pleural cavity needs mechanical drainage . Without drainage, antibiotics cannot penetrate the thick fibrinous collections , leading to persistent infection. ICD alone (Option C) Drainage without antibiotics will not treat the underlying infection , leading to recurrence and sepsis . Wait and watch (Option D) Empyema needs urgent intervention . Delayed treatment can lead to fibrothorax (thickened pleura), lung entrapment, and sepsis .

@Neet_pg_bot

Q10: A man presented with a history of stab injury to the arm. On examination, there was a hematoma, and radial and ulnar pulses were not felt. A 3.5cm longitudinal tear is noted in the brachial artery. Which among the following is the best treatment option? (Q858346)

A. Primary repair with end-to-end anastomosis

B. Repair with great saphenous vein graft

C. Repair with prosthetic graft

D. Repair with saphenous vein patch

Correct Answer: B. Repair with great saphenous vein graft

Explanation: This patient presents with a severe brachial artery injury, causing the absence of radial and ulnar pulses, indicating compromised blood flow to the arm's distal part. Urgent surgical intervention is crucial to restore blood flow and prevent ischemic complications. Using a great saphenous vein graft from the patient's lower extremity is a suitable option for arterial repair, facilitating reestablishment of blood flow and preservation of distal circulation. Primary repair with end-to-end anastomosis (Option A) Primary repair alone may not be feasible or successful in achieving adequate vessel approximation and blood flow restoration. Repair with prosthetic graft (Option C) . Prosthetic grafts can be used for arterial repairs, they are typically reserved for larger vessels or when autologous vein grafts are not available or suitable. In this case, with a 3.5cm tear in the brachial artery, a prosthetic graft may not be the optimal choice. Repair with saphenous vein patch (Option D) : the tear in the brachial artery is longitudinal and 3.5cm in length, which may require a more substantial vascular reconstruction with a graft rather than a patch.

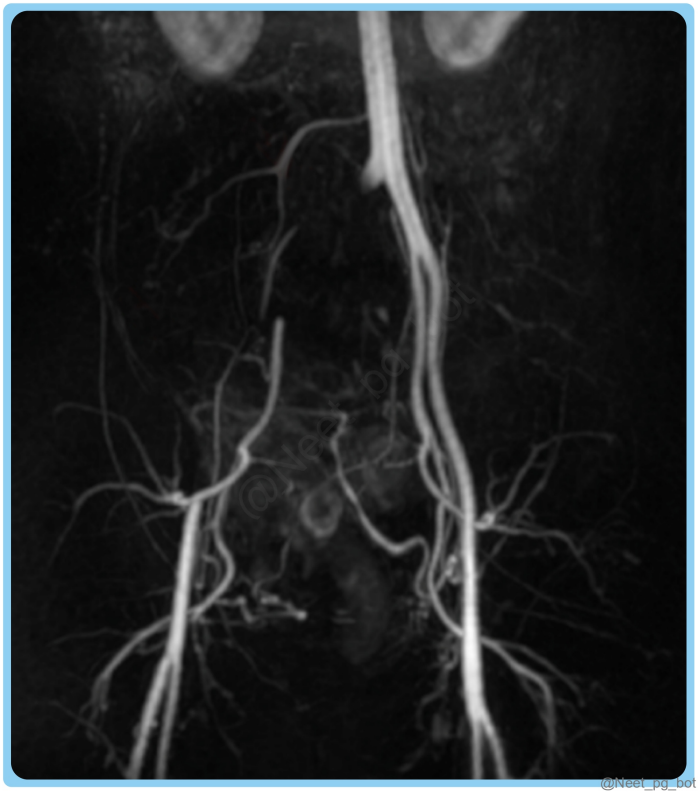
↑ *Back to this question in Part A*

@Neet_pg_bot



Q11: A 70-year-old female patient presents with pain in the thigh during walking. MRA shows complete long-segment occlusion of the right common iliac artery extending into the proximal external iliac artery, with distal reconstitution through internal iliac collaterals. What is the best surgical management? (Q856200)

A. PTA with stenting

B. Femoroiliac bypass

C. Aortofemoral bypass

D. Aorto-iliac bypass

Correct Answer: C. Aortofemoral bypass

Explanation: The MRA demonstrates complete long-segment occlusion of the common iliac artery extending into the proximal external iliac artery, with distal flow maintained only through collateral circulation . This pattern represents a TASC II C/D aorto-iliac occlusive lesion , for which open surgical reconstruction is the recommended treatment. Aortofemoral bypass provides the most durable long-term patency in extensive aorto-iliac occlusion. PTA with stenting (Option A): Suitable only for short-segment (TASC A/B) lesions. Not appropriate for long, chronic occlusions. Femoroiliac bypass (Option B): Used only when the disease is limited to the distal iliac artery or when the patient cannot undergo aortic surgery. Aorto-iliac bypass (Option D): More commonly used for bilateral aorto-iliac occlusion such as Leriche syndrome. The lesion here is unilateral.

@Neet_pg_bot

Q12: According to the CEAP classification, What will be the stage in this patient as the patient presents with the same problem again and again? (Q856207)

A. C2

B. C1

C. C4a

D. C5

Correct Answer: A. C2

Explanation: According to the CEAP (Clinical- Etiology- Anatomy- Pathology) , the stage in this case is C2, as the patient is experiencing recurrent symptoms, indicating that varicose veins are likely the underlying cause, which corresponds to stage C2. Feature Classification For clinical classification: No signs of venous disease Telangiectasia (<1 mm) or reticular veins (1-3 mm dilated veins) Varicose veins (>3 mm) Edema Pigmentation or eczema LDS or atrophic blanche Corona phlebectatica Healed venous ulcer Active venous ulcer Clinical class can be further characterised as symptomatic (s), asymptomatic (a) or recurrent following previous successful treatment or healing (r), e.g. C2a, C2s, C6r. C0 C1 (Option B ruled out) C2 (Option A) C3 C4a (Option C ruled out) C4b C4c C5 (Option D ruled out) C6 For etiological classification: Congenital Primary Secondary (post-thrombotic) No venous cause identified Ec Ep Es En For anatomical classification: Superficial veins Perforator veins Deep veins No venous location identified As Ap Ad An For pathophysiological classification: Reflux Obstruction Reflux and obstruction No venous pathophysiology identified Pr Po Pr,o Pn LDS: {{caption_text}} Pigmentation/Eczema: {{caption_text}} Atrophic blanche: {{caption_text}} Corona phlebectatica: {{caption_text}}

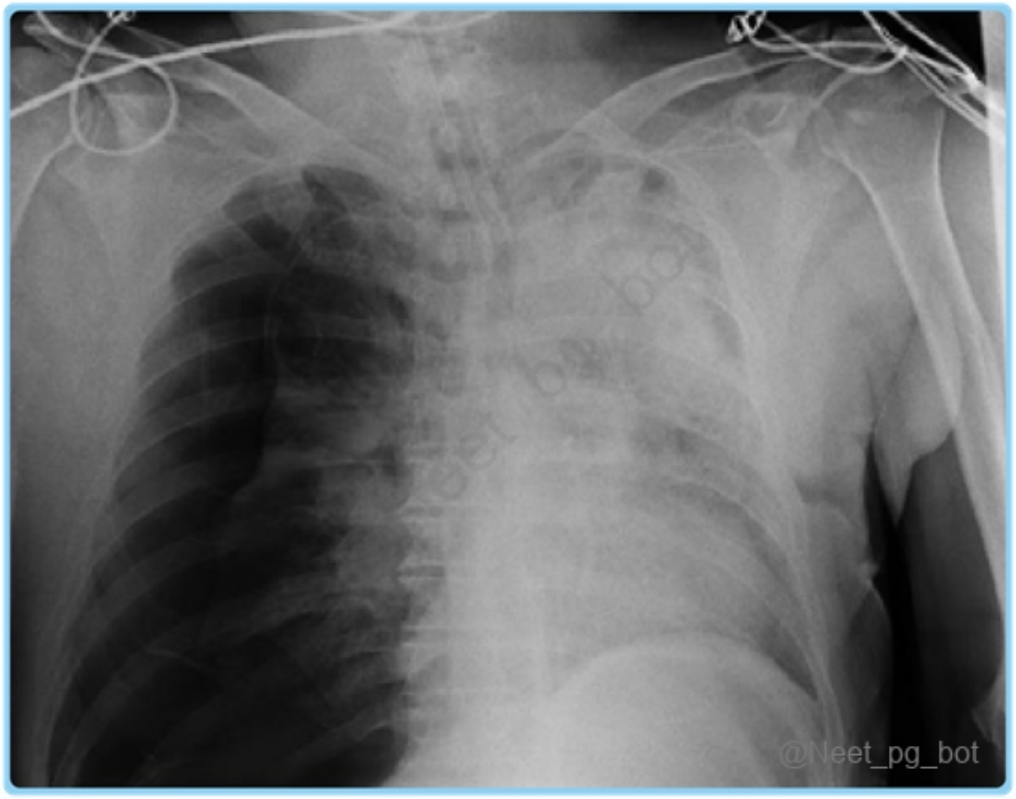
CEAP

↑ *Back to this question in Part A*

@Neet_pg_bot



Q13: What is the appropriate course of action for managing a 25-year-old male patient who was brought to the emergency room following a road traffic accident? The patient has a respiratory rate of 25 breaths per minute and a blood pressure of 80/45 mmHg. During examination, hyper-resonance is detected on the right side of the chest. Please refer to the provided chest X-ray for further evaluation. (Q856746)

A. Wide bore needle insertion in the 5th intercostal space (ICS)

B. Wide bore needle insertion in the 5th ICS followed by an intercostal drain in the 5th ICS

C. Aspiration of the pleural fluid

D. No intervention is needed

Correct Answer: B. Wide bore needle insertion in the 5th ICS followed by an intercostal drain in the 5th ICS

Explanation: The patient presents with a traumatic injury after a road traffic accident . His clinical findings, along with the given chest X-ray, are suggestive of tension pneumothorax. A wide bore needle is inserted into the 5th intercostal space at the mid-axillary line to decompress the pleural space and allow the trapped air to escape, which is the first emergency intervention in suspected tension pneumothorax . After the initial needle decompression, the next step is to insert a chest tube (intercostal drain) in the same location to allow for continuous drainage of air or fluid from the pleural space. (Options A & D ruled out) This will help the lung re-expand and prevent the

pneumothorax from recurring. Aspiration of the pleural fluid (Option C) is done for pleural effusion , where fluid accumulates in the pleural space. In this case, the clinical findings suggest pneumothorax , where air is trapped, not fluid. Therefore, aspiration is not the correct approach here.

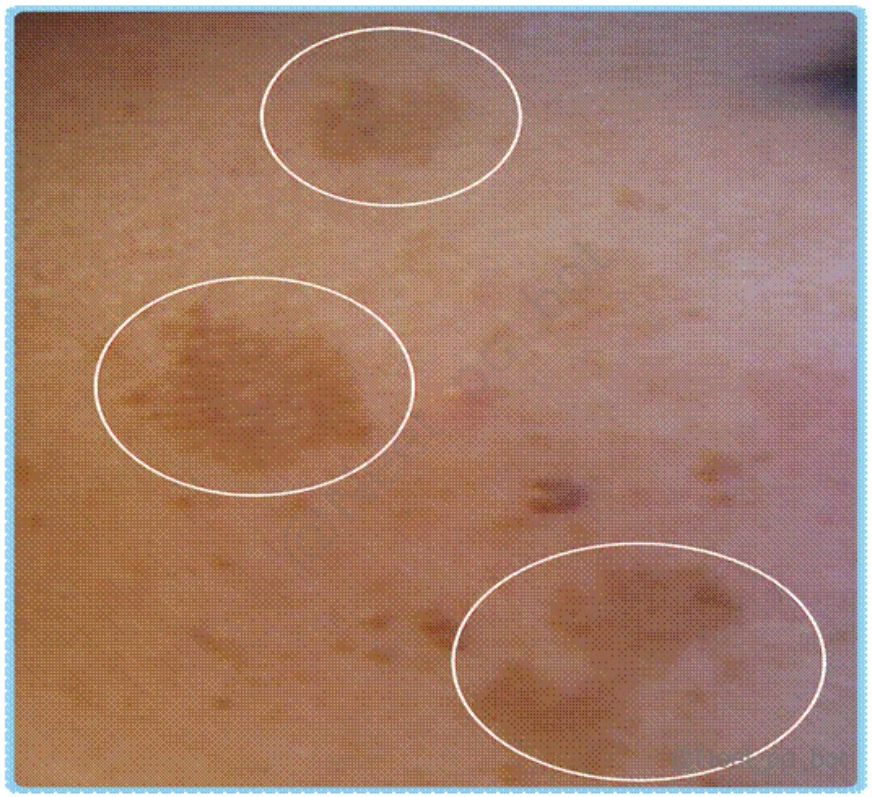
@Neet_pg_bot

Q14: A bus conductor was diagnosed with varicose veins. On examination, skin eczema and lipodermatosclerosis were noted. According to the CEAP classification system, he would be classified as: (Q856753)

A. C1



B. C2

C. C3

D. C4

Correct Answer: D. C4

Explanation: In this case, the bus conductor has skin eczema and lipodermatosclerosis , which are indicative of chronic venous insufficiency , hence classified as C4 . The CEAP (Clinical, Etiological, Anatomical, and Pathophysiological) classification system is used to classify chronic venous disorders CEAP (Clinical, Etiological, Anatomical, and Pathophysiological) classification Clinical classification: C0 No signs of venous disease C1 Telangiectasia (<1 mm) or reticular veins (1-3 mm dilated veins) C2 Varicose veins (>3 mm) C3 Edema C4 C4a - Pigmentation or eczema C4b - LDS or atrophic blanche C4c - Corona phlebectatica C5 Healed venous ulcer C6 Active venous ulcer Clinical class can be further characterised as symptomatic (s), asymptomatic (a) or recurrent following previous successful treatment or healing (r), e.g. C2a, C2s, C6r. ↑ *Back to this question in Part A*

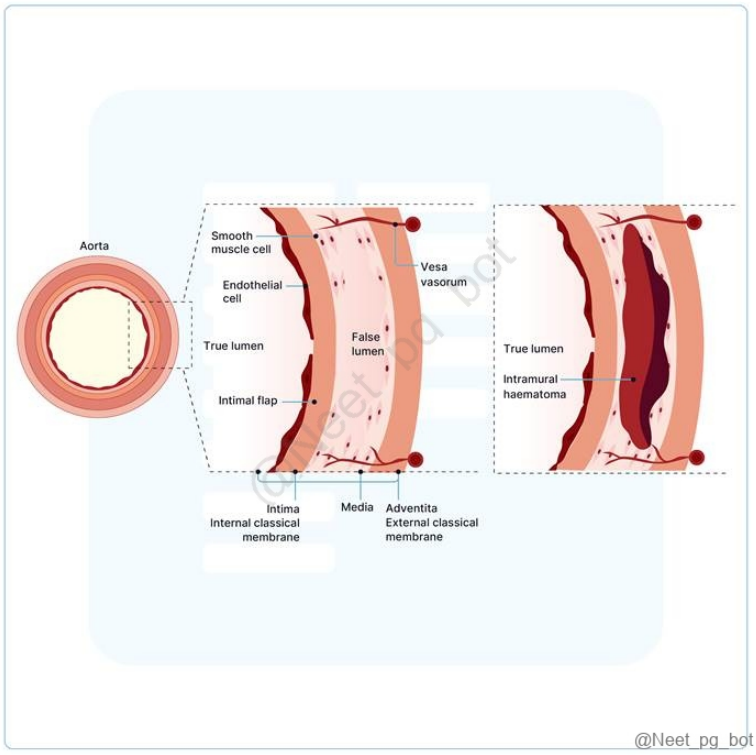
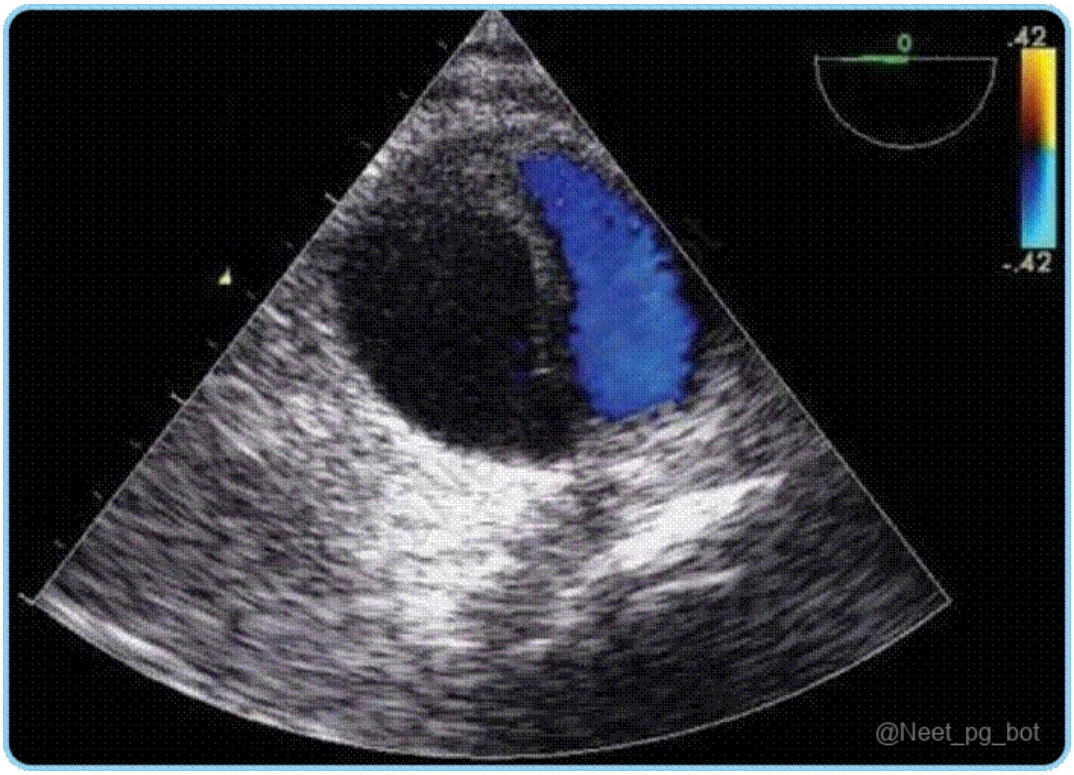
@Neet_pg_bot

Q15: A 40-year-old smoker presents with sudden, severe, tearing chest pain radiating to his back, shortness of breath, and mild nausea. His BP is 190/110 mmHg, and heart rate is 105 bpm. What is the initial management? (Q857860)

A. Control blood pressure



B. Urgent surgery



C. Wait and watch

D. Blood transfusion

Correct Answer: A. Control blood pressure

Explanation: The case scenario of a smoker presenting with severe, tearing chest pain radiating to his back, shortness of breath, and mild nausea, along with a BP of 190/110 mmHg and heart rate of 105 bpm, is likely experiencing Aortic Dissection , where the initial management focuses on BP control. It occurs when a defect or a flap occurs in the aorta, resulting in blood tracking into aortic tissues, splitting the medial layer, and creating a false lumen. Clinical features Sudden onset of severe, tearing chest, radiating to the interscapular region Renal pain and renal failure Paraplegia Syncope Weakness Hypotension or shock Investigations Stable Patient: CT angiography is the standard investigation of choice. Unstable Patients (SBP<100 mm of HG, HR>100 bpm) : TEE (TransEsophageal Echocardiography) (preferred investigation of choice) MRI can also be done if CT is unequivocal. Chest x-ray reveals widening of mediastinum along with left-sided pleural effusion {{caption_text}} TEE of an aortic dissection within the descending part Management Initial Management: Initial management of all types of aortic dissection includes: Blood pressure control (which is usually high at presentation) (Option A) Strict pain management, Prompt referral for specialist management Surgical Management Type A (or type I and II) dissections Type B (or type III) dissections Those involving the ascending aorta usually require surgical intervention. Synthetic graft if needed Anastomosis Endovascular stenting of type A dissections. Initial management: Antihypertensive drugs Monitoring on an acute care unit Complicated cases: If pain worsens, fails to resolve, or malperfusion signs appear (e.g., organ, limb, or neurological symptoms) Percutaneous endovascular stents Surgery (rarely used) Urgent surgery (Option B) : Although surgery is often required for aortic dissection, blood pressure control is the initial and most critical step before surgery. Stabilizing the patient with medications like labetalol helps reduce the force on the aorta, preventing further dissection or rupture. Surgery would follow once the patient is stabilized. Wait and watch (Option C) is not an option for aortic dissection. Aortic dissection is a medical emergency that requires immediate intervention. Delaying treatment with a "wait and watch" approach can lead to life-threatening complications, such as rupture or organ failure. Blood transfusion (Option D) may be necessary if there is significant blood loss, but it is not the first line of management for aortic dissection. The priority is stabilizing the patient with blood pressure control to minimize the risk of further dissection or rupture before considering other interventions like a transfusion.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page, 970-971.

↑ *Back to this question in Part A*

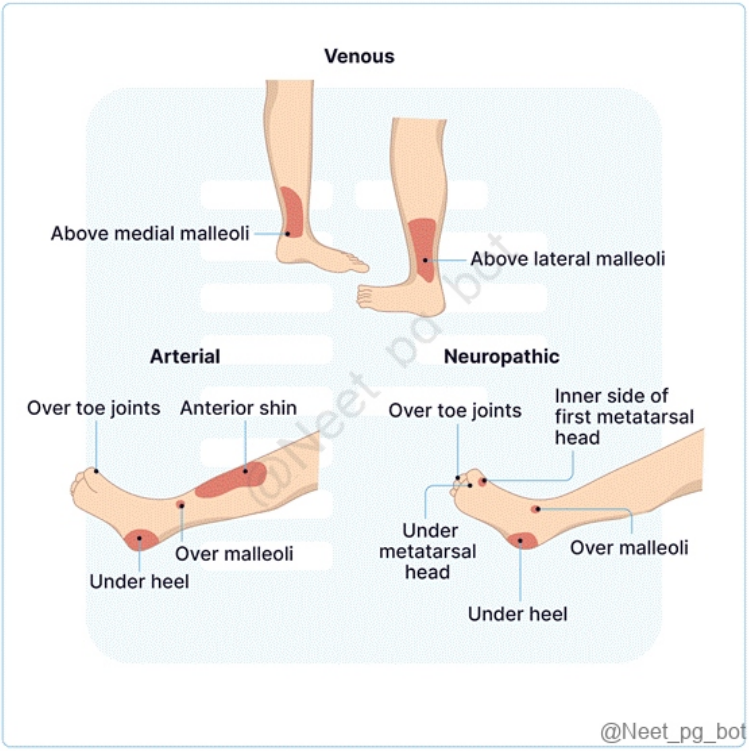
@Neet_pg_bot

Q16: What is the most likely diagnosis of the lesion shown in the image below? (Q856766)

A. Arterial insufficiency

B. Neuropathic ulcer

C. Venous ulcer



D. Tuberculous ulcer

Correct Answer: B. Neuropathic ulcer

Explanation: The given image is suggestive of a neurogenic ulcer, which is a common type of ulcer seen in individuals with peripheral neuropathy and is often associated with diabetes or other conditions that cause nerve damage. The loss of sensation in the affected area leads to unawareness of trauma or pressure , making individuals more prone to developing these ulcers over time. Non-healing, painless, shallow, and punched-out appearance is characteristic of these ulcers and they commonly appear on weight-bearing areas like the feet or toes because these areas endure the most pressure. Clinical features of different ulcers Features Venous ulcer (Option C) Arterial

ulcer (Option A) Neuropathic ulcer (Option B) Pressure ulcer Site Gaiter's area (area between malleolus and calf) At distal ends of limbs, such as toes, feet and legs. Over toe joints, under the feet, heel, over malleoli, under the metatarsal head, etc Seen over pressure points, most common are ischium, greater trochanter, sacrum, hee, malleolus, occiput, etc Appearance Vertically oval with a sloping edge and will not penetrate deep fascia. Punched-out edges are seen in this type of ulcer. Ulcers can be associated with gangrene and abscesses; osteomyelitis can be seen here. Punched out ulcer with bone as a base. Cause Caused by ambulatory chronic venous hypertension due to varicose veins. This occurs due to severe arterial insufficiency of digital and medium-sized arteries, leading to ischemia and tissue death in the region. It is caused due to repeated trauma and ischemia due to microangiopathy in diabetic patients . It is tissue necrosis and ulceration due to prolonged pressure on any part of the body. Characteristics It is initially painful, then chronically becomes painless. It heals on rest and treatment but reforms again. It is intensely painful; distal pulses are not palpable, and associated with shiny skin, brittle nails and loss of hair over the region. It is also known as diabetic ulcer since it is seen in diabetic patients. It is common in bedridden patients with head injuries, neurological deficits, and comatose and stroke-ridden patients. Tuberculous ulcer (Option D) occurs when tuberculosis affecting the lungs spreads to the skin . This type of ulcer is relatively uncommon but can develop in individuals with advanced or untreated TB. These ulcers typically have distinct characteristics like an undermined edge and necrotic base and may show signs like scarring or lymphadenopathy.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: Which of the following adverse effects is not observed following a massive blood transfusion? (Q856773)

A. Hypocalcemia

B. Hypercalcemia

C. Hypokalemia

D. Hyperkalemia

Correct Answer: B. Hypercalcemia

Explanation: Hypercalcemia is not commonly seen in massive blood transfusions. In fact, the risk is usually the opposite (hypocalcemia) due to citrate-binding calcium. Massive blood transfusion refers to the transfusion of a large volume of blood products over a relatively short period. While blood transfusions can be life-saving, they can also be associated with certain adverse effects. Complications of massive blood transfusion Complication Cause Effect Hypothermia Transfusion of cold blood (stored at 4°C). Body temperature drops, leading to impaired clotting mechanisms (coagulopathy) and worsening bleeding. Coagulopathy Dilution of clotting factors and platelets due to transfusion; consumption of clotting factors by ongoing haemorrhage. Impaired blood clotting, prolonged bleeding time, increased risk of continued bleeding. Citrate Toxicity Large volumes of transfused blood contain citrate, which binds to calcium. Hypocalcemia leads to muscle cramps, seizures, and cardiac arrhythmias. Hypocalcemia (Option A ruled out) Packed red blood cells (PRBCs) and other blood products are preserved with citrate , an anticoagulant. Citrate binds to ionised calcium (Ca^{2}■) in the recipient's blood, reducing the free calcium level - hypocalcemia Presents as muscle spasms, cardiac arrhythmias, and decreased myocardial contractility Hyperkalemia (Option D ruled out) Potassium leaks from stored red blood cells into plasma during storage. Elevated potassium levels (hyperkalemia) can cause cardiac arrhythmias, potentially leading to cardiac arrest. Hypokalemia (Option C ruled out) Potassium may shift intracellularly once transfused red blood cells are metabolically revived. Hypokalemia, causing muscle weakness, paralysis, and cardiac arrhythmias. Metabolic Alkalosis Rapid metabolism of citrate into bicarbonate. Increased pH (alkalosis) can lead to muscle twitching, irritability, and impaired oxygen release from haemoglobin. Metabolic Acidosis Inadequate tissue perfusion leads to lactic acid accumulation. Lowered blood pH (acidosis) leads to confusion, fatigue, rapid breathing, and worsened cardiovascular function. Transfusion Related Acute Lung Injury (TRALI) Antibodies in transfused blood activate the recipient's immune response, causing inflammation and fluid buildup in the lungs. Non-cardiogenic pulmonary oedema, presenting as acute respiratory distress with hypoxia within 6 hours of transfusion. Transfusion Associated Circulatory Overload (TACO) Volume of transfused blood exceeds the patient’s capacity to manage, leading to fluid overload. Pulmonary edema, shortness of breath, hypertension, and signs of heart failure. Iron Overload Repeated transfusions lead to excessive accumulation of iron. Iron deposits in organs (e.g., liver, heart, pancreas), lead to organ damage and failure over time. Hemolytic Reactions ABO or Rh incompatibility. Rapid destruction of red blood cells (hemolysis), causing fever, chills, hemoglobinuria, and potentially acute renal failure or shock. Allergic Reactions Reaction to proteins in transfused blood products. Symptoms range from mild itching, rash, or hives to severe anaphylaxis (airway constriction, low blood pressure, shock). Bacterial Contamination Blood products are contaminated during collection or storage. Sepsis is characterized by fever, chills, low blood pressure, and possibly septic shock.

@Neet_pg_bot

Q18: A 55-year-old man with IHD presents with sudden, severe, generalised abdominal pain and multiple episodes of vomiting. On examination, the pulse rate is 118 bpm, rhythm is irregularly irregular, and BP is 90/60 mmHg. The abdomen appears soft and non-distended, and bowel sounds are absent. Which of the following could be a likely diagnosis in this case? (Q856298)

A. Acute severe pancreatitis

B. Ruptured aortic aneurysm

C. Acute mesenteric ischemia

D. Peptic ulcer perforation

Correct Answer: C. Acute mesenteric ischemia

Explanation: Acute mesenteric ischemia is the most likely diagnosis due to the patient's risk factors (IHD), sudden onset of severe abdominal pain, vomiting, hypotension, and absent bowel sounds. This condition is caused by a reduction or cessation of blood flow to the intestines, leading to tissue ischemia. Acute mesenteric ischemia Aspects Description Definition Sudden reduction in blood supply to the intestines, leading to ischemia and potential necrosis. Commonly involves the Superior mesenteric artery (SMA). Clinical Features Pain: Severe, sudden-onset abdominal pain disproportionate to physical findings. Others: Nausea, vomiting, diarrhea, bloody stools, shock. Risk Factors Cardiovascular: Atrial fibrillation, recent MI, heart failure. Vascular: Atherosclerosis, vasculitis. Others: Hypercoagulable states. Radiological Features CT Angiography: Preferred diagnostic tool; reveals SMA occlusion, String of sausage sign , bowel wall thickening, pneumatosis intestinalis, portal venous gas. {{caption_text}} Management Initial: IV fluids, broad-spectrum antibiotics, pain control. Definitive: Anticoagulation (e.g., IV heparin), surgical embolectomy, bowel resection. Vasodilators (e.g., papaverine) can be used intra-arterially to relieve vasospasm. Acute severe pancreatitis (Option A) presents with severe epigastric pain that can radiate to the back, but not generalised abdominal pain. The patient also often has elevated pancreatic enzymes (amylase/lipase), and abdominal tenderness would usually be present. The absence of bowel sounds and the patient's cardiac symptoms are suggestive of acute mesenteric ischemia. Ruptured aortic aneurysm (Option B) is a life-threatening condition that causes severe, tearing abdominal pain and sudden, severe hypotension. This patient lacks key signs like a pulsatile mass, significant tenderness, or acute collapse, making it less likely. Peptic ulcer perforation (Option D) presents with acute abdominal pain, tachycardia, guarding and rigidity of the anterior

abdominal wall, it can lead to peritonitis and sepsis. The soft, non-distended abdomen in this case and the absence of these physical findings suggest this is less likely.

@Neet_pg_bot

Q19: What is the management approach for a 50-year-old male patient who has a 40 mm abdominal aortic aneurysm detected during his routine annual checkup? (Q854937)

A. Urgent endovascular aneurysm repair

B. Surgery is indicated if the aneurysmal diameter is > 55mm

C. Urgently wheel the patient to OT for surgery

D. Surgery is indicated only if the aneurysm is > 77mm

Correct Answer: B. Surgery is indicated if the aneurysmal diameter is > 55mm

Explanation: According to guidelines, surgery is generally recommended for abdominal aortic aneurysms greater than 5.5 cm (55 mm) in diameter. Management of abdominal aortic aneurysm depends on the aneurysm size, symptoms, and patient's condition. A 40 mm abdominal aortic aneurysm (AAA) is considered smaller than the threshold for surgical intervention. (Option A ruled out) . Management of Abdominal Aortic Aneurysm (AAA) Aspect Details Surveillance Small AAAs (3.0–3.9 cm): Monitor every 2–3 years using ultrasound. Medium AAAs (4.0–5.4 cm): Monitor every 6–12 months with ultrasound. Large AAAs (≥5.5 cm): Surgical intervention recommended; if not, frequent imaging and clinical review. Medical Management Risk Factor Modification : Smoking Cessation Blood Pressure Control Cholesterol Management: Statins recommended. Surgical Intervention (Option C & D ruled out) I ndications for Surgery: Aneurysm Diameter ≥ 55 mm (High risk of rupture) Rapid Growth: > 5 mm increase in six months. Symptomatic AAAs : Consider surgery. Surgical Options : Open Surgical Repair: Using a Dacron graft, which is durable and has higher morbidity. Endovascular Aneurysm Repair (EVAR): Less invasive, requires long-term surveillance for complications.

@Neet_pg_bot

Q20: Which of the following statements regarding intermittent claudication is accurate? (Q854944)

A. Felt at rest

B. Most commonly felt in the calf muscles

C. Day-to-day distance is variable

D. Relieved after getting out of bed

Correct Answer: B. Most commonly felt in the calf muscles

Explanation: - Most commonly felt in the calf muscles: Intermittent claudication is a condition caused by peripheral arterial disease (PAD) , which leads to insufficient blood flow to the muscles, particularly during exercise or physical exertion. The pain is typically muscle pain , cramping , or aching , and it most commonly affects the calf muscles because of their large muscle mass and high demand for oxygen during activity. The pain occurs with activity and is relieved by rest . (Options A & D ruled out) Boyd's classification of intermittent claudication : Grade Description Grade 0: Asymptomatic No symptoms of claudication, even with exercise Grade I: Mild claudication Able to walk more than 200 meters (about 650 feet) before onset of symptoms Grade II: Moderate claudication Able to walk between 50 and 200 meters (about 160 to 650 feet) before onset of symptoms Grade III: Severe claudication Able to walk less than 50 meters (about 160 feet) before onset of symptoms Grade IV: Ischemic rest pain Pain occurs at rest or with minimal exertion Day-to-day distance is variable (Option C) and

is incorrect because the distance a person can walk before pain sets in is usually fairly consistent over time in intermittent claudication.

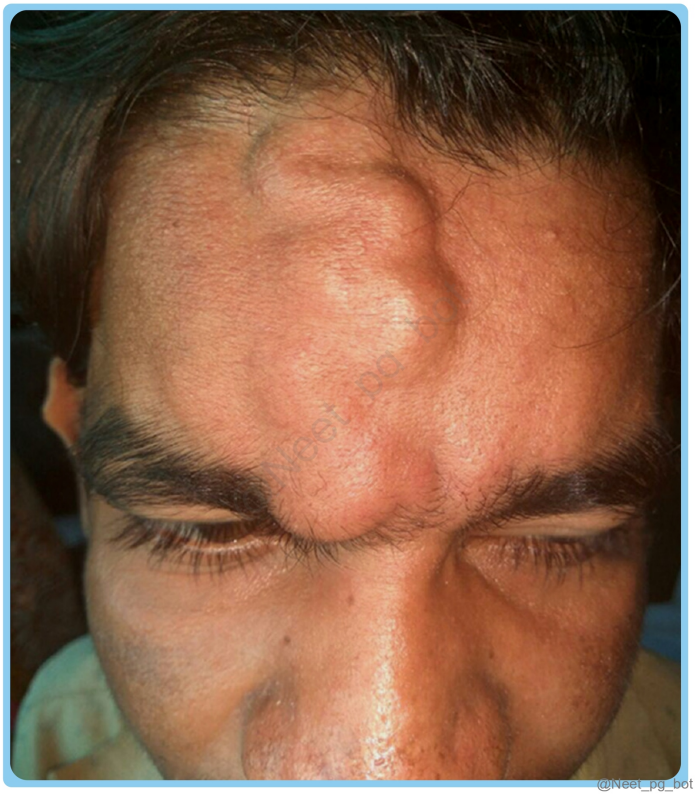
@Neet_pg_bot



Q21: What is the most probable diagnosis for a 41-year-old female patient who presented with a twisted swelling on the scalp and face, accompanied by a pulsating sensation and a bruit heard during auscultation? (Q854947)

A. Neurofibromatosis

B. Liposarcoma

C. Cirsoid Aneurysm

D. Varicocele

Correct Answer: C. Cirsoid Aneurysm

Explanation: In this case, the most likely diagnosis is a cirsoid aneurysm , given the pulsatile swelling, the bruit heard on auscultation, and the location of the lesion (scalp/face). It is a vascular malformation characterised by abnormal communication between arteries and veins, leading to variceal dilatation of the draining veins . This results in a pulsatile swelling, often associated with a palpable thrill and an audible bruit, which are hallmark signs of this condition. The mass in a cirsoid aneurysm can cause cosmetic concerns and may also lead to local pain , headache , tinnitus , and hemorrhage . Treatment for cirsoid aneurysm typically involves surgical fistula repair through simple ligation or endovascular embolisation techniques (using coils or cyanoacrylate). In some cases, gross total resection by a plastic surgery team is also done. Neurofibromatosis (Option A) is benign nerve sheath tumours (neurofibromas) that may present as skin nodules or masses. These tumours would not produce the characteristic pulsatile swelling or bruit associated with a cirsoid aneurysm. Liposarcomas (Option B) are malignant tumours of the adipose tissue . They can cause swelling or mass, but unlike a cirsoid aneurysm , they do not present with a pulsatile sensation or an audible bruit . Varicocele (Option D) is a condition characterised by the enlargement of veins within the scrotum, commonly occurring on the left side. It is not relevant to the case presented, as the description mentions a tortuous swelling over the left side of the scalp and face, not the scrotum.

@Neet_pg_bot

Q22: According to the TNM staging, a patient with lung cancer of size 2.5 cm is staged as: (Q854986)

A. T1b

B. T1c

C. T2a

D. T1a

Correct Answer: B. T1c

Explanation: Given that the tumour size is 2.5 cm , it falls under T1c (as it is > 2 cm but ≤ 3 cm). AJCC 8TH Edition of TNM Staging of Lung Carcinoma Primary Tumor (T) T1 T1a(mi) Minimally invasive carcinoma T1a ≤ 1 cm (Option D ruled out) T1b 1 - 2 cm (Option A ruled out) T1c 2 - 3 cm T2 Involvement of the main bronchus with the involvement of carina Involvement of visceral pleura Association with atelectasis or obstructive pneumonitis T2a 3 - ≤4 cm (Option C ruled out) T2b 4 - ≤5 cm T3 > 5 - ≤7 cm OR Direct invasion of the Chest wall, Phrenic nerve, Pericardium, (Or) Satellite nodules in the same lobe T4 > 7 cm in greatest dimension (Or) Any tumour with invasion of the mediastinum, diaphragm, heart, great vessels, recurrent laryngeal nerve, carina, trachea, oesophagus, spine (Or) Separate tumours in different lobes of the ipsilateral lung. Lymph Node (N) N1 Ipsilateral peribronchial and/or hilar nodes and intrapulmonary nodes N2 Ipsilateral mediastinal and/or subcarinal nodes N3 Contralateral mediastinal or hilar; ipsilateral/contralateral scalene/supraclavicular Distant Metastasis

(M) M1 Distant metastasis M1a Tumor in contralateral lung or pleural/pericardial nodule/malignant effusion M1b Single extrathoracic metastasis, including single non-regional lymph node M1c Multiple extrathoracic metastases in one or more organs

@Neet_pg_bot

Q23: Which of the following is not a component of Thoracoscore? (Q855018)

A. Performance status

B. Complication of surgery

C. ASA grading

D. Priority of surgery

Correct Answer: B. Complication of surgery

Explanation: The Thoracoscore is a risk assessment tool used to evaluate the operative risk in patients undergoing thoracic surgery , but complications of surgery are not a component of it. The components of thoracoscore are: Age: <55 years, 55-65 years, >65 years Sex ASA Classification: ≤2, ≥3 (Option C ruled out) Performance status (Zubrod scale): ≤2, ≥3 (Option A ruled out) Severity of dyspnea (Medical Research Council Scale): ≤2, ≥3 Surgery Priority: Elective, Urgent/Emergency (Option D ruled out) Extent of resection: Pneumonectomy, Other Diagnosis: Malignant, Benign Comorbidity score

References:

NIH Link

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: What is the probable diagnosis for a 50-year-old male who is a long-term smoker and experiences pain in both thighs and buttocks while walking approximately 500 meters? (Q858494)

A. Arterial disease involving the superficial femoral artery

B. Arterial disease with aortoiliac involvement

C. Femoral venous insufficiency

D. Arterial disease involving the profunda femoris artery

Correct Answer: B. Arterial disease with aortoiliac involvement

Explanation: Given the bilateral claudication affecting the thighs and buttocks, along with the patient's smoking history, the most probable diagnosis is arterial disease with aortoiliac involvement. The muscle group affected in claudication is one anatomical level below the level of arterial disease. Aortoiliac disease typically presents with bilateral symptoms such as pain in the buttocks , thighs , and sometimes the calves , which worsens with exertion. The pain is due to claudication caused by reduced blood flow to the lower extremities due to atherosclerosis or stenosis, commonly associated with chronic smoking. Arterial disease involving the superficial femoral artery (Option A) generally causes pain in the calf , not the thighs or buttocks , and it usually affects one leg, not both. Therefore, the bilateral nature of the pain makes this diagnosis less likely. Femoral venous insufficiency (Option C) presents with swelling & varicose veins rather than claudication pain. The pain described here is intermittent and related to exertion, which is more typical of arterial disease, not venous insufficiency. Arterial disease involving the profunda femoris artery (Option D) would lead to pain in the thigh (and possibly one leg), not typically in both the thigh and buttock . Also, the pattern of bilateral pain favours the involvement of aortoiliac vessels .

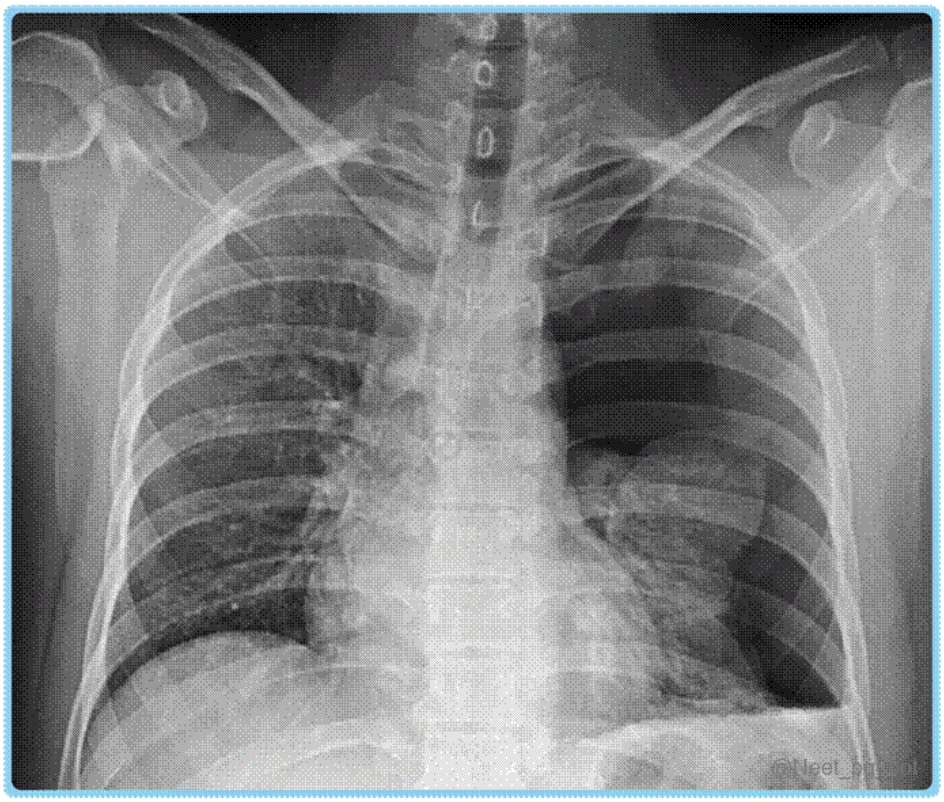
Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1024

↑ *Back to this question in Part A*

@Neet_pg_bot



Q25: What would be the appropriate course of action for managing a 25-year-old male patient who was brought to the emergency department after a road traffic accident (RTA)? The patient has a respiratory rate of 25 breaths per minute and a blood pressure of 80/45 mmHg. During examination, hyper-resonance is detected over the left side of the chest. The provided chest x-ray is shown below. (Q859600)

A. Wide bore needle insertion in the right 5th ICS

B. Wide bore needle insertion in the left 5th ICS followed by an intercostal drain

C. Aspiration of the pleural fluid

D. No intervention is needed

Correct Answer: B. Wide bore needle insertion in the left 5th ICS followed by an intercostal drain

Explanation: The patient presents with a traumatic injury after a road traffic accident ; his clinical findings, along with the given chest X-ray suggest tension pneumothorax. A wide bore needle is inserted into the 5th intercostal space at the mid-axillary line to decompress the pleural space and allow the trapped air to escape, which is the first emergency intervention in suspected tension pneumothorax . After the initial needle decompression, the next step is to insert a chest tube (intercostal drain) in the same location to allow for continuous drainage of air or fluid from the pleural space. (Options A & D ruled out) This will help the lung re-expand and prevent the pneumothorax from recurring. Aspiration of the pleural fluid (Option C) is done for pleural effusion , where fluid accumulates in the pleural space. In this case, the clinical findings suggest pneumothorax , where air is trapped, not fluid. Therefore, aspiration is not the correct approach here.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 374

↑ *Back to this question in Part A*

@Neet_pg_bot

Q26: A male patient presents with impotence and absent femoral pulse. The pain in the gluteal region is observed. At which level has the pathology occurred? (Q855764)

A. Bilateral popliteal arteries

B. Bilateral internal iliac arteries

C. Aortoiliac bifurcation

D. Bilateral femoral arteries

Correct Answer: C. Aortoiliac bifurcation

Explanation: Aortoiliac bifurcation pathology is the most likely cause of the combination of symptoms described. Leriche's syndrome refers to a specific form of aortoiliac occlusion that results from the blockage or narrowing of the aortoiliac bifurcation , leading to reduced blood flow to the lower limbs and pelvic organs. Clinical features of this syndrome include: Impotence Claudication Absent femoral pulses Gluteal pain Vessels involved and common sites of obstruction (in Atherosclerosis) Vessel Common Sites of Obstruction Related Manifestations/Findings Aorta Infrarenal aorta Bilateral lower limb ischemia, absent femoral pulses Iliac arteries Common iliac bifurcation Unilateral lower limb ischemia, absent femoral pulse. Pain in the buttock is due to a block in the common iliac or aortoiliac segment (30%), often associated with impotence and is called Leriche's syndrome. Femoral artery (Option D ruled out) Common femoral artery Calf claudication, absent popliteal and distal pulses Popliteal artery (Option A ruled out) Adductor canal Calf and foot ischemia, absent pedal pulses Tibial arteries Proximal or mid-calf Foot ischemia, absent pedal pulses Subclavian artery Proximal subclavian Arm ischemia, absent radial/ulnar pulses. Subclavian steal syndrome: Obstruction of the first part of the subclavian artery can cause reverse blood flow through the vertebral artery, providing collateral circulation to the arm but affecting the posterior brain and upper limb, with steal being occult, partial, or complete. Brachial artery Mid-humerus level Forearm and hand ischemia, absent radial/ulnar pulses Bilateral internal iliac arteries (Option B) can lead to impotence and pain in the gluteal region, but they do not cause the absence of a femoral pulse.

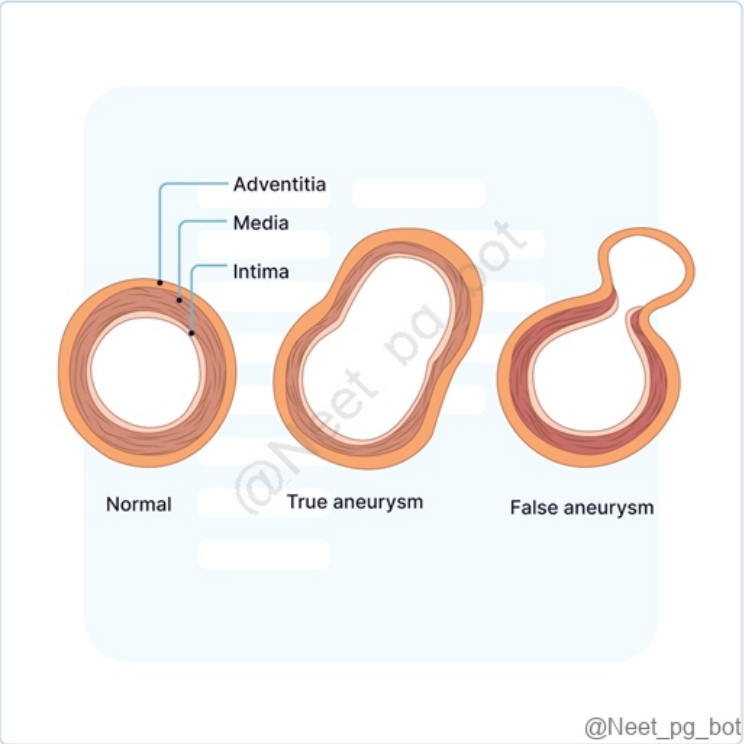
@Neet_pg_bot

Q27: A patient presents with a tender pulsatile mass, as shown in the image below. What will be done next for this patient? (Q855769)

A. Ultrasound Doppler

B. Needle aspiration



C. CT angiogram with percutaneous management

D. Intravenous antibiotics for 7 days

Correct Answer: A. Ultrasound Doppler

Explanation: A tender pulsatile mass is typically suggestive of an arterial aneurysm, and to assess the nature of the mass and its underlying cause, an Ultrasound Doppler is the most appropriate initial diagnostic test. Ultrasound Doppler is a non-invasive imaging technique that allows evaluation of blood flow and vessel structure, and it can differentiate between a true aneurysm and a pseudoaneurysm. Aspect True Aneurysm False (Pseudoaneurysm) Definition Involves all three layers of the arterial wall. Involves only a layer of fibrous tissue outside the vessel. Wall Structure Intima, media, and adventitia are involved. Only fibrous tissue surrounds the breach. Morphology Fusiform or saccular. Typically spherical or ovoid. Aetiology Atherosclerosis, genetic conditions. Trauma, surgery, or arterial puncture. Clinical Features May be asymptomatic until complications arise. Often presents with a pulsatile mass or pain. Common Locations Large arteries (e.g., aorta, iliac). Peripheral arteries (e.g., femoral, popliteal). Diagnosis Detected by ultrasound, CT, and MRI. Detected by ultrasound or angiography. Management Surgical repair or endovascular techniques. Repair or percutaneous methods (e.g., thrombin injection). Needle aspiration (Option B) is typically used for fluid collections (e.g., abscesses or cysts) and is not suitable for pulsatile masses that are suspected to be related to vascular conditions like aneurysms or pseudoaneurysms. Aspiration would not provide useful information for such vascular masses, and bleeding could possibly worsen if the mass is an aneurysm. CT angiogram with percutaneous management (Option C) may be necessary for detailed evaluation and treatment of vascular abnormalities, but it is not the first step in diagnosis. An ultrasound Doppler is done first because it is less invasive and can quickly confirm or rule out a vascular abnormality. Intravenous antibiotics for 7 days (Option D) are appropriate for treating infections like abscesses or cellulitis but would not be the correct treatment for a pulsatile mass, which suggests a vascular etiology rather than infection.

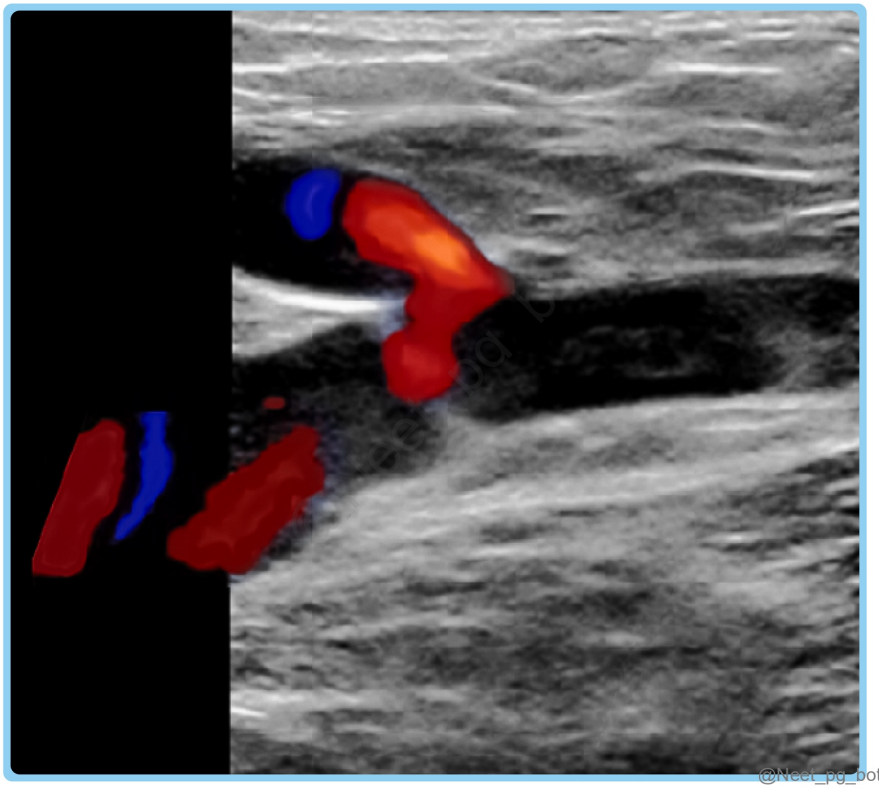
Bailey & Love's Short Practice of Surgery, 28th Edition, Pages 1005,1017-1024

↑ *Back to this question in Part A*

@Neet_pg_bot



Q28: A patient presents with sudden onset right leg pain. An investigation was done, and the obtained image is shown below. What is the investigation? (Q855821)

A. Digital subtraction angiography

B. Ultrasound Doppler

C. MR angiography

D. Plethysmography

Correct Answer: B. Ultrasound Doppler

Explanation: The investigation performed here is an Ultrasound Doppler , which is commonly used to evaluate blood flow and detect vascular occlusion or stenosis in peripheral arteries. It provides a non-invasive method to assess blood flow through the arteries and veins, helping to identify thrombosis, embolism , or vascular abnormalities . In the case of acute leg pain, a Doppler ultrasound can quickly identify whether there is a blockage in the femoral, popliteal, or tibial arteries , which would be consistent with acute limb ischemia . Other options: Digital subtraction angiography (Option A) is an invasive imaging technique used to visualise blood vessels, typically in the case of suspected complex vascular abnormalities or prior to interventional procedures like angioplasty or stent placement . DSA is not typically used as the first-line diagnostic tool in cases of acute leg pain. MR angiography (Option C) is a non-invasive imaging technique that uses MRI to visualize blood vessels and assess for blockages or aneurysms . While MRA is useful for evaluating vascular disease, it is often reserved for more complex cases as it may be less available and more time-consuming than CT angiography. Plethysmography (Option D) is a non-invasive test that measures changes in blood volume in an organ or limb to assess circulation. It is not typically used as the first-line investigation for acute limb pain.

References:

NIH Link .

↑ *Back to this question in Part A*

@Neet_pg_bot

Q29: A 39-year-old male who had a road traffic accident and suffered from chest trauma was admitted to the ER. About 1800 ml of blood loss from the chest tube in an hour. What is the next step in management for this condition? (Q820129)

A. Emergency Thoracotomy

B. Conservative for next 6-hours

C. Continue resuscitation

D. Wait & watch

Correct Answer: A. Emergency Thoracotomy

Explanation: Correct Option A - Emergency Thoracotomy: In a case where a 39-year-old male has suffered chest trauma with heavy bleeding in the lungs and significant blood loss (1800 ml) from the chest tube in an hour, an emergency thoracotomy is the appropriate next step. A thoracotomy involves making an incision into the chest wall to access the thoracic cavity. This procedure allows direct control of bleeding, repair of injuries, and potential life-saving measures. Given the severity of the situation and the rapid blood loss, immediate surgical intervention is necessary. Incorrect Options: Option B - Conservative for next 6 hours: Conservative management involves monitoring and treating the patient without immediate surgical intervention. However, in a case of heavy bleeding with ongoing blood loss, waiting for 6 hours is not appropriate. This delay could lead to further deterioration and worsening of the patient's condition. Option C - Continue resuscitation: While resuscitation is important, in a situation with significant and ongoing blood loss as described, simply continuing resuscitation without addressing the underlying cause (bleeding) may not be effective. Direct intervention to control the bleeding is crucial. Option D - Wait & watch: Waiting and watching the patient's condition without taking immediate action to control the bleeding could be dangerous in this scenario. The patient is actively bleeding with a large volume of blood loss, which requires prompt intervention to stabilize their condition.

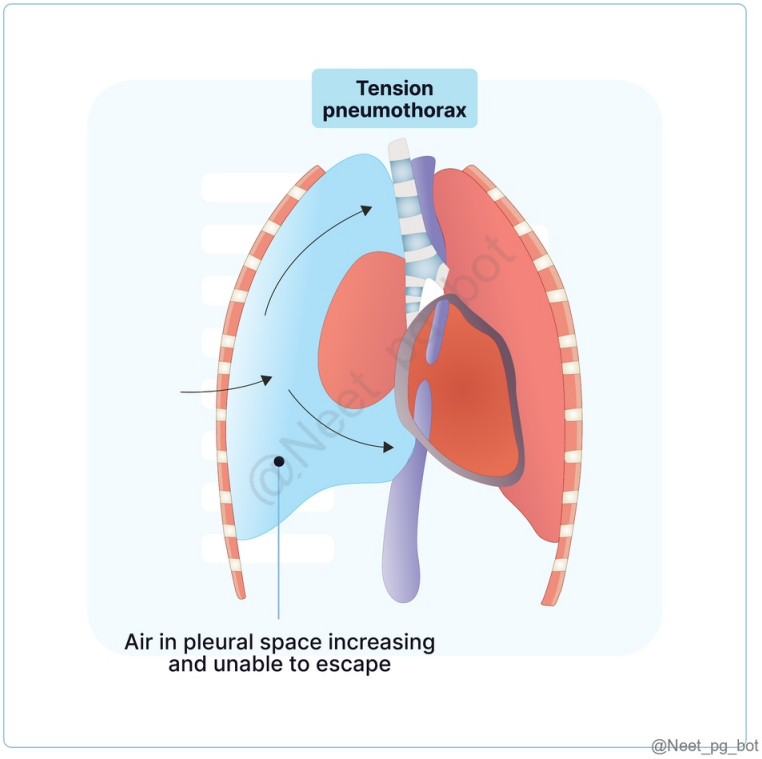
@Neet_pg_bot

Q30: A 30-year-old male presented to EMT with H/o Penetrating chest trauma. On examination, severe tracheal deviation was present. What is the immediate step of management? (Q866927)

A. Needle decompression



B. Chest X-ray

C. E-FAST

D. O2 support at 100%

Correct Answer: A. Needle decompression

Explanation: History of penetrating trauma, severe tracheal deviation after chest trauma strongly suggests tension pneumothorax. Tension pneumothorax is a life-threatening emergency caused by one-way air entry into the pleural space, leading to: Increased intrathoracic pressure → collapse of the ipsilateral lung → pushes mediastinum away from affected side. Mediastinal shift → compression of the opposite lung and major vessels Obstructive shock → ↓ venous return, ↓ cardiac output Do NOT wait for imaging like CXR or E-FAST; immediate decompression is required. Needle decompression → large-bore cannula into the 5th intercostal space (mid-axillary line), followed by ICD (chest tube) placement. Incorrect Options: Chest X-ray (Option B) – Imaging delays life-saving intervention; done after stabilizing the patient. E-FAST (Option C) – Bedside ultrasound is useful in trauma, but here the diagnosis is clinical, and urgent treatment is the priority. O■ support at 100% (Option D) – Oxygen is supportive but will not relieve the life-threatening pressure in the pleural space.

@Neet_pg_bot

Q31: In a chronic limb ischemia patient, what is the ABI below which gangrene is imminent: (Q865388)

A. 0.5

B. 0.3

C. 0.9

D. 1

Correct Answer: B. 0.3

Explanation: An Ankle Brachial Index < 0.3 indicates an imminently threatened leg and requires urgent vascular assessment/revascularisation to prevent major amputation. Chronic Limb Threatening Ischemia (CLTI) is defined as rest pain or tissue loss (ulcers, or gangrene) supported by ischemia defined by the hemodynamic criteria of low ankle or toe pressures, or low transcutaneous oxygen (TcO2) values. Ankle pressure criteria range from less than 40–70mmHg, toe pressures less than 30–50mmHg, TcO2 less than 20–40mmHg. CLTI is assessed by measuring Ankle Brachial Pressure Index or Ankle Brachial Index (ABPI/ABI). ABPI is measured supine by checking the systolic blood pressure in both upper and lower limbs (brachial, posterior tibial, and dorsalis pedis arteries). The higher value from each limb is used to calculate the ABPI. This index is calculated as: ABI = Systolic BP in the Ankle/ Systolic BP in the arm Interpretations are as follows: Value Interpretation 0.1 - 0.4 Critical limb ischemia 0.5 - 0.9 Intermittent claudication 1.0 - 1.2 Normal > 1.2 Calcified vessels (seen in patients with DM, End stage renal disease)

@Neet_pg_bot

Q32: A 56 years old man presents with the following pathology, which of the following is correct? (Q866445)

A. Sclerotherapy is the best treatment

B. Lipodermatosclerosis/eczema can occurs

C. Telangiectasia is rare

D. No possibility of venous ulcer

Correct Answer: B. Lipodermatosclerosis/eczema can occurs

Explanation: The image depicts varicose veins , which over time can cause chronic venous insufficiency (CVI) . Long-standing venous hypertension leads to skin and subcutaneous tissue changes, including: Venous eczema Lipodermatosclerosis Hyperpigmentation Venous ulcers Sclerotherapy is the best treatment (Option A): Sclerotherapy is effective for small varicosities or recurrent veins , not for large primary saphenous varicose veins , which are usually treated with endovenous ablation or surgical ligation/stripping . Telangiectasia is rare (Option C): Incorrect. Telangiectasias (spider veins) are common in chronic venous disease. No possibility of venous ulcer (Option D): Incorrect. Venous ulcers are a well-recognized complication of advanced varicose veins (CEAP class 6).

.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q33: A chronic smoker presents with leg pain after walking 100 meters. On examination, there is an absent pulse in the bilateral dorsalis pedis, anterior tibial, and posterior tibial arteries, but no gangrene is noted. Intermittent claudication is

suspected. Which of the following statements about this condition is correct? (Q853070)

A. Pain is more at night and sleep

B. Pain aggravated by standing and relieved by bending forward

C. Development of pain on the 1st step of walking

D. Pain develops after walking some distance and is relieved by rest

Correct Answer: D. Pain develops after walking some distance and is relieved by rest

Explanation: Pain develops after walking some distance and relieved by rest is the correct description of intermittent claudication . This is a classic symptom of peripheral artery disease (PAD) . The pain is typically muscle pain , cramping , or aching , and it most commonly affects the calf muscles because of their large muscle mass and high demand for oxygen during activity. Boyd's classification of intermittent claudication : Grade Description Grade 0: Asymptomatic No symptoms of claudication, even with exercise Grade I: Mild claudication Able to walk more than 200 meters (about 650 feet) before onset of symptoms Grade II: Moderate claudication Able to walk between 50 and 200 meters (about 160 to 650 feet) before onset of symptoms Grade III: Severe claudication Able to walk less than 50 meters (about 160 feet) before onset of symptoms Grade IV: Ischemic rest pain Pain occurs at rest or with minimal exertion Pain is more at night and sleep (Option A) : Night pain is more characteristic of rest pain in advanced PAD, not intermittent claudication. Pain aggravated by standing and relieved by bending forward (Option B) : This description is more consistent with neurogenic claudication and is typical of lumbar canal stenosis , where pain worsens with standing or walking and is relieved by bending forward or sitting. Development of pain on the 1st step of walking (Option C) is associated with osteoarthritis , whereas the pain in intermittent claudication develops after walking for a certain distance, not immediately when taking the first step.

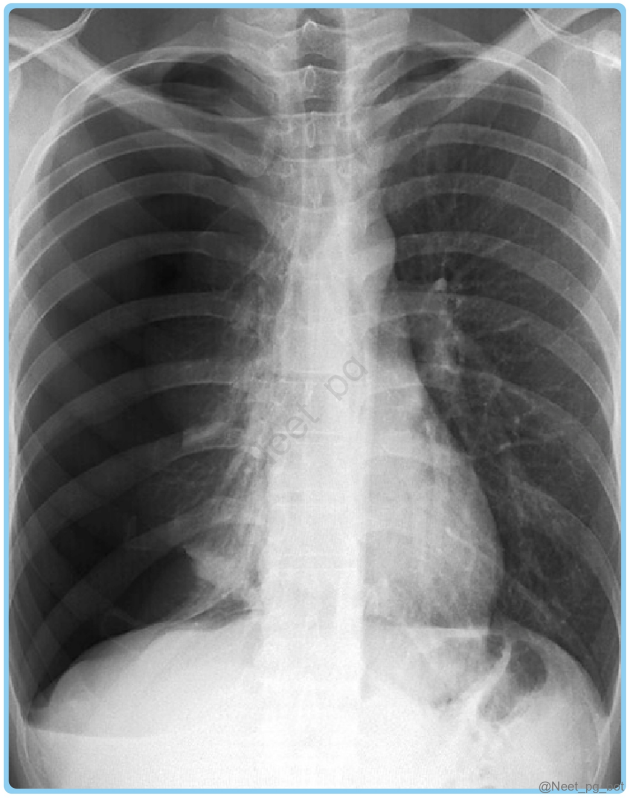
Bailey & Love’s Short Practice of Surgery, 28th Edition, Pages 998, 999.

↑ *Back to this question in Part A*

@Neet_pg_bot



Q34: Following a fight between 2 groups, a boy was brought with severe pain in the chest, distended neck veins, dyspnea, and a BP of 80/50 mmHg. X-ray shows the following findings: What is the diagnosis? (Q852683)

A. Tension pneumothorax

B. Primary Spontaneous Pneumothorax

C. Traumatic Pneumothorax

D. Bilateral Pneumothorax

Correct Answer: A. Tension pneumothorax

Explanation: Clinical Presentation: Severe chest pain, dyspnea, distended neck veins (JVD), and hypotension (80/50 mmHg) suggest a life-threatening tension pneumothorax . Trauma history (fight) further supports the diagnosis. Increased Intrathoracic Pressure → Impaired Venous Return → Distended Neck Veins (JVD) As intrathoracic pressure rises, it compresses the superior vena cava (SVC) and right atrium , obstructing venous return to the heart. This results in jugular venous distension (JVD) due to backed-up blood in the venous system . Decreased Preload & Cardiac Output → Hypotension (Low BP) The compression of the right atrium and ventricle reduces blood filling (preload), decreasing stroke volume and cardiac output . This leads to severe hypotension and, if untreated, cardiac arrest due to obstructive shock. X-ray Findings: Hyperlucency (increased radiolucency) on the right side due to air accumulation. Mediastinal shift to the left due to increased intrathoracic pressure. Depressed diaphragm on the affected side. Absence of lung markings on the affected side. Management: Immediate needle decompression at the 2nd intercostal space (midclavicular line) followed by chest tube placement . Pneumothorax Types and Features Type Cause Clinical Features X-ray Findings Tension Pneumothorax Trauma, mechanical ventilation Severe dyspnea, hypotension, JVD, tracheal deviation Mediastinal shift away from affected side, hyperlucency Primary Spontaneous Pneumothorax Ruptured subpleural blebs (tall, thin males) Sudden dyspnea, pleuritic pain Hyperlucency without mediastinal shift Traumatic Pneumothorax Blunt/penetrating trauma, rib fractures Dyspnea, pain, absent breath sounds Hyperlucency, no mediastinal shift unless tension develops Bilateral Pneumothorax Rare, seen in severe trauma, barotrauma Respiratory distress, hypoxia Bilateral hyperlucency Primary Spontaneous Pneumothorax (Option B): incorrect because it occurs without trauma and does not cause severe hypotension or mediastinal shift. Traumatic Pneumothorax (Option C): incorrect because not all traumatic pneumothoraces lead to tension , and tension features (JVD, severe

hypotension, tracheal shift) are key here. Bilateral Pneumothorax (Option D): incorrect because the X-ray shows a unilateral pneumothorax , not bilateral lung collapse.

@Neet_pg_bot

Q35: A 62-year-old male presents with left leg swelling and pain for 5 days and has a positive D-dimer test. Duplex ultrasonography confirms an extensive DVT involving the left popliteal and femoral veins. Which of the following is the most appropriate initial management strategy? (Q852702)

A. Unfractionated heparin followed by warfarin

B. LMWH followed by oral anticoagulant

C. Catheter-directed thrombolysis

D. IVC filter placement

Correct Answer: B. LMWH followed by oral anticoagulant

Explanation: Treatment of DVT: Anticoagulation: For initial management of acute DVT without contraindications to anticoagulation, the current recommended approach is to start with LMWH and transition to an oral anticoagulant. This approach has several advantages: LMWH provides rapid anticoagulation without the need for monitoring. Oral anticoagulants have shown non-inferiority or superiority to warfarin in large clinical trials. They have a better safety profile and do not require regular INR monitoring. This regimen allows for outpatient management in many cases, reducing hospitalization rates. Investigation of DVT: Venous Doppler with Duplex scanning Non-invasive; detects thrombus by impaired blood flow and inability to compress veins. Presence of echogenic material completely filling the lumen of vein Absence of compressibility Absence of blood flow Venogram Accurate for detecting and locating thrombus and differentiating occlusive and non-occlusive thrombus but less commonly used due to invasiveness. Impedance Plethysmography Measures changes in venous volume and flow using a cuff. Less useful for calf DVT and previous thrombosis. Fibrin and Fibrinogen Assays Measures fibrin degradation products, including D-dimer. D-dimer has a high negative predictive value. Radioactive Fibrinogen Study Uses radiolabeled fibrinogen to detect thrombus. Less commonly used. Magnetic Resonance

Venous Imaging (MRVI) Non-invasive; Useful for imaging iliac veins and IVC. Management of DVT : Initial Anticoagulation Subcutaneous LMWH: Rapidly anticoagulate confirmed DVT cases. Intravenous Unfractionated Heparin: For patients with significant renal impairment. Fondaparinux or Bivalirudin: Alternatives for those with heparin sensitivity or heparin-induced thrombocytopenia. Transition to Oral Anticoagulation Duration: At least 3 months or longer based on risk factors or recurrence. Novel anticoagulants (NOACs): Rivaroxaban, Apixaban (factor Xa inhibitors), Dabigatran (direct thrombin inhibitor). Vitamin K Antagonists: Warfarin (alternative to NOACs). Monitoring Anticoagulation Heparin: Activated partial thromboplastin time (APTT). Warfarin: INR maintained between 2.0 to 3.0. For Patients with contraindications to Anticoagulation Temporary IVC Filter: Consider if bleeding risk prevents anticoagulation or to prevent pulmonary embolism. It does not treat the existing thrombus and is associated with long-term complications. (Option D) Endovascular Surgery Thrombus removal, lysis, and stenting. Beneficial in selected patients, especially those with iliofemoral thrombosis, to reduce risk of chronic post-thrombotic syndrome. Unfractionated heparin followed by warfarin (Option A) was the traditional approach. But it has largely been superseded by LMWH and DOACs due to the need for hospitalization, frequent aPTT monitoring for unfractionated heparin, and long-term INR monitoring for warfarin. Catheter-directed thrombolysis (Option C) is generally reserved for massive iliofemoral DVT with severe symptoms or limb-threatening situations. It carries a higher risk of bleeding and is not first-line therapy for most DVT cases.

@Neet_pg_bot

Q36: Which type of ulcer is given below? (Q844296)

A. Venous ulcer

B. Arterial ulcer

C. Trophic ulcer

D. Diabetic foot

Correct Answer: A. Venous ulcer

Explanation: Correct Option A - Venous ulcer: These ulcers are commonly found on the lower legs, particularly around the ankles. They typically have irregular borders, are shallow, and may present with a moist base. They are associated with chronic venous insufficiency, where poor blood flow in the veins leads to high pressure and fluid leakage in the tissues. Surrounding skin shows hyperpigmentation (hemosiderin deposition), lipodermatosclerosis, eczema-like changes, and edema. Incorrect Options: Option B - Arterial ulcer: These ulcers are generally found on the feet or toes and are characterized by well-defined, punched-out edges. They are usually painful, and the skin around the ulcer is often pale or cool to the touch. Arterial ulcers result from poor blood flow due to arterial disease, such as peripheral artery disease (PAD), which impairs oxygen and nutrient delivery to tissues. Option C - Trophic ulcer: Trophic ulcers are less common and are associated with conditions that cause nerve damage, such as diabetes or leprosy. These ulcers are typically painless and occur on areas prone to trauma or pressure. The affected skin may be dry and necrotic, and the ulcers are usually located on areas with poor sensation. Option D - Diabetic foot: Diabetic foot ulcers can occur anywhere on the foot and are often associated with diabetes-related neuropathy and peripheral vascular disease. They are typically found on pressure points and can have a deep, necrotic base. The ulcers may be surrounded by calloused skin and are often complicated by infection.

@Neet_pg_bot

Q37: What is the appropriate management for a patient presenting with constant chest pain and radiological findings of stanford type A aortic dissection? (Q844300)

A. Surgical management

B. Vasodilator

C. Beta blocker

D. Beta blocker plus vasodilator

Correct Answer: A. Surgical management

Explanation: Correct Option A - Surgical Management: Type A dissections involve the ascending aorta, which carries the highest risk of: Aortic rupture Cardiac tamponade Acute aortic regurgitation Coronary artery occlusion Surgical intervention is indicated in cases of aortic dissection, especially if the dissection involves the ascending aorta or if there are signs of compromise to vital organs. Surgery is typically required for Type A aortic dissections (involving the ascending aorta) due to the high risk of life-threatening complications. Immediate surgical repair aims to stabilize the aorta, prevent further dissection, and manage complications. Incorrect Options: Option B - Vasodilator: Vasodilators alone are not typically the first-line treatment for aortic dissection. While they can help manage hypertension, they do not address the critical need to control the force of blood flow through the aorta, which is crucial in the acute management of dissection. Option C - Beta Blocker: Beta blockers are a cornerstone in the medical management of aortic dissection. They reduce heart rate and blood pressure, thereby decreasing the shear stress on the aortic wall and preventing further dissection. Beta blockers are particularly important in Type B dissections (involving only the descending aorta) where surgery may not be immediately necessary. Option D - Beta Blocker plus Vasodilator: In some cases, a combination of beta blockers and vasodilators may be used to manage blood pressure and reduce heart rate. However, for aortic dissection, the immediate priority is to control blood pressure and heart rate, with beta blockers being the primary treatment. Vasodilators can be used in conjunction if needed to further control blood pressure, but they are not a replacement for beta blockers.

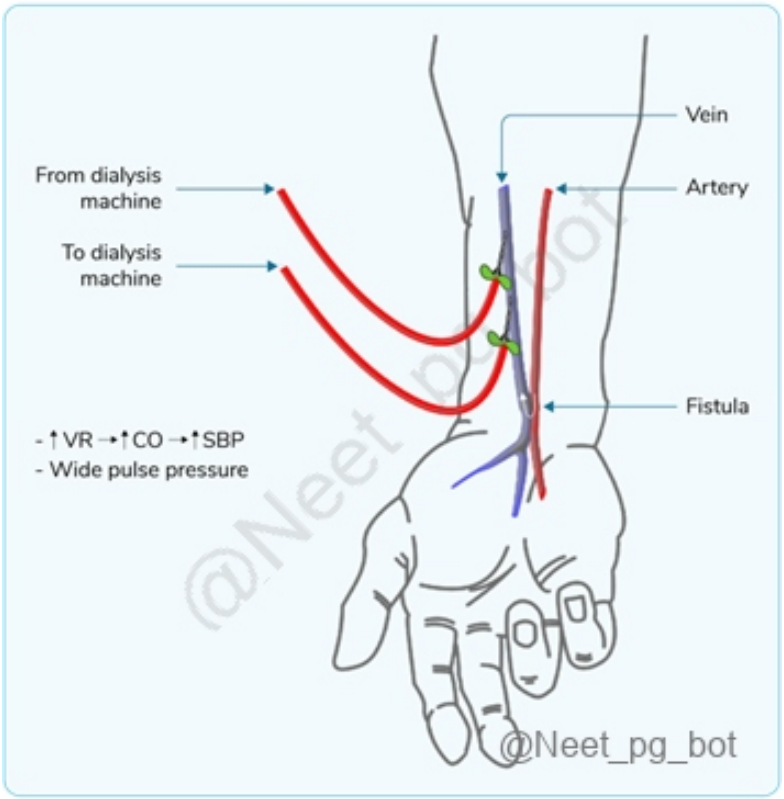
@Neet_pg_bot

Q38: A patient presented to the outpatient department with a dilated, tortuous vein in the leg. The patient reported a history of trauma to the same area 10 years prior. Upon examination, a pulsatile vein was also noted. What is the most likely diagnosis? (Q860393)

A. Varicose vein



B. Angiofibroma

C. Hemangioma

D. A-V Fistula

Correct Answer: D. A-V Fistula

Explanation: The pulsatile nature of the vein in this case suggests an A-V fistula , as it indicates direct arterial blood flow into the venous system. The patient's history of trauma further supports this diagnosis, since A-V fistulas can result from penetrating injuries or iatrogenic causes. Arteriovenous Fistula (AVF) AVF is a communication between an artery and a vein that may be either congenital or acquired (trauma or surgical) . Structurally, they are arterialised (become dilated, tortuous and thick-walled). Physiologically, there is an increase in venous return (as blood starts flowing from arteries to veins, which causes an increase in cardiac output, which in turn results in an increase in systolic BP, leading to cardiac failure. On examination, there is a presence of pulsatile swelling, a thrill and auscultation reveals machinery murmur (buzzing continuous murmur) Nicoladoni's / Branham's sign is observed in AVF: On pressing the artery proximal to the fistula, there is a decrease in the size of the pulsatile mass, disappearance of palpable thrill and decrease in heart rate. Surgically created Arterio-Venous fistula: It is commonly used for patients with end-stage renal disease who require hemodialysis. Aspect Details Purpose Used for hemodialysis Provides high blood flow for effective dialysis Site Selection Prefer distal placement Non-dominant arm is typically used Arterial Quality Requires a strong arterial pulse for success Vein Preservation Avoid placing venous lines in the arm intended for fistula Examples of Surgically created fistulas are: Brescia-Cimino fistula: It is created between the Radial artery and the Cephalic vein. Snuff Box fistula: It is created between the Posterior branch of the radial artery and Cephalic vein Feinberg fistula: It is created between the Radial artery and the Basilic vein. Incorrect Options: Varicose veins (Option A) are dilated, tortuous veins, but they are not pulsatile and are typically not associated with trauma or arterial involvement. Angiofibromas (Option B) are benign tumors of blood vessels and fibrous tissue, but they would not typically present with a pulsatile vein or a history of trauma. Hemangiomas (Option C) are benign vascular tumors that usually appear as red or blue lesions and are not typically pulsatile. They are more common in infants and children.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1023,1024

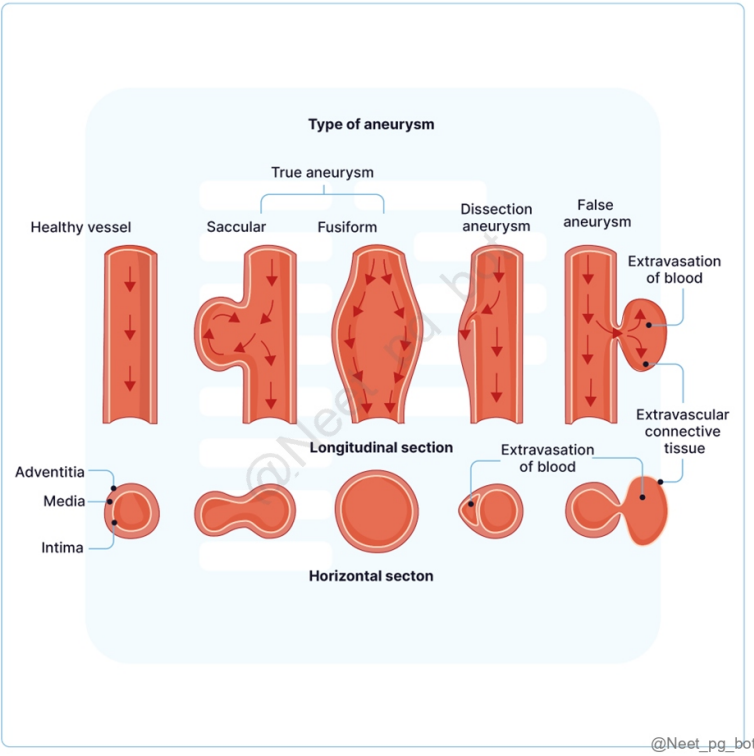
SRB's Manual of Surgery, 6th Edition, Page 334

↑ *Back to this question in Part A*

@Neet_pg_bot

Q39: An elderly man with a chronic history of IV drug use presents with progressively increasing swelling in the groin on the right side. The swelling is non-fluctuant but pulsatile on examination. He has diminished pulses distal to the swelling on the same side. What is the next step in the management of this patient? (Q860455)

A. CT angiography followed by surgery



B. Oral antibiotics and observation

C. Compression stocking

D. Incision and drainage

Correct Answer: A. CT angiography followed by surgery

Explanation: The pulsatile nature of the swelling, along with diminished distal pulses & history of chronic IV drug use , most likely suggests pseudoaneurysm. CT angiography is the gold standard for diagnosing pseudoaneurysms, as it provides detailed imaging of the blood vessels and helps in planning surgical or endovascular repair. Surgical treatment or endovascular embolisation may be required depending on the size and location of the pseudoaneurysm. Aspect True Aneurysm False (Pseudoaneurysm) Definition Involves all three layers of the arterial wall. Involves only a layer of fibrous tissue outside the vessel. Wall Structure Intima, media, and adventitia are involved. Only fibrous tissue surrounds the breach. Morphology Fusiform or saccular. Typically spherical or ovoid. Aetiology Atherosclerosis, genetic conditions. Trauma, surgery, or arterial puncture. Clinical Features May be asymptomatic until complications arise. Often presents with a pulsatile mass or pain. Common Locations Large arteries (e.g., aorta, iliac). Peripheral arteries (e.g., femoral, popliteal). Diagnosis Detected by ultrasound, CT, and MRI. Detected by ultrasound or angiography. Management Surgical repair or endovascular techniques. Repair or percutaneous methods (e.g., thrombin injection). Incorrect Options: Oral antibiotics and observation (Option B) would not be appropriate here because there is no indication of infection (e.g., no fluctuance or signs of abscess), and this is a likely vascular issue requiring surgical intervention. Compression stockings (Option C) are used to treat venous insufficiency or varicose veins. Incision and drainage (Option D) are typically used for abscesses or collections of pus, & should be avoided in this case.

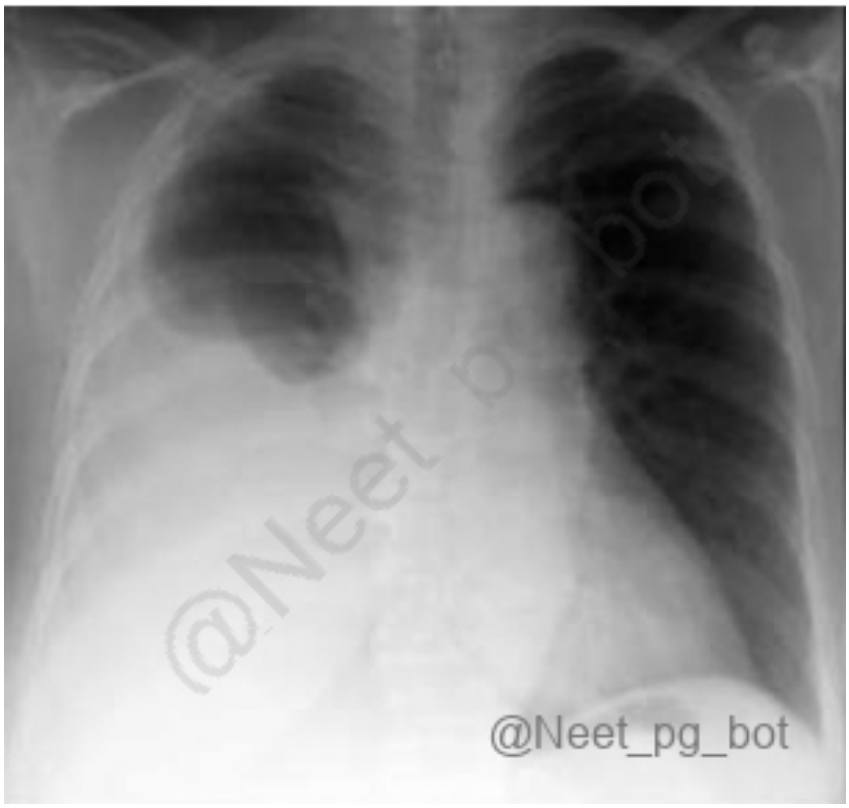
Bailey & Love's Short Practice of Surgery, 28th Edition, Page 798

↑ *Back to this question in Part A*

@Neet_pg_bot



Q40: A 32-year-old male presents to the emergency department after sustaining a stab wound to the right side of his chest. He is in acute distress, with a heart rate of 120 beats per minute, blood pressure of 90/60 mmHg, and respiratory rate of 28 breaths per minute. On physical examination, there are decreased breath sounds on the right side. A chest X-ray is shown below. What is the diagnosis? (Q840044)

A. Pneumothorax

B. Hemothorax

C. Tension Pneumothorax

D. Hydrothorax

Correct Answer: B. Hemothorax

Explanation: The chest X-ray shows a homogeneous white opacity occupying the right hemithorax, which indicates fluid, not air. In trauma patients, such opacity most commonly represents blood collection in the pleural cavity. The patient sustained a stab wound, a classic cause of intrathoracic bleeding. He also presents with hypotension (90/60 mmHg), which strongly supports significant blood loss. Tachycardia and dyspnea further correlate with a large hemothorax compromising lung expansion. Breath sounds are decreased on the right, matching the side of opacification. Incorrect Options: Option A - Pneumothorax: Would appear as a hyperlucent (black) area without lung markings. The X-ray instead shows a white fluid opacity, not air. Option C - Tension Pneumothorax: Shows mediastinal shift and a dark hemithorax filled with air. No mediastinal shift or air-filled space is seen here. Option D - Hydrothorax: Occurs from serous fluid due to CHF, renal, or liver disease. In trauma, pleural fluid is blood, making hydrothorax unlikely.

@Neet_pg_bot

Q41: A patient presents with calf pain while walking a certain distance. The pain is severe enough that he must stop and rest before continuing. According to Boyd's

grading, which of the following grades best describes this condition? (Q860217)

A. Grade 1

B. Grade 2

C. Grade 3

D. Grade 4

Correct Answer: C. Grade 3

Explanation: Grade III is characterised by pain that persists during walking, and the patient has to stop and rest to relieve the pain. Boyd's classification of intermittent claudication : Grade Description Grade I Pain develops after walking a certain distance (claudication distance). The pain subsides due to increased blood flow and collateral circulation. Grade II Pain persists even while continuing to walk, but the patient can still walk with effort. Grade III Patient must stop and rest to relieve the pain; walking becomes significantly impaired. Grade IV Patient experiences rest pain, and the pain persists even at rest, indicating severe arterial disease.

SRB's Manual of Surgery, 6th Edition, Page 162

↑ *Back to this question in Part A*

@Neet_pg_bot

Q42: A man presented with a history of stab injury over the arm. On examination, there was the presence of hematoma, and radial and ulnar pulses were not felt. A 3.5 cm longitudinal tear is noted in the brachial artery. Which of the following is the best treatment option? (Q857300)

A. Primary repair with end-to-end anastomosis

B. Repair with great saphenous vein graft

C. Repair with prosthetic graft

D. Repair with saphenous vein patch

Correct Answer: B. Repair with great saphenous vein graft

Explanation: In this patient with a longitudinal tear to the brachial artery due to a stab injury, the best treatment is to repair it with a great saphenous vein interposition graft harvested from an uninjured leg. Great saphenous vein is the ideal graft: Matches arterial pulsatile flow and size. (Elastic property) Non-thrombogenic with superior long-term patency. Best for small vessels like popliteal and tibial arteries. Other grafts: Cephalic vein and lesser

saphenous vein can be used, but the cephalic vein may be problematic in trauma cases. Timing of Definitive Repair: It is performed once: Hemorrhage is controlled. Coagulopathy and acidosis are corrected. Body temperature is normalised. End-to-end anastomosis (Option A) can only be done when the arterial ends can be easily approximated without tension. If there is a significant gap or tension, a graft is necessary to bridge the gap. Prosthetic grafts (Option C) , such as PTFE (polytetrafluoroethylene), are used in cases where there is trauma to the native saphenous vein or a size mismatch between the artery and the graft. Prosthetic grafts are often considered when vein grafts are not available or not suitable. PTFE is effective for proximal injuries (brachial, popliteal) but inferior for more distal extremity injuries. Saphenous vein patch (Option D) is primarily used to close arteriotomy sites in procedures like carotid endarterectomy , where a patch is used to widen the artery or close the site of an incision, rather than being used for a direct tear repair.

@Neet_pg_bot

Q43: After undergoing surgery to correct a left-sided varicocele, a 30-year-old male patient inquires about the primary route through which venous drainage occurs following the surgery. How should the surgeon correctly respond to the patient's question? (Q857310)

A. Cremasteric veins

B. Penile veins

C. Ectopic drainage in the iliac fossa

D. Testicular veins

Correct Answer: A. Cremasteric veins

Explanation: After surgery for a varicocele, which involves ligating the abnormal veins (high ligation of the internal spermatic vein) in the scrotum, venous drainage is redirected through the cremasteric veins . These veins are part of the venous system of the spermatic cord and are an important alternative route for venous drainage from the testicle once the abnormal venous flow is corrected. Varicocele: Pathophysiology: The pampiniform plexus drains the testis and epididymis. The testicular veins converge at the inguinal ring and ascend retroperitoneally. The left testicular vein drains into the left renal vein, and the right testicular vein drains into the inferior vena cava. Cremasteric veins provide an alternative venous return, draining into the inferior epigastric veins. Causes: Antireflux valve failure at the junction of the testicular vein and renal vein or inferior vena cava causes reflux. Nutcracker effect from compression of the left testicular vein between the superior mesenteric artery and aorta. Angulation at the junction of the left testicular vein and renal vein. Rare causes include renal tumours , deep vein thrombosis , and pampiniform plexus thrombosis . An isolated right-sided varicocele warrants imaging to rule out retroperitoneal masses. Other options: Option B: Penile veins Penile venous drainage does not contribute

meaningfully to testicular venous outflow. These veins drain the corpora and skin of the penis, not the spermatic cord or testes. Option C: Ectopic drainage in the iliac fossa Although aberrant venous connections may exist, they are not the primary or consistent drainage route after a varicocelectomy. They are anatomical variations, not predictable pathways. Option D: Testicular veins The internal spermatic (testicular) vein is ligated during varicocelectomy, so it cannot remain the primary drainage route. Collaterals—not the original vein—take over the function.

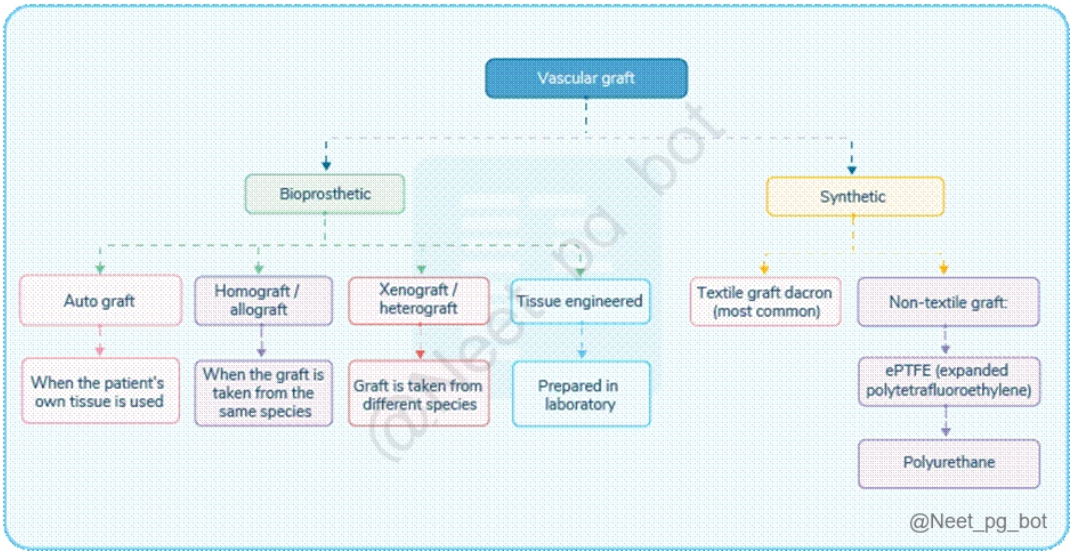
Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1563

↑ *Back to this question in Part A*

@Neet_pg_bot

Q44: Which is the least commonly used graft for coronary artery bypass graft (CABG)? (Q857806)

A. Long saphenous vein



B. Internal mammary artery

C. Intercostal artery

D. Radial artery

Correct Answer: C. Intercostal artery

Explanation: The intercostal artery is the least commonly used graft in Coronary Artery Bypass Graft (CABG) due to its limited availability and potential complications, with the long saphenous vein, internal mammary artery, and radial artery being preferred options. It is a procedure done by using a vascular graft for bypassing the blocked site of arteries and allowing the flow of blood to the heart muscles. Indications: Triple vessel stenosis Left main stem stenosis Chronic stable angina Angina with persistent chest pain >70% blockage of coronary vessels Classification of Vascular grafts: Bioprosthetic grafts LIMA (Left Internal Mammary Artery) (Option B ruled out) Long saphenous vein: Most commonly used in infra-inguinal surgeries due to small and medium-sized vessels. (Option A ruled out) Synthetic grafts Dacron: Most commonly used synthetic graft in supra inguinal surgeries due to large vessels. Polyurethane ePTFE (expanded polytetrafluoroethylene) Most preferred graft for CABG is LIMA , but the Long saphenous vein is more commonly used due to its extra length and it is easy to handle. Radial artery (Option D) is a commonly used graft in CABG, offering comparable long-term patency to the internal mammary artery and is particularly useful for smaller coronary arteries. It’s a good alternative to vein grafts, but requires careful harvesting and postoperative monitoring for complications.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 946-953.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q45: In a patient with aortic dissection, injury to which of the following structure will cause hiccups? (Q820139)

A. Phrenic nerve

B. Abdominal aorta

C. Thoracic aorta

D. Spinal accesory nerve

Correct Answer: A. Phrenic nerve

Explanation: Correct option A - Phrenic nerve: In a patient with aortic dissection, injury to the phrenic nerve can cause hiccups. Phrenic nerve receives contributions from the cervical nerve roots (C3-C5) and travels along the mediastinum and pericardium, running close to the thoracic aorta. An aortic dissection, particularly involving the ascending aorta or arch, can lead to irritation or compression of the phrenic nerve, causing it to become hyperactive. This hyperactivity can manifest as hiccups, which are involuntary contractions of the diaphragm. Incorrect options: Option B, C and D are incorrect.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q46: A 56-year-old patient presented with varicose veins. What is the investigation of choice for varicose veins? (Q820163)

A. Duplex scan

B. Plethysmography

C. MRI

D. CT

Correct Answer: A. Duplex scan

Explanation: Correct option A - Duplex scan: Duplex scan is the investigation of choice for varicose veins. It is a non-invasive imaging technique that combines conventional ultrasound with Doppler ultrasound. It allows visualization of blood flow in the veins and can identify abnormalities, such as reflux (backward flow of blood) in the veins, which is a common finding in varicose veins. It provides valuable information about the anatomy and function of the veins, helping to guide treatment decisions. Incorrect options: Option B - Plethysmography: Plethysmography is a technique used to measure changes in the volume of an organ or limb. While it can provide information about blood volume changes, it is not as specific or accurate in diagnosing the underlying causes of varicose veins as duplex ultrasound. Option C - MRI (Magnetic Resonance Imaging): While MRI can provide detailed images of soft tissues, it is usually reserved for more complex cases or when other imaging methods are inconclusive. Duplex ultrasound is preferred due to its cost-effectiveness and accuracy in diagnosing varicose veins. Option D - CT (Computed Tomography): CT scans involve ionizing radiation and are generally used for specific indications. Duplex ultrasound is safer, non-invasive and more suitable for evaluating venous abnormalities like varicose veins.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q47: What is the most preferred site for the insertion of the intercostal tube drain? (Q820173)

A. Upper border of lower rib

B. Lower border of upper rib

C. Lower border of lower rib

D. Middle of intercostal space

Correct Answer: A. Upper border of lower rib

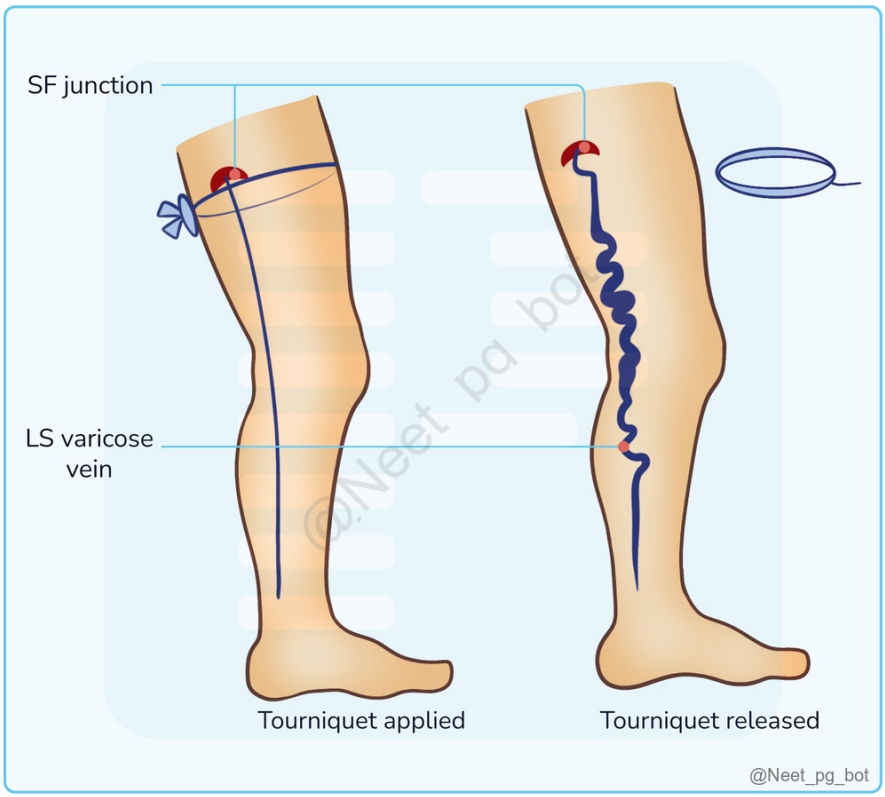
Explanation: Correct option A - Upper border of lower rib The upper border of lower rib is the most preferred site because it helps to avoid injury to important structures like the neurovascular bundle that runs along the lower border of the rib. By inserting the needle just above the upper border of the lower rib, there's a decreased risk of damaging these structures. Incorrect options: Option B, C and D are not the preferred sites for the insertion of intercostal tube drain.

↑ *Back to this question in Part A*

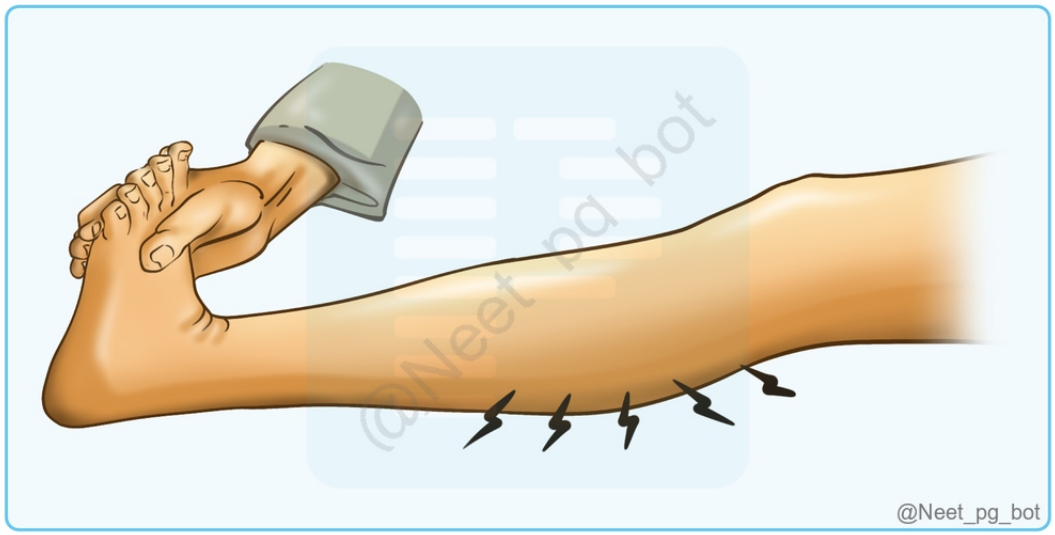
@Neet_pg_bot

Q48: A patient presents with dull, aching pain and tortuous veins in both lower limbs. Which test would be appropriate for evaluating superficial femoral vein (SFJ) competence? (Q854740)

A. Fegan's test



B. Homan’s test



C. Modified Perthes test

D. Brodie Trendelenburg test

Correct Answer: D. Brodie Trendelenburg test

Explanation: The Brodie-Trendelenburg test/ Trendelenburg I test is done to determine the patency of the saphenofemoral junction. Procedure: The patient is asked to lie in the supine position. The leg is elevated, the vein is emptied by “milking,” and a tourniquet is tied just below the saphenofemoral junction. The patient is asked to stand up quickly. The tourniquet is released. Observation: When there is rapid filling of blood from above, this signifies saphenofemoral incompetence. Other tests for varicose veins: Modified Perthe’s test (Option C) : For DVT After elevating the limb and emptying the veins, a tourniquet is applied at the SFJ and the patient is asked to walk around for a few minutes. If the dilated veins become more prominent, it signifies deep venous obstruction. Three tourniquet test: for specific perforator Fegan’s test for perforator (Option A) : On standing, the line of varicosity is marked, and then the veins are emptied in the supine position. The examiner palpates along the marked line and notices any pits or gaps in the deep fascia that signify perforator incompetence at that site. Pratt’s test for perforator: Applying pressure to the calf muscle; if it feels tense and causes pain, it may indicate acute deep vein thrombosis (DVT). Morrisey’s cough impulse test for SFJ incompetence: The patient is asked to turn their face away from the examiner and cough while the examiner keeps a finger at the SFJ, and an expansile cough impulse is felt. Signifies SFJ incompetence. Ian-Aird test for SFJ incompetence. Homan’s test (Option B) is a test for deep vein thrombosis (DVT) rather than venous insufficiency. It involves dorsiflexing the foot and assessing for pain in the calf, which may suggest a clot.

References:

SRB's Manual of Surgery, 6th Edition, Page 223,224

↑ *Back to this question in Part A*

@Neet_pg_bot

Q49: A 62-year-old patient presents with pain in the calf muscles while walking. The pain subsides with rest. Which of the following is not typically seen in intermittent claudication? (Q854759)

A. Cramping in the muscles during exercise

B. Pain starting on taking the first step

C. The most common cause is atheroma

D. The level of occlusion cannot be decided based on symptoms

Correct Answer: B. Pain starting on taking the first step

Explanation: Intermittent claudication typically involves cramping pain in the calf muscles during exercise (such as walking), which subsides with rest. The pain usually starts after walking for a certain distance and is relieved by rest, not immediately upon taking the first step. Boyd's classification of intermittent claudication : Grade Description Grade 0: Asymptomatic No symptoms of claudication, even with exercise Grade I: Mild claudication Able to walk more than 200 meters (about 650 feet) before onset of symptoms Grade II: Moderate claudication Able to walk between 50 and 200 meters (about 160 to 650 feet) before onset of symptoms Grade III: Severe claudication Able to walk less than 50 meters (about 160 feet) before onset of symptoms Grade IV: Ischemic rest pain Pain occurs at rest or with minimal exertion Incorrect Options: Cramping in the muscles during exercise (Option A) : Intermittent claudication is characterised by pain or cramping in the muscles during exercise, usually affecting the lower extremities. The most common cause is atheroma (Option C) : Atheroma, which is the accumulation of fatty plaques in the arteries, is the primary cause of intermittent claudication. The narrowing of the arteries due to atheroma restricts blood flow to the muscles during physical activity, resulting in pain. Level of occlusion cannot be decided based on symptoms (Option D) : The exact level of arterial occlusion cannot be determined by symptoms alone in intermittent claudication. Diagnostic tests, such as ankle-brachial index (ABI) or angiography, are needed to assess the location and extent of arterial blockage. ABI/ABPI: ABPI (Ankle brachial pressure index) is measured supine by checking the systolic blood pressure in both upper and lower limbs (brachial, posterior tibial, and dorsalis pedis arteries). The higher value from each limb is used to calculate the ABPI. This index is calculated as: ABI / ABPI = Systolic BP in the Ankle/ Systolic BP in the arm Interpretations are as follows: Value Interpretation 0.1 - 0.4 Critical limb ischemia 0.5 - 0.9 Intermittent claudication 1.0 - 1.2 Normal > 1.2 Calcified vessels (seen in patients with DM, End stage renal disease)

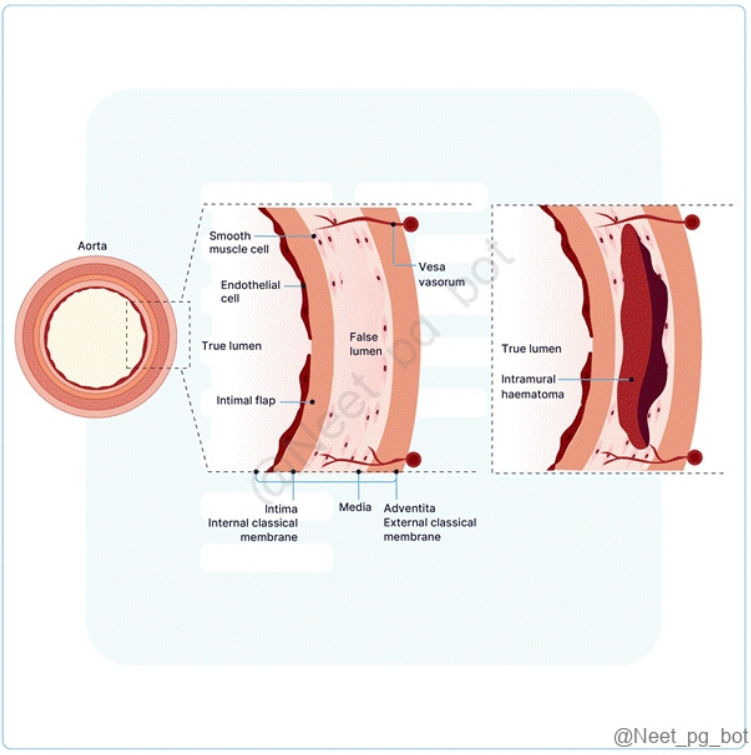
Sabiston Textbook of Surgery, 21st Edition, Page 1773

↑ *Back to this question in Part A*

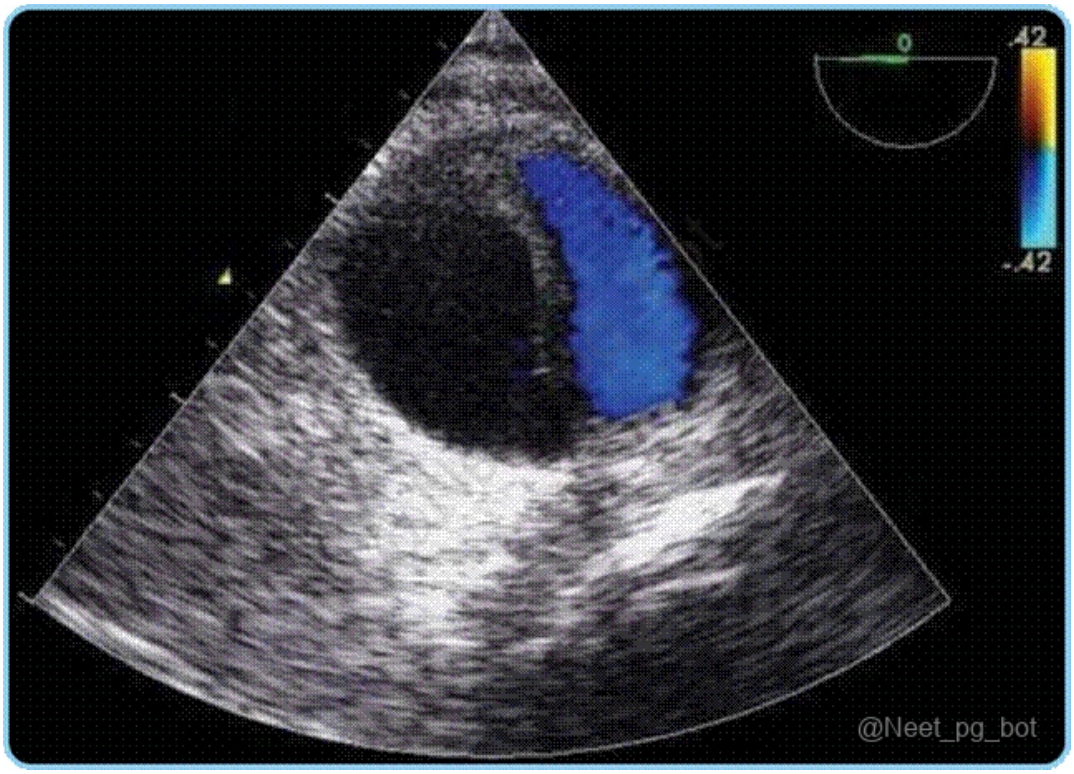
@Neet_pg_bot

Q50: A patient presents with a sudden onset of chest pain shooting to the neck and interscapular region. X-ray shows a widened mediastinum. Blood pressure is 110/90 mmHg in the right upper limb and 160/100 mmHg in the left upper limb. What is the most likely diagnosis? (Q855199)

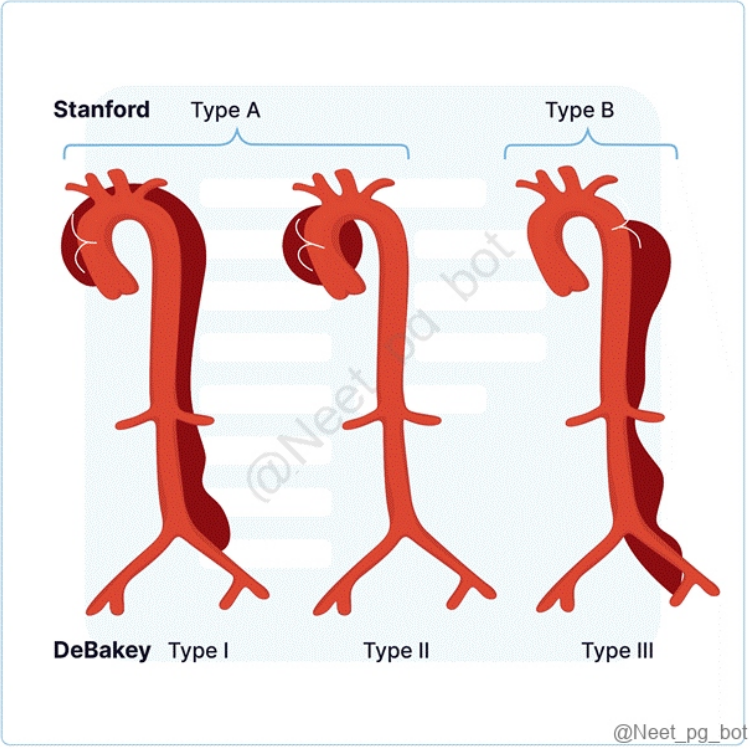
A. Acute coronary syndrome



B. Acute pulmonary embolism



C. Acute aortic dissection



D. Esophageal rupture

Correct Answer: C. Acute aortic dissection

Explanation: Acute aortic dissection often presents with sudden, severe chest pain radiating to the neck and interscapular region. A widened mediastinum on X-ray is a classic sign. The significant difference in blood pressure between the right and left upper limbs suggests aortic dissection, as it can cause unequal blood flow due to dissection of the aortic wall. Aortic Dissection: Occurs when a defect or a flap occurs in the aorta, resulting in blood tracking into aortic tissues, splitting the medial layer, and creating a false lumen. {{caption_text}} Clinical features: Sudden onset of severe, tearing chest, radiating to the interscapular region Renal pain and renal failure Paraplegia Syncope Weakness Hypotension or shock Investigations: If the patient is stable, CT angiography is the standard investigation of choice. In the case of unstable patients (SBP<100 mm of HG, HR>100 bpm), the preferred investigation of choice will be TEE (TransEsophageal Echocardiography)(Option C) MRI can also be done if CT is unequivocal. Chest x-ray reveals widening of mediastinum along with left-sided pleural effusion. {{caption_text}} TEE of an aortic dissection within the descending part DeBakey Classification (Based on the pattern of dissection) Type I Both ascending and descending aorta are involved Type II Only the ascending aorta is involved Type III Only the descending aorta is involved Stanford Classification (Based on whether the ascending aorta is involved in aortic dissection) Type A Only the ascending aorta or both ascending and descending aorta is involved. (It includes both Type I and Type II of DeBakey's classification) Type B Only the descending aorta is involved. (It includes Type III of DeBakey's classification) {{caption_text}} Acute coronary syndrome (Option A): This condition usually presents with central chest pain radiating to the left arm or jaw, often accompanied by sweating, nausea, and shortness of breath. The difference in blood pressure between the arms is not a characteristic feature of acute coronary syndrome. Acute pulmonary embolism (Option B) typically presents with sudden onset dyspnea, chest pain, and possibly hemoptysis. While an ECG might show signs of right heart strain or sinus tachycardia, it does not cause a discrepancy in blood pressure between the limbs. Esophageal rupture (Option D) often occurs after severe vomiting (e.g., Boerhaave's syndrome) and presents with severe chest pain. The X-ray would typically show mediastinal air rather than a widened mediastinum.

@Neet_pg_bot

Q51: A construction worker presents to the OPD with complaints of white fingers. He has been working in the cement and concrete industry and has spent 20 years using heavy machinery drills and polishing wood and furniture. What is the most likely etiology for this condition? (Q855246)

A. Candidal infection of the fingers due to continuous exposure to water

B. Exposure to thinners and paints

C. Continuous exposure to cement and concrete

D. Continuous exposure to drills and machines

Correct Answer: D. Continuous exposure to drills and machines

Explanation: The patient's symptoms of white fingers are suggestive of the vibration-induced white finger (VWF) or hand-arm vibration syndrome (HAVS) , a secondary form of Raynaud syndrome, which is caused by prolonged exposure to vibrating tools and machinery. This condition leads to reduced blood flow and ischemia in the fingers, resulting in the characteristic whiteness of the fingers. Raynaud's Syndrome: Raynaud's syndrome is the peripheral arterial manifestation of a collagen vascular disease, such as systemic lupus erythematosus or rheumatoid arthritis. It shares clinical features with Raynaud's disease but is often more severe. It can also occur due to vibrating tool use , a recognised industrial disease known as vibration white finger . Clinical features: The symptoms are similar to Raynaud's disease but can be more aggressive. In secondary Raynaud's syndrome (due to collagen diseases), there may be necrosis of digits and multiple amputations . Management: Primary treatment focuses on addressing the underlying condition . Conservative measures can be helpful, including: Nifedipine Steroids Vasospastic antagonists Sympathectomy generally provides poor outcomes and is not recommended . Prevention: Patients with a vibrated white finger should avoid vibrating tools to prevent further damage. Other options: Option A: Candidal infection from water exposure - Candidiasis causes paronychia, nail fold swelling, and discharge—not episodic blanching triggered by cold or vibration. Option B: Exposure to thinners and paints - These may cause dermatitis or inhalational toxicity but not vasospastic white fingers. Option C: Continuous exposure to cement and concrete - Cement exposure can lead to irritant dermatitis and alkaline burns, not vibration-induced vasospasm

@Neet_pg_bot

Q52: Identify the given condition: (Q855253)

A. Venous ulcer

B. Malignant ulcer

C. Arterial ulcer

D. Trophic ulcer

Correct Answer: D. Trophic ulcer

Explanation: Trophic ulcers, also called neuropathic ulcers, occur due to a loss of sensation and an impaired ability to protect the skin, often resulting from conditions like peripheral neuropathy or poor circulation. These ulcers usually have well-defined borders and a pale or pink wound bed, commonly located in weight-bearing areas where pressure or friction is frequent. Type of Ulcer: Type History Lesion Characteristics Pain Ischemic/Arterial Smoking, intermittent claudication Irregular edges, poor granulation tissue, dry necrotic base; round or punched-out with sharp demarcation {{caption_text}} Severe, particularly at night; relieved by dependency Venous Varicose veins, DVT, trauma, surgery, multiple pregnancies Shallow, irregular/shaggy shape, granulating base, fibrinous material with moderate to heavy exudate {{caption_text}} Mild; relieved by elevation Neurotrophic Numbness, paresthesias, burning, loss of sensation in the foot, DM Punched-out, deep sinus, variable depth, partial thickness to severe, involving the tendon, fascia, joint capsule, or bone None Malignant Ulcer History of skin cancer (e.g., basal or squamous cell carcinoma) Irregular, raised borders, ulcerating tumour with hard, indurated tissue Often painful, it can be associated with bleeding or foul odour

@Neet_pg_bot

Q53: A patient with varicose veins complains of eczema in the same region. According to the CEAP guidelines, what is the stage of the clinical classification? (Q855257)

A. C2

B. C3

C. C4a

D. C4b

Correct Answer: C. C4a

Explanation: According to the CEAP (Clinical, Etiological, Anatomical, and Pathophysiological) classification system for chronic venous disease, C4a refers to skin changes such as eczema or pigmentation in the presence of varicose veins. The CEAP (Clinical- Etiology- Anatomy- Pathology) classification for chronic venous disorders: Clinical Classification (C): Class Description C0 No visible or palpable signs of venous disease C1 Telangiectasia or reticular veins (<1–3 mm) C2 Varicose veins (>3 mm) C3 Edema without skin changes C4a Pigmentation or eczema C4b Lipodermatosclerosis (LDS) or atrophie blanche C4c Corona phlebectatica C5 Healed venous ulcer C6 Active venous ulcer Each class can be followed by a modifier : a = Asymptomatic s = Symptomatic r = Recurrent (after successful treatment/healing) Example : C2s, C6r Etiological Classification (E) Code Description Ec Congenital Ep Primary Es Secondary (e.g., post-thrombotic) En No venous etiology identified Anatomical Classification (A) Code Description As Superficial veins Ap Perforator veins Ad Deep veins An No venous location identified Pathophysiological Classification (P) Code Description Pr Reflux Po Obstruction Pr,o Reflux and obstruction Pn No identifiable pathology {{caption_text}} {{caption_text}} Pigmentation/Eczema LDS {{caption_text}} {{caption_text}} Atrophic blanche Corona phlebectatica

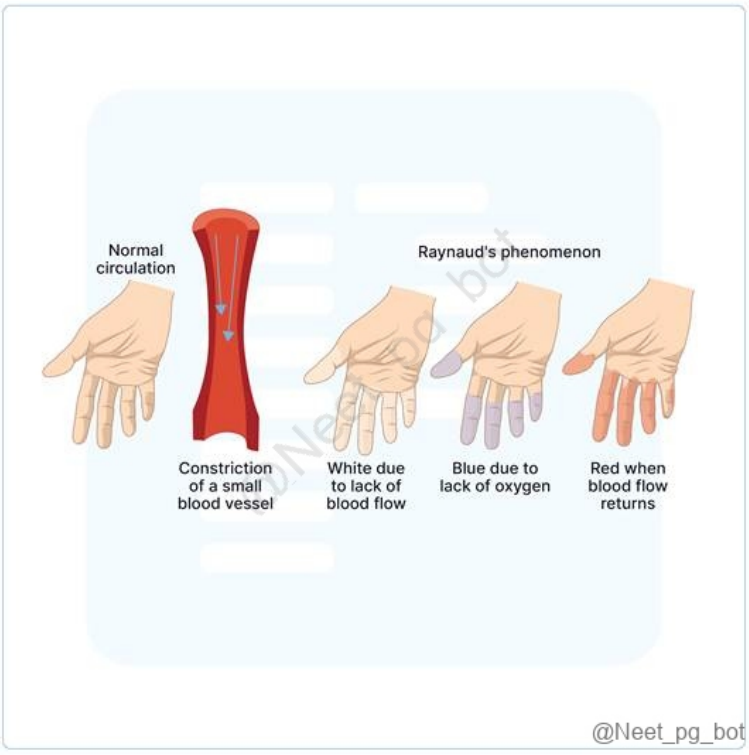
@Neet_pg_bot

Q54: A 17-year-old woman with no comorbidities presents with numbness and paraesthesia of the fingers along with the characteristic finding as shown in the image below. She has no history of smoking or history of other illnesses. She mentions the episodes occur when she is under excess stress or during cold temperatures. What is the most likely diagnosis? (Q857783)

A. Buerger's disease

B. Atherosclerosis



C. Raynaud's phenomenon

D. Giant cell arteritis

Correct Answer: C. Raynaud's phenomenon

Explanation: The scenario of a young woman experiencing numbness, paresthesia, and bluish discoloration of the fingers during cold stress or excessive stress, with no comorbidities, smoking history, or other illnesses, is most likely diagnosed as Raynaud's Phenomenon . Category Description Definition It is characterized by episodic reduction in blood flow, typically in the fingers, triggered by cold exposure or stress. Clinical Features Pallor: Skin becomes pale or white due to reduced blood flow. Cyanosis: Skin turns blue or purple due to deoxygenation of blood. Rubor: Skin turns red as blood flow returns, often with swelling and tingling. Cold Sensitivity: Cold, numb fingers. Pain: Pain during the cyanotic phase. Swelling and Tingling: Occurs in the rubor phase. Types Primary Raynaud Phenomenon (Raynaud Disease): Occurs without underlying disease. More common and has a better prognosis. Secondary Raynaud Phenomenon (Raynaud Syndrome): Occurs due to an underlying condition (e.g., scleroderma, lupus). Often more severe. Management Lifestyle Modifications: Avoid cold exposure, stress reduction, and smoking cessation. Medications: Calcium channel blockers (e.g., nifedipine), alpha-blockers (e.g., prazosin), and other vasodilators. Avoidance of Triggers: Avoid cold, beta-blockers, and caffeine. Advanced Treatments: Surgical sympathectomy for severe cases. Diagnosis Clinical Presentation and History: Based on symptoms and triggers. Nailfold Capillaroscopy: To examine capillary changes. Blood Tests: To identify underlying autoimmune or connective tissue diseases. Sequence of events in Raynaud’s phenomenon: Pallor : The initial phase where the skin becomes pale or white due to reduced blood flow and vasospasm. Cyanosis : Followed by a blue or purple colour due to continued reduced blood flow and lack of oxygen. Rubor : The final phase is where the skin turns red as blood flow returns and the area warms up. Buerger’s disease (thromboangiitis obliterans) (Option A) is an inflammatory condition affecting small and medium-sized arteries and veins, leading to clot formation and reduced blood flow. It is most commonly seen in young male smokers and is characterized by painful ischemia, ulceration, or gangrene of the fingers or toes. This diagnosis is unlikely due to the absence of smoking history, risk factors, and ulcerative symptoms. {{caption_text}} Atherosclerosis (Option B) is the buildup of fatty plaques in arteries, often seen in older individuals with risk factors like smoking, high cholesterol, hypertension, and diabetes. This diagnosis is unlikely for the young woman, as she has no comorbidities or risk factors, and atherosclerosis typically presents with chronic symptoms such as pain or claudication, rather than intermittent symptoms triggered by cold or stress. Giant cell arteritis (GCA) (Option D) affects large arteries in people over 50, causing headaches, scalp tenderness, jaw claudication, and vision issues.

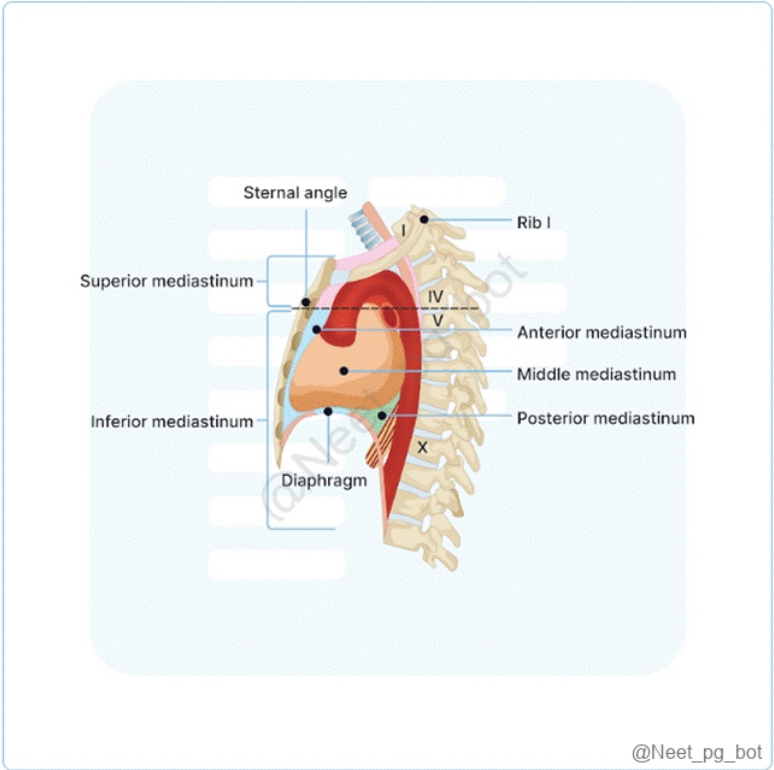
@Neet_pg_bot

Q55: All of the following are classic anterior mediastinal masses EXCEPT: (Q857785)

A. Parathyroid adenoma



B. Lymphoma

C. Teratoma

D. Thymoma

Correct Answer: B. Lymphoma

Explanation: Lymphoma is a tumor of both the anterior and middle mediastinum. Tumors of mediastinum Anterior mediastinum Middle mediastinum Posterior mediastinum Thymomas (Option D ruled out) Thymic carcinomas Thymic cyst Germ cell tumors (Option C ruled out) Lymphomas Parathyroid adenomas (Option A ruled out) Carcinoid tumour Fibroma Lymphomas (Option B) Tumors of the heart and great vessels Tumours of the trachea, mainstem bronchi, and oesophagus Aortic pathologies such as aortic aneurysm, abscess, or dissection. Pericardial cysts Bronchogenic cysts Neuroenteric cyst Mesothelial cyst Pheochromocytoma Neurilemomas (schwannomas) Neurofibromas Ganglioneuromas Ganglioneuroblastomas Neuroblastomas Pheochromocytomas

@Neet_pg_bot

Q56: While washing clothes in cold water, a female patient exhibits color changes in her hands from white to red . Which of the following drugs is best suited for this patient? (Q793884)

A. ACE inhibitors

B. Calcium channel blockers

C. Thiazides

D. Alpha-blockers

Correct Answer: B. Calcium channel blockers

Explanation: Correct Option B - Calcium channel blockers: The symptoms described in the question suggest that the patient is experiencing Raynaud's phenomenon. In this condition, the blood vessels in the fingers and toes spasm and temporarily restrict blood flow. This can cause the affected areas to turn white, blue, and red. Cold temperatures or emotional stress can trigger the spasms. The best-suited drug for this patient would be a calcium channel blocker. These drugs work by relaxing the smooth muscle in the blood vessel walls, which can help to prevent or reduce the frequency of vasospasms. Calcium channel blockers are often used as first-line therapy for Raynaud's phenomenon. Incorrect Options: Option A - ACE inhibitors: ACE inhibitors are a type of blood pressure medication that works by blocking the production of angiotensin II, a hormone that can constrict blood vessels. However, they are ineffective in treating vasospastic disorders like Raynaud's phenomenon. Option C - Thiazides: Thiazides are a type of diuretic used to treat high blood pressure and edema, but they do not affect the blood vessels in a way that would be useful for treating Raynaud's phenomenon. Option D - Alpha-blockers: Alpha-blockers are another type of blood pressure medication that blocks the alpha receptors on blood vessel walls, causing them to relax and dilate. However, alpha-blockers are ineffective in treating Raynaud's phenomenon because they do not target the underlying vasospasms.

@Neet_pg_bot

Q57: Which of the following provides long-lasting results in a coronary artery bypass graft (CABG) ? (Q793485)

A. Long saphenous vein

B. Internal mammary artery

C. Poly tetra fluoro eythlene (PTFE)

D. Gastroepiploic artery

Correct Answer: B. Internal mammary artery

Explanation: Correct Option B - Internal mammary artery: The internal mammary artery is the vessel that provides long-lasting results in a coronary artery bypass graft (CABG). Coronary artery bypass grafting is a surgical procedure that is used to improve blood flow to the heart muscle by bypassing blocked or narrowed coronary arteries. During the procedure, a healthy blood vessel from another part of the body is grafted onto the blocked or narrowed artery, creating a new route for blood to flow to the heart. The internal mammary artery is located inside the chest, and it supplies blood to the chest wall and the heart muscle. It is an ideal vessel for CABG because it is resistant to the development of atherosclerosis (a buildup of plaque inside the artery), which can lead to

re-narrowing or blockage of the grafted vessel over time. Incorrect Options: Option A - Long saphenous vein: The long saphenous vein is often used in CABG procedures, may develop atherosclerosis and become blocked over time, leading to the need for repeat surgeries. Option C - Poly tetra fluoro eythlene (PTFE): PTFE is a synthetic material that can be used in CABG, but it may also develop atherosclerosis over time. Option D - Gastroepiploic artery: The gastroepiploic artery is another option, but it is not as commonly used as the internal mammary artery.

Q13 (p. 1594) *Q14 (p. 1595)*

Q1: Which of the following is the most common type of primary liver tumor? (Q848891)

A. Metastasis

B. Hepatocellular carcinoma

C. Hepatoblastoma

D. Hemangioma

Correct Answer: B. Hepatocellular carcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hepatocellular carcinoma (HCC) is the most common type of primary liver tumor. It arises from hepatocytes and is frequently associated with chronic liver diseases such as hepatitis B and C, as well as cirrhosis. Metastatic tumors are the most common type of liver tumor overall (Option A). The liver is a common site for metastasis from cancers such as colorectal, breast, and lung cancer. Hepatoblastoma is the most common pediatric liver cancer but is much less common than HCC in adults. (Option C) Hemangioma is the most common benign liver tumor and is usually asymptomatic, often discovered incidentally during imaging for other reasons. (Option D)

References:

Bailey & Love's Short Practice of Surgery (28th Edition), Page 1214.

SRB's Manual of Surgery (6th Edition), Page 598, 599.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: A 55-year-old male patient with a history of chronic hepatitis B presents with abdominal discomfort and weight loss. Imaging studies reveal a primary liver tumor with multiple metastatic lesions. Considering the typical metastatic pattern of liver tumors, what is the most likely site of these metastases? (Q848892)

A. Bones

B. Brain

C. Lungs

D. Kidneys

Correct Answer: C. Lungs

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Primary liver tumors, such as hepatocellular carcinoma (HCC), typically metastasize to specific sites in a common order: Lungs : The lungs are the most common site for metastasis from HCC. Pulmonary metastases often occur due to the extensive blood flow from the liver to the lungs. Lymph nodes : Regional lymph nodes are also frequently involved in metastasis from liver tumors. Bones : Metastasis to bones can occur and may present with symptoms such as bone pain or fractures. Brain : While less common, brain metastases can occur in advanced stages of liver cancer. Kidneys : Metastasis to the kidneys is not typical for primary liver tumors.

@Neet_pg_bot

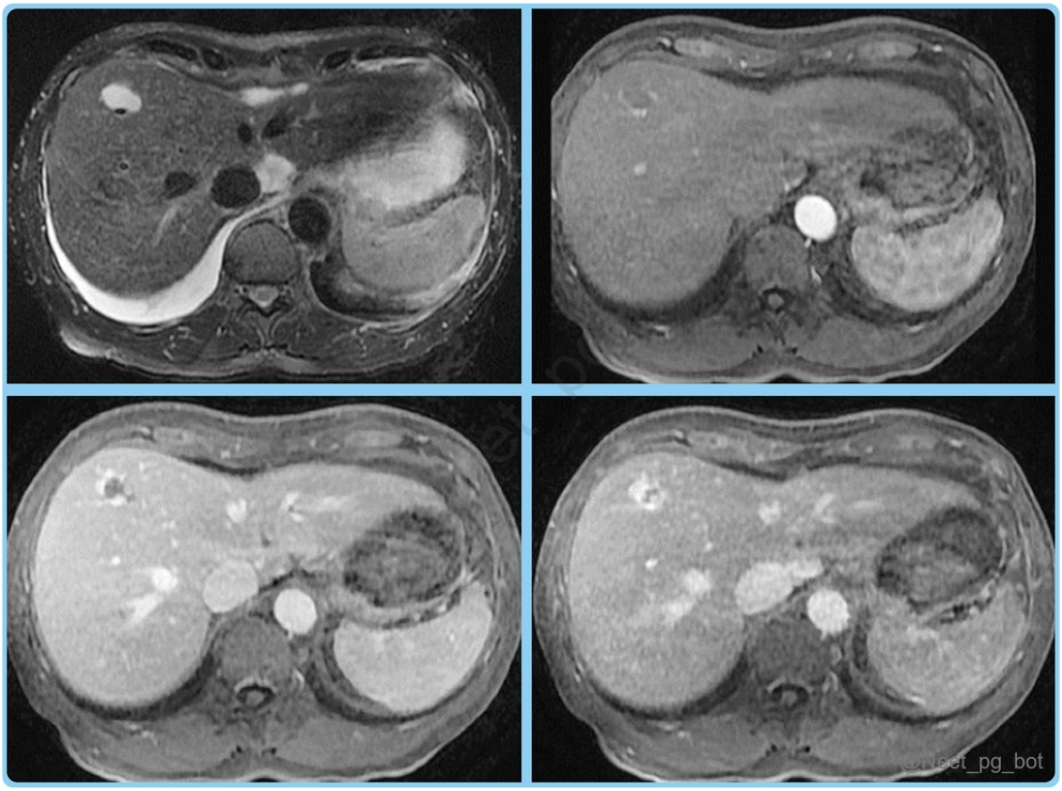
Q3: A 45-year-old woman is incidentally found to have a 5 cm hepatic lesion on an ultrasound performed for evaluation of vague abdominal discomfort. A

contrast-enhanced MRI shows a lesion with peripheral nodular enhancement and centripetal filling in the delayed phase. What is the most appropriate management for this patient? (Q848893)

A. Immediate surgical resection

B. Percutaneous biopsy

C. Observation with periodic imaging



D. Radiofrequency ablation

Correct Answer: C. Observation with periodic imaging

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: A hepatic lesion was incidentally discovered on ultrasound, commonly associated with hepatic hemangiomas. MRI reveals peripheral nodular enhancement with centripetal filling in the delayed phase, highly specific for hepatic hemangiomas. Given these imaging features and the absence of symptoms or abnormal liver function, the diagnosis of a hepatic hemangioma is strongly supported. Management For small, asymptomatic hemangiomas, the standard management is observation with periodic imaging. Surgical intervention is reserved for cases where the hemangioma is symptomatic, exceeds 10 cm, shows diagnostic uncertainty after imaging, ruptures, or leads to Kasabach-Merritt syndrome. When surgery is indicated, the preferred approach is enucleation with arterial inflow control.

Hepatic hemangioma -review- - PMC

Liver Masses: A Clinical, Radiological and Pathological Perspective For

↑ *Back to this question in Part A*

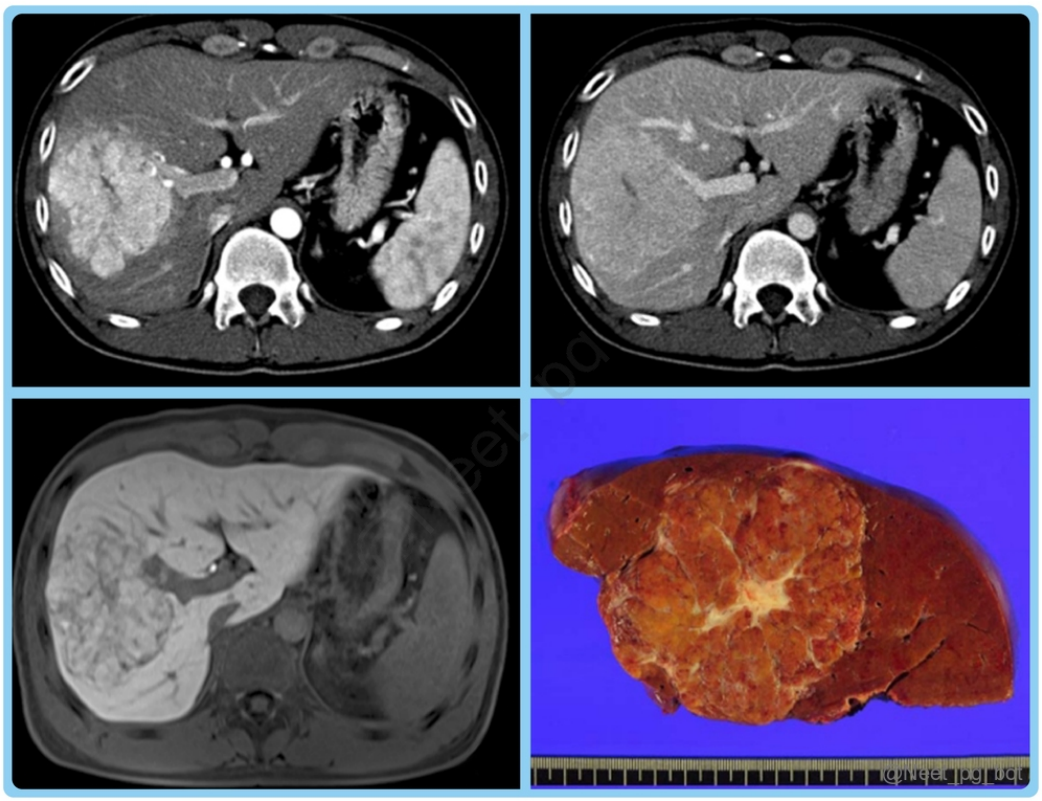
@Neet_pg_bot

Q4: During a routine abdominal ultrasound of a 35-year-old female, a liver lesion was noted. imaging with a CECT scan shows a central stellate scar within the lesion. What is the most likely diagnosis? (Q848894)

A. Hepatocellular carcinoma

B. Focal nodular hyperplasia

C. Hepatic adenoma



D. Hemangioma

Correct Answer: B. Focal nodular hyperplasia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Focal nodular hyperplasia (FNH) is the 2nd most common benign tumor of the liver. It is typically asymptomatic and often discovered incidentally during imaging for other reasons. It is more common in females Diagnosis: The investigation of choice for FNH is contrast-enhanced CT (CECT), which typically shows a characteristic central stellate scar due to the presence of a central feeding arteriole with multiple peripheral branches. Angiography may show a spoke-wheel or cartwheel pattern due to abnormal vascularity. A : arterial phase B : portal phase C : magnetic resonance imaging(MRI) D : pathological examination of the resected specimen.

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1213

Schwartz's Principles of Surgery, 11th Edition, Page 1376

Sabiston Textbook of Surgery, 21st Edition, Pages 1464, 1465

SRB's Manual of Surgery, 6th Edition, Page 599

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 24-year-old woman presents with complaints of right upper quadrant abdominal pain for the past few weeks. She has a history of using oral contraceptive pills for the past 5 years. On examination, the physician palpates a slightly tender, smooth, and well-defined mass in the right upper quadrant. Which of the following is the most likely diagnosis? (Q848895)

A. Hepatocellular carcinoma

B. Hepatic hemangioma

C. Hepatic adenoma

D. Focal nodular hyperplasia

Correct Answer: C. Hepatic adenoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hepatic adenoma is a benign proliferative disorder of hepatocytes. They are more common in females on OCPs . They are characterized by poorly supported peripherally located blood vessels. This can lead to: An increased risk of hemorrhage and necrosis Abdominal pain A high risk of tumor rupture (30-50%). In contrast, the risk of rupture in hepatocellular carcinoma is only 3-5%. An increased risk of tumour rupture during pregnancy Hepatocellular carcinoma (Option A) usually occurs in older patients with chronic liver disease (cirrhosis, hepatitis B/C). It is typically associated with weight loss, cachexia, and liver dysfunction , not isolated OCP use. A 24-year-old healthy woman on OCPs is highly unlikely to have HCC, so this option is ruled out. Hepatic hemangioma (Option B) is the most common benign liver tumor , but it is usually asymptomatic and found incidentally. It is typically non-tender and does not present with pain unless very large. It has no strong association with OCP use , making it less likely here. Focal Nodular Hyperplasia (Option D) occurs in young women but is not strongly linked to OCP use . It is usually asymptomatic and incidentally detected , unlike this painful presentation. It has a central stellate scar on imaging and low risk of rupture , so pain and tenderness are uncommon.

@Neet_pg_bot

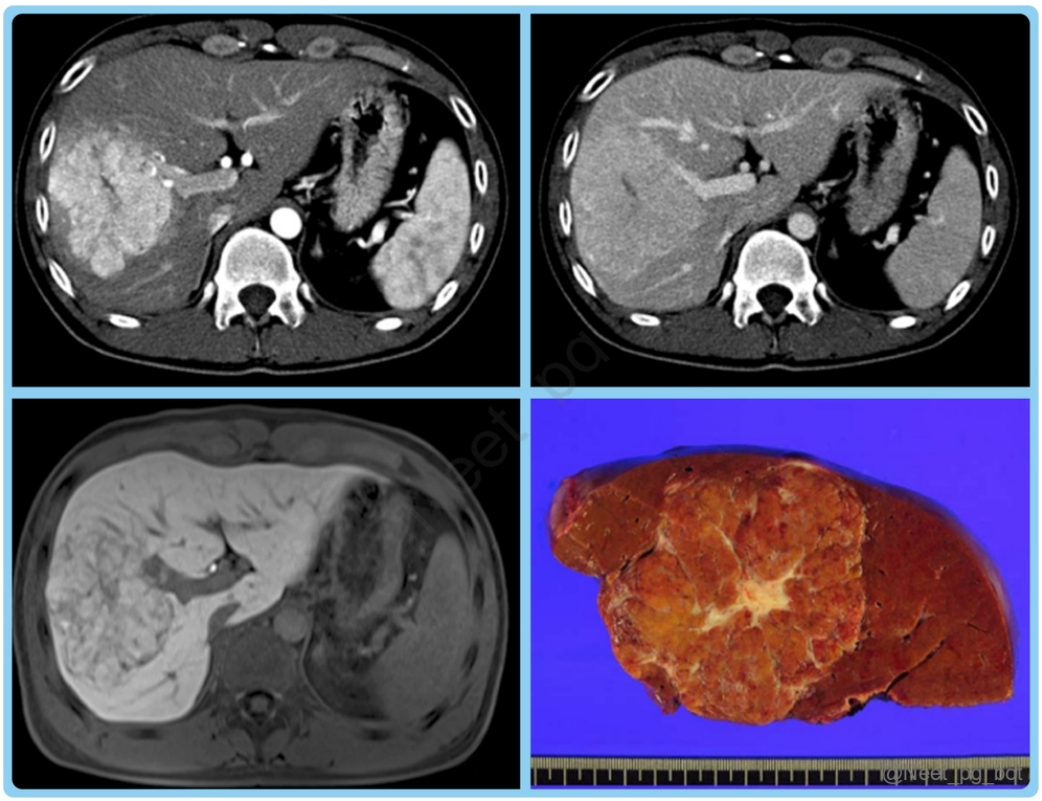
Q6: In which of the following conditions are these CECT findings seen? (Q848896)

A. Focal nodular hyperplasia

B. Serous cystadenoma of the pancreas

C. Renal oncocytoma

D. All of the above



Correct Answer: D. All of the above

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The above CECT image shows a C entral Stellate Scar, most commonly seen in Focal Nodular Hyperplasia. This is because of the central feeding arteriole, which has multiple peripheral branches. It can also be seen in: Fibrolamellar variant of Hepatocellular carcinoma Serous cystadenoma of the pancreas (Option B ruled out) Renal oncocytoma ■■■■■■■(Option C ruled out) ■■■■■■■ A : arterial phase B : portal phase C : magnetic resonance imaging(MRI) D : pathological examination of the resected specimen.

↑ *Back to this question in Part A*

@Neet_pg_bot

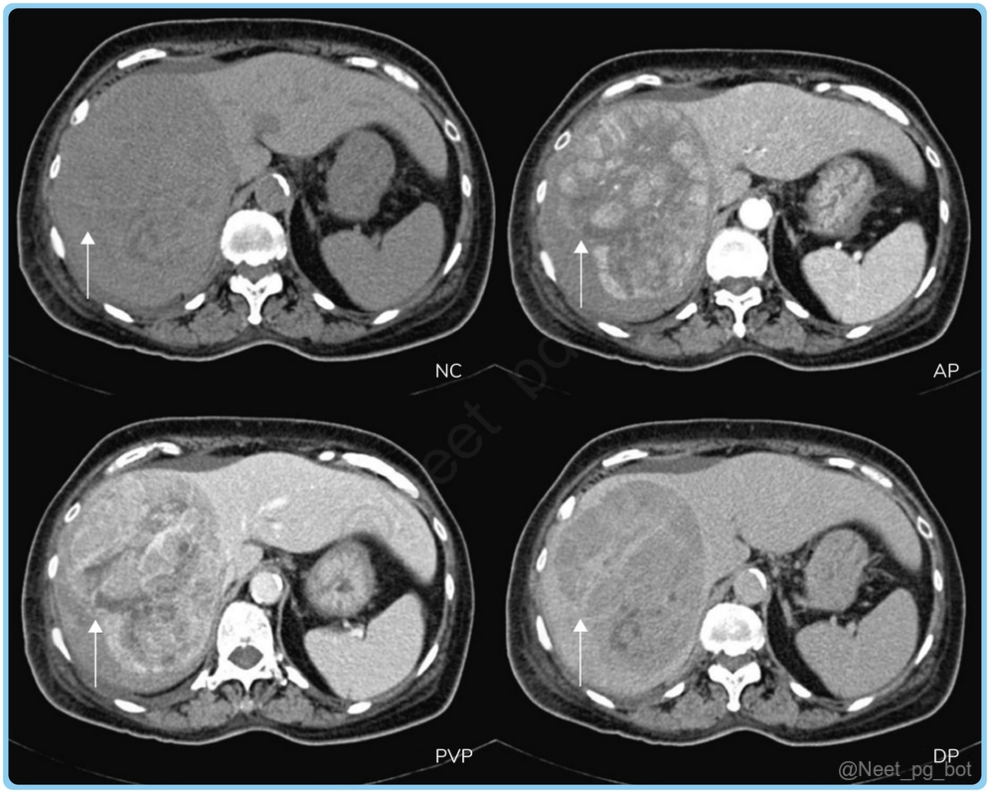
Q8: A 55-year-old man with a history of chronic hepatitis C and cirrhosis presents to the clinic with complaints of fatigue, unintentional weight loss, and abdominal discomfort. On physical examination, you note mild ascites and hepatomegaly. The serum alpha-fetoprotein level is elevated. What is the investigation of choice in this patient? (Q848902)

A. MRI with MRCP

B. CECT

C. Triple phase CT



D. Liver biopsy

Correct Answer: C. Triple phase CT

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In a patient with known risk factors for hepatocellular carcinoma (HCC) , such as chronic hepatitis C and cirrhosis, and elevated serum alpha-fetoprotein levels, the investigation of choice is Triple phase CT. The preferred method for definitive diagnosis of HCC is a Triple Phase CT scan , which highlights arterial hypervascularization and venous washout. A triple-phase CT scan has the following phases: Arterial Phase - HCC shows hyperenhancement due to its arterial blood supply. Portal Venous Phase - HCC may appear isodense or hypodense as it becomes less conspicuous compared to the surrounding liver tissue. Delayed Phase - HCC exhibits washout, a characteristic feature - appearing hypodense relative to the liver parenchyma.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 12-year-old boy presents with a history of fatigue, abdominal distension, and jaundice. He has a known diagnosis of liver cirrhosis secondary to chronic hepatitis B infection. Recently, he has developed a palpable liver mass, and imaging studies confirm the presence of hepatocellular carcinoma. Which of the following parameters is not typically used in the prognosis of his condition? (Q848903)

A. Serum bilirubin

B. Serum ammonia

C. Serum albumin

D. Prothrombin time/INR

Correct Answer: B. Serum ammonia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The prognosis of hepatocellular carcinoma (HCC) in patients with underlying liver cirrhosis is heavily influenced by liver function, which is often assessed using the Child-Pugh (CP) score. Serum ammonia is typically associated with hepatic encephalopathy rather than being a direct measure used in the prognosis of HCC. Therefore, it is not typically used in the prognosis of hepatocellular carcinoma. Child-Pugh Score Parameter 1 Point 2 Points 3 Points Serum Bilirubin (mg/dL) < 2 2-3 > 3 Serum Albumin (g/dL) > 3.5 2.8-3.5 < 2.8 Prothrombin Time/ INR < 4 <1.7 4-6 1.7–2.2 > 6 >2.2 Ascites None Mild Moderate to Severe Encephalopathy None Grade 1-2 Grade 3-4 Class A : 5-6 points (well-compensated disease) Class B : 7-9 points (significant functional compromise) Class C : 10-15 points (decompensated disease)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 24-year-old female from Southeast Asia presents with abdominal pain and a palpable liver mass. She has no history of hepatitis B or C infection, and no signs of cirrhosis. Imaging studies show a well-circumscribed, non-encapsulated tumor in the liver with a central stellate scar. Laboratory tests reveal normal alpha-fetoprotein levels but elevated neurotensin and B12 binding globulin. What is the most likely diagnosis? (Q848906)

A. Scirrhous Variant of Hepatocellular Carcinoma

B. Fibrolamellar Variant of Hepatocellular Carcinoma

C. Cholangiocarcinoma

D. Metastatic Liver Cancer

Correct Answer: B. Fibrolamellar Variant of Hepatocellular Carcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Fibrolamellar Variant of Hepatocellular Carcinoma, unlike other variants of HCC, has the following characteristics: Seen in young patients (<35 years), and the incidence is the same in Males &Females Well-circumscribed non-encapsulated tumor with a fibrous stroma and lamellar structure. Not associated with hepatitis B, hepatitis C, or cirrhosis. Presence of a central stellate scar on imaging. Normal alpha-fetoprotein levels, along with elevated neurotensin and B12 binding globulin. The investigation of choice is CECT, and the treatment is resection of the tumor-infested hepatic region. Scirrhous Variant of Hepatocellular Carcinoma (Option A) occurs in older patients and is usually associated with cirrhosis . It does not characteristically show a central stellate scar on imaging. AFP may be elevated , unlike this case. Cholangiocarcinoma (Option C) is typically seen in older individuals , often associated with: Primary sclerosing cholangitis Chronic biliary disease Imaging shows irregular mass with biliary duct dilatation , not a well-circumscribed lesion with central scar Tumor markers: CA 19-9 elevated , not neurotensin/B12 binding globulin Metastatic Liver Cancer (Option D) usually presents as multiple liver lesions , not a single well-circumscribed mass. No central stellate scar pattern typical of fibrolamellar HCC. Clinical history often reveals a primary tumor elsewhere .

@Neet_pg_bot

Q12: A 2-year-old male presents with an asymptomatic palpable abdominal mass detected during a routine physical examination. The child has a history of low birth weight and no history of hepatitis B or C infection. Laboratory tests reveal elevated alpha-fetoprotein levels. Imaging studies show a large intra-abdominal mass. Biopsy confirms hepatoblastoma. Which of the following statements about hepatoblastoma is incorrect? (Q848907)

A. Hepatoblastoma is the most common primary malignancy of the liver in children.

B. The most common route of spread for hepatoblastoma is lymphatic.

C. Hepatoblastoma is not associated with Hepatitis B or C infection.

D. The most characteristic laboratory abnormality is thrombocytosis.

Correct Answer: B. The most common route of spread for hepatoblastoma is lymphatic.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The most common route of spread for hepatoblastoma is hematogenous, not lymphatic. Hematogenous spread primarily involves the lungs as the most common site of metastasis. Hepatoblastoma Incidence The most common primary malignancy of the liver in children Age Group Most patients are less than 18 months old All patients are less than 3 years old Associated with Familial Adenomatous Polyposis Beckwith-Wiedemann Syndrome Low Birth Weight (LBW) Not associated with Hepatitis B or C, metabolic disorders, or cirrhosis Clinical Presentation Asymptomatic palpable intra-abdominal mass (hepatomegaly) Laboratory Findings Elevated alpha-fetoprotein level in 90% of patients Thrombocytosis (Most characteristic) Route of Spread; MC organ of metastasis Hematogenous; Lungs Diagnosis Biopsy (Investigation of choice) CECT (Radiological Investigation of choice) Management No metastasis- Resection Metastasis- Resection + Neoadjuvant Chemotherapy (Vincristine, Cisplatin, 5-Fluorouracil)

@Neet_pg_bot

Q13: A 55-year-old male with a history of chronic liver disease secondary to hepatitis C presents for evaluation due to worsening ascites, jaundice, and weight loss. He has been diagnosed with hepatocellular carcinoma (HCC). Imaging reveals a single liver lesion measuring 4 cm in diameter with no evidence of vascular invasion or extrahepatic spread. Laboratory studies show stable liver function tests and AFP levels below 100 ng/mL. Which of the following criteria is the most critical in determining his eligibility for liver transplantation? (Q848908)

A. Tumor size less than or equal to 5 cm

B. Absence of portal vein thrombosis

C. AFP (Alpha-fetoprotein) levels below 400 ng/mL

D. Platelet count greater than 100,000/µL

Correct Answer: A. Tumor size less than or equal to 5 cm

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Milan Criteria is used to determine the eligibility of patients with hepatocellular carcinoma (HCC) for liver transplantation. It helps to select patients who are most likely to benefit from the transplant, with a lower risk of cancer recurrence Milan Criteria for Liver Transplantation Criteria Details Tumor Size and Number Single tumor ≤ 5 cm in diameter Up to three tumors, each ≤ 3 cm in diameter Absence of Vascular Invasion No evidence of invasion of the major blood vessels by the tumor No Extrahepatic Spread No metastasis or spread of the tumor outside the liver

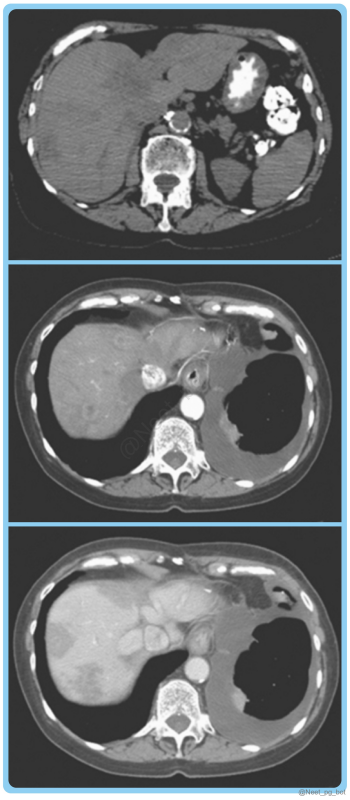
@Neet_pg_bot



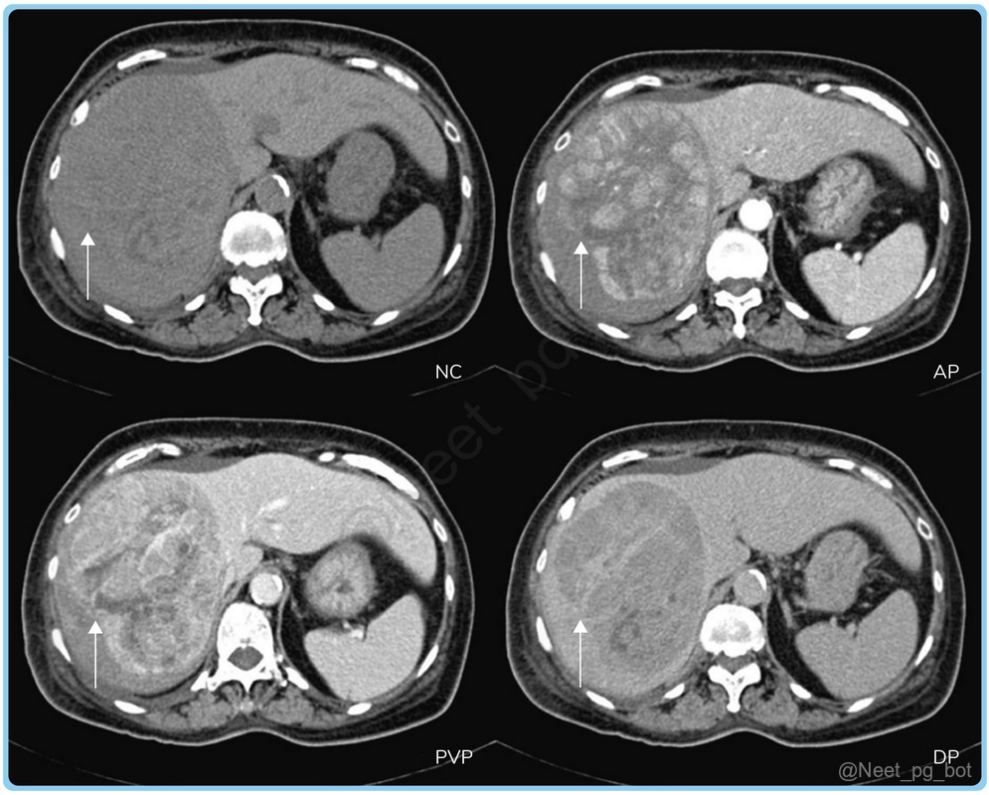
Q14: From the below given triple phase CT scan, which of the following statements is true regarding Liver cancer? (Q848909)

A. Hypodense in arterial phase in HCC

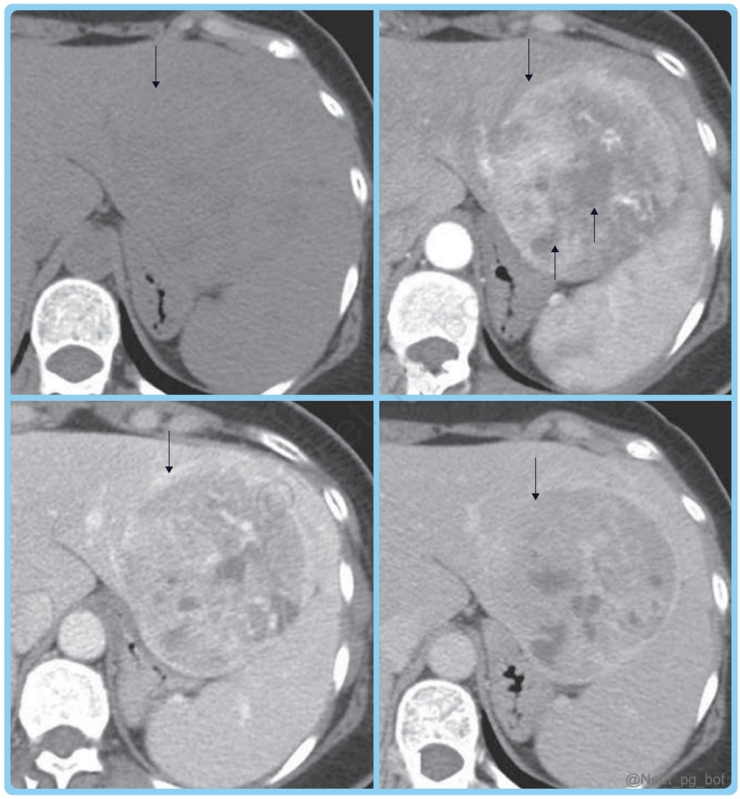
B. Hyperdense in arterial phase in Metastasis liver disease

C. Hyperdense in non-contrast CT in HCC

D. Hypodense in venous phase in Metastasis liver disease



Correct Answer: D. Hypodense in venous phase in Metastasis liver disease



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Triple-phase CT in Different Liver Pathologies Phase Arterial Phase Portal Venous Phase Delayed Phase Hepatocellular Carcinoma (HCC) Hypervascular with intense enhancement; lesion appears hyperdense compared to surrounding liver. Washout of contrast; lesion appears hypodense (darker) compared to liver tissue. Further washout; lesion remains hypodense or becomes isodense (similar density to liver). Liver Metastasis Hypovascular metastases appear hypodense. Hypervascular metastases (e.g., neuroendocrine tumors) may show rim enhancement. Lesions appear hypodense and become more distinct. Lesions remain hypodense, continuing to

stand out from liver tissue. Triple Phase CT in Hepatic Cell Carcinoma Triple Phase CT in Liver Metastasis

Q13 (p. 1615) *Q14 (p. 1616)*

Q1: A 45-year-old female who recently underwent bone marrow transplantation presents with abdominal pain and swelling. The clinical features resonate with hepatic veno-occlusive disease and a transvenous hepatic biopsy confirms the diagnosis. Which of the following symptoms is NOT a part of the clinical triad of hepatic veno-occlusive disease? (Q849016)

A. Tender hepatomegaly

B. Hyperbilirubinemia (jaundice)

C. Retention of fluid (ascites)

D. Portal hypertension

Correct Answer: D. Portal hypertension

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical triad of veno-occlusive disease includes tender hepatomegaly, hyperbilirubinemia (jaundice), and retention of fluid (ascites) While portal hypertension can be a complication of VOD, it is not part of the clinical triad Hepatic veno-occlusive disease / Sinusoidal Obstruction Syndrome Definition Hepatic venous outflow obstruction caused by endothelial sclerosis of sublobular hepatic veins and venules Etiology The most common cause in Western countries: Bone marrow transplantation Chemotherapy agents: Cytarabine, Thioguanine, Gemtuzumab, Ozogamicin Immunosuppressive agents: Azathioprine Consumption of bush teas: Crotalaria and Senecio (contain pyrrolizidine alkaloids) Clinical Features (Triad) Tender hepatomegaly Hyperbilirubinemia (jaundice) Retention of fluid (ascites) Diagnosis Investigation of choice: Biopsy Management SSPCS (Side-to-side portocaval shunt): Only if hepatic venous outflow obstruction with IVC sparing Liver transplantation: For hepatic failure Defibrotide: Improves survival

@Neet_pg_bot

Q2: Which of the following is a pre-sinusoidal cause of portal hypertension? (Q849006)

A. Cirrhosis

B. Budd-Chiari syndrome

C. Congestive cardiac failure

D. Schistosomiasis

Correct Answer: D. Schistosomiasis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Schistosomiasis is one of the pre-sinusoidal intrahepatic Causes of Portal Hypertension. Pre-sinusoidal Extrahepatic Portal vein thrombosis Splenic vein thrombosis Myelofibrosis Arterioportal shunt Tropical splenomegaly Intrahepatic Schistosomiasis Congenital hepatic fibrosis Portal infiltration (e.g., sarcoidosis) Drugs and toxins Sinusoidal ■■■■■■■ Cirrhosis (Option A ruled out) Post-sinusoidal ■■■■■■■■ ■■■■■■■■ Hepatic vein occlusion: Budd-Chiari syndrome (Option B ruled out) Veno-occlusive disease Congestive cardiac failure (Option C ruled out)

References:

Bailey and Love’s Short Practice of Surgery, 28th Edition, Page 1203-1204.

↑ *Back to this question in Part A*

@Neet_pg_bot

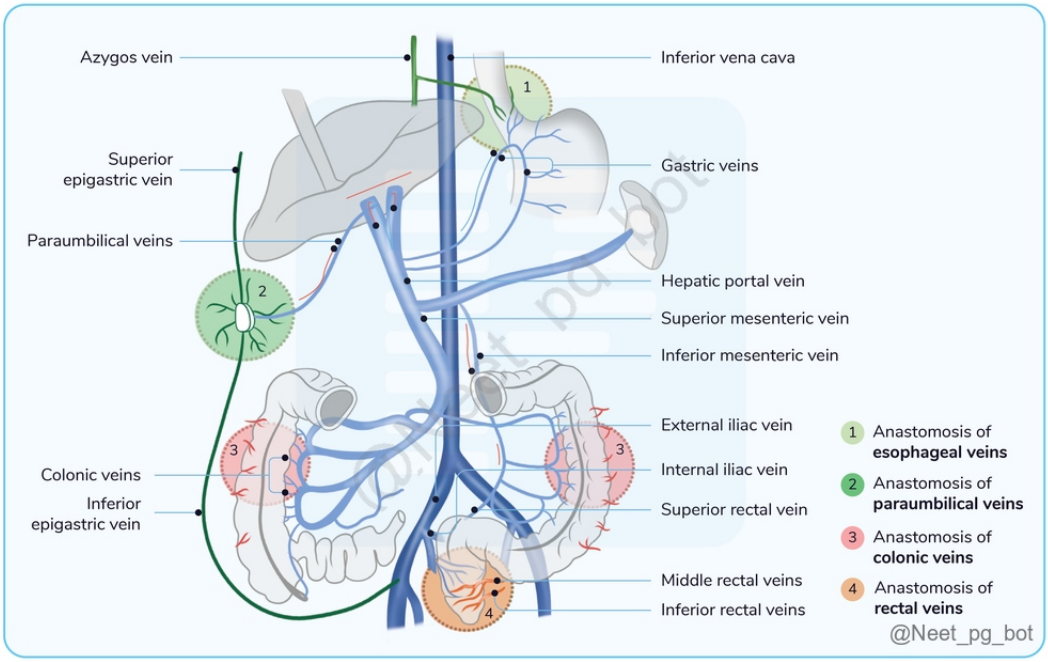
Q3: A 52-year-old man presents to the emergency department with worsening abdominal distension and visible abdominal veins. He has a history of chronic alcohol abuse and has been experiencing increasing fatigue and jaundice. Collaterals are between the paraumbilical vein &.....: Which of the following vessels is involved in this condition? (Q849007)

A. Left gastric vein

B. Superior and inferior epigastric vein

C. Superior mesenteric vein

D. Inferior vena cava



Correct Answer: B. Superior and inferior epigastric vein

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Caput medusae is a clinical sign associated with portal hypertension . It occurs due to increased pressure in the portal venous system, resulting in the development of engorged veins around the umbilicus. It usually forms a shunt between the paraumbilical vein and the inferior and superior epigastric vein . Sites of portosystemic anastomosis:

Portal venous component	Systemic venous component	Manifestation and site
Left gastric vein (aka coronary vein)	Azygous vein	Esophageal varices at GE junction (A)
Superior rectal vein	Middle and inferior rectal veins	Rectal varices (internal hemorrhoids) at the rectum (B)
Paraumbilical vein	Superior and inferior epigastric vein	Caput medusae at the umbilicus (C)

@Neet_pg_bot

www.ncbi.nlm.nih.gov/pmc/articles/PMC5198179/

www.ncbi.nlm.nih.gov/pmc/articles/PMC5198179/

↑ *Back to this question in Part A*

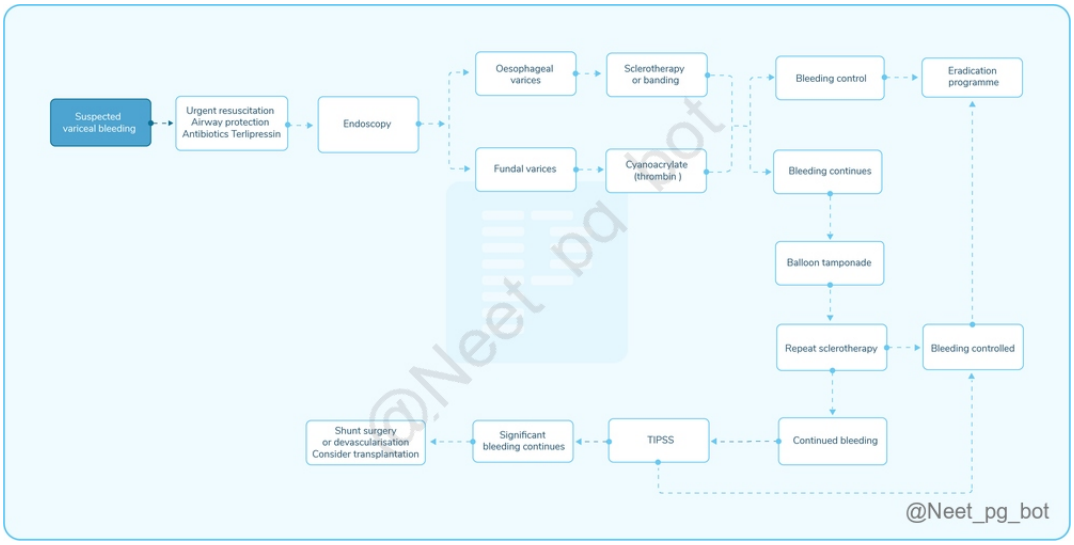
@Neet_pg_bot

Q4: A 55-year-old man with a history of cirrhosis presents to the emergency department with hematemesis and melena. He is hypotensive and tachycardic. Which of the following is the most appropriate initial step in management? (Q849008)

A. Order an urgent upper endoscopy

B. Administer a proton pump inhibitor

C. Request a CT scan of the abdomen



D. Initiate fluid resuscitation

Correct Answer: D. Initiate fluid resuscitation

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The immediate priority in managing variceal bleeding is stabilizing the patient's condition. This involves the airway, breathing, and circulation. Establishing intravenous access with large-bore cannulae allows for rapid fluid resuscitation , ideally with blood transfusions, to restore circulatory volume and address hypotension. While endoscopy (Option A) is crucial for diagnosis and definitive treatment of variceal bleeding, it should only be performed after the patient is hemodynamically stable. Proton pump inhibitors (Option B) reduce gastric acid secretion but have no role in the initial management of acute variceal bleeding. CT scanning (Option C) can help evaluate the liver and portal vein, but it is not a priority during the initial resuscitation phase.

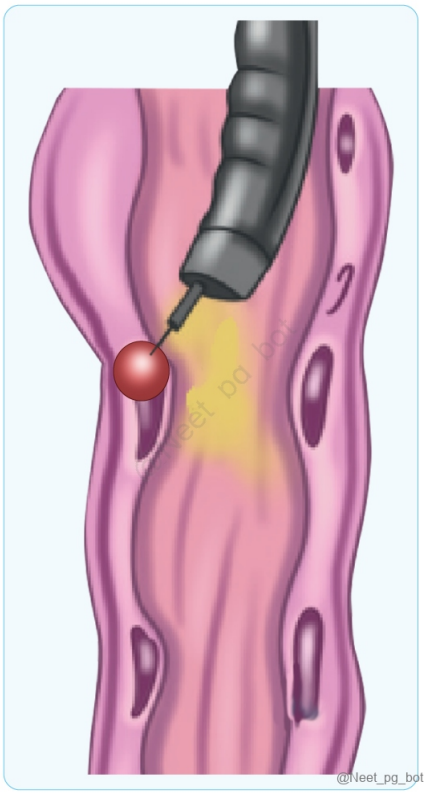
Bailey and Love’s Short practice of surgery, 28th Edition, Page 1203-1204.

↑ *Back to this question in Part A*

@Neet_pg_bot



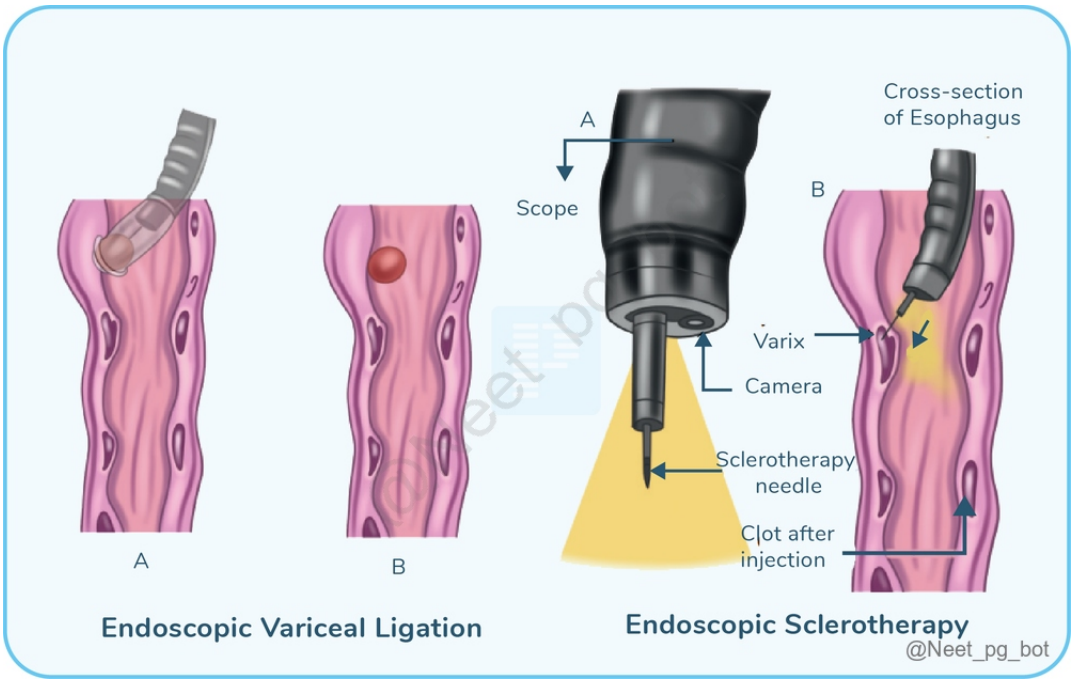
Q5: Which of the following statements is true about the image below? (Q849009)

A. Technically difficult to perform

B. Decreased chances of perforation

C. Always preferred over ligation

D. Lack of depth perception is present



Correct Answer: D. Lack of depth perception is present

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The image is a procedure of Endoscopic sclerotherapy commonly done in the case of esophageal variceal bleeding. Endoscopic sclerotherapy , while easier to perform, has a higher risk of esophageal perforation due to reduced depth perception during the procedure. A double-channel endoscope equipped with a bridge is essential for performing sclerotherapy. The bridge facilitates suction during the injection process and enhances the maneuverability of the needle. The sclerosants commonly used include Sodium Tetradecyl Sulfate, ethanolamine oleate , etc. Treatment of Choice to Control Bleeding: Endoscopic Variceal Ligation (Option C) is preferred over endoscopic sclerotherapy for controlling bleeding from variceal hemorrhage. EVL is technically more challenging to perform but carries a lower risk of esophageal perforation compared to sclerotherapy.

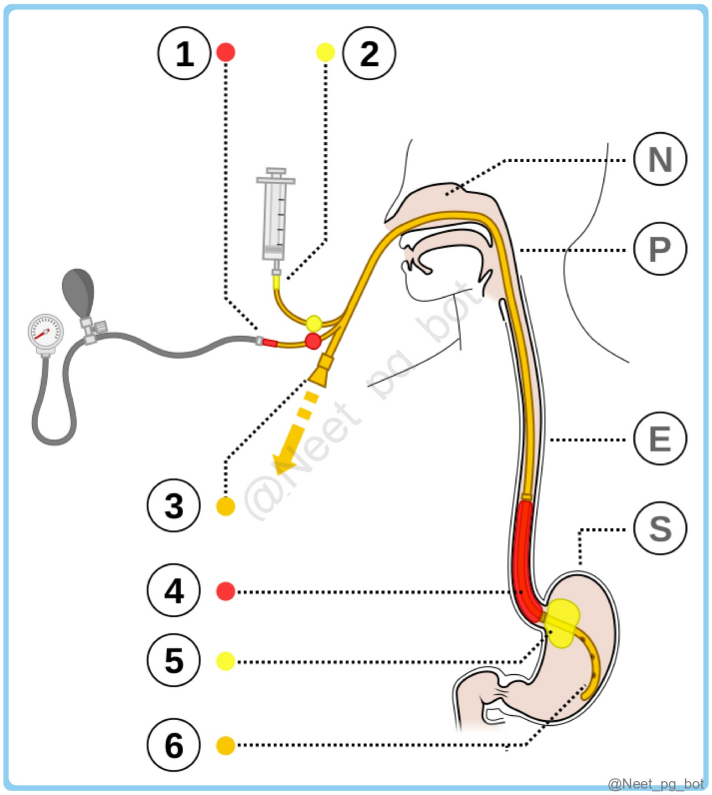
Bailey and Love's practice of Surgery, 28th Edition, Page 1205

↑ *Back to this question in Part A*

@Neet_pg_bot



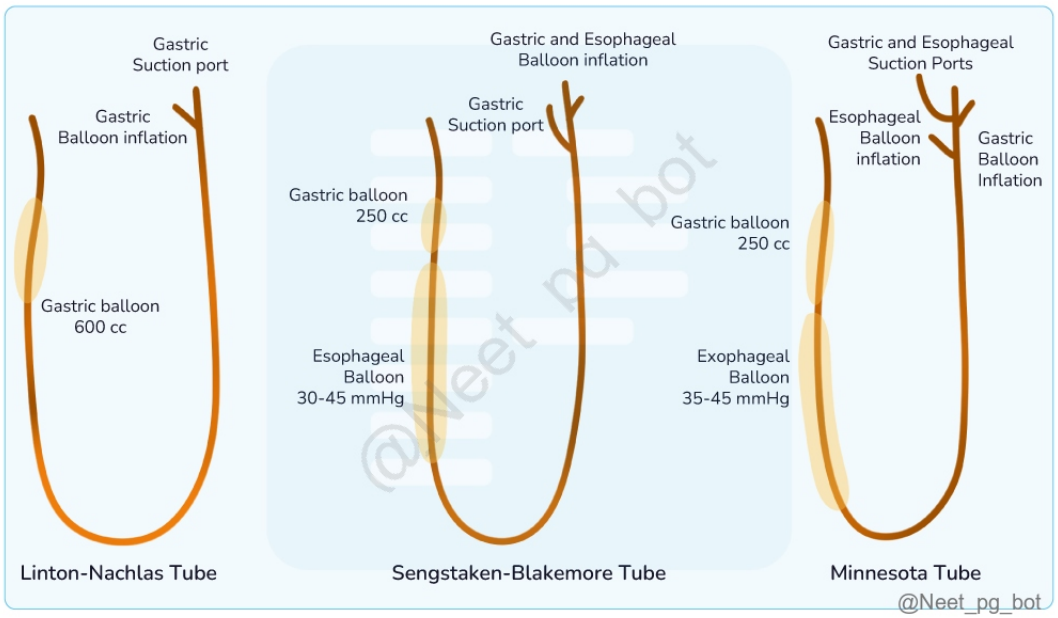
Q6: Identify the tube shown in the following image used in the management of portal hypertension. (Q849010)

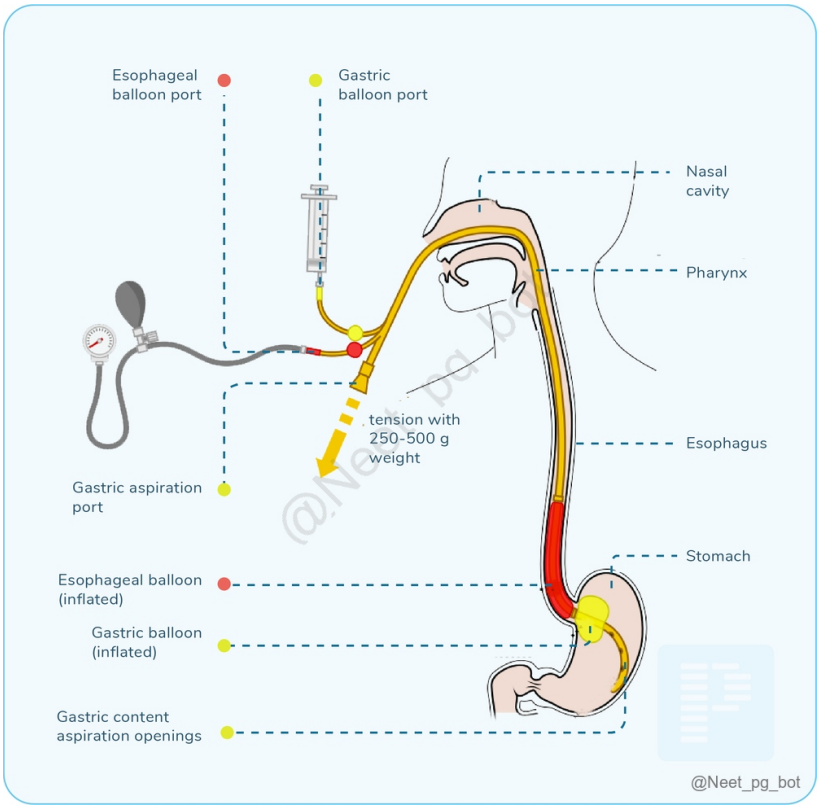
A. Sengstaken-Blakemore tube

B. Minnesota tube

C. Linton-Nachlas tube

D. Nasogastric (Ryle's) tube





Correct Answer: A. Sengstaken-Blakemore tube

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Sengstaken-Blakemore tube is used to manage esophageal variceal bleeding. The tube has 3 lumens and 2 inflatable balloons: Lumens : Gastric Aspiration Lumen : This lumen allows for the drainage of gastric contents. It helps to monitor and manage any bleeding from the stomach. Gastric Balloon Lumen : This lumen is connected to the gastric balloon and is used to inflate it with air or saline, anchoring the tube in place within the stomach. Esophageal Balloon Lumen : This lumen is connected to the esophageal balloon and is used to inflate it, applying pressure to the esophageal varices to stop bleeding. Balloons : Gastric Balloon : Positioned in the stomach, this balloon is inflated to anchor the tube and to apply pressure to the area of bleeding if necessary. Esophageal Balloon : This balloon is inflated within the esophagus to exert pressure directly on the bleeding varices, helping to control hemorrhage. The tube is inserted through the nose or mouth and carefully advanced into the stomach. Once in position, the balloons are sequentially inflated to apply pressure on the bleeding varices, effectively controlling hemorrhage. This intervention is temporary and used in the emergency setting until definitive treatments, such as endoscopic procedures, can be performed. The Minnesota tube (Option B) is similar to the Sengstaken-Blakemore tube but with an additional lumen for the suction of esophageal secretions. The Linton-Nachlas tube (Option C) is used for the decompression of the stomach and the prevention of aspiration in cases of massive upper gastrointestinal hemorrhage. It is not commonly used for esophageal varices but rather for general decompression and bleeding control in the stomach. Nasogastric (Ryle's) tube (Option D) is used for gastric decompression, feeding, and administering medications. It is not designed for controlling esophageal variceal bleeding.

Sabiston Textbook of Surgery, 21st Edition, Page 1446.

↑ *Back to this question in Part A*

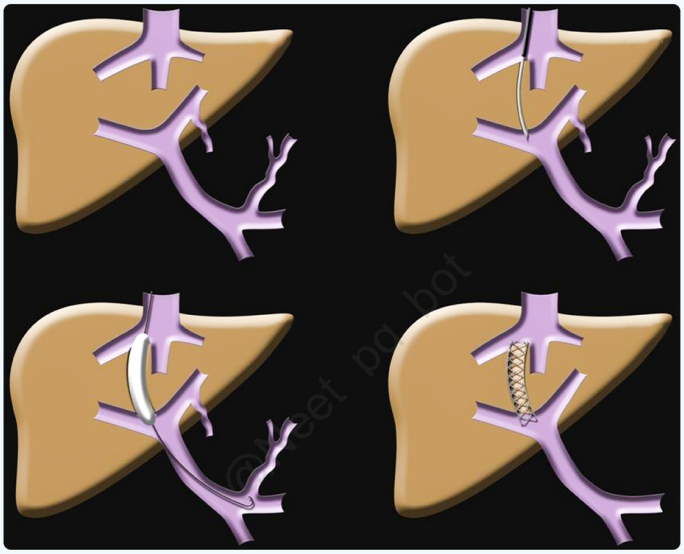
@Neet_pg_bot

Q7: A 60-year-old patient with refractory ascites secondary to cirrhosis undergoes Transjugular intrahepatic portosystemic shunt placement. Two days post-procedure, the patient develops severe dyspnea, peripheral edema, jugular venous distension, and hypotension. A Doppler ultrasound reveals a patent shunt. Which of the following is the most likely cause of the patient's symptoms? (Q849011)

A. Right heart failure

B. Hepatorenal syndrome

C. Pulmonary hypertension



D. Porto-pulmonary hypertension

Correct Answer: A. Right heart failure

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Post-TIPSS, the increased preload from the diverted blood flow can overwhelm the right heart, leading to right heart failure. This presents as severe dyspnea, peripheral edema, jugular venous distension, and hypotension. The management includes the use of diuretics to reduce fluid overload. TIPSS (Transjugular Intrahepatic Porto Systemic Shunt) It is a nonselective shunt used to treat complications of portal hypertension. The liver is accessed through the Jugular vein and the stent is placed to create a channel between the right Hepatic vein and the right branch of the portal vein. Reduces portal pressure by diverting blood flow. Indications Contraindications Variceal bleeding Refractory ascites Hepatic hydrothorax Budd Chiari Syndrome Portal Hypertensive gastropathy Severe hepatic encephalopathy Severe heart failure Severe pulmonary hypertension Uncontrolled systemic infection Polycystic liver disease The hepatorenal syndrome (Option B) occurs in advanced liver disease characterized by renal failure due to altered renal perfusion without structural kidney damage. It presents with renal dysfunction (e.g., oliguria, elevated serum creatinine) rather than severe dyspnea, peripheral edema, and jugular venous distension. Pulmonary hypertension (Option C) can occur in liver disease but is less likely to cause acute severe dyspnea, peripheral edema, and jugular venous distension immediately post-TIPSS. This condition usually develops gradually and presents with symptoms like fatigue, chest pain, and dyspnea on exertion. Porto-pulmonary hypertension (Option D) develops over time and is characterized by increased pulmonary artery pressure.

Steps in a TIPS procedure :

A Portal hypertension has caused the coronary vein (arrow) and the umbilical vein (arrowhead) to dilate and flow in reverse.
B A needle has been introduced (via the jugular vein) and is passing from the hepatic vein into the portal vein
C The tract is dilated with a balloon.
D After placement of a stent, portal pressure is normalized

Bailey & Love Short Practice of Surgery, 28th Edition, Page 1205.

↑ *Back to this question in Part A*

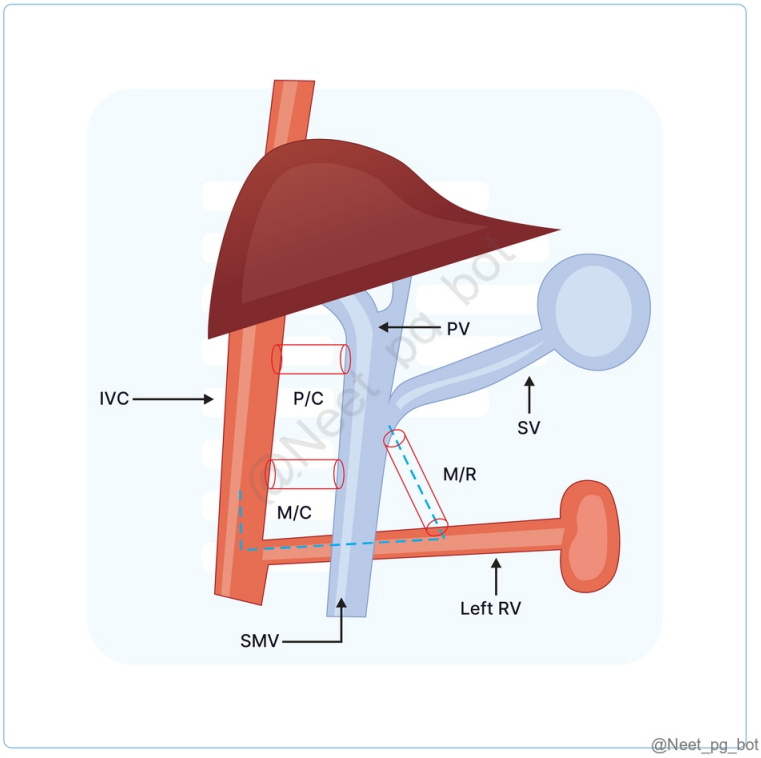
@Neet_pg_bot

Q8: Which of the following complications is most likely to occur after the creation of a side-to-side portocaval shunt (SSPCS)? (Q849012)

A. Encephalopathy

B. Renal failure

C. Recurrent variceal bleeding



D. Portal vein thrombosis

Correct Answer: A. Encephalopathy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Encephalopathy is a common complication following the creation of a non-selective shunt like the side-to-side portocaval shunt (SSPCS). This is because the shunt allows portal blood which contains toxins, to bypass the liver and enter the systemic circulation directly, leading to hepatic encephalopathy. Non-Selective Shunts: Non-selective shunts are surgical procedures used to manage portal hypertension by diverting blood flow from the portal venous system directly into the systemic circulation, bypassing the liver. This reduces portal pressure and decreases complications like variceal bleeding. However, they also reduce hepatic blood flow, potentially leading to liver ischemia and worsening hepatic function. Side-to-side portocaval Shunt (SSPCS) involves a side-to-side anastomosis between the portal vein and the inferior vena cava. Used for conditions such as Budd-Chiari syndrome, veno-occlusive disease, and refractory ascites. Most widely performed shunt due to its effectiveness in reducing portal pressure. High risk of hepatic encephalopathy due to the diversion of blood away from the liver, reducing its detoxification capacity. Other Non-Selective Shunts: Eck Fistula is an end-to-side portocaval shunt where the portal vein is divided, and its proximal part is sutured to the inferior vena cava. Interposition Grafts - A vascular graft is used to connect the portal vein to the systemic circulation. Types include portocaval, mesocaval (superior mesenteric vein to inferior vena cava), and mesorenal (superior mesenteric vein to left renal vein) grafts. Used when a direct shunt is not feasible or preferred. IVC - Inferior Vena Cava; P/C - Porto-caval; M/C - Meso-caval; M/R - Meso-renal; PV - Portal Vein; SMV - Superior Mesenteric Vein; SV - Splenic Vein; Left RV - Left Renal Vein

References:

Sabiston Textbook of Surgery, 21st Edition, Page 1448.

↑ *Back to this question in Part A*

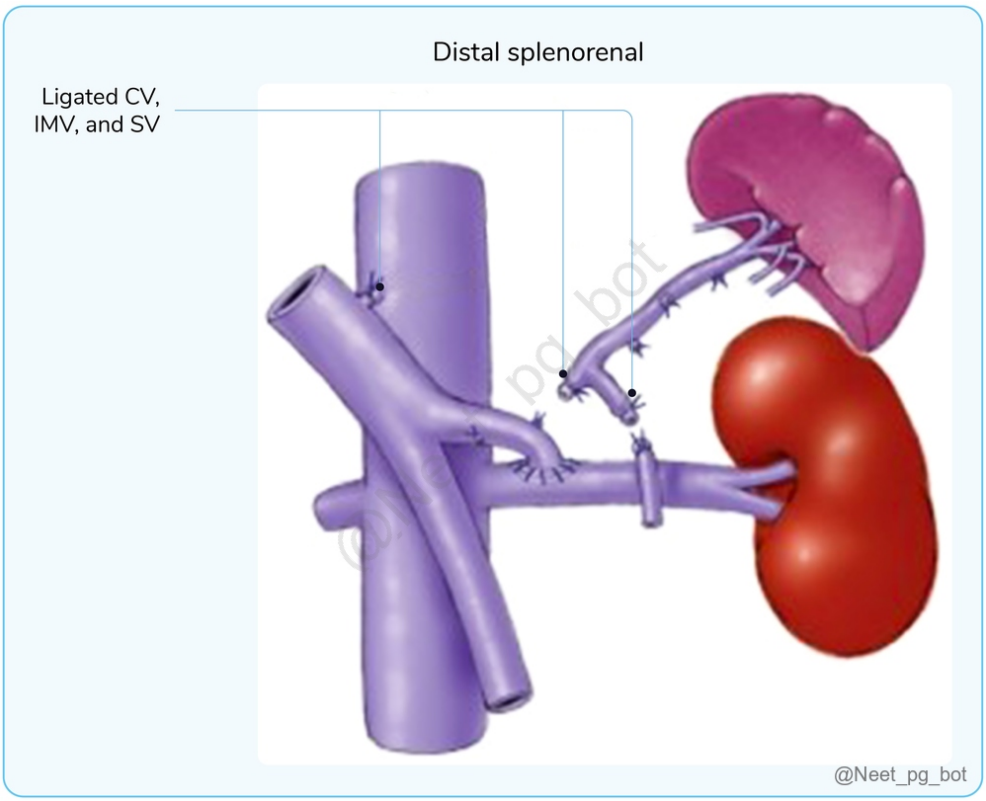
@Neet_pg_bot

Q9: Which selective shunt procedure is associated with the preservation of portal perfusion to the liver while effectively decompressing varices? (Q849013)

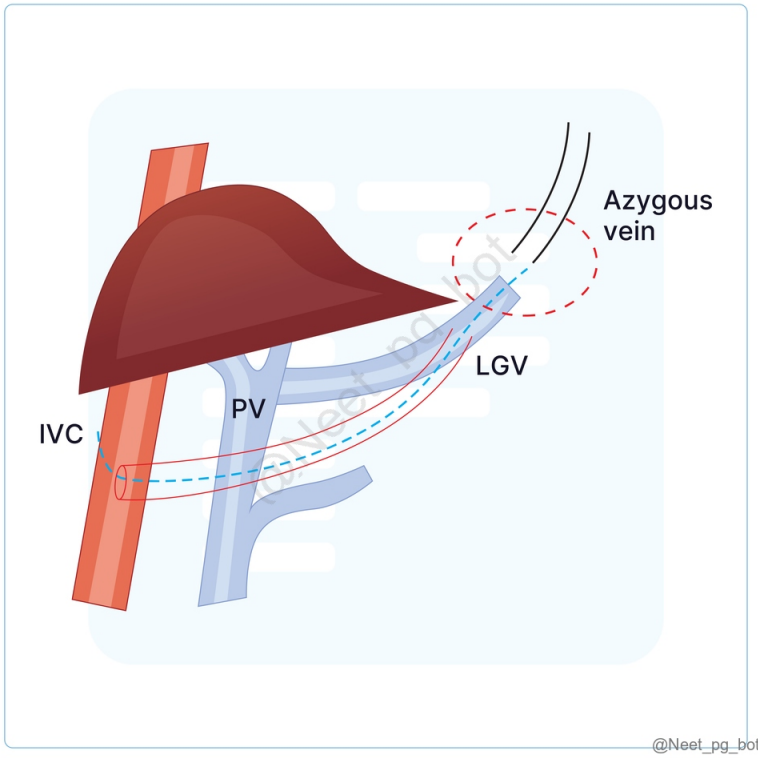
A. Distal splenorenal shunt (DSRS)

B. Proximal splenorenal shunt (PSRS)

C. Side-to-side portocaval shunt (SSPCS)



D. Interposition grafts



Correct Answer: A. Distal splenorenal shunt (DSRS)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Selective shunts are designed to divert blood from specific parts of the portal system, preserving some hepatic portal perfusion and reducing the risk of hepatic encephalopathy. Distal Splenorenal Shunt (DSRS) or Warren Shunt The distal part of the splenic vein is anastomosed to the left renal vein. Selectively decompresses the spleen and gastroesophageal junction varices while maintaining hepatic portal flow. Lower risk of encephalopathy compared to non-selective shunts. Inokuchi Shunt Involves an interposition graft between the left gastric vein and the inferior vena cava. Used for selectively draining the gastroesophageal junction, particularly in patients with gastroesophageal varices. Proximal splenorenal shunt (Option B) after splenectomy, connects the proximal splenic vein to the left renal vein but does not specifically focus on preserving portal perfusion to the liver. Side-to-side portocaval shunt (Option C) diverts a significant portion of portal blood flow to the inferior vena cava, reducing portal pressure but not preserving liver perfusion. Interposition grafts (Option D) are non-selective shunts that can be used to connect the portal vein to the systemic circulation.

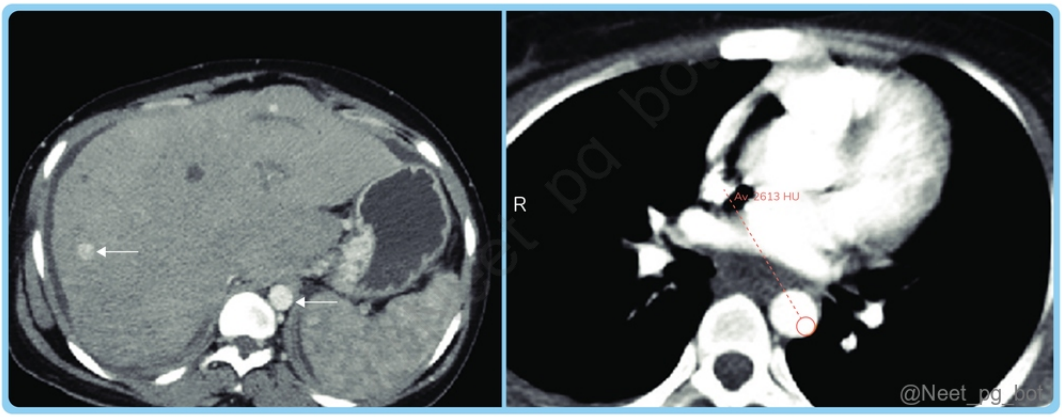
@Neet_pg_bot

Q10: In a patient with Budd Chiari Syndrome, which of the following imaging findings is most indicative of chronic disease? (Q849014)

A. Enlarged caudate lobe

B. Ascites

C. Hepatic vein thrombosis



D. Splenomegaly

Correct Answer: A. Enlarged caudate lobe

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The enlarged caudate lobe is a hallmark of chronic Budd Chiari Syndrome. The caudate lobe has its own venous drainage directly into the inferior vena cava, allowing it to remain viable and potentially enlarge when the rest of the liver is affected by venous outflow obstruction. Budd-Chiari Syndrome Etiology The most common cause is hepatic venous thrombosis. Other causes include inferior vena cava obstruction. Risk Factors: Polycythemia vera Thrombophilic disorders Malignancies Clinical Features The characteristic triad includes ascites, hepatomegaly, and abdominal pain. Jaundice, encephalopathy, anorexia, and fatigue may occur if hepatic failure develops. Diagnosis Venography is the investigation of choice, showing spider web collaterals if the hepatic veins are involved, or vena cavography if the inferior vena cava is obstructed Treatment Treatment includes anticoagulants, thrombolysis (if within the window period), and surgical intervention. In cases of liver failure, liver transplantation is the treatment of choice Ascites (Option B) can occur in both acute and chronic Budd Chiari Syndrome and is not specific to the chronic stage of the disease. While hepatic vein thrombosis (Option C) is a key feature of Budd-Chiari Syndrome, it can be present in both acute and chronic stages and does not specifically indicate chronicity. Splenomegaly (Option D) is a common finding due to portal hypertension but can be seen in both acute and chronic phases, thus not specifically indicative of chronic disease.

References:

Bailey & Love Short Practice of Surgery, 28th Edition, Page 1208

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A 12-year-old boy presents with a history of recurrent episodes of gastrointestinal bleeding. He has no history of liver disease, jaundice, or ascites. Physical examination reveals moderate splenomegaly but no hepatomegaly. Doppler ultrasound of the abdomen shows obstruction at the confluence of the splenic vein and the superior mesenteric vein. What is the most likely diagnosis? (Q849015)

A. Cirrhosis

B. Non-Cirrhotic Portal Fibrosis (NCPF)

C. Extrahepatic Portal Vein Obstruction (EHPVO)

D. Budd-Chiari Syndrome

Correct Answer: C. Extrahepatic Portal Vein Obstruction (EHPVO)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Extrahepatic Portal Vein Obstruction (EHPVO) is characterized by obstruction of the portal vein outside the liver, commonly at the confluence of the splenic vein and superior mesenteric vein. It is often seen in younger patients 1st to 2nd decade of life and can present with gastrointestinal bleeding and splenomegaly without signs of liver disease Other options: Cirrhosis (Option A) typically presents with signs of liver disease, such as jaundice, ascites, and hepatomegaly, none of which are present in this patient. Non-Cirrhotic Portal Fibrosis (NCPF) (Option B) involves the intrahepatic branches of the portal vein and typically presents in the 2nd to 4th

decades of life, with more severe splenomegaly. It is associated with certain substances such as Vinyl chloride, Arsenic, and Copper. Budd-Chiari Syndrome (Option D) involves obstruction of the hepatic veins, often presenting with hepatomegaly, ascites, and liver dysfunction, which are not seen in this patient.

www.ncbi.nlm.nih.gov/pmc/articles/PMC4455142/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 45-year-old man presents to the emergency department with a 3-day history of left upper quadrant abdominal pain and nausea. He has a history of chronic pancreatitis due to alcohol abuse. Physical examination reveals tenderness in the left upper quadrant and splenomegaly. Abdominal CT scan without contrast shows a thrombus in the splenic vein. What type of varices are likely to be seen on endoscopic examination? (Q849017)

A. Esophageal varices

B. Gastric varices

C. Esophageal and gastric varices, with esophageal predominant

D. Duodenal varices

Correct Answer: B. Gastric varices

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This clinical scenario is typical of splenic vein thrombosis (SVT) , a condition often associated with chronic pancreatitis. The patient's history of chronic pancreatitis, left upper quadrant pain, splenomegaly, and the CT finding of a thrombus in the splenic vein all point to this diagnosis.Splenic vein thrombosis predominantly shows gastric varices on endoscopy. Splenic vein thrombosis Etiology Pancreatic disorders (most common) : Acute or chronic pancreatitis Pancreatic cancer Abdominal trauma or surgery Hypercoagulable states Pathophysiology Obstruction of splenic vein leading to increased pressure in splenic circulation Development of collateral circulation (left-sided portal hypertension) Formation of gastric (predominantly) and esophageal varices Splenomegaly due to congestion Diagnosis CT or MRI showing splenic vein occlusion Endoscopic ultrasound Angiography (less commonly used) Clinical signs : splenomegaly, gastric varices, normal liver function Treatment Treat underlying cause (e.g., pancreatitis) Anticoagulant therapy using LMWH Splenectomy

for symptomatic patients or those with bleeding varices Endoscopic management of bleeding varices Esophageal varices (Option A) are more commonly associated with cirrhosis and generalized portal hypertension, rather than isolated splenic vein thrombosis. While it's possible to have both esophageal and gastric varices (Option C), the predominance of esophageal varices is more characteristic of portal hypertension (as seen in cirrhosis) rather than splenic vein thrombosis. Duodenal varices (Option D) are rare and usually associated with generalized portal hypertension or portal vein thrombosis, not isolated splenic vein thrombosis.

↑ *Back to this question in Part A*

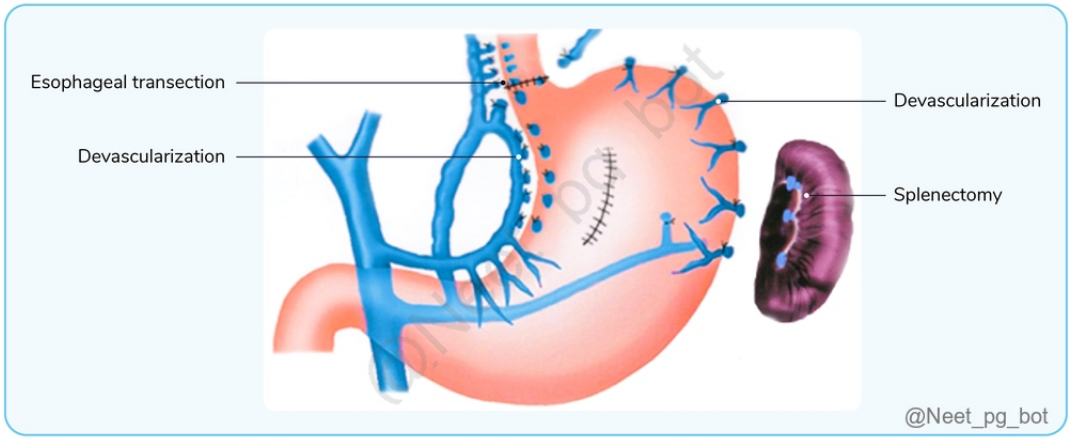
@Neet_pg_bot

Q13: A 60-year-old male with a history of cirrhosis presents with recurrent esophageal variceal bleeding that has not responded to endoscopic treatments. The patient is scheduled for a Sugiura procedure. Which of the following components is NOT part of the Sugiura procedure? (Q849018)

A. Splenectomy

B. Esophagogastric devascularization

C. Intraesophageal portacaval shunt



D. Esophageal transection

Correct Answer: C. Intraesophageal portacaval shunt

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Sugiura procedure includes: Splenectomy Esophagogastric devascularization: Surgically cutting off the blood supply to the esophagus to reduce the pressure in the varices and prevent bleeding. Esophageal transection: Diverting blood flow away from the esophageal varices, such as creating a shunt or performing other decompression techniques Sugiura procedure is used to manage recurrent esophageal variceal bleeding that does not improve on conventional treatment protocols.

Bailey & Love's Short practice of surgery, 28th Edition, Page 1206.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 48-year-old male is diagnosed with portal hypertension. Hepatic venous pressure gradient (HVPG) measurements are taken to assess the severity of his portal hypertension. Based on the prognostic values of HVPG, what are the cut-off HVPG values for clinically significant portal hypertension and increased risk of acute variceal bleeding respectively? (Q849019)

A. ≥6 mm Hg, ≥10mm Hg

B. ≥8 mm Hg, ≥12 mm Hg

C. ≥10 mm Hg, ≥12 mm Hg

D. ≥16 mm Hg, ≥18 mm Hg

Correct Answer: C. ≥10 mm Hg, ≥12 mm Hg

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Clinically significant portal hypertension is defined by an HVPG of ≥10 mm Hg. HVPG of ≥12 mm Hg is associated with an increased risk of acute variceal bleeding. These cut-off values are used to evaluate the prognosis of patients with chronic liver disease and portal hypertension. Prognostic value of HPVG in patients of Chronic Liver Disease & Portal HTN HVPG-Values Significance 1-5 mm Hg Normal 6-10 mm Hg Preclinical sinusoidal portal hypertension ≥10 mm Hg Clinically significant portal hypertension ≥12 mm Hg Increased risk

for rupture of varices ≥16 mm Hg Increased risk of mortality ≥20 mm Hg Treatment failure and mortality in acute variceal bleeding

Q1: Which of the following is not a risk factor for gallbladder carcinoma? (Q849000)

A. Smoking

B. Gallstones

C. Porcelain gallbladder

D. Hepatitis B

Correct Answer: A. Smoking

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: While smoking is a risk factor for several cancers, it is not specifically recognized as a risk factor for gallbladder carcinoma. Risk Factors For Carcinoma GB Gallstones : 90% of gallbladder carcinoma cases are associated with gallstones. (Option B) The risk of developing carcinoma in gallstone disease is 7-10 times higher than in the general population. Relative risk based on stone size: Less than 2 cm: Lower risk 2-3 cm: Relative risk of 2.5 More than 3 cm: Relative risk of 10 or more Other Conditions : Choledochal cyst Anomalous pancreaticobiliary duct junction (20%) Cholesteroses of the gallbladder Gallbladder polyps (more than 1 cm in size, more than 3 in number, or adenomatous polyps) Porcelain gallbladder (Option C) : 25% risk of malignant transformation, with 90% being inoperable tumours Infections and Inflammatory Conditions : Chronic typhoid carriers Inflammatory bowel disease Hepatitis B (Option D) and hepatitis C virus infections Other factors: Polypoid lesions (GB polyp) Xanthogranulomatous cholecystitis Nitrosamines Carcinogens

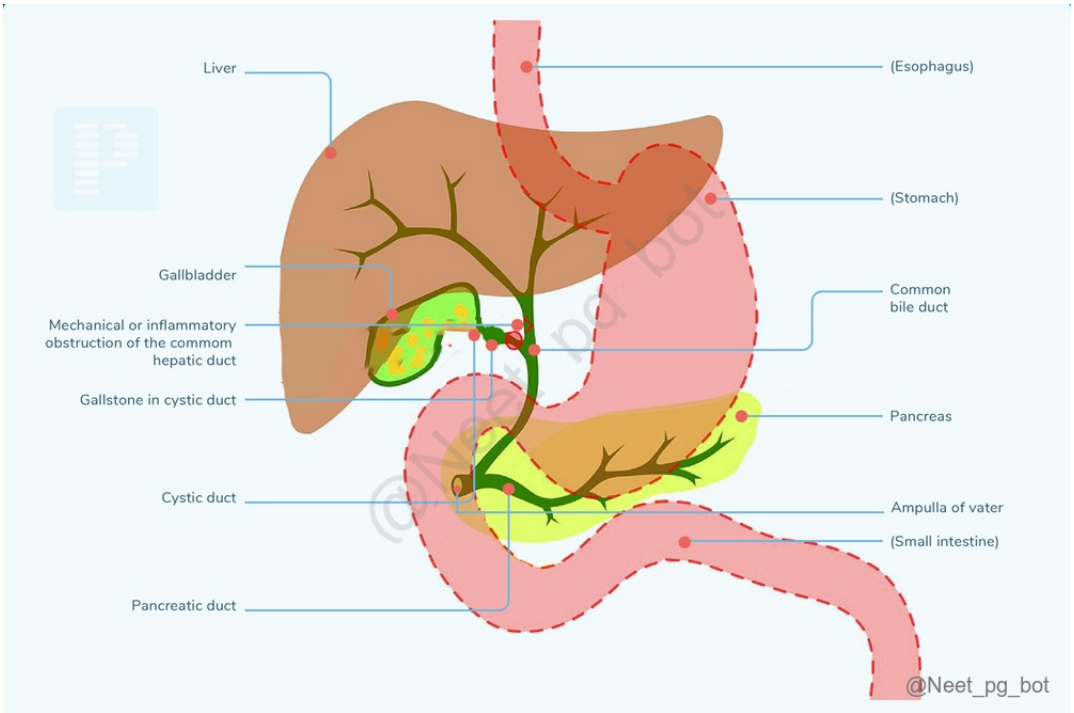
Q2: A 65-year-old female presents with severe right upper quadrant pain, jaundice, and a history of recurrent cholangitis. Imaging reveals a cholecystocholedochal fistula involving up to two-thirds of the circumference of the common bile duct. Which type of Mirizzi syndrome is seen in this patient? (Q848994)

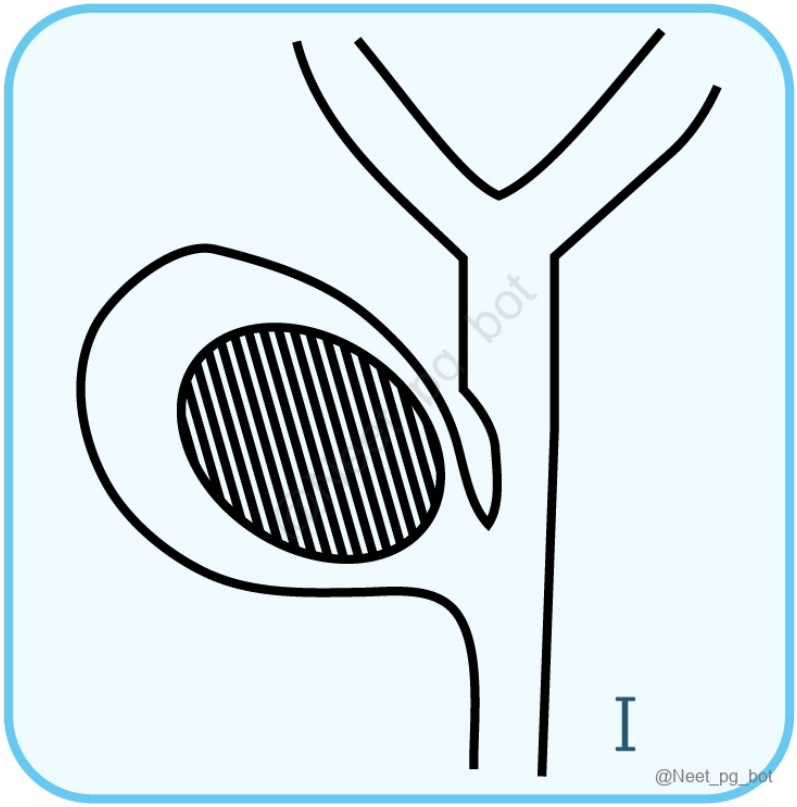
A. Type I

B. Type II

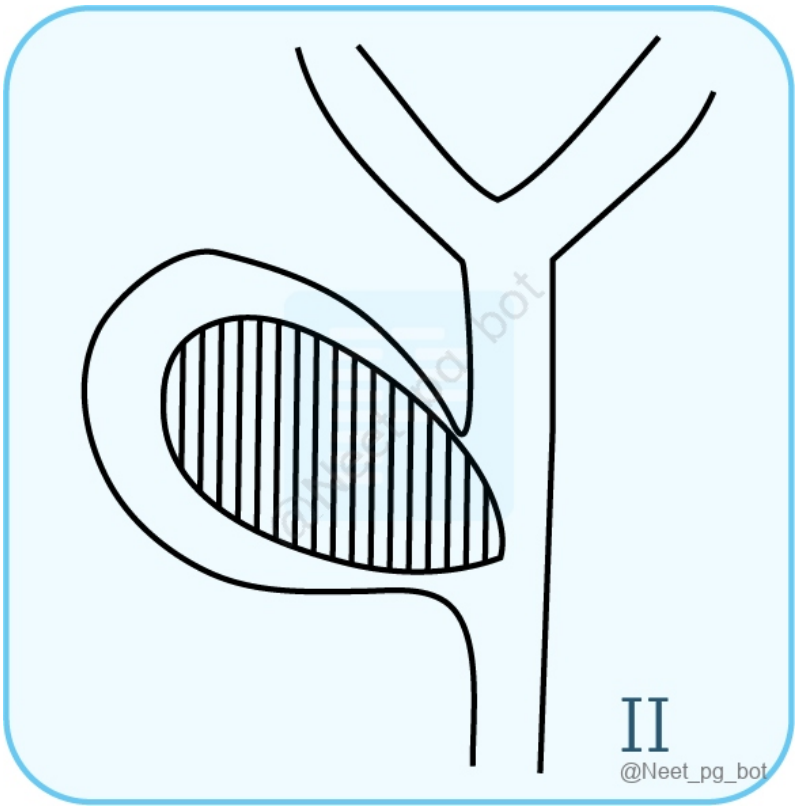
C. Type III



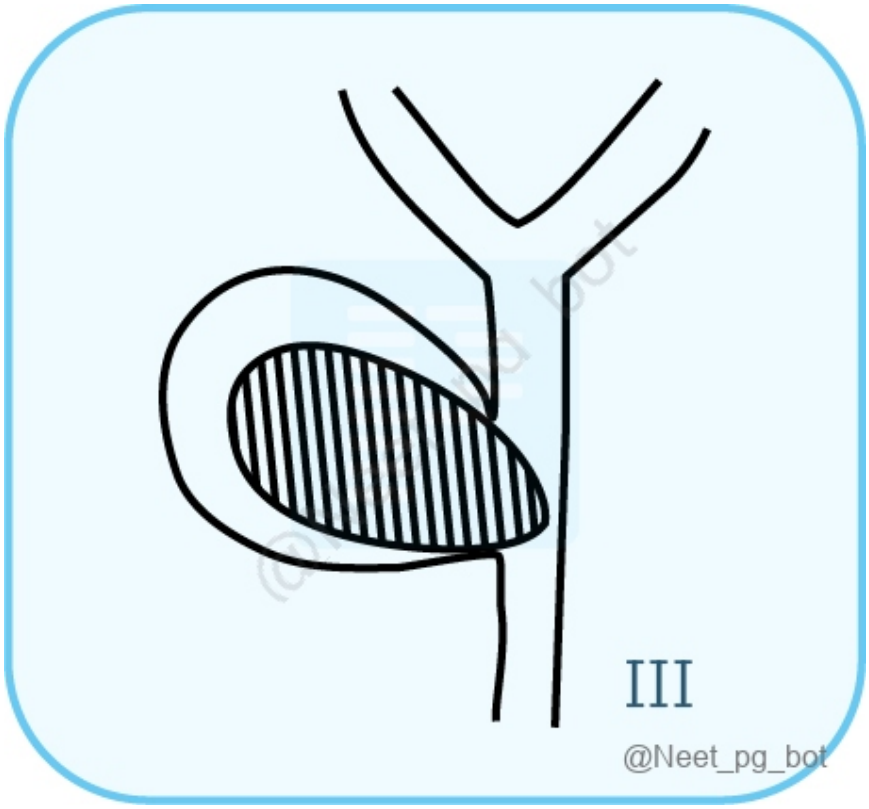
D. Type IV



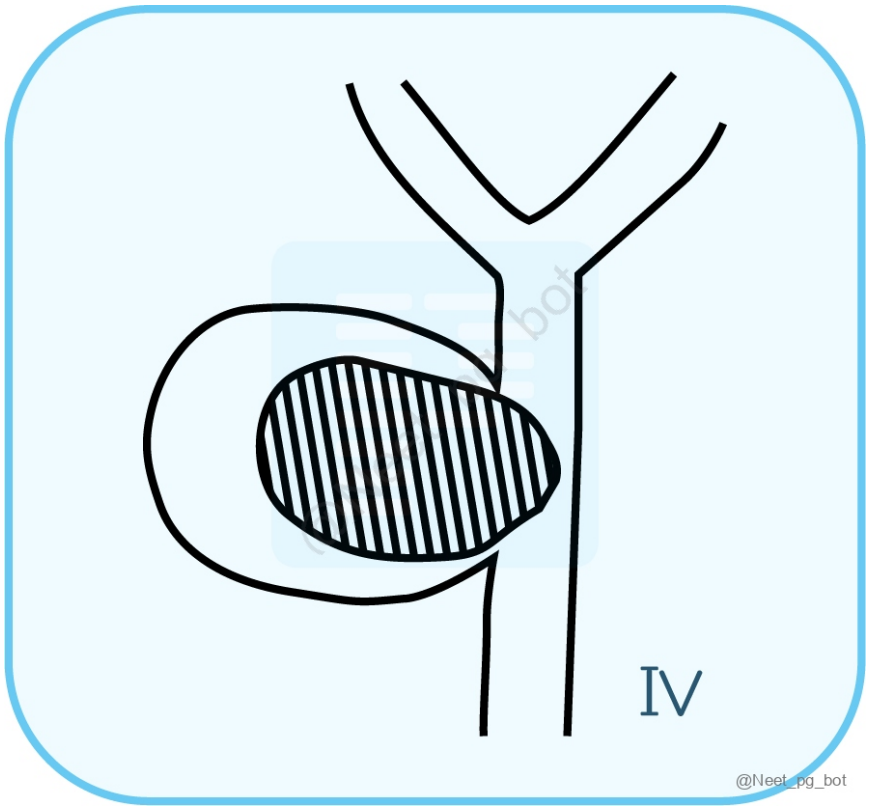
Correct Answer: C. Type III



■ *Listen (English)*



■ *Listen (Hindi)*



Explanation: In this scenario, the imaging findings indicate that the fistula involves up to two-thirds of the circumference of the CBD, consistent with Type III Mirizzi syndrome Mirizzi's syndrome It is seen in 1% of all cholecystectomies where a gallstone impacts the gallbladder wall, leading to compression and pressure necrosis. This often results in adherence to the common hepatic duct (CHD) or common bile duct (CBD) wall and can occasionally lead to a cholecystocholedochal fistula. Csendes Classification : Mirizzi's Type Features Image Type I Extrinsic compression of the CBD/CHD by a large impacted stone in Hartmann's pouch; IA- the presence of cystic duct IB- is obliterated cystic duct Type II The stone has eroded the CBD/CHD less than 1/3rd circumference of the CBD/CHD forming a fistula Type III Involving up to 2/3rd of the circumference of CBD/ CHD Type IV Cholecystocholedochal fistula (>2/3rd) involving the entire circumference of the CBD/CHD TypeV Cholecystocholedochal fistula with cholecystoenteric fistula without gallstone ileus (VA) or with gallstone ileus (VB)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 75-year-old male in the ICU with sepsis and multiple organ failure develops sudden right upper quadrant pain and fever. Ultrasound reveals a distended gallbladder with thickened walls and no gallstones. Which of the following is not a predisposing factor for acalculous cholecystitis? (Q848992)

A. Parenteral nutrition

B. Extensive burns

C. Hypertension

D. Diabetes

Correct Answer: C. Hypertension

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypertension is not an established predisposing factor for acalculous cholecystitis Acalculous cholecystitis Acalculous cholecystitis is an acute inflammation of the gallbladder that occurs without the presence of gallstones. It is typically observed in critically ill patients or in patients who have undergone major surgeries, trauma, burns, or prolonged illness with multi-system failure. Causes Predisposing Factors Gallbladder distention Bile stasis Ischemia Cystic artery occlusion Primary bacterial infections (e.g., E. coli, Salmonella, Clostridia) may contribute Critically ill ICU patients Patients on parenteral nutrition (Option A) Extensive burns (Option B) Sepsis Major surgeries (especially non-biliary) Multiple trauma Prolonged illness with multiple organ system failure Elderly males Diabetic patients (Option D) Patients on atherosclerotic agents. Patients with AIDS Presence of malignancies (biliary or other)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 75-year-old female with a history of cholelithiasis presents with acute abdominal pain, vomiting, and signs of bowel obstruction. O/E, she has abdominal distension and high-pitched bowel sounds. A radiograph shows pneumobilia and a calcified gallstone in the right lower quadrant. CT confirms an abnormal gallbladder with air and fluid accumulation. What is the most appropriate management for this patient? (Q848991)

A. Cholecystectomy and fistula repair

B. Endoscopic removal of the gallstone

C. Enterolithotomy

D. Conservative management with IV fluids and antibiotics

Correct Answer: C. Enterolithotomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Given the clinical scenario with Rigler's triad (small bowel obstruction, pneumobilia, and ectopic gallstone) and the corresponding imaging findings, the most likely diagnosis is gallstone ileus . The optimal initial surgical management is enterolithotomy , which effectively relieves the intestinal obstruction by removing the impacted gallstone. Effects and Complications of Gallstones: Gallbladder Common bile duct and pancreas Small intestine Acute cholecystitis Chronic cholecystitis Mucocele Empyema Gangrene Perforation Carcinoma gallbladder CBD stones Biliary obstruction (Jaundice) Acute pancreatitis Mirizzi syndrome Gallstone ileus leading to intestinal obstruction Gallstone Ileus Acute cholecystitis→ erosion of inflamed tissues → Formation of a cholecystointestinal fistula→ Gallstone ileus Small gallstones typically pass through the intestines, but stones 2–5 cm in size can become impacted, usually in the terminal ileum or at the ileocecal valve. Clinical Manifestations: Acute, intermittent, or chronic episodes of partial or complete gastrointestinal obstruction. Signs of obstruction include dehydration, abdominal distension and tenderness, high-pitched bowel sounds, and obstructive jaundice. Diagnosis: Plain Abdominal Radiograph: Partial or complete intestinal obstruction Pneumobilia or contrast material in the biliary tree Calcified gallstone with position changes on serial films (tumbling sign) CT Scan: Superior sensitivity (up to 93%) Shows abnormal gallbladder with air, air-fluid level, or fluid accumulation with an irregular wall Management: Management of intestinal obstruction Enterolithotomy: The most common surgical procedure A longitudinal incision on the antimesenteric border proximal to the site of impaction Gallstone is brought to a non-edematous bowel segment by gentle manipulation and extraction. Cholecystoenteric fistula resection only if the patient is stable and there are residual gallstones that may cause infection or recurrent ileus Cholecystectomy and fistula repair (Option A): While important, this is not the initial step due to the patient's unstable condition and intestinal obstruction. Endoscopic removal of the gallstone (Option B): Not feasible for this condition due to the intestinal obstruction. Conservative management with IV fluids and antibiotics (Option D): Not sufficient for resolving the mechanical obstruction.

Bailey and Love Short manual of surgery, pg no 1244,12

↑ *Back to this question in Part A*

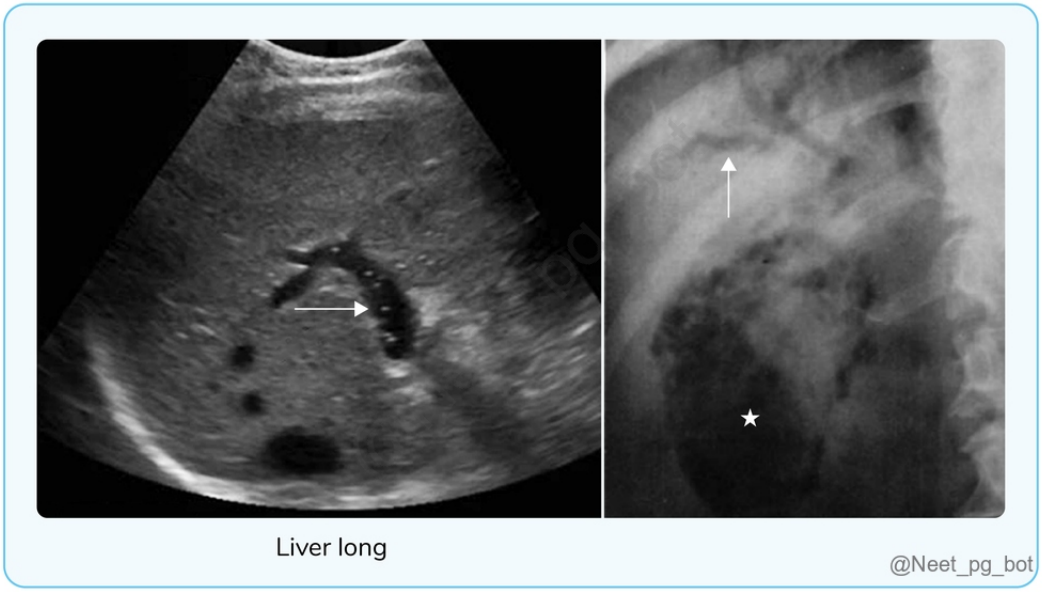
@Neet_pg_bot

Q5: A 65-year-old male with a history of diabetes presents with severe right upper quadrant pain, fever, and jaundice. Imaging reveals gas within the gallbladder wall. Which of the following organisms is most likely to be the causative agent in this patient's condition? (Q848990)

A. Clostridium perfringens

B. Staphylococcus aureus

C. Streptococcus pyogenes



D. Pseudomonas aeruginosa

Correct Answer: A. Clostridium perfringens

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient is presenting with emphysematous cholecystitis, a severe form of acute cholecystitis characterized by the presence of gas in the gallbladder wall. This condition is often caused by gas-forming bacteria. Clostridium perfringens is the most commonly implicated bacterium in this condition, especially in patients with underlying diabetes. Causative Organisms of Emphysematous Cholecystitis: Clostridium perfringens Clostridium welchii Escherichia coli Klebsiella Management of Emphysematous Cholecystitis: Initial Stabilization (Resuscitation) Nil per oral (NPO) IV fluids (correct dehydration, shock) Electrolyte correction Broad-spectrum IV antibiotics: Coverage for anaerobes (Clostridium) + gram-negative organisms Example: Piperacillin–tazobactam / Carbapenems Definitive Management Emergency cholecystectomy Usually open cholecystectomy (due to severe inflammation) Laparoscopy may be attempted in stable patients If Patient is Unstable/High-risk Percutaneous cholecystostomy (USG-guided) Temporary life-saving measure Followed by an interval cholecystectomy

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1235

www.healthline.com/health/emphysematous-cholecystitis#symptoms

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: A 65-year-old female presents with right upper quadrant pain and nausea. An ultrasound reveals a 1.5 cm gallbladder polyp, and a follow-up scan shows an increase in size from the previous scan six months ago. She also has a history of gallstones. Which of the following factors increases the risk of invasive cancer in gallbladder polyps? (Q848996)

A. Age less than 60 years

B. Presence of gallstones

C. Polyp size more than 0.5 cm

D. The same polyp size on repeated scans

Correct Answer: B. Presence of gallstones

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The presence of gallstones increases the risk of malignancy Ultrasonography demonstrating a gallbladder polyp Cholesterol polyp Adenomatous polyp More common Small <10 mm Multiple Benign Pedunculated Less common Large >10mm Single Premalignant Sessile Factors that increase the risk of invasive cancer in adenomatous polyp: Age more than 60 years (Option A) Presence of gallstone Size of polyp more than 1 cm (Option C) Documented increase in size on repeated scans (Option D) Treatment: Cholecystectomy is recommended for symptomatic patients or as a preventive measure to reduce the risk of cancer in individuals who have additional conditions like gallstones, primary sclerosing cholangitis (PSC), biliary colic, or pancreatitis. Polyps in patients over 50, sessile polyps with wall thickening exceeding 4 mm, and those larger than 10 mm warrant surgical removal. Smaller polyps should be monitored, with surgery indicated if there is evidence of growth.

www.ncbi.nlm.nih.gov/pmc/articles/PMC6969319/

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1247

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 70-year-old female presents with vague right upper quadrant discomfort, but she is mostly asymptomatic. An abdominal X-ray reveals extensive calcification of the

gallbladder wall. There is bluish appearance and brittle consistency of the gallbladder. What is the most likely diagnosis? (Q848999)

A. Gallbladder carcinoma

B. Cholesterolosis

C. Porcelain gallbladder

D. Acute cholecystitis

Correct Answer: C. Porcelain gallbladder

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The findings of extensive calcification of the gallbladder wall, along with the bluish appearance and brittle consistency, are characteristic features of a porcelain gallbladder. Porcelain Gallbladder Definition Also known as a calcified gallbladder, characterized by extensive calcium encrustation in the gallbladder wall Characteristics Bluish appearance of the gallbladder Brittle consistency of the gallbladder wall Clinical Features Most patients are asymptomatic Increased risk of malignancy Diagnosis Incidental findings on abdominal X-ray or CT Treatment Early laparoscopic cholecystectomy is recommended due to the increased risk of malignancy Gallbladder carcinoma (Option A): While there is an increased risk of malignancy associated with porcelain gallbladder, the symptoms and imaging findings in this scenario point more directly to porcelain gallbladder rather than cancer itself, especially given that the patient is asymptomatic. Cholesterolosis (Option B): This condition is characterized by lipid accumulation in the gallbladder mucosa and does not present with calcification of the gallbladder wall. Acute cholecystitis (Option D): This would typically present with acute pain, fever, and signs of inflammation, which are not described in this scenario.

@Neet_pg_bot

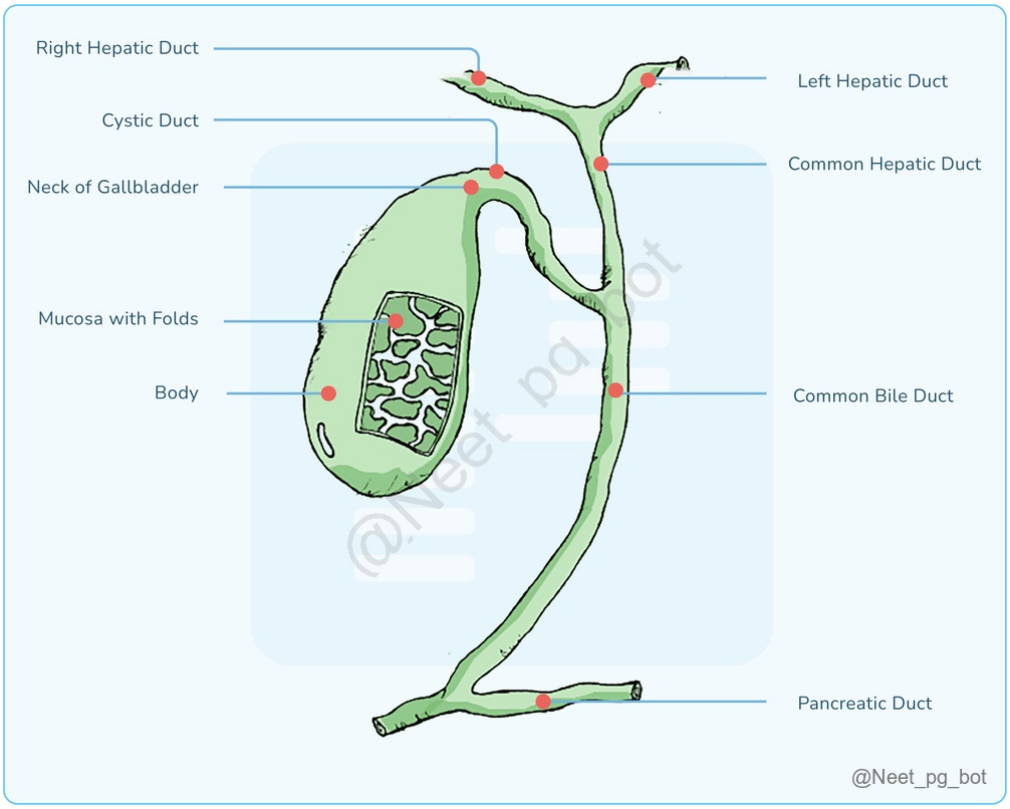
Q8: A 50 y/o woman undergoing laparoscopic cholecystectomy is found to have a structure that appears to have a spiral configuration. What is the most likely anatomical feature being observed? (Q843481)

A. Vasa vasorum

B. Sphincter of Oddi

C. Accessory Pancreatic Duct

D. Valves of Heister



Correct Answer: D. Valves of Heister

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The Valves of Heister are spiral mucosal folds within the cystic duct. They help regulate the flow of bile and prevent excessive emptying of the gallbladder. These folds are a key feature of the cystic duct and are noted during cholecystectomy. The cystic duct serves as the conduit between the gallbladder, where bile is stored, and the common bile duct, which carries bile to the duodenum. The Sphincter of Lütkens is a muscular structure encircling the cystic duct which plays a role in regulating bile flow into and out of the gallbladder.

@Neet_pg_bot

Q9: Which of the following risk factors is associated with both gallbladder cancer and cholangiocarcinoma? (Q849001)

A. Gallstones

B. Porcelain gallbladder

C. Primary sclerosing cholangitis (PSC)

D. Hepatitis C virus infection

Correct Answer: C. Primary sclerosing cholangitis (PSC)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Primary sclerosing cholangitis (PSC), particularly when associated with inflammatory bowel disease (IBD), is a major risk factor for both gallbladder cancer and cholangiocarcinoma. Aspect Gallbladder Cancer Cholangiocarcinoma Risk Factors Gallstones, porcelain gallbladder, PSC, abnormal pancreatic-biliary junction PSC, congenital cystic disease, hepatolithiasis, liver flukes Clinical Presentation Abdominal pain, early satiety, anorexia, weight loss, jaundice, Courvoisier's sign Similar non-specific symptoms, jaundice, Courvoisier's sign Diagnosis USG, CT, MRI/MRCP, elevated ALT, AST, CA19-9, and ERCP/PTC, staging laparoscopy Similar diagnostic tools and markers Treatment Radical en bloc resection for resectable cases Hepatic/bile duct resection, pancreaticoduodenectomy, transplantation for select cases Prognosis Poor, low 5-year survival rate Poor, low 5-year survival rate Gallstones (Option A) are strongly associated with gallbladder cancer, while the relationship with cholangiocarcinoma is less clear. Porcelain gallbladder (Option B) is a risk factor for gallbladder cancer only Hepatitis C virus infection (Option D) is a risk factor primarily for cholangiocarcinoma.

Bailey & Love’s Short Practice of Surgery, Ed 28, Pg 1256-1259

↑ *Back to this question in Part A*

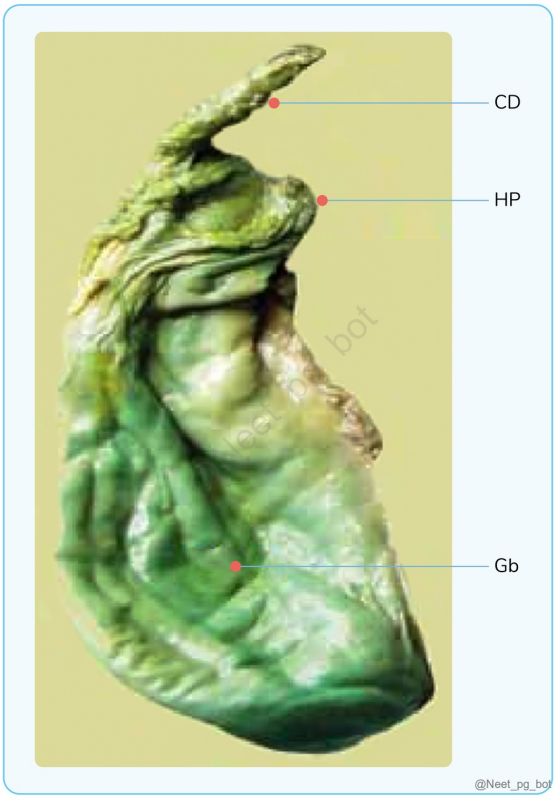
@Neet_pg_bot

Q10: A 45 y/o patient presents with recurrent right upper quadrant pain and nausea. Imaging reveals a pathological outpouching in the infundibular region of the gallbladder containing multiple gallstones. What is this feature known as? (Q843479)

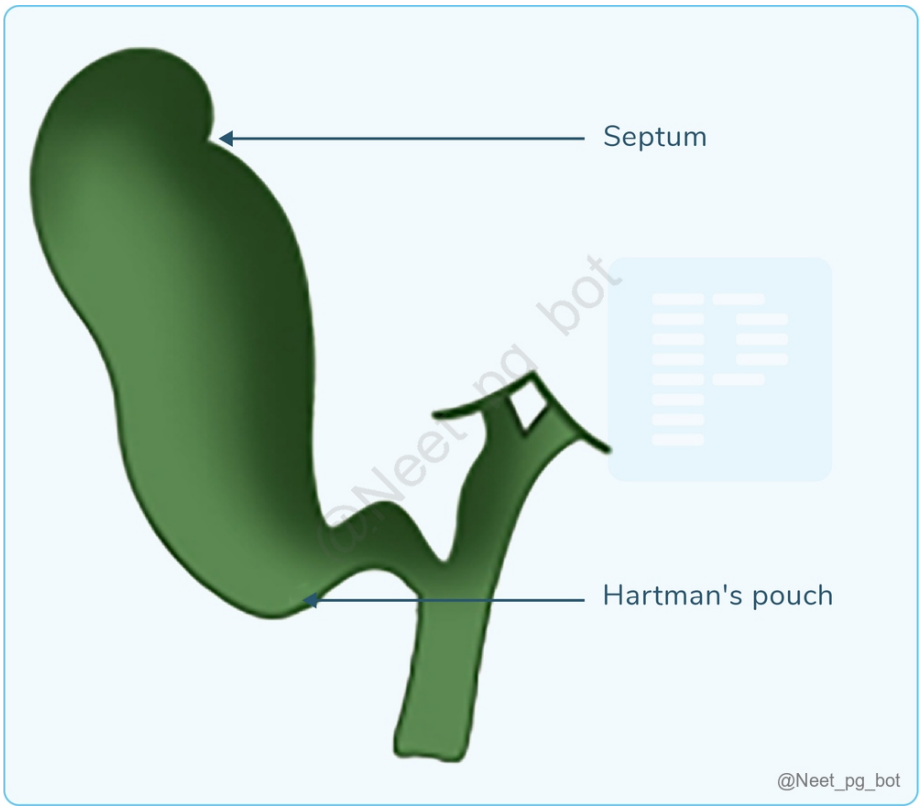
A. Phrygian cap

B. Floating gallbladder

C. Hartmann's pouch



D. Gallbladder carcinoma



Correct Answer: C. Hartmann's pouch

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hartmann's pouch is a pathological outpouching in the infundibular region of the gallbladder, typically associated with the presence of gallstones. It results from adhesions forming between the cystic duct and the neck of the gallbladder. CD - Cystic duct HP - Hartmann’s pouch Gb - Gall Bladder Phrygian cap (Option A): is a benign congenital anatomical variant of the gallbladder, characterized by a fold at the fundus that creates a cap-like appearance. It does not involve the presence of gallstones. A floating gallbladder (Option B) is a rare anatomical pathological variant where the gallbladder is not properly attached and can move within the abdominal cavity. It does not result in an outpouching containing stones. Gallbladder carcinoma (Option D) is a malignant tumour of the gallbladder and does not match the patient’s imaging results of outpouching.

@Neet_pg_bot

Q11: Which layer of the gastric wall is considered the strongest? (Q843478)

A. Mucosa

B. Submucosa

C. Muscularis Externa

D. Serosa

Correct Answer: B. Submucosa

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The submucosa is rich in collagen and provides the strongest structural support among the gastric wall layers. It is the strongest layer. Layers Features Serosa Outermost layer Covered by peritoneum Muscularis Propria / Muscularis externa Divided into Outer longitudinal layer Inner circular layer Contains Auerbach Plexus Submucosa Collagen-rich connective tissue layer Strongest It contains a network of blood vessels, lymphatics, and Meissner Plexus Mucosa Has 3 layers Surface epithelium - innermost layer in contact with the lumen Lamina Propria - connective tissue layer Muscularis Mucosa - rugae formation

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 65 y/o female presents with a 3-month history of intermittent upper right quadrant pain, weight loss, and loss of appetite. She has jaundice and a palpable mass in the right upper quadrant. Laboratory tests reveal mild anaemia, leukocytosis, and elevated CA19-9 and carcinoembryonic antigen. USG suggests a gallbladder mass and a CT scan confirms the mass without distant metastases. What is the most appropriate next step in management? (Q849002)

A. Immediate laparoscopic cholecystectomy

B. Percutaneous biopsy of the gallbladder mass

C. Referral for palliative chemotherapy

D. Laparoscopic examination for staging

Correct Answer: D. Laparoscopic examination for staging

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Given the patient's symptoms, physical findings, and elevated tumor markers, gallbladder cancer is highly suspected. Although imaging studies have been done, accurate staging is crucial before deciding on a definitive treatment. A laparoscopic examination will help to detect any peritoneal metastasis, liver surface

deposits and small volume carcinomatosis that could preclude surgical resection, thereby guiding the appropriate management plan. Diagnosis and staging of Gallbladder cancer: Non-specific indicators Anemia Leukocytosis Slight increase in transaminases Tumor markers Elevated CA19-9 Elevated carcinoembryonic antigen (in ~80% of patients) Diagnostic Imaging Ultrasonography (USG): Initial diagnosis CT Scans: Thorax, abdomen, and pelvis for confirmation and staging MRI/MRCP: For accurate preoperative staging PET Scans: To identify metastatic disease Staging and Biopsy Preoperative Staging: Crucial to assess local disease extent and rule out distant metastases Percutaneous Biopsy: Guided by radiological imaging for unresectable tumors Laparoscopic Examination: Detects peritoneal or liver metastases that preclude surgery Immediate laparoscopic cholecystectomy (Option A): This is generally considered if the diagnosis is benign or if it's a straightforward case of symptomatic gallbladder disease. Given the suspicion of malignancy (indicated by elevated tumor markers and imaging findings), it is crucial to stage the disease before proceeding with surgical intervention. Percutaneous biopsy of the gallbladder mass (Option B): While this could be useful, gallbladder cancers are often difficult to biopsy percutaneously, and the risk of seeding the tumor or causing complications is a concern. Referral for palliative chemotherapy (Option C): This should only be considered if there is confirmed advanced or metastatic cancer. In this case, there is no evidence of distant metastases from the CT scan.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 1258

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: Which of the following surgeons is correctly matched with their pioneering laparoscopic procedure and year of achievement? (Q849005)

A. Professor Erich Mühe - First video-assisted laparoscopic cholecystectomy in 1987

B. Dr. Philippe Mouret - First laparoscopic cholecystectomy in 1985

C. Dr. Kurt Semm - First laparoscopic appendicectomy in 1983

D. Professor Erich Mühe - First laparoscopic appendicectomy in 1983

Correct Answer: C. Dr. Kurt Semm - First laparoscopic appendicectomy in 1983

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Dr. Kurt Semm performed the first laparoscopic appendicectomy in 1983. Professor Erich Mühe of Germany is acknowledged as the pioneer who performed the first laparoscopic cholecystectomy in 1985. (Options A & D ruled out) Dr. Philippe Mouret performed the first video-assisted laparoscopic cholecystectomy in 1987. (Option B ruled out)

↑ *Back to this question in Part A*

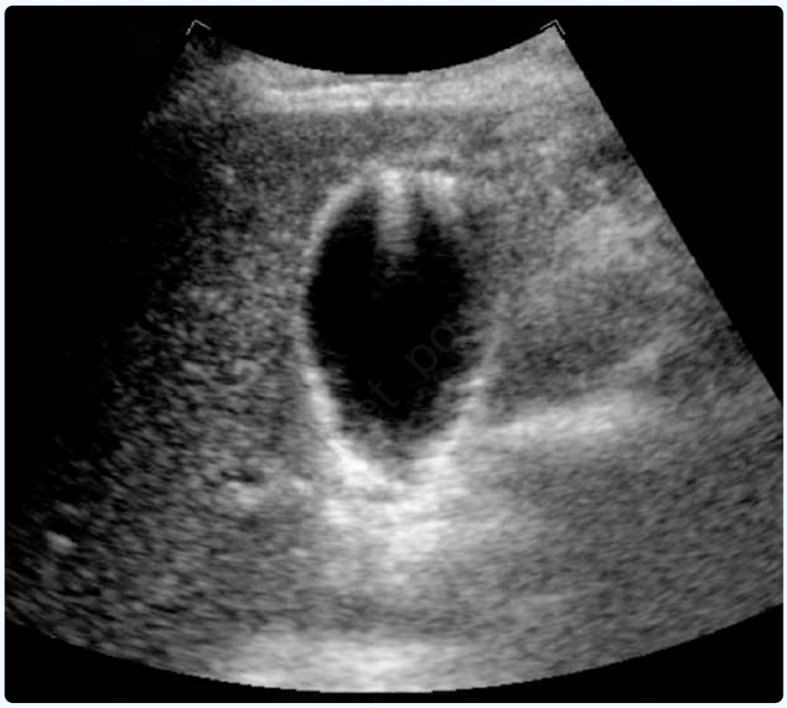
@Neet_pg_bot

Q14: A 62-year-old male presents with intermittent right upper quadrant pain and nausea. An ultrasound shows significant thickening of the gallbladder wall and hyperproliferation of the mucosa. Which of the following is NOT a USG finding in Adenomyomatosis? (Q848998)

A. Diamond ring sign

B. Comet tail artefacts

C. V-shaped artefacts



D. Porcelain appearance

Correct Answer: D. Porcelain appearance

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Porcelain appearance is usually seen as associated with calcifications of the gall bladder and not adenomyomatosis Adenomyomatosis Definition A benign condition characterised by hyperplastic changes in the gallbladder wall, often associated with cholesterol stones Characteristics Hyperplastic Changes: Overgrowth of the gallbladder mucosa Significant thickening of the muscle layer Deposition of cholesterol crystals in the deep Rokitansky-Aschoff sinuses Diagnosis Ultrasound Findings: Diamond ring sign. (Option A) Comet tail artefacts. (Option B) V-shaped artefacts. (Option C) Treatment Symptomatic Patients with Gallstones: Laparoscopic cholecystectomy

References:

www.ncbi.nlm.nih.gov/books/NBK482244/#

Bailey & Love's Short Practice of Surgery, 27th Edition, Page 1245

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 58-year-old male, with past h/o cholesterol stones, presents with intermittent right upper quadrant pain and occasional nausea.USG reveals the gallbladder mucosa has a coarse, granular appearance with small nodules and some larger polypoid formations. On performing laparoscopic cholecystectomy of this patient, the following appearance of the gall bladder was observed. What is the most likely diagnosis? (Q848997)

A. Acute cholecystitis

B. Porcelain gallbladder

C. Cholesterolosis

D. Gallbladder carcinoma

Correct Answer: C. Cholesterolosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: These specific ultrasound findings and the specimen along with the association with cholesterol stones are characteristic of Strawberry Gallbladder (Cholesterolosis) . Accumulation of lipids (triglycerides, cholesterol precursors, and cholesterol esters) in the gallbladder mucosa. Appearance: Nodules <1 mm in diameter in about two-thirds of cases, giving the mucosa a coarse, granular look. Remaining one-third of cases - Nodules are larger and polypoid (polypoid form). Yellow lipid deposits on a hyperaemic mucosa background create the ‘strawberry gallbladder’ appearance Might be associated with cholesterol stones. Management: Laparoscopic cholecystectomy in symptomatic patients. Acute cholecystitis (Option A): Typically presents with more acute symptoms, such as severe right upper quadrant pain, fever, and leukocytosis, without the specific ultrasound appearance described. Porcelain gallbladder (Option B): Characterized by extensive calcium encrustation of the gallbladder wall, giving a bluish, brittle appearance, not mentioned in the scenario. Gallbladder carcinoma (Option D): Typically associated with more serious symptoms and imaging findings of masses or irregular thickening, not specifically described in this scenario.

References:

Sabiston Textbook of Surgery, 21st edition, Page 1499

Bailey and Love Short manual of surgery, 27th Edition, Page 1245

↑ *Back to this question in Part A*

@Neet_pg_bot

Q16: A 65 y/o presents with jaundice, weight loss, and abdominal pain. O/E a palpable mass is noted in the right upper quadrant. Imaging studies reveal a mass involving the gallbladder, with signs of local invasion but no distant or lymph node metastasis. A biopsy confirms gallbladder carcinoma. Based on the TNM classification, which stage is most likely for this patient's tumour? (Q849003)

A. T1a N0 M0

B. T2b N1 M0

C. T3 N0 M0

D. T4 N2 M1

Correct Answer: C. T3 N0 M0

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's presentation of jaundice, weight loss, abdominal pain, and a palpable mass, along with imaging showing local invasion but no distant metastasis, suggests an advanced stage. According to the TNM classification: T3 : Tumor perforates the serosa and/or invades the liver or adjacent organs. N0 : No regional lymph node metastasis. M0 : No distant metastasis. This corresponds to T3 N0 M0. T1a N0 M0 (Option A) T1a tumours invade only the lamina propria. They do not invade the liver or perforate the serosa. The presence of direct liver invasion rules out T1a. T2b N1 M0 (Option B) T2b indicates tumour invading the perimuscular connective tissue on the hepatic (liver) side of the gallbladder, but the option also includes N1 (regional node positive). The vignette specifies no regional lymph-node involvement, so any option with N1 is inconsistent with the findings. T4 N2 M1 (Option D) This indicates very advanced disease (invasion of main portal vein or two or more extrahepatic organs, and/or advanced nodal disease and distant metastasis). The stem states local invasion only, without nodal or distant spread, so this is not applicable.

References:

radiopaedia.org/articles/gallbladder-cancer-staging-ajcc-8th-edition?lang=us

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: A 58 y/o presents with jaundice, weight loss, and upper right abdominal pain. Imaging studies including CT and MRI reveal a mass in the gallbladder with local

invasion into the liver but no distant metastasis. The patient undergoes a laparoscopic examination confirming the staging. What is the most appropriate treatment approach for this patient? (Q849004)

A. Endoscopic stenting to relieve jaundice

B. Radical en bloc resection of the gallbladder, liver wedge, and regional lymph nodes

C. Palliative chemotherapy

D. No further treatment if the tumor is confined to the mucosa

Correct Answer: B. Radical en bloc resection of the gallbladder, liver wedge, and regional lymph nodes

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: For a patient with gallbladder cancer of T3 N0 M0 staging, radical en bloc resection is the most appropriate treatment approach. This involves the surgical removal of the gallbladder, the invaded portion of the liver, and potentially affected regional lymph nodes. This approach aims to achieve clear margins and effectively treat the localized disease, offering the best chance for a cure in the absence of distant metastasis. Staging aims to: Assess local disease . Detects metastatic disease in the liver, peritoneum, lymphatics, or locations outside the abdomen. Treatment Based on Stage: If Gallbladder cancer is found incidentally on resection of the gallbladder for gallstones, then: If early disease: For a disease confined to the mucosa , if negative cystic duct margin and no recurrence on imaging: No further treatment For transmural disease- Radical en bloc resection of the gallbladder fossa, liver wedge, and regional lymph nodes. If advanced Cancer: Non-operative palliative care. Endoscopic/percutaneous methods to relieve obstructive jaundice. Adenocarcinoma: Early-stage limited to the mucosa: No additional treatment is required if imaging shows no recurrence. Beyond mucosa: Extensive surgery involving gallbladder fossa, a portion of the liver, and nearby lymph nodes. Endoscopic stenting to relieve jaundice (Option A): Given the cancer's local invasion into the liver, endoscopic stenting alone does not provide a treatment for the cancer itself. Palliative chemotherapy (Option C): Typically used for cancers that are not amenable to surgical resection or have spread beyond the local area (distant metastasis). No further treatment if the tumor is confined to the mucosa (Option D) : Since local invasion into the liver is present, a more aggressive treatment approach is required.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Pages 1258, 1259

↑ *Back to this question in Part A*

@Neet_pg_bot

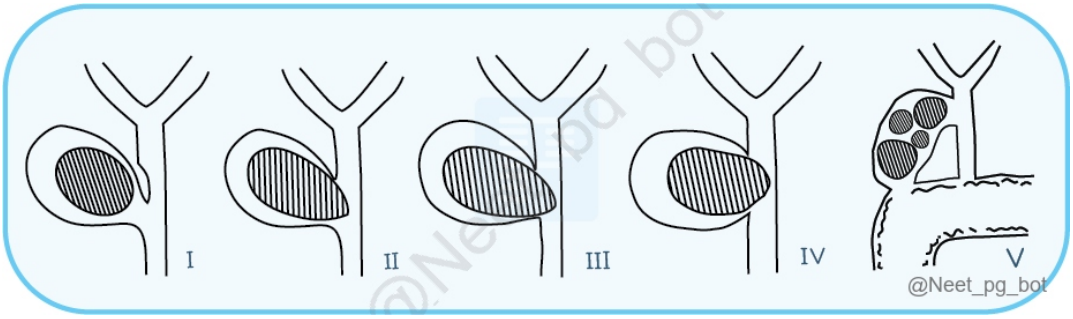
Q18: A 58-year-old male presents with right upper quadrant pain, jaundice, and fever. Imaging reveals a gallstone eroding less than one-third of the circumference of

the common bile duct. What is the management? (Q848995)

A. Bilio-enteric anastomosis

B. Percutaneous cholecystostomy

C. Subtotal/Partial cholecystectomy + ERCP stenting



D. Partial cholecystectomy with choledochoplasty

Correct Answer: D. Partial cholecystectomy with choledochoplasty

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: This patient's presentation matches the features of Type II Mirizzi syndrome, characterized by a gallstone eroding less than one-third of the circumference of the common bile duct (CBD) or common hepatic duct (CHD). Type II Mirizzi syndrome is managed by partial cholecystectomy with choledochoplasty. Csendes classification: Mirizzi's Type Features Treatment Type I Extrinsic compression of the CBD/CHD by a large impacted stone in Hartmann's pouch; IA- the presence of cystic duct IB- is obliterated cystic duct Subtotal/Partial cholecystectomy + ERCP stenting (Option C ruled out) Type II The stone has eroded the CBD/CHD less than 1/3rd circumference of the CBD/CHD forming a fistula Partial cholecystectomy with choledochoplasty Type III Involving up to 2/3rd of the circumference of CBD/ CHO Partial cholecystectomy with choledochoplasty Type IV Cholecystocholedochal fistula (>2/3rd) involving the entire circumference of the CBD/CHD Bilio-enteric anastomosis (Option A ruled out) TypeV Cholecystocholedochal fistula with cholecystoenteric fistula without gallstone ileus (VA) or with gallstone ileus (VB) Bilio-enteric anastomosis Percutaneous cholecystostomy (Option B): Typically a temporary measure for critically ill patients who cannot undergo immediate surgery

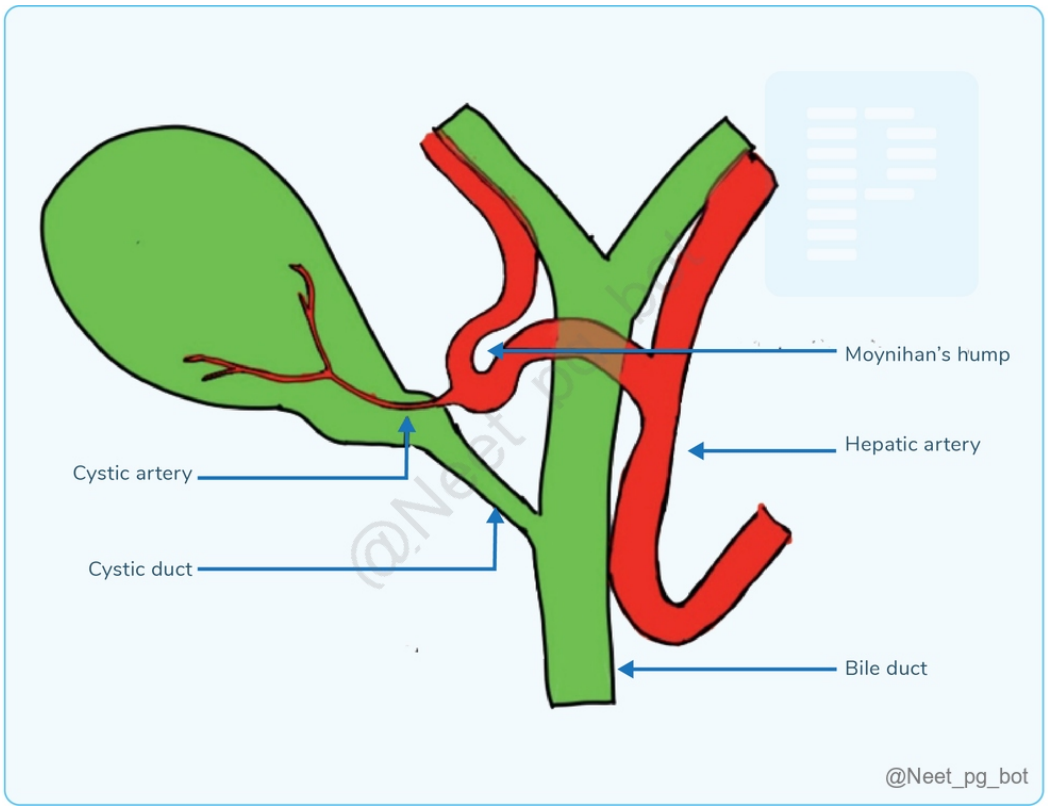
@Neet_pg_bot

Q19: A 45-y/o female presents with symptomatic gallstones and is scheduled for laparoscopic cholecystectomy. During the procedure, the surgeon encounters difficulty due to unexpected anatomical variations. The right hepatic artery appears very tortuous and is located close to the cystic duct. What is the most likely anatomical anomaly encountered in this case? (Q843338)

A. Phrygian cap

B. Moynihan Hump

C. Floating Gallbladder



D. Mirizzi Syndrome

Correct Answer: B. Moynihan Hump

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Moynihan's hump , also known as the ' caterpillar turn ,' describes a very tortuous common or right hepatic artery in front of the cystic duct's origin. This tortuosity often results in a short cystic artery, increasing the risk of arterial injury during cholecystectomy. It is the most dangerous anomaly to be encountered during laparoscopic cholecystectomy as it can lead to heavy bleeding due to injury to the arteries. Phrygian cap (Option A) is a congenital variant of the gallbladder characterized by a fold at the fundus that resembles a cap. It is a benign condition and is typically asymptomatic, with its appearance being consistent with a cap-like structure on ultrasound. It has no clinical significance and does not affect gallbladder function. Floating gallbladder (Option C) refers to an abnormal positioning of the gallbladder within the abdominal cavity, often due to a lack of supporting attachments. This condition does not present as a cap-like fold on ultrasound. Mirizzi syndrome (Option D) occurs when a gallstone migrates from the gallbladder and obstructs or compresses the common bile duct, often due to a stone in the lower end of the cystic duct ulcerating into the common bile duct.

SRB's Manual of Surgery, 6th Edition, Pg. 627

↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: A 70-year-old critically ill male in the ICU with sepsis and multiple organ failure presents with sudden onset of right upper quadrant pain, fever, and jaundice. Bedside ultrasonography shows a distended gallbladder with thickened walls and pericholecystic fluid but no gallstones. What is the treatment of choice for this patient? (Q848993)

A. Laparoscopic cholecystectomy

B. Oral antibiotics and observation

C. Endoscopic retrograde cholangiopancreatography (ERCP)

D. Percutaneous cholecystostomy

Correct Answer: D. Percutaneous cholecystostomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Given the clinical scenario and the USG findings, this patient is most likely suffering from Acalculous cholecystitis. Percutaneous cholecystostomy is the most appropriate management for a critically ill, unstable patient with acalculous cholecystitis, as it provides effective drainage and infection control with minimal risk. Treatment: Initial Management: Early broad-spectrum antibiotics Fluid resuscitation Definitive Treatment: Laparoscopic Cholecystectomy: Most definitive treatment Safe even with severe acute inflammation if the patient is stable for surgery For Critically Ill, Unfit for Surgery Patients: Percutaneous Cholecystostomy : Preferred treatment Approximately 90% improvement rate with a cholecystostomy tube Interval Cholecystectomy : Can be considered after recovery, but not mandatory in the absence of gallstones or other gallbladder pathology Laparoscopic cholecystectomy (Option A): Although this is the definitive treatment for cholecystitis, it is often too risky for critically ill, unstable patients due to the invasive nature of the procedure and the need for general anaesthesia. Oral antibiotics and observation (Option B): This approach is insufficient for acalculous cholecystitis, which typically requires more aggressive intervention to manage the infection and decompress the gallbladder. Endoscopic retrograde cholangiopancreatography (ERCP) (Option C): While ERCP can be useful for managing bile duct stones and obstructions, it is not the standard treatment for acalculous cholecystitis, which involves inflammation of the gallbladder without gallstones.

@Neet_pg_bot

Q21: A 45-year-old woman with asymptomatic gallstones is being evaluated for prophylactic cholecystectomy. Which of the following is NOT typically considered an indication for prophylactic cholecystectomy? (Q848989)

A. Gallstones larger than 3 cm

B. Presence of gallstones in the common bile duct

C. Asymptomatic small gallbladder polyps

D. Undergoing bariatric surgery

Correct Answer: C. Asymptomatic small gallbladder polyps

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Small asymptomatic gallbladder polyps are generally not an indication for prophylactic cholecystectomy unless they are larger than 1 cm or have other risk factors for malignancy. Prophylactic Cholecystectomy: Prophylactic cholecystectomy involves the removal of the gallbladder in patients with gallstones who are asymptomatic. This procedure is considered when the potential risk of gallstone-related complications outweighs the surgical risks. Specific situations warranting prophylactic cholecystectomy include: Large Gallstones (Option A) : Stones >3 cm have a higher likelihood of causing complications. Choledocholithiasis (Option B) : Gallstones in the common bile duct increase the risk of cholangitis and pancreatitis. Chronic Hemolytic Conditions : Conditions like sickle cell disease and hereditary spherocytosis lead to pigment stone formation. Gallbladder Polyps : Polyps >1 cm may become malignant, justifying prophylactic surgery. Suspicion of Malignancy : Anomalous pancreatic ductal drainage may raise concern for cancer. Porcelain Gallbladder : Calcified gallbladder walls are linked to a higher cancer risk. High-Risk Ethnic Groups : Certain groups, such as Native Americans and people from northern India, have a higher incidence of gallbladder cancer associated with gallstones. Transplant Patients : Prophylactic removal during transplantation can prevent future complications. Bariatric Surgery (Option D) : Concurrent gallbladder removal during bariatric surgery can reduce future risks. Absolute contraindications for laparoscopic cholecystectomy include: Sepsis : Risk of complications and need for extensive surgery. Severe Bleeding Disorders : Difficult hemorrhage control. Empyema of the gallbladder Gangrenous cholecystitis Portal hypertension Peritonitis

Bailey & Love’s Short Practice of Surgery, Ed 28, Pg 1244

Contraindications of laparoscopic cholecystectomy

Absolute Contraindications for Laparoscopic Cholecystectomy

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: Which of the following is an indication for dissolution therapy in gallstone management? (Q848988)

A. Non-functioning gallbladder

B. Stone larger than 1.5 cm

C. Cholesterol stones which are typically radiolucent

D. Multiple stones

Correct Answer: C. Cholesterol stones which are typically radiolucent

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Dissolution therapy is indicated for cholesterol stones, which are usually radiolucent, in patients with a functioning gallbladder and stones smaller than 1 cm. Dissolution Therapy for Gallstones: Mechanism: Bile Acids: Medications like chenodeoxycholic acid (CDCA) and ursodeoxycholic acid (UDCA) dissolve cholesterol gallstones by inhibiting cholesterol absorption from the gut and reducing cholesterol synthesis in the liver. HMG-CoA Reductase Inhibition: These medications inhibit HMG-CoA reductase, a key enzyme in cholesterol production, and UDCA also hinders cholesterol absorption in the gastrointestinal tract. Indications: Functioning gallbladders Cholesterol stones (typically radiolucent) Single stone smaller than 1 cm Elderly patients or those unfit for surgery Contraindications: Non-functioning gallbladder (Option A) Stone larger than 1 cm (Option B) Radio-opaque stones Multiple stones (Option D) Drawbacks: Duration: Long-term medication use, often up to two years. Efficacy: Inconsistent results and incomplete stone dissolution. Cost: Expensive treatment. Side Effects: Diarrhea, pruritus, and liver dysfunction.

SRB's Manual of Surgery, Ed 6, Page 642

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A 60-year-old patient with a history of diabetes and hypertension presents with right upper quadrant pain, fever, and elevated white blood cell count. According to the Tokyo Guidelines (2013/2018), what is the recommended treatment approach if the patient is diagnosed with Grade II acute cholecystitis and does not respond to antibiotic treatment and supportive care? (Q848987)

A. Early laparoscopic cholecystectomy within 5-7 days.

B. Immediate discharge with oral antibiotics.

C. Early gallbladder drainage followed by delayed/elective cholecystectomy.

D. Delayed cholecystectomy after 6 weeks.

Correct Answer: C. Early gallbladder drainage followed by delayed/elective cholecystectomy.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Early gallbladder drainage is recommended for patients with Grade II acute cholecystitis with failure of response to antibiotics and general supportive care. Delayed/elective cholecystectomy can be considered if the patient's performance status improves. Acute cholecystitis grading: Grade Features I Mild Cholecystitis II Moderate Cholecystitis Along with one of the following Increased TLC (> 18,000/mm 3) Lasting > 72 hours Palpable tender mass in RUQ of the abdomen Biliary peritonitis, pericholecystic abscess, gangrenous cholecystitis, hepatic abscess, emphysematous cholecystitis III Severe Cholecystitis along with organ dysfunction Tokyo Guidelines for Acute Cholecystitis Treatment (2013/2018) 1. Initial Non-Operative Treatment: Nil by Mouth :

Patients should not eat or drink until the pain subsides. Intravenous Fluids : Administered until pain resolves. Analgesics : Pain management. Antibiotics : Broad-spectrum antibiotics effective against Gram-negative aerobes (e.g., cefazolin, cefuroxime, ciprofloxacin). 2. Definitive treatment: Grade 1 If fit for surgery- then do early laparoscopic cholecystectomy (Option A) If unfit: Give antibiotics and supportive care Observe Then do delayed laparoscopic cholecystectomy Grade 2 First antibiotics and supportive care are to be given If fit for surgery- then do early laparoscopic cholecystectomy If unfit: GB drainage via tube cholecystectomy (tube compresses GB, hence causing a decrease in inflammation) Then do delayed laparoscopic cholecystectomy (Option D) Grade 3 First antibiotics and supportive care are to be given If no negative predictive factors and good performance status: Then do early laparoscopic cholecystectomy If negative predictive factors are present Then do Tube cholecystectomy/drainage first. If the patient then shows Good performance status - do delayed laparoscopic cholecystectomy Poor performance status - observe Timing of Surgery Early Cholecystectomy : Performed within 5-7 days of symptom onset. Shortens hospital stays but has a higher conversion rate to open surgery. Delayed Cholecystectomy : Surgery is delayed approximately 6 weeks if early cholecystectomy is not indicated.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Pages 1244-1246

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: A 45-year-old patient presents with right upper quadrant (RUQ) pain and fever. On examination, the clinician notes localized tenderness over the right hypochondrium. USG of the abdomen reveals gallbladder wall thickness of about 5mm along with the presence of pericholecystic fluid. According to the Tokyo Guidelines, which combination of findings would confirm a diagnosis of acute cholecystitis? (Q848986)

A. RUQ tenderness, elevated C-reactive protein, gallbladder wall thickening on USG.

B. Murphy's sign, fever, normal gallbladder wall on USG.

C. Palpable RUQ mass, normal white blood cell count, pericholecystic fluid on USG.

D. RUQ pain, elevated C-reactive protein, no imaging finding

Correct Answer: A. RUQ tenderness, elevated C-reactive protein, gallbladder wall thickening on USG.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Above case meets all criteria (local sign, systemic sign, and characteristic imaging findings) for diagnosing acute cholecystitis. Tokyo Guidelines for Acute Cholecystitis (2013/2018) A) Local Signs of Inflammation : Murphy's sign Right upper quadrant (RUQ) pain/ tenderness, or a palpable mass. B) Systemic

Signs of Inflammation: Fever Elevated CRP Elevated WBC C) Imaging Findings: Gallbladder wall thickening (>3 mm) Pericholecystic fluid, Ultrasonographic Murphy's sign. Suspected acute cholecystitis is diagnosed when one local sign and one systemic sign of inflammation are present. Other options: Option B: Murphy’s sign, fever, normal gallbladder wall on USG Meets local + systemic signs Fails imaging criteria → cannot confirm diagnosis Option C: Palpable RUQ mass, normal WBC, pericholecystic fluid on USG Systemic signs missing (normal WBC and no fever mentioned) Tokyo Guidelines require systemic inflammation for confirmation Option D: RUQ pain, elevated CRP, no imaging finding Imaging is mandatory for confirmation Without imaging evidence → only "suspected" cholecystitis, not "definite"

Bailey & Love’s Short Practice of Surgery, Ed 28, Page 1235, 1236, 1244

↑ *Back to this question in Part A*

@Neet_pg_bot

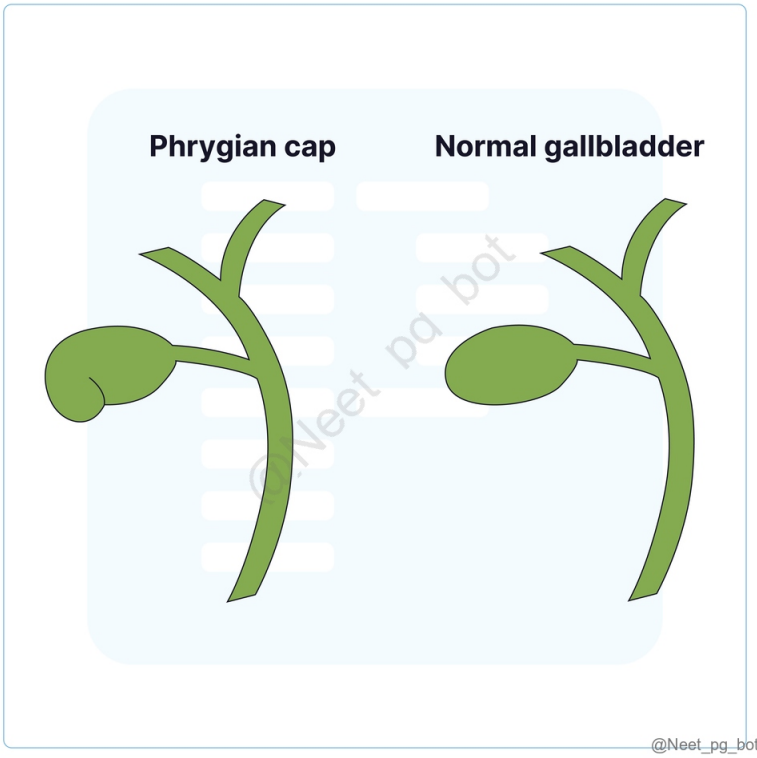
Q25: An ultrasound image of the gallbladder is consistent with a congenital anatomical variant. What is the most likely diagnosis? (Q843484)

A. Floating gallbladder

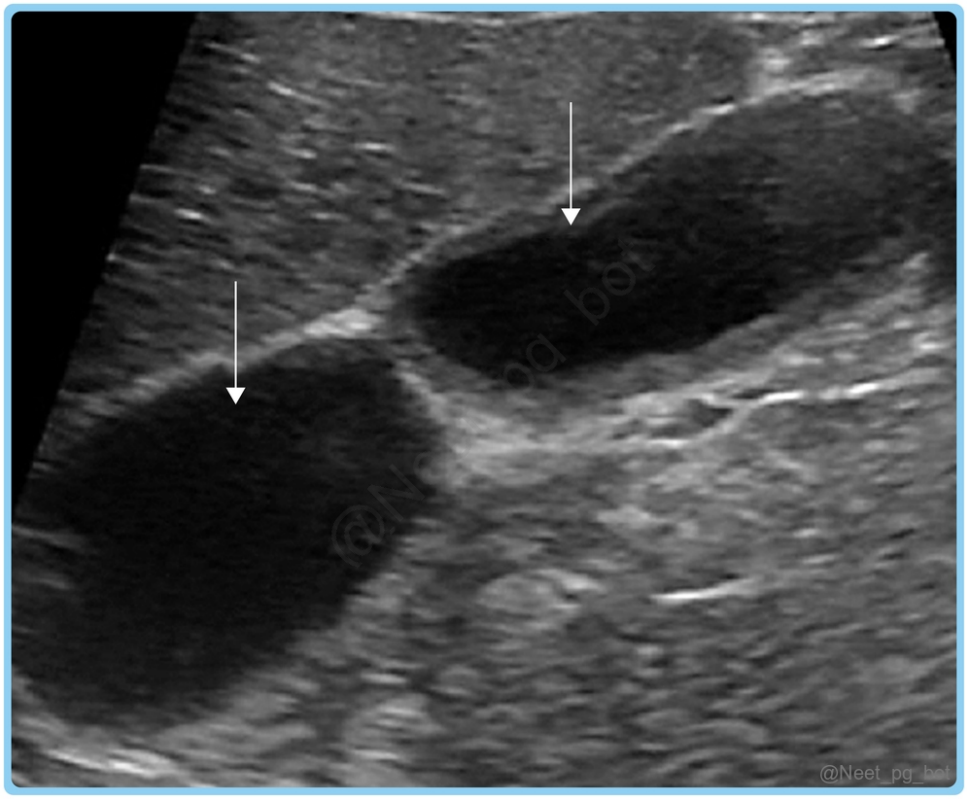
B. Accessory gallbladder

C. Phrygian cap

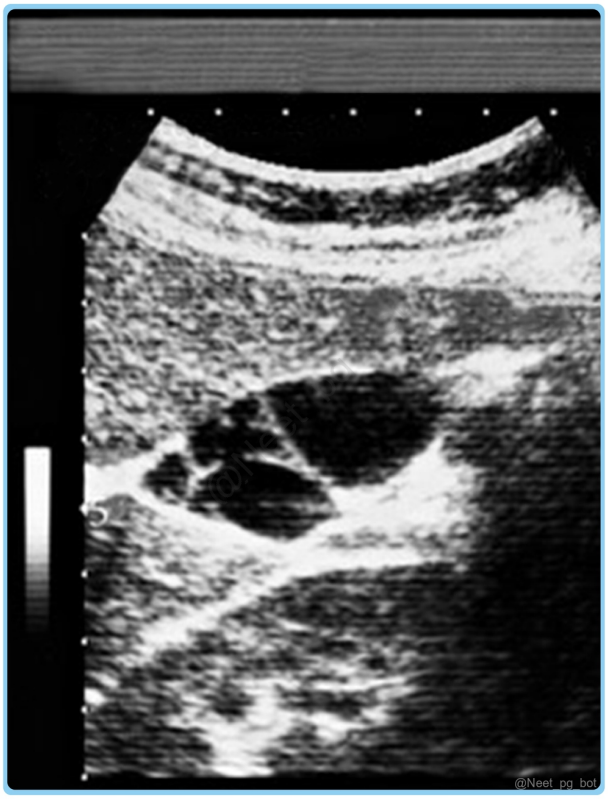
D. Gallbladder septum



Correct Answer: C. Phrygian cap



- *Listen (English)*
- *Listen (Hindi)*



Explanation: A Phrygian cap is a congenital variant of the gallbladder characterized by a fold at the fundus that resembles a cap. It is a benign condition and is typically asymptomatic, with its appearance being consistent with a cap-like structure on ultrasound. It has no pathological significance and does not affect gallbladder function. A floating gallbladder (or gallbladder volvulus) (Option A) refers to abnormal positioning of the gallbladder within the abdominal cavity, often due to the presence of an abnormally long mesentery from the gallbladder to the liver bed, allowing it to float freely. This makes the gallbladder prone to volvulus. This condition does not present as a cap-like fold on ultrasound. An accessory gallbladder (Option B) is a rare condition where an additional gallbladder exists alongside the normal one. It appears as a separate entity on imaging. A gallbladder septum (Option D) is an abnormal partition within the gallbladder that can be mistaken for a Phrygian cap. It appears as a distinct partition.

@Neet_pg_bot

Phrygian cap
Normal gallbladder
@Neet_pg_bot

@Neet_pg_bot

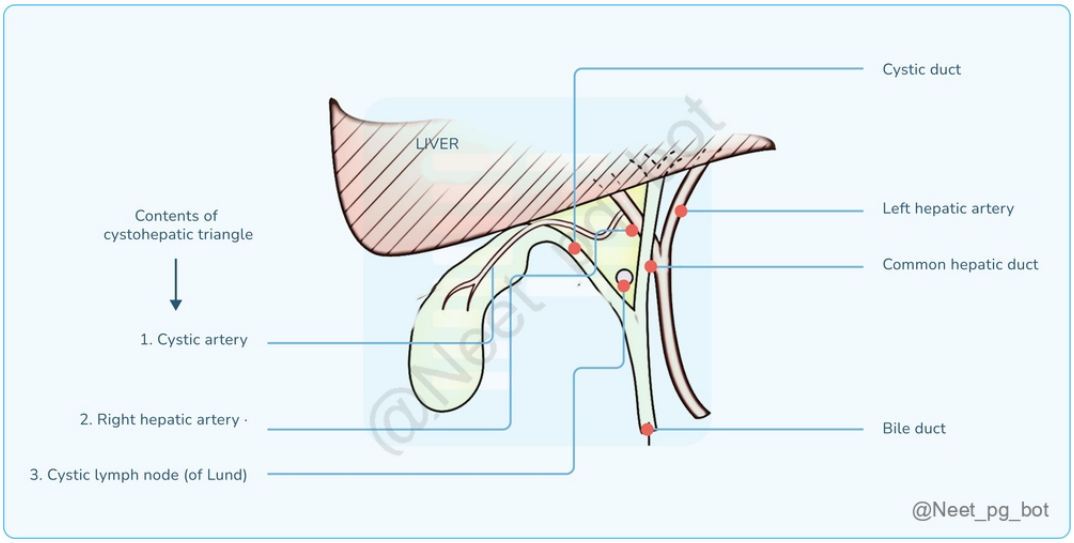
Q26: A 45 y/o woman presents to the ER with severe right upper quadrant abdominal pain, nausea, and vomiting. She has a history of gallstones and is diagnosed with acute cholecystitis. During laparoscopic cholecystectomy, the surgeon encounters difficulty identifying the cystic artery due to inflammation. Which anatomical landmarks within

Calot's triangle would be most helpful in locating the cystic artery? (Q843480)

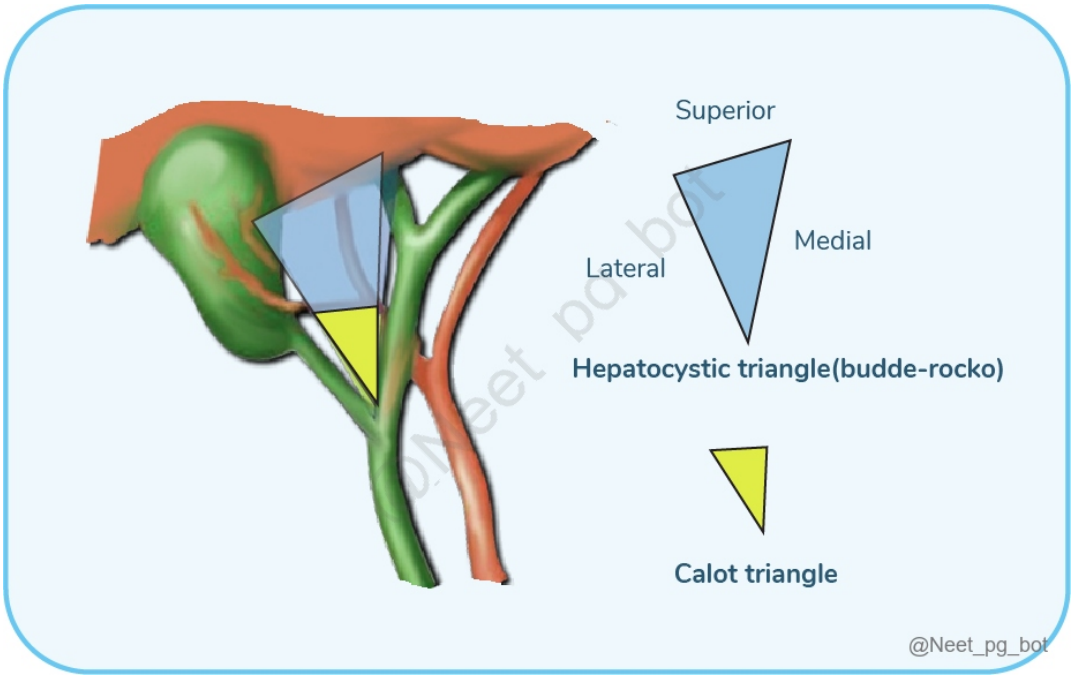
A. Gallbladder fundus

B. Cystic lymph node

C. Common bile duct



D. Portal vein



Correct Answer: B. Cystic lymph node

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The cystic lymph node, or Lund’s node , is located within Calot's triangle. It serves as an important landmark for identifying the cystic artery. Inflammation or anatomical variations can obscure typical landmarks, making the cystic lymph node a valuable reference point during surgery. Calot's triangle, also known as the cystohepatic triangle, is an important anatomical area during gallbladder surgery. The boundaries of Calot's triangle are defined by: Cystic duct (lateral boundary) Common hepatic duct (medial boundary) The inferior surface of the liver (superior boundary) The contents of Calot's triangle typically include the cystic artery, which supplies blood to the gallbladder, and the cystic lymph node (Lund’s node). Identification of these structures is crucial during a cholecystectomy to avoid accidental injury to the biliary or vascular systems. Note: The term "hepatocystic triangle" is often used interchangeably with Calot's triangle. It emphasizes the inclusion of the liver's inferior surface as part of the boundaries, along with the cystic duct and the common hepatic duct. Other options: Option A: Gallbladder fundus The fundus is NOT within Calot's triangle - it's located superiorly/laterally Calot's triangle is in the hepatocystic region, near the neck of gallbladder The fundus is too distant from the cystic artery to serve as a useful landmark Option C:Common bile duct (CBD) While the CBD forms the medial/inferior boundary of Calot's triangle, it's NOT within the triangle The CBD is an important structure to avoid injuring, not a landmark for finding the cystic artery Option D: Portal vein The portal vein is located posterior and deep to Calot's triangle It's in the hepatoduodenal ligament, behind the bile duct NOT an anatomical boundary or contents of Calot's triangle

Bailey and Love's Short Practice of Surgery, 28th Edition, Pg. 1232, 1233

SRB's Manual of Surgery, 6th Edition, Pg. 623, 656

↑ *Back to this question in Part A*

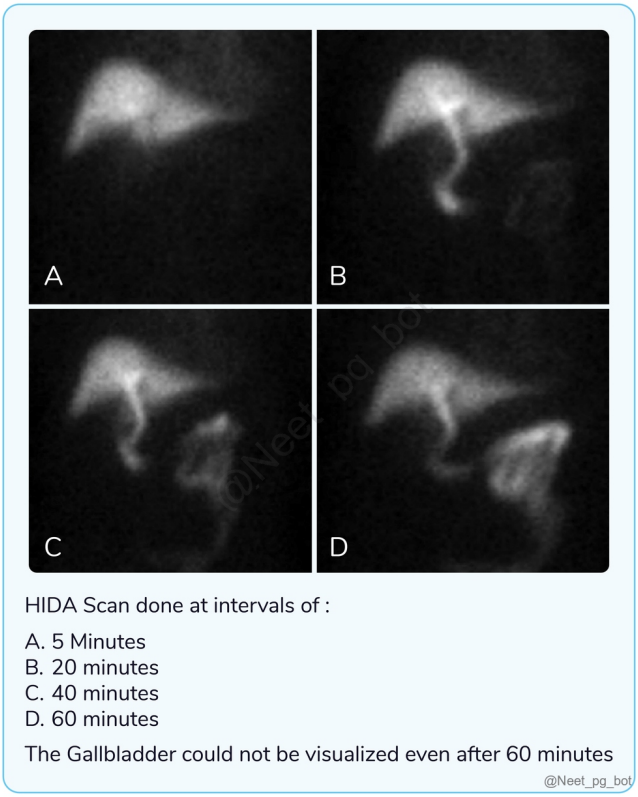
@Neet_pg_bot

Q27: A 45 y/o woman presents with severe right upper quadrant pain, fever, and nausea. She has a history of pain after fatty meals. O/E, she has right upper quadrant tenderness and a positive Murphy's sign. Lab tests show elevated alkaline phosphatase, bilirubin, transaminases, and leukocytosis. Which investigation is best to confirm this patient's diagnosis? (Q843342)

A. USG- Sonographic Murphy's sign positive.

B. Plain X-Ray- Identifies radio-opaque gallstones

C. CT Scan- Pericholecystic fluid, Impacted stones, gallbladder wall thickness



D. HIDA Scan- Non-visualization of the gallbladder

Correct Answer: D. HIDA Scan- Non-visualization of the gallbladder

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient’s clinical features and lab results are suggestive of acute cholecystitis. HIDA Scan can be used to confirm (Gold standard) acute cholecystitis when ultrasound findings are inconclusive. Non-visualization of the gallbladder on a HIDA scan indicates cystic duct obstruction, a key characteristic of acute cholecystitis thus making it a diagnostic feature. ASPECT INVESTIGATIONS Investigation of Choice/ Initial Inv. Ultrasound Abdomen: Reveals the presence or absence of gallstones. Posterior acoustic shadowing Thickening of the gallbladder wall. Sonographic Murphy's sign may be positive. (tenderness in the abdomen due to pressure of the ultrasound probe over the visualized gallbladder) (Option A) Gold Standard Combination of clinical assessment, laboratory findings, and imaging results: Patient history : This includes the presence of symptoms like right upper quadrant pain, fever, and a positive Murphy's sign on physical examination. Laboratory tests : Findings might include mild elevations in alkaline phosphatase, bilirubin, transaminases, and leukocytosis. Imaging : Ultrasound is the primary imaging tool, with HIDA scans and CT scans serving as supplementary tools when needed. Other Investigations HIDA/PIPIDA Radioisotope Study : Useful for assessing gallbladder visualization. Non-visualization of the gallbladder is diagnostic. CT Scan Abdomen : Identifies perforation, pericholecystic fluid, impacted stones, gallbladder wall thickness, and edema. (Option C) Useful for detecting stones in the common bile duct (CBD). Plain X-ray Abdomen : Identifies radio-opaque gallstones (10% of cases). (Option B) Rules out other causes of acute abdominal pain. May show gas in the emphysematous gallbladder. Useful to rule out duodenal ulcer perforation or peritonitis. Liver Function Tests (LFT) Total White Blood Cell Count (WBC Count)

Bailey and Love’s Short Practice of Surgery, 28th Edition, Pg. 1244

SRB’s Manual of Surgery, 6th Edition, Pg. 634, 636

Sabiston Textbook of Surgery, 21st edition, Pg. 1499, 1500

Sonographic Murphy’s sign

↑ *Back to this question in Part A*

@Neet_pg_bot

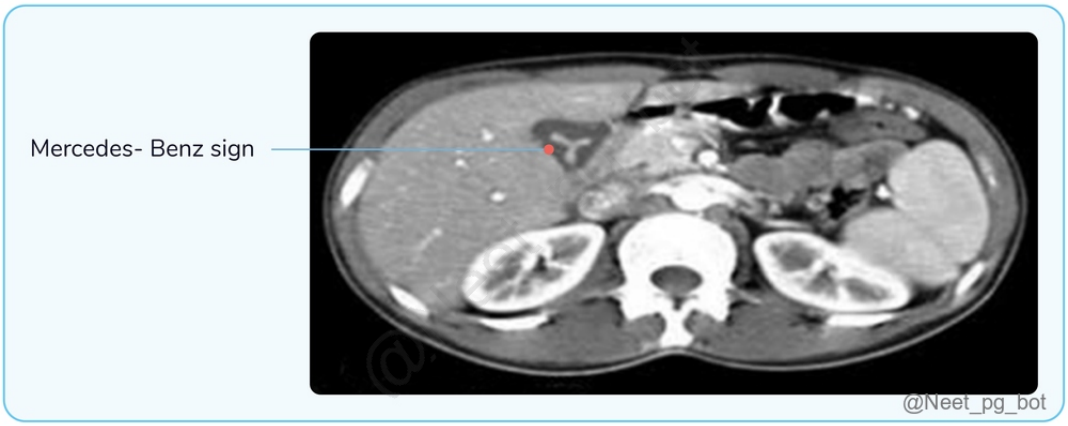
Q28: A 45 y/o woman presents to the ER with severe right upper quadrant pain radiating to her back. She has a h/o gallstones. O/E, she exhibits tenderness in the right upper quadrant. An abdominal CT scan shows a characteristic triradiate pattern of gas within a gallstone. Based on the CT findings, which of the following signs is most likely being described? (Q843341)

A. Murphy sign

B. Mermaid sign

C. Stellate scar sign

D. Mercedes-Benz sign



Correct Answer: D. Mercedes-Benz sign

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The "Mercedes Benz sign" and "seagull sign" are terms used to describe the appearance of specific types of radiopaque gallstones on plain radiographs and CT scans which have a radiolucent triradiate (Mercedes Benz sign) or biradiate (seagull sign) fissure in the centre containing nitrogen gas resembling the Mercedes-Benz logo. Murphy sign (Option A) is a clinical finding elicited during a physical exam that indicates gallbladder inflammation and acute cholecystitis While palpating the right upper quadrant, the examiner observes if the patient stops breathing voluntarily when the examiner exerts pressure under the right costal margin. Mermaid sign (Option B) and Stellate scar sign (Option C) are not established radiological terms related to gallstones and can be seen in conditions like ‘fetal abnormalities’ and ‘renal cell carcinoma’ respectively.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q29: Which of the following statements accurately describes a characteristic of pigment stones? (Q843340)

A. Black pigment stones are associated with bacterial β-glucuronidase activity in the bile duct.

B. Black pigment stones are associated with hemolysis.

C. Brown pigment stones are associated with excess bilirubin from hemolysis.

D. Black pigment stones are primarily composed of calcium bilirubinate and cholesterol.

Correct Answer: B. Black pigment stones are associated with hemolysis.

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Black pigment stones are associated with conditions causing hemolysis such as hereditary spherocytosis, and sickle cell disease, and are mainly composed of insoluble bilirubin pigment polymers. Feature Black Pigment Stones Brown Pigment Stones Composition Insoluble bilirubin pigment polymer, calcium phosphate, calcium bicarbonate Calcium bilirubinate, calcium palmitate, calcium stearate, cholesterol (Option D) Location Gallbladder Bile ducts Associated Conditions Hemolysis (hereditary spherocytosis, sickle cell disease), cirrhosis Bile stasis, infection, foreign bodies or parasites in the bile duct (Clonorchis sinensis, Ascaris lumbricoides) Pathophysiology Excess bilirubin from hemolysis precipitates in the gallbladder (Option C) Bacterial β-glucuronidase deconjugates bilirubin in the bile duct; unconjugated bilirubin precipitates (Option A) Image

Bailey and Love’s Short Practice of Surgery, 28th Edition, Pg. 1243

Sabiston Textbook of Surgery, 21st edition, Pg. 1497

↑ *Back to this question in Part A*

@Neet_pg_bot

Q30: A 49-y/o woman presents with intermittent right upper quadrant pain that worsens after fatty meals. She has a history of Sickle cell disease and has been on total parenteral nutrition (TPN) for the past six months due to severe Crohn's disease post-ileal resection. She also gives a h/o OCP usage for 5 years. The patient underwent cholecystectomy which showed the following finding. Which of the following factors is least likely to contribute to the formation of this patient's condition? (Q843339)

A. Total parenteral nutrition

B. Sickle cell disease

C. Ileal resection due to Crohn's disease

D. OCP usage

Correct Answer: B. Sickle cell disease

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The image shows cholesterol gallstones. They are the most common type of gallstone in Europe and the U.S., accounting for 80% of cases. They form when cholesterol precipitates out of bile and combines with calcium salts, bile acids, bile pigments, and phospholipids. Cholesterol makes up between 50% and 99% of these gallstones. Sickle cell disease is not associated with cholesterol Gallstones but rather with black pigment stones because these stones occur in hemolytic states. Cholesterol Gallstones Formation Mechanism Cholesterol precipitates out into crystals when the concentration exceeds the solubility Contributing Factors Obesity High-calorie diet Oral contraceptives (Option D) Ileal disease/resection (Option C) Abnormal gallbladder emptying Supersaturation of Bile High cholesterol and lipid concentrations in bile secreted from the liver The concentration of bile in the Gallbladder Bile is concentrated through the absorption of water and sodium, increasing solutes and calcium Crystal Nucleation Cholesterol crystallizes when concentration exceeds solubility; accelerated by glycoproteins and immunoglobulins Gallbladder Dysmotility Increased stasis due to abnormal motility, promoting stone formation Associated Conditions Prolonged fasting Total parenteral nutrition (Option A) Vagotomy Use of somatostatin analogues

Q1: A 50 year old woman presents with complaints of persistent fatigue, itching, and mild right upper quadrant abdominal pain. On examination, she has jaundice and hepatomegaly. Laboratory tests reveal elevated alkaline phosphatase and positive anti-mitochondrial antibodies. What is the most likely diagnosis? (Q843496)

A. Primary biliary cirrhosis

B. Primary sclerosing cholangitis

C. Autoimmune hepatitis

D. Drug-induced liver disease

Correct Answer: A. Primary biliary cirrhosis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's symptoms, including fatigue, itching, jaundice, and hepatomegaly, along with elevated alkaline phosphatase and positive anti-mitochondrial antibodies, are characteristic of primary biliary cirrhosis (PBC) . PBC is an autoimmune disorder leading to the gradual destruction of intrahepatic bile ducts, resulting in cholestasis and liver damage. Primary sclerosing cholangitis (Option A) also presents with cholestasis but is more often associated with inflammatory bowel disease (IBD). PSC involves both intrahepatic and extrahepatic bile ducts, which would typically be identified in imaging studies. This patient has no history of IBD, and the presentation and test results align more closely with PBC. Autoimmune hepatitis (Option C) is characterized by elevated serum transaminases rather than an isolated elevation in alkaline phosphatase. It is not commonly associated with anti-mitochondrial antibodies. While drug-induced liver disease (Option D) can cause cholestasis and elevated liver enzymes, the presence of specific antibodies (AMA), the chronic nature of the patient's symptoms and the absence of drug history are more indicative of an autoimmune process like PBC .

@Neet_pg_bot

Q2: A 70 year old male presents with painless obstructive jaundice, significant weight loss, and a palpable, non-tender mass in the right hypochondrium. Imaging reveals a mass at the liver hilum with no evidence of distant metastasis. What is the correct management of this patient? (Q848917)

A. Stenting through PTC or ERCP

B. Portal region clearance with hemihepatectomy

C. Extensive bile duct resection, nodal clearance, caudate lobe removal, and cholecystectomy

D. Chemotherapy with 5-FU and cisplatin

Correct Answer: C. Extensive bile duct resection, nodal clearance, caudate lobe removal, and cholecystectomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical scenario is suggestive of perihilar cholangiocarcinoma, given the presentation of painless jaundice, weight loss, and a palpable mass at the liver hilum with no evidence of distant metastasis, indicating that the tumor is operable. Extensive bile duct resection, nodal clearance, caudate lobe removal, and cholecystectomy are the correct surgical management, aiming for complete resection of the tumor. Management of cholangiocarcinoma: Surgical options (if operable) Portal region clearance with hemi-hepatectomy (for intrahepatic type) Hemi-hepatectomy or extensive bile duct resection, nodal clearance, caudate lobe removal, cholecystectomy (for perihilar type) Whipple's pancreaticoduodenectomy (for distal tumors) Palliative options (if operable) Stenting to relieve jaundice (through PTC or ERCP or intraoperatively) Chemotherapy 5-Fluorouracil (5-FU) Gemcitabine Cisplatin Radiotherapy External Beam Radiotherapy (ERBT) in combination with chemotherapy Stenting through PTC or ERCP (Option A): This is a palliative option for inoperable cases to relieve jaundice. Portal region clearance with hemihepatectomy (Option B) : Appropriate for intrahepatic type, not specifically for perihilar cholangiocarcinoma. Chemotherapy with 5-FU and cisplatin (Option D): This is an option for adjuvant or palliative treatment, not the primary management for an operable tumour.

Bailey and Love’s Short Practice of Surgery, 28th Edition, Page 1256,1257

↑ *Back to this question in Part A*

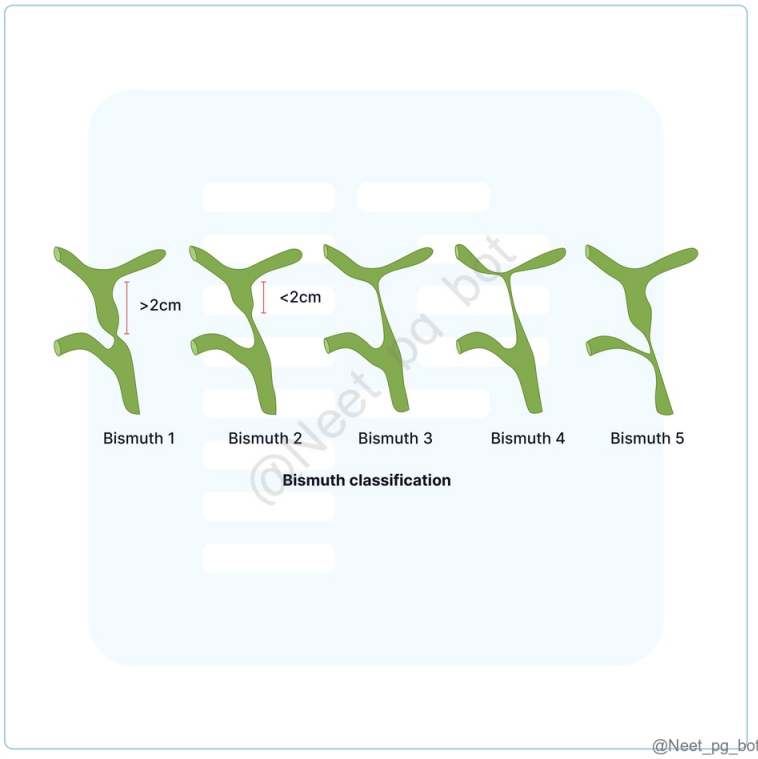
@Neet_pg_bot

Q3: A 55 year old woman undergoes a cholecystectomy, after which she develops jaundice and abdominal pain. Imaging reveals a bile duct stricture at the confluence of the right and left hepatic ducts, but the ducts themselves are intact. According to the Bismuth classification, what type of stricture does she have? (Q843542)

A. Type I

B. Type II

C. Type III



D. Type IV

Correct Answer: C. Type III

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Type III strictures are located at the confluence of the right and left hepatic ducts, with the ducts themselves remaining intact. This matches the description given in the scenario. Bismuth classification for biliary strictures Type I Common hepatic duct stump >2cm Stricture is Low (Option A) Type II Common hepatic duct stump <2cm Stricture is mid (Option B) Type III Hilar stricture with intact confluence Stricture is high Type IV Hilar stricture with destroyed confluence (Option D) Type V Stricture involving aberrant right sectoral duct with or without stricture of common hepatic duct Drawbacks of bismuth classification: No information about the bile leak No information about the types of injuries in laparoscopic surgeries

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 25-year-old woman presents with persistent right upper quadrant pain for several days, fever, and jaundice. On examination, right upper quadrant tenderness is present. On USG, cystic dilation of the common bile duct is seen. Which of the following malignancies is not associated with this condition? (Q848898)

A. Cholangiocarcinoma

B. Squamous Cell carcinoma

C. Pancreatic Carcinoma

D. Renal cell carcinoma

Correct Answer: D. Renal cell carcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical scenario points to a choledochal cyst due to the presence of right upper quadrant pain, jaundice, and ultrasound showing cystic dilation of the common bile duct, which are hallmark features of this condition. Choledochal cysts, congenital dilatations of the intra- and/or extrahepatic biliary system, can present at any age. Renal carcinomas are not seen to be associated with choledochal cysts. Clinical features of choledochal cysts: Patients may present with jaundice, fever, abdominal pain, and a right upper quadrant mass. Pancreatitis is a frequent presentation in adults. Approximately 60% of cases are diagnosed before the age of 10 years. The classical triad of jaundice, right upper quadrant mass, and abdominal pain is present in only a minority of patients (0–17%) Malignancies associated with choledochal cysts may arise within the cyst or elsewhere within the liver or pancreaticobiliary tract. Patients with choledochal cysts have an increased risk of developing malignancies like: Cholangiocarcinoma (Option A) Squamous cell carcinoma (Option B) Bile duct sarcoma Hepatoma Pancreatic carcinoma (Option C) Gallbladder carcinoma

Diagnosis and Management of Choledochal Cysts

Choledochal Cyst and Malignancy

Choledochal cyst

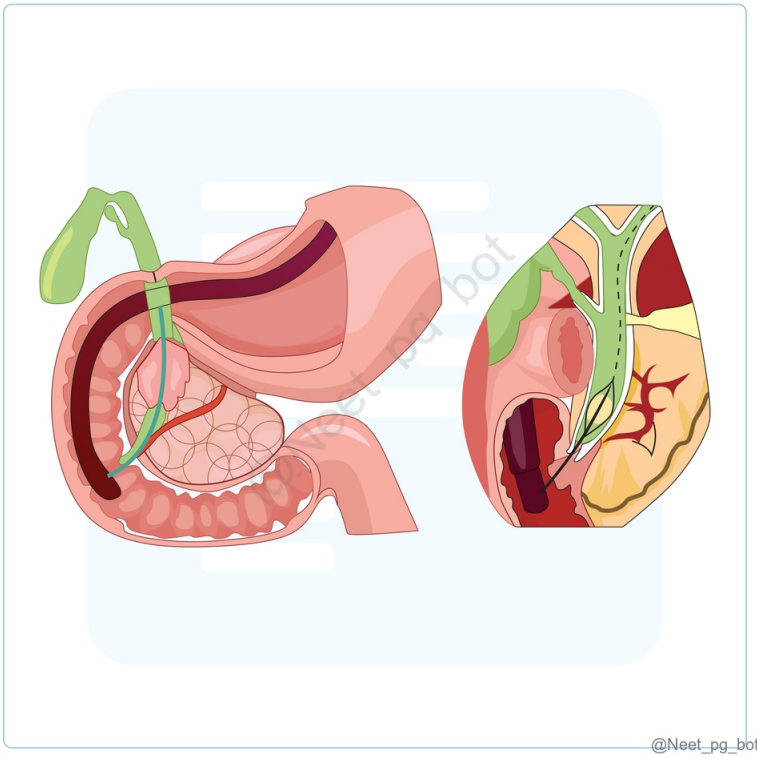
↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 45-year-old woman presents with worsening abdominal pain, jaundice, and fever. Ultrasound shows a choledochal cyst and bile duct obstruction. What imaging study is most appropriate for the next step in management? (Q848899)

A. CT Scan

B. Magnetic Resonance Cholangiopancreatography



C. Endoscopic Retrograde Cholangiopancreatography

D. Percutaneous Transhepatic Cholangiography

Correct Answer: C. Endoscopic Retrograde Cholangiopancreatography

- *Listen (English)*
- *Listen (Hindi)*

Explanation: ERCP is appropriate in this scenario as it allows for both diagnostic evaluation and therapeutic interventions. It enables the physician to obtain detailed images of the bile ducts, perform tissue sampling, decompress obstructions, and treat conditions like choledocholithiasis. INVESTIGATIONS - CHOLEDOCHAL CYST Ultrasound The first imaging test that is performed. Confirms the presence of the cyst. Reveals anatomical details, including bile duct and pancreatic duct relationship. Magnetic Resonance Cholangiopancreatography (MRCP) (Option B) Non-invasive imaging technique. Provides detailed images of the gallbladder and biliary system. Highly sensitive (>90%) and specific (>99%) for identifying common bile duct stones. Visualizes biliary anatomy and the extent of dilatation. Endoscopic Retrograde Cholangiopancreatography (ERCP): Invasive procedure with endoscope and contrast material. Diagnostic and therapeutic capabilities (tissue sampling, decompression, treatment of choledocholithiasis). Effective but has a complication rate of up to 10%. Percutaneous Transhepatic Cholangiography (PTC) (Option D) Invasive procedure with a needle directly into the liver. Useful for intrahepatic biliary disease or when ERCP is not feasible. Helps delineate surgical anatomy and enables drainage catheter and stent placement. CT SCAN (Option A) Mainly to see the intrahepatic biliary system Other Tests Hepatobiliary nuclide Scanning Liver Function Tests MRCP: Excellent for diagnosis, sensitive, and specific. ERCP: Preferred for treatment due to therapeutic capabilities, and higher complication risk. PTC: Useful when ERCP is not feasible, especially in cases with dilated biliary systems

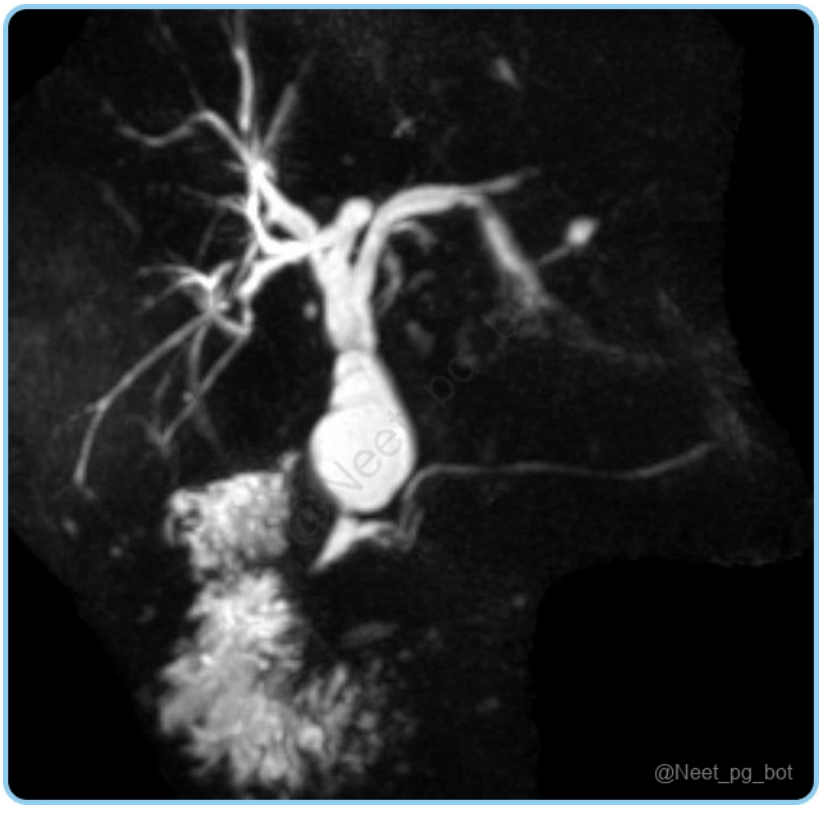
↑ *Back to this question in Part A*

@Neet_pg_bot



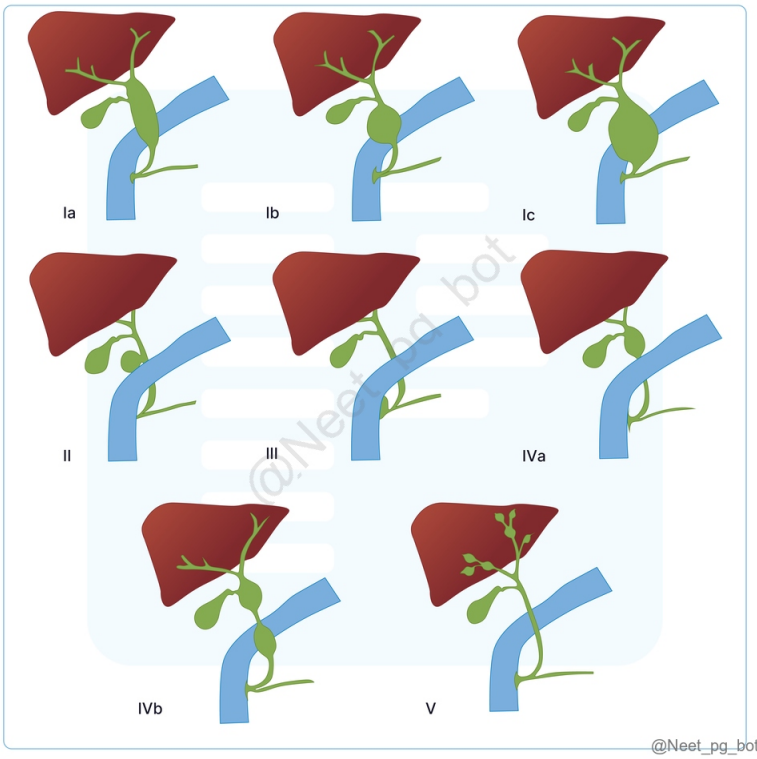
Q6: MRCP imaging studies done for a 35 year old woman who presented with a history of recurrent cholangitis, jaundice, and right upper quadrant pain reveal the following. Based on the Todani classification, what is the most appropriate surgical treatment for this patient? (Q848897)

A. Liver transplantation

B. Transduodenal sphincteroplasty

C. Roux-en-Y hepaticojejunostomy

D. Partial hepatectomy



Correct Answer: C. Roux-en-Y hepaticojejunostomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Imaging shows an anomalous pancreaticobiliary junction , with a high junction of the pancreatic duct with the common bile duct resulting in a long common channel. There is fusiform dilation of the common bile duct, compatible with a type I choledochal cyst. The recommended treatment for Type I cysts is complete surgical excision, cholecystectomy, and Roux-en-Y hepaticojejunostomy. Choledochal cysts are congenital anomalies characterized by the dilatation of the intrahepatic and/or extrahepatic bile ducts. The exact cause of choledochal cysts is unknown, but they are thought to be premalignant. Todani modification of Alonso- Lej classification Type I Ia Cystic dilation of the extrahepatic bile duct (Most common) Ib Focal segmental dilation of extrahepatic bile duct Ic Fusiform dilation of extrahepatic bile duct Type II Diverticular dilation of extrahepatic bile duct Type III Dilatation of intraduodenal part of bile duct (choledochocele) Type IV IV a Dilatation of both intra and extrahepatic bile duct IV b Multiple cysts involving extrahepatic bile duct only Type V Multiple cysts involving intrahepatic bile duct only (Caroli's disease) Type Treatment Type I Complete excision, cholecystectomy, Roux-en-Y hepaticojejunostomy Type II Complete excision Type III Transduodenal excision or sphincteroplasty (Option B) ; endoscopic drainage may suffice Type IVa Tailored to anatomy: extrahepatic cysts treated like Type I; partial hepatectomy (Option D) and reconstruction for localized intrahepatic involvement Type IVb Managed like Type I Type V (Caroli disease) Resection for unilobar disease; liver transplantation for diffuse disease (Option A)

↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: During a laparoscopic cholecystectomy, a lateral injury to the Common Bile Duct is identified. What is the most appropriate next step in management? (Q882176)

A. Continue the laparoscopic procedure and place a drain

B. Convert to open procedure with T-tube drainage

C. Ligate the duct proximal to the injury

D. Close the abdomen and refer for ERCP

Correct Answer: B. Convert to open procedure with T-tube drainage

Explanation: A lateral injury to the CBD identified intraoperatively represents a Strasberg type D injury. The recommended management is immediate repair in the same sitting. Conversion to an open procedure allows proper exposure, assessment of the extent of injury, and controlled biliary drainage using a T-tube after primary repair. This approach reduces the risk of bile leak, stricture formation, and long-term morbidity when expertise is available. Continue the laparoscopic procedure and place a drain (Option A): Drain placement alone is inadequate and leads to persistent bile leak, biliary peritonitis, and stricture formation. Ligate the duct proximal to the injury (Option C): Ligation of the CBD causes obstructive jaundice and secondary biliary cirrhosis and is never appropriate. Close the abdomen and refer for ERCP (Option D): ERCP is useful for postoperative bile leaks or minor injuries, not for a recognized intraoperative CBD injury, where immediate surgical repair is preferred.

References:

Bailey and Love's Short Practice of Surgery, 28th Edition, Page 1236

↑ *Back to this question in Part A*

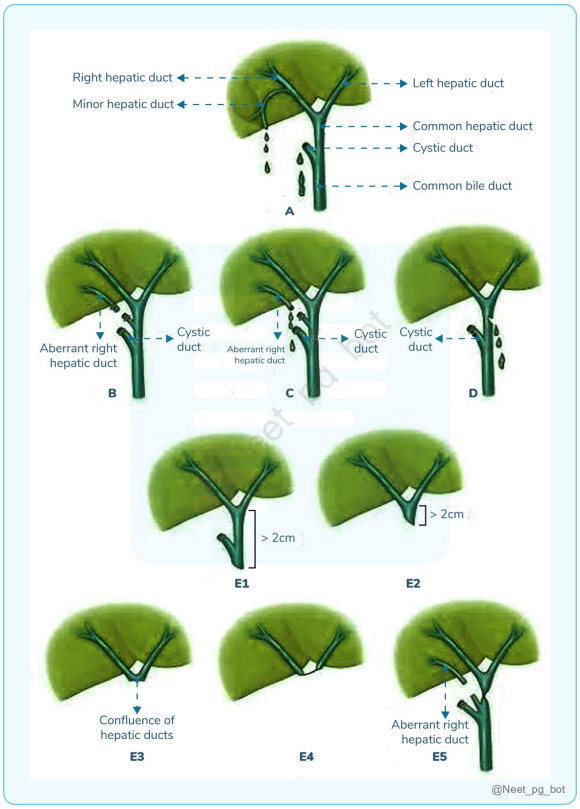
@Neet_pg_bot

Q8: According to the Strasberg classification, what type of bile duct injury does this image show? (Q848919)

A. Class A

B. Class B

C. Class C



D. Class D

Correct Answer: A. Class A

- *Listen (English)*
- *Listen (Hindi)*

Explanation: Class A of Strasberg's classification of bile duct injuries involves leakage of bile from the cystic duct or an accessory duct that is still connected to the common bile duct, which matches the given image. The Strasberg classification divides bile duct injuries into five main classes: Type A (M/C) Cystic duct stump leak or leak from sub-vesical duct of Luschka Type B Ligation or occlusion of aberrant right sectoral duct Type C Transection without occlusion of the aberrant right sectoral duct Type D Injury to the lateral wall of the Common hepatic duct Type E E1 to E5 Bismuth classification

References:

Bailey and Love's Short Practice of Surgery, 28th Edition, Page 1252

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 45-year-old male presents with severe colicky pain in the upper right quadrant, jaundice, and episodes of haematemesis and melaena. He had a history of blunt abdominal trauma a few weeks ago. Which is the investigation of choice for detecting the bleeding site in this patient? (Q848918)

A. Liver Function Tests

B. Ultrasound of the abdomen

C. Selective arteriography

D. Upper GI endoscopy

Correct Answer: C. Selective arteriography

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical features and history provided in the clinical scenario point to a diagnosis of Hemobilia. Selective arteriography is the investigation of choice, with a 90% success rate in detecting the bleeding site , providing detailed vascular imaging necessary for precise diagnosis and treatment planning. Hemobilia is bleeding from the liver or, less commonly, from the gallbladder into the biliary tract due to abnormal communication between a blood vessel and a bile duct or any part of the biliary tree. Causes Trauma Vascular Diseases Liver Diseases Others Accidental blunt trauma Iatrogenic trauma Percutaneous diagnostic and therapeutic procedures Hepatic artery diseases (10%) Hepatic artery aneurysm (common cause) Malignant liver diseases (more common, 5%) Benign liver diseases Parasitic liver diseases (e.g., hydatid disease) Arterial hemobilia(common) Portal hypertension Gallstones (rare) Portal venous hemobilia (rare) Clinical Features Quinckes Triad Pain : Colicky Jaundice : Obstructive Jaundice Gastrointestinal Bleeding : Hematemesis Melaena Investigations Imaging: Ultrasound (US) of the abdomen Selective arteriography (test of choice) CT angiogram Treatment Initial Management: Antibiotics Blood transfusions Selective arterial embolization (Transarterial Embolisation, TAE) Surgical Intervention (rare, indicated in failed TAE): Laparotomy Ligation of the bleeding vessel or hepatic artery Excision of aneurysm Hepatic resection Liver Function Tests (LFTs) (Option A) : These tests help assess liver function but do not identify the bleeding site. Ultrasound (US) of the abdomen (Option B) : Useful for initial evaluation and detecting biliary dilation or hepatic lesions but not as specific for locating the bleeding source. Upper GI endoscopy (Option D) : Useful in identifying upper gastrointestinal bleeding but has limited value in diagnosing hemobilia, as it can only detect the source in about 10% of cases.

Sabiston Textbook of Surgery, 21st Edition, Page 1158.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q10: A 65 year old female presents with painless jaundice and a palpable, non-tender, globular mass in the right hypochondrium. Imaging suggests an obstructed biliary system. The patient has no history of gallstones. Based on Courvoisier's law, which of the following conditions is not an exception to the rule? (Q848916)

A. Double impacted stone

B. A large stone in Hartmann's pouch

C. Empyema of the gallbladder with a CBD stone

D. Chronic cholecystitis with multiple gallstones

Correct Answer: D. Chronic cholecystitis with multiple gallstones

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Chronic cholecystitis with multiple gallstones is not an exception, as the gallbladder is typically contracted, fibrotic, and non-distensible in chronic cholecystitis. It simply defies courvoisier's law. Courvoisier's Law : It states that in a patient with jaundice, if there is a palpable gallbladder, it is not due to stones Gallbladder and Stones: In obstruction due to common bile duct (CBD) stones, the gallbladder does not distend. The gallbladder is typically chronically inflamed, thickened, fibrotic, contracted, and nondistensible in the presence of stones. Gallbladder and Malignancy: In malignancies such as carcinoma of the head of the pancreas or periampullary carcinoma, the gallbladder will be distended and palpable. The gallbladder presents as a non-tender, globular, smooth, soft, dull mass that moves with respiration and tumourorizontal mobility, located to the right of the rectus muscle in the right hypochondrium. Exceptions to Courvoisier's Law Double Impacted Stone (Option A) : One stone in the CBD and another in the cystic duct, leading to mucocele of the gallbladder. A large Stone in Hartmann's Pouch (Option B) : Obstructing the cystic duct, causing distention of the gallbladder. Empyema Gallbladder with CBD Stone (Option C) : Infection and accumulation of pus in the gallbladder combined with CBD stone obstruction. Ampullary vs Periampullary carcinoma: Ampullary Periampullary They originate in the ampulla of Vater. They originate in the pancreas, bile duct, or intestines close to the ampulla of Vater. They have a better survival rate than periampullary cancers. Poorer survival rate.

↑ *Back to this question in Part A*

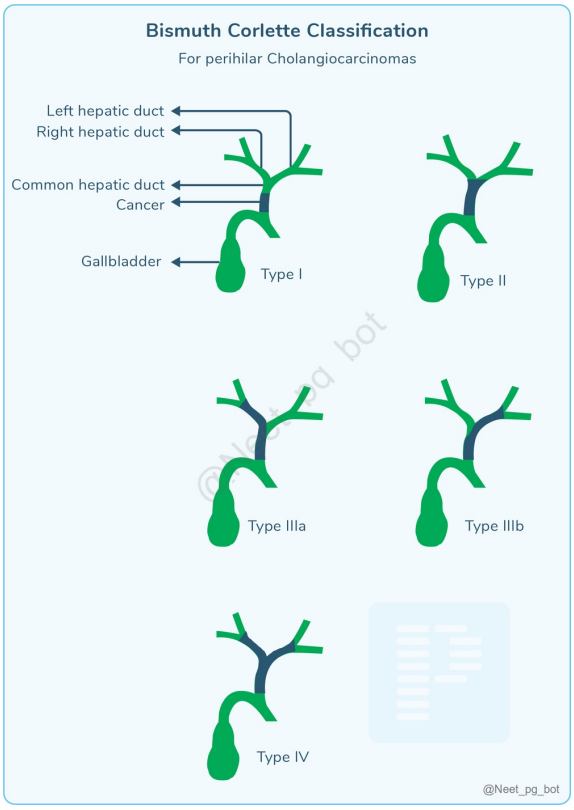
@Neet_pg_bot

Q11: A 58 year old female presents with painless obstructive jaundice, significant weight loss, and anorexia. Imaging reveals a tumour involving the confluence of the right hepatic duct and left hepatic duct, extending into both ducts. Based on the Bismuth-Corlette classification, which type of perihilar cholangiocarcinoma is most consistent with these findings? (Q848915)

A. Type 1

B. Type 2

C. Type 3A



D. Type 4

Correct Answer: D. Type 4

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: In this scenario, the tumor involves the confluence and extends into both the RHD and LHD, indicating Type 4 cholangiocarcinoma. Bismuth Corlette's classification of perihilar cholangiocarcinoma Type 1 Below the confluence of RHD and LHD Type 2 Reaching the confluence of RHD and LHD Type 3A Type 3B Involving CHD with RHD Involving CHD with LHD Type 4 Involving confluence and both RHD and LHD or multicentric tumor

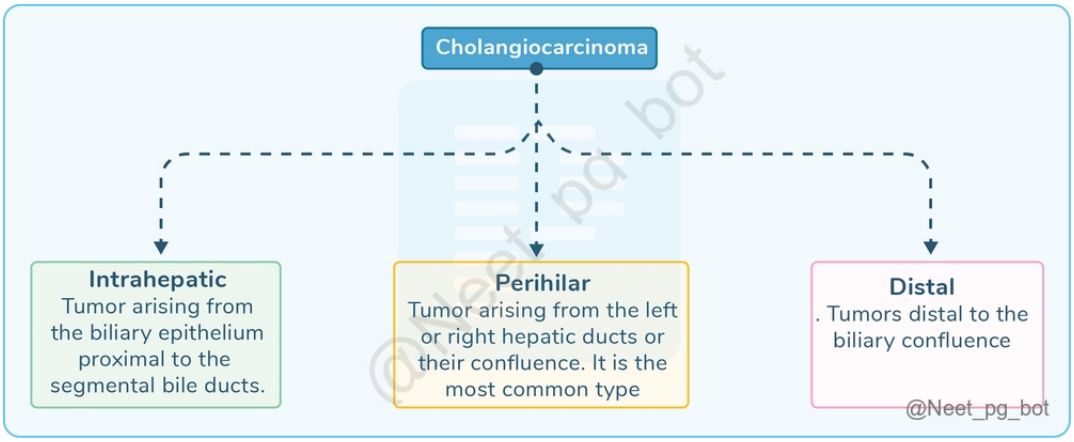
@Neet_pg_bot

Q12: Which of the following is not a risk factor for cholangiocarcinoma? (Q848914)

A. Primary sclerosing cholangitis

B. Hepatitis C

C. Clonorchis sinensis infestation



D. Alcohol consumption

Correct Answer: D. Alcohol consumption

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Alcohol consumption is not specifically a risk factor for cholangiocarcinoma Cholangiocarcinoma Cholangiocarcinoma is an aggressive adenocarcinoma of the bile ducts, commonly presenting as obstructive jaundice. Risk Factors Biliary and Liver Conditions : Primary sclerosing cholangitis (PSC) (Option A) Choledochal cyst Hepatolithiasis Caroli's disease Infections : Clonorchis sinensis infestation (Option C) Hepatitis B and C (Option B) (risk factors for intrahepatic cholangiocarcinoma) Genetic Conditions : Lynch syndrome II Other Conditions : Multiple biliary papillomatosis Previous biliary enteric anastomosis Toxins : Thorotrast Nitrosamines Dioxin Types based on its location

@Neet_pg_bot

Q13: Which of the following is the classical triad of acute cholangitis? (Q848911)

A. Pain, jaundice, fever

B. Pain, jaundice, shock

C. Fever, jaundice, ↑WBC

D. Pain, ↑WBC, ↑Bilirubin

Correct Answer: A. Pain, jaundice, fever

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Pain, jaundice, fever - this triad, known as Charcot's triad - indicates cholangitis . Cholangitis Aetiology Often due to obstruction in the biliary tree, leading to bacterial infection by organisms like Klebsiella, E. coli, Enterobacter, Pseudomonas, and Citrobacter species. Symptoms Charcot's triad - pain, jaundice, fever Additional tenderness in the epigastrium and right hypochondrium is common. Severe Form: Reynolds pentad - persistent pain, fever, jaundice, shock, and altered mental status Indicates acute obstructive suppurative cholangitis. Lab Findings Elevated white blood cell count, bilirubin, and alkaline phosphatase levels. Chronic cases may show lobar or segmental atrophy or hypertrophy. Recurrent Pyogenic Cholangitis More common in East Asian populations, caused by intrahepatic stones and infections Risk factors include parasitic infections like Clonorchis sinensis and Ascaris lumbricoides. Pain, jaundice, shock (Option B): This option is incorrect as shock is not part of Charcot's triad but is part of Reynolds's pentad. Fever, jaundice, ↑WBC (Option C): ↑WBC, although it does occur in cholangitis, is not a component of Charcot's triad. Pain, ↑WBC, ↑Bilirubin (Option D): ↑Bilirubin, although it does occur in cholangitis, is not a component of Charcot's triad.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 40 year old patient is experiencing persistent abdominal pain and elevated serum amylase after undergoing ERCP. The pain began shortly after the procedure. Which of the following is the most likely cause of the patient's symptoms? (Q848910)

A. Post-ERCP pancreatitis

B. Post-ERCP duodenal perforation

C. Post-ERCP cholangitis

D. Post-ERCP sphincter stenosis

Correct Answer: A. Post-ERCP pancreatitis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Elevated serum amylase and abdominal pain shortly after ERCP strongly suggest pancreatitis, a common complication Complications of ERCP: Duodenal perforation Hemorrhage post-sphincterotomy Pancreatitis It can be severe with extensive pancreatic necrosis Associated with a significant mortality rate Use of per-rectal indometacin/diclofenac to reduce risk Sepsis Other complications: Cholangitis Sphincter stenosis Post-ERCP duodenal perforation (Option B) : Typically presents with severe pain and peritoneal signs rather than elevated amylase. Post-ERCP cholangitis (Option C) : Usually involves fever and jaundice, not elevated amylase alone. Post-ERCP sphincter stenosis (Option D) : Causes obstructive symptoms over time, not acute pain and elevated amylase.

References:

Bailey and Love's Short Practice of Surgery, 28th Edition, Page 156

SRB's Manual of Surgery, 6th Edition, Page 625

↑ *Back to this question in Part A*

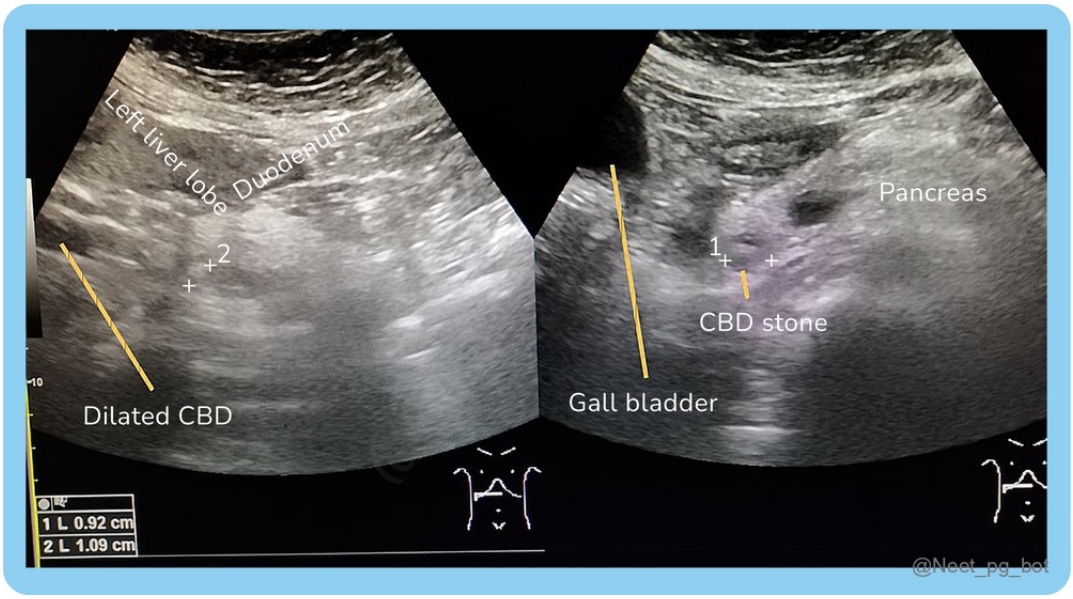
@Neet_pg_bot

Q15: A 55 year old male with history of obesity and a low-protein diet presents with intermittent abdominal pain, jaundice, and recurrent episodes of dark urine and light-colored stools. Recently, he developed a fever with chills. Blood tests show elevated WBC count and abnormal liver function tests. MRCP reveals multiple pigmented stones in the common bile duct and intrahepatic ducts. What is the most likely cause of his condition? (Q843489)

A. Primary Choledocholithiasis

B. Secondary Choledocholithiasis

C. Gallstone ileus



D. Chronic Pancreatitis

Correct Answer: A. Primary Choledocholithiasis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The patient's symptoms of intermittent abdominal pain, jaundice, dark urine, light-colored stools, and recent fever suggest primary choledocholithiasis, where stones form directly in the bile ducts and cause recurrent symptoms. Primary stones form within the bile ducts due to biliary stasis, infections, or congenital conditions. Primary stones can be present in intrahepatic ducts as well as in the common bile ducts. They are often multiple and pigmented, as seen in this patient's MRCP results. Primary CBD stone Secondary CBD stone Formed inside the common bile duct The most common stone is the brown stone. More common in developing countries due to worm infestations such as Ascaris and Clonorchis sinensis. Formed in the gall bladder which slips into the common bile duct. The most common type: is cholesterol stone More common in developed countries Secondary choledocholithiasis (Option B): They cause obstruction and symptoms like biliary colic and jaundice. However, the presence of multiple pigmented stones in both the common bile duct and intrahepatic ducts suggests primary stones rather than secondary ones. Gallstone ileus (Option C): It involves a large gallstone causing mechanical intestinal obstruction, typically in the terminal ileum, following erosion into the duodenum. This condition presents with signs of intestinal obstruction, not intermittent jaundice and fever as seen in this scenario. (sab 1502) Chronic pancreatitis (Option D): It involves persistent inflammation of the pancreas, often causing continuous abdominal pain and malabsorption. This patient's symptoms do not align with chronic pancreatitis. Ultrasound showing CBD stone Symptoms Features Pain Biliary colic to non-specific abdominal pain. Biliary colic is a sudden, severe, colicky pain in the right upper quadrant that radiates to the back and shoulder. It is precipitated by a fatty or heavy meal and can last for a few hours. The pain is typically located in the epigastrum and right hypochondrium. Jaundice Jaundice, a yellowing of the skin and eyes, is the most common clinical manifestation of choledocholithiasis. It occurs due to the obstruction of bile flow, leading to the accumulation of bilirubin in the blood. The jaundice associated with choledocholithiasis is likely to be painful because the onset of obstruction is often acute. Fever The presence of fever with chills and rigors is suggestive of cholangitis, a serious complication of choledocholithiasis. Cholangitis occurs when the obstruction of the bile duct leads to bacterial infection and inflammation. Charcot’s triad : Pain + Fever + Jaundice Reynauld’s pentad : Mental status changes + Hypotension + Charcot’s triad Changes in urine and stool Obstruction of the bile duct can lead to darkening of the urine and lightening of the stools. Steatorrhea, or fatty stools, may occur due to the impaired absorption of fat and fat-soluble vitamins caused by the lack of bile in the intestines. Other symptoms Pruritus (itching), loss of appetite, weight loss, nausea, and vomiting.

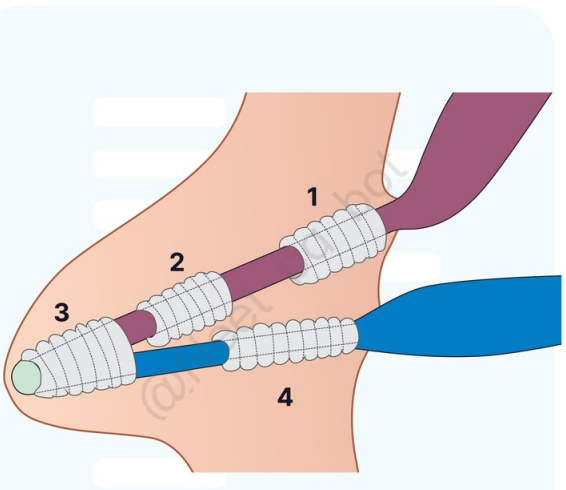
@Neet_pg_bot

Q16: How many sphincters make up the Sphincter of Oddi Complex? (Q848889)

A. 12

B. 9

C. 6



D. 4

Correct Answer: D. 4

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The Sphincter of Oddi Complex consists of four smooth muscle sphincters: Superior Choledochal Sphincter: Also known as the Sphincter of Boyden Inferior Choledochal Sphincter Sphincter Ampullae Sphincter Pancreaticus They are located within the duodenal wall These sphincters collaborate to Manage and regulate the secretion of neighbouring fluids from the bile duct and pancreatic ducts Prevent reflux from the duodenum into the biliary and pancreatic ducts.

@Neet_pg_bot

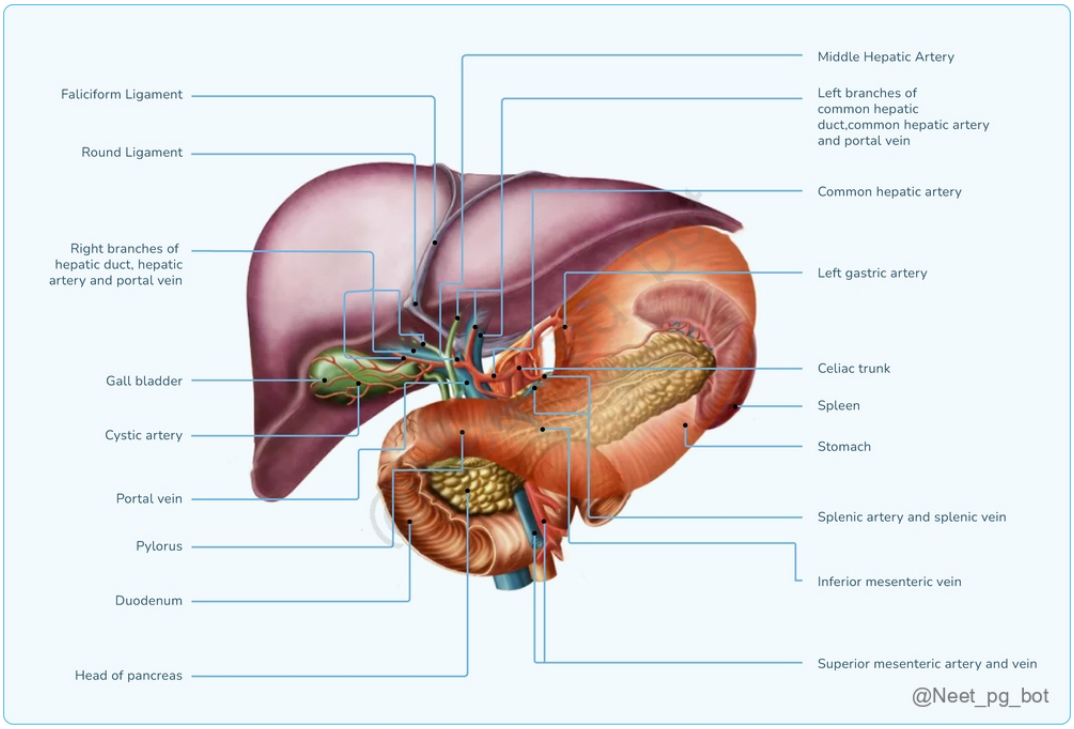
Q17: During a gallbladder surgery, the surgeon identifies the hepatic artery running medially and carefully avoids injuring a structure located laterally to it. Which of the following is the most likely structure located lateral to the hepatic artery? (Q848888)

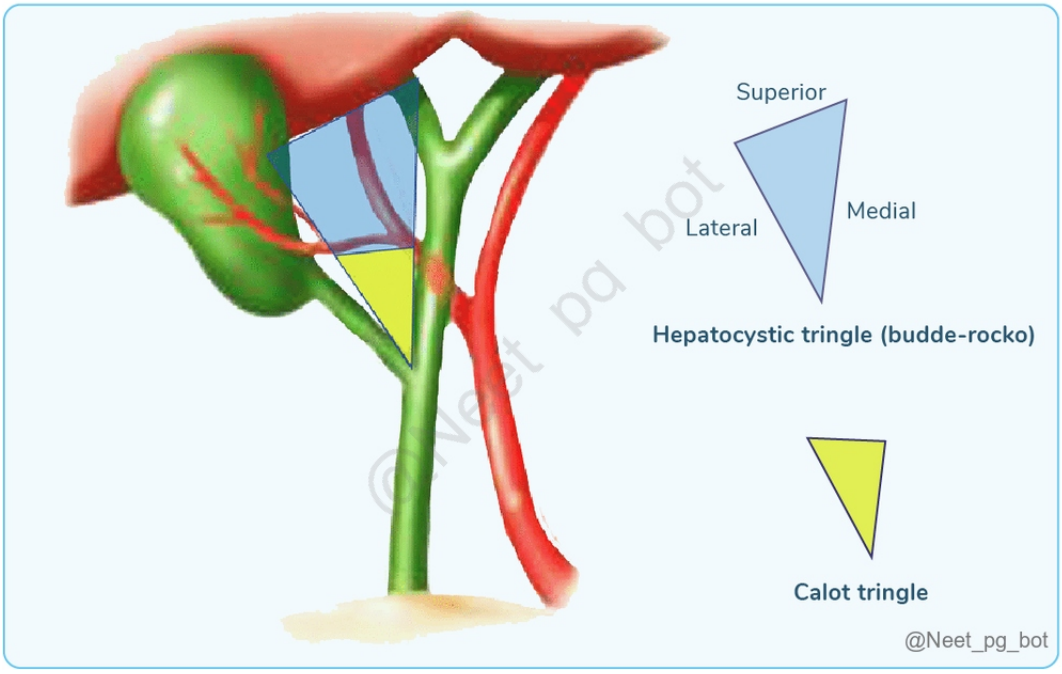
A. Common hepatic duct

B. Portal vein

C. Cystic artery



D. Common bile duct



Correct Answer: D. Common bile duct

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The common bile duct runs lateral to the hepatic artery throughout its course, making it the correct answer. Hepatic Artery and Its Relations Origin : Arises from the coeliac axis. Transition : Becomes the hepatic artery proper after giving off the gastroduodenal artery. Accompanies the portal vein and bile duct, forming the portal triad. Course : Crosses posterior to the common bile duct (CBD). Lies anterior to the portal vein at the porta hepatis. Relations : The hepatic artery is always medial to the common bile duct throughout its course. Divisions : Right hepatic artery: Passes between the bile duct (laterally) and portal vein (medially); divides into anterior and posterior branches. Left hepatic artery: Curves anteriorly, and divides into segmental branches. Calot's Triangle (Hepatobiliary Triangle) Borders : Inferior : Cystic duct. Medial : Common hepatic duct. Lateral : Cystic artery. Clinical Importance : Landmark for safe identification of cystic duct and artery during gallbladder surgery. Common hepatic duct (Option A) : Medial to the hepatic artery, not lateral. Portal vein (Option B) : Lies posterior to the hepatic artery, not lateral. Cystic artery (Option C) : Forms part of Calot's triangle but is not lateral to the hepatic artery.

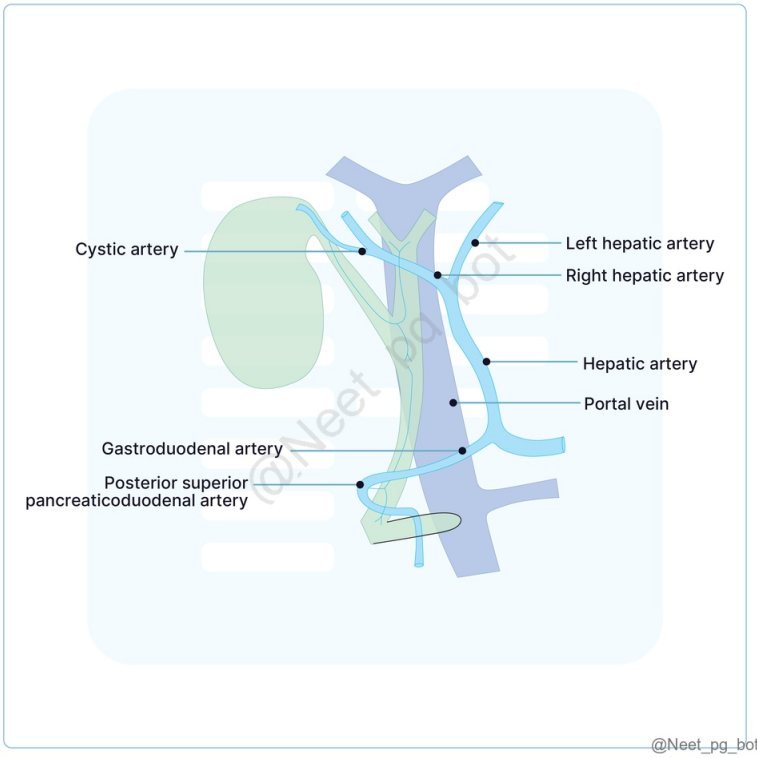
@Neet_pg_bot

Q18: Which artery primarily supplies the common hepatic duct and the common bile duct? (Q848887)

A. Gastroduodenal artery

B. Pancreaticoduodenal artery

C. Right hepatic artery



D. Left hepatic artery

Correct Answer: C. Right hepatic artery

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The common hepatic duct and CBD receive blood supply from the right hepatic and cystic arteries. Blood Supply of the Bile Ducts The biliary tree receives its blood supply entirely from arteries, unlike the hepatic parenchyma, which has dual perfusion from the portal vein. This makes the biliary tree vulnerable to ischemic injury. Cystic Artery: Typically branches from the right hepatic artery but may also originate from the left hepatic, proper hepatic, common hepatic, gastroduodenal, or superior mesenteric arteries. It can pass either posterior or anterior to the CBD. The common hepatic duct and CBD receive blood supply from the right hepatic and cystic arteries. Branches of the posterosuperior pancreaticoduodenal (Option B) and gastroduodenal arteries (Option A) supply the inferior bile duct (distal to the duodenal bulb). These smaller branches can merge into two vessels along the CBD, posing a risk of ischemic injury if damaged during surgical dissection. The left hepatic artery (Option D) primarily supplies the left lobe of the liver. It does not significantly contribute to the blood supply of the common hepatic or bile duct.

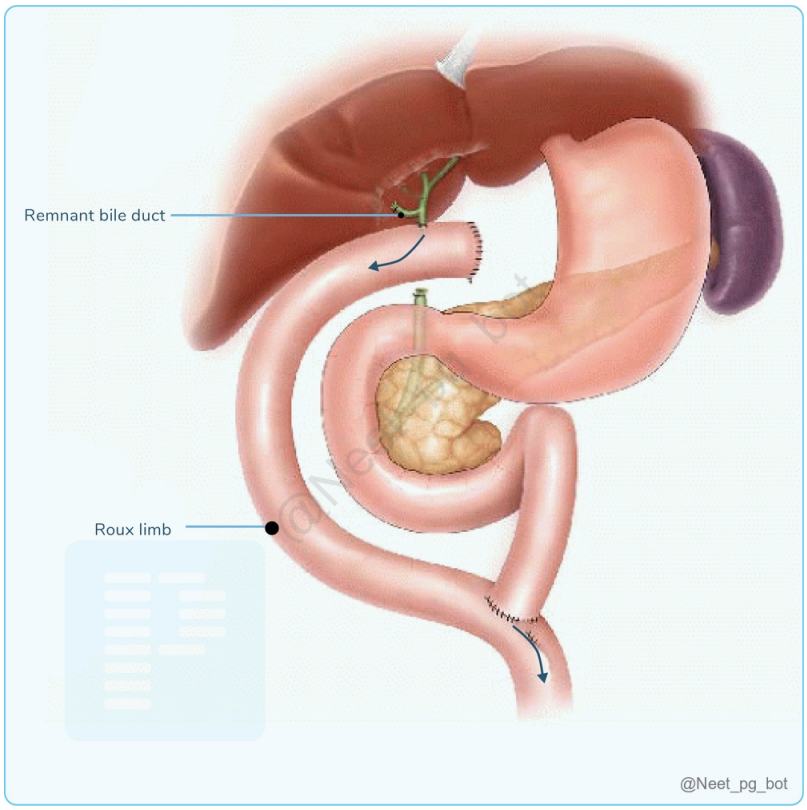
@Neet_pg_bot

Q19: A 50 year old man presents with jaundice and abdominal pain one week after a cholecystectomy. Imaging confirms a bile duct injury with a complete transection of the common bile duct. What is the recommended management for this injury at this stage? (Q843544)

A. Immediate surgical repair

B. Conservative management with antibiotics and observation

C. Delay repair for 4-6 weeks and then perform Roux-en-Y choledochojejunostomy



D. Endoscopic stenting and balloon dilation

Correct Answer: C. Delay repair for 4-6 weeks and then perform Roux-en-Y choledochojejunostomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Delaying the repair for 4-6 weeks allows for the inflammation to subside, which facilitates easier identification and dissection of the bile ducts during surgery. A Roux-en-Y choledochojejunostomy is a common and effective reconstructive technique used to restore bile flow by connecting the common bile duct to a loop of the jejunum. Immediate surgical repair (Option A) is preferred if the bile duct injury is identified intraoperatively. Postoperative repair is avoided due to inflammation and edema, which increase complication risks. Conservative management with antibiotics and observation (Option B) insufficient for complete bile duct transection; surgical intervention is necessary to restore biliary continuity Endoscopic stenting and balloon dilation (Option D) are suitable for bile leaks and strictures but are ineffective for complete bile duct transections, which require surgical reconstruction.

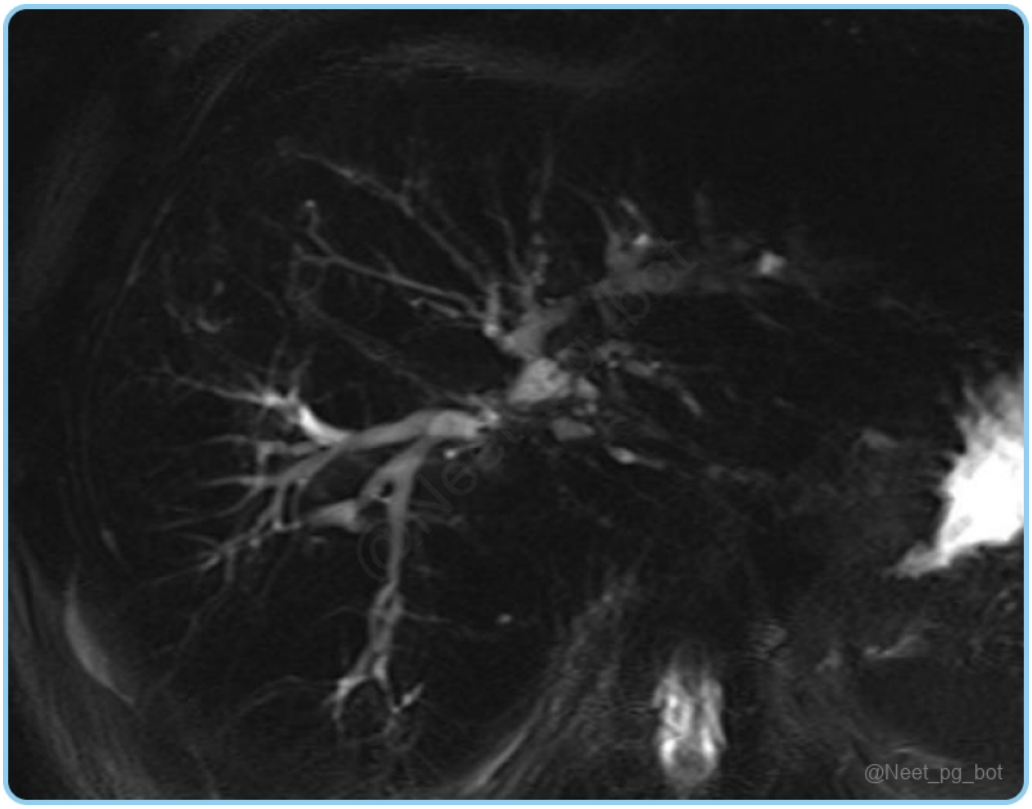
References:

Bailey and Love's Short Practice of Surgery, 28th Edition, Page 1252

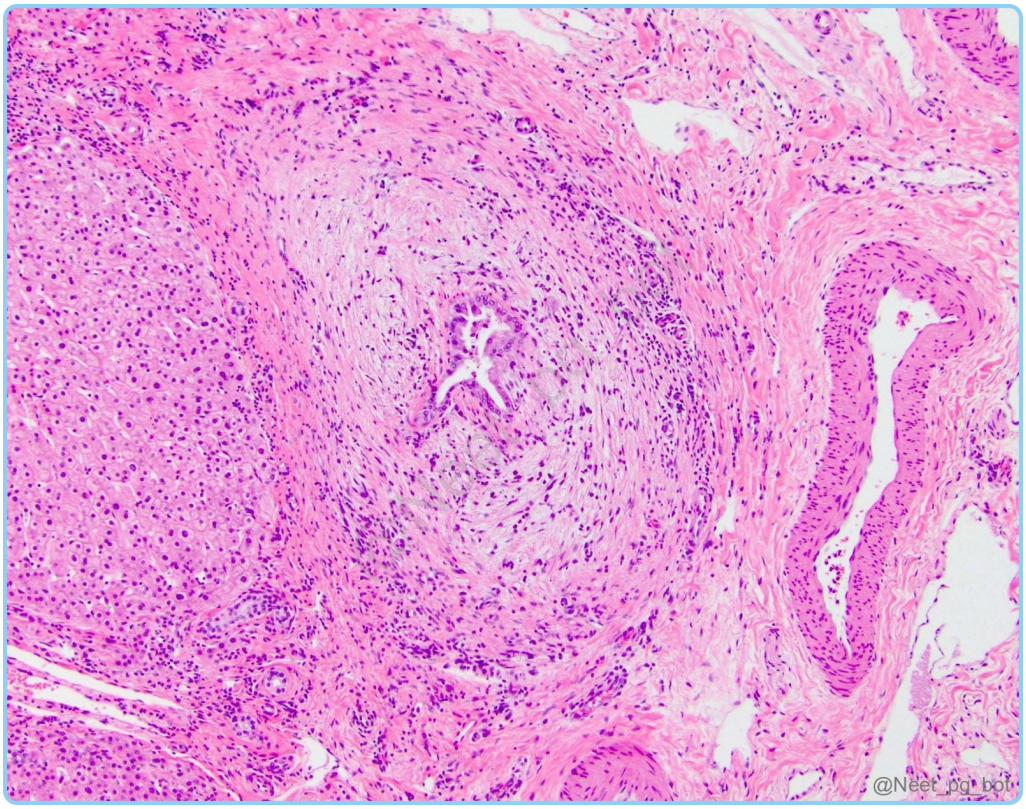
SRB's Manual of Surgery, 6th Edition, Page 658

↑ *Back to this question in Part A*

@Neet_pg_bot



Q20: A 40 year old male with a history of ulcerative colitis presents with fatigue, pruritus, jaundice, elevated ALP, and GGTP. The MRCP and Liver biopsy show the following findings. Despite endoscopic stenting, his symptoms persist, and liver function continues to decline. What is the most definitive treatment option for this patient? (Q843541)

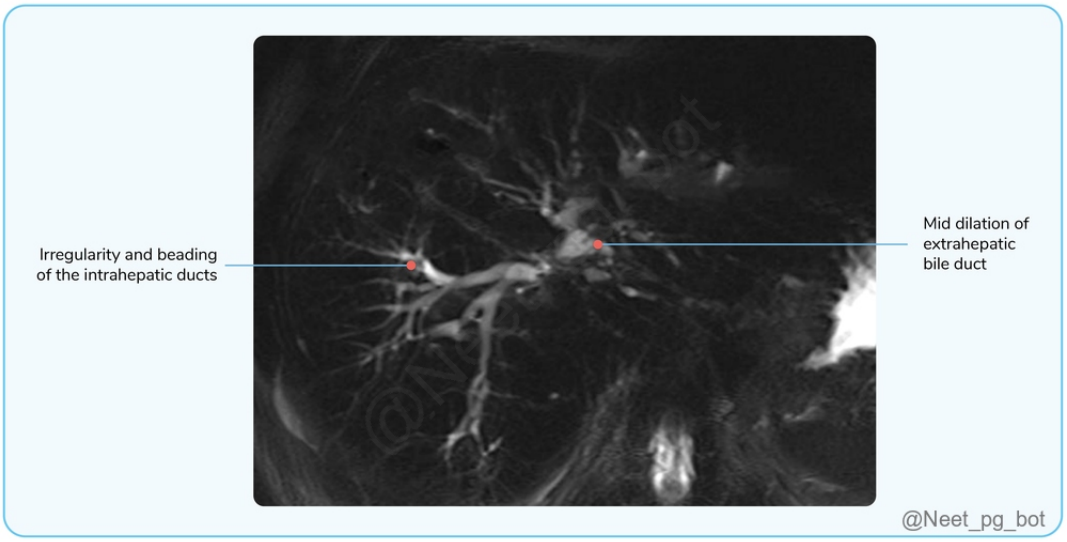


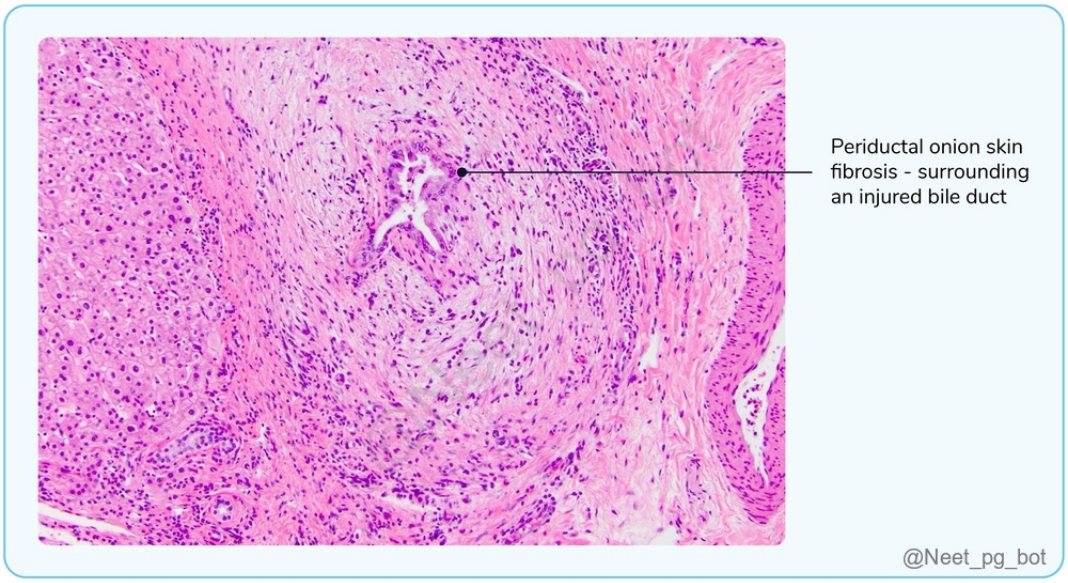
A. Antibiotics and cholestyramine

B. Endoscopic retrograde cholangiopancreatography

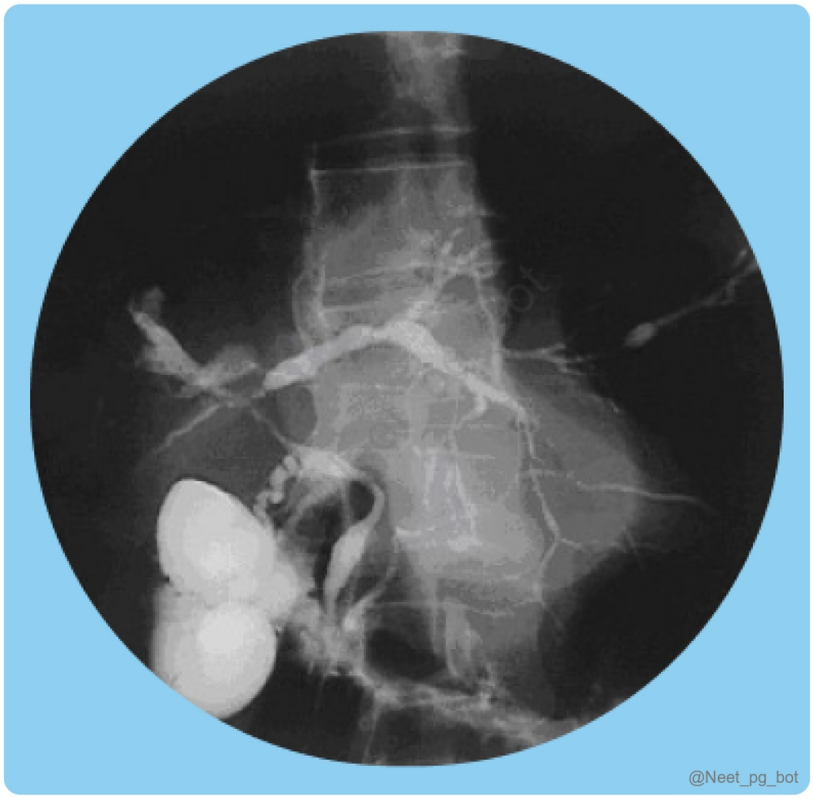
C. Liver transplantation

D. Operative resection





Correct Answer: C. Liver transplantation



■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The given scenario points towards Primary Sclerosing Cholangitis (PSC) . MRCP shows multifocal diffuse dilation and stricturing of the intrahepatic and extrahepatic biliary trees. Liver biopsy reveals concentric periductal onion skin fibrosis. MRCP Histology Liver transplantation is the most definitive treatment for PSC patients who progress to cirrhosis and liver failure. It offers the best long-term outcomes, with a 5-year survival rate above 80%. Investigations: 1. ERCP: Shows multifocal diffuse dilation and stricturing of the intrahepatic and/or extrahepatic biliary trees. This pattern is called “beading” or “chain of lakes” and is characteristic of PSC. Can be used therapeutically to treat major strictures. Cholangiogram of Primary Sclerosing Cholangitis 2. MRCP: Helps in the diagnosis and surveillance of PSC patients 3. LFT: Showing elevated ALP and GGTP levels. 4. Liver biopsy: showing concentric periductal “onion skinning” due to fibrosis. Treatment: Treatment of choice: Liver transplantation. To control inflammation: UDCA (ursodeoxycholic acid) and antibiotics For pruritis: Cholestyramine Antibiotics and cholestyramine (Option A): Antibiotics can help manage superimposed infections, and cholestyramine can relieve pruritus associated with cholestasis. However, these treatments do not stop the progression of primary sclerosing cholangitis (PSC) or address liver failure. Endoscopic retrograde cholangiopancreatography (ERCP) (Option B): ERCP is useful for treating strictures and alleviating bile duct obstructions. However, it is not a definitive treatment for PSC and does not prevent the progression of liver failure. Operative resection (Option D): Operative resection may be considered for selected patients with predominantly extrahepatic disease, but it is not the standard treatment for advanced PSC with cirrhosis and declining liver function. Liver transplantation remains the definitive treatment in such cases.

↑ *Back to this question in Part A*

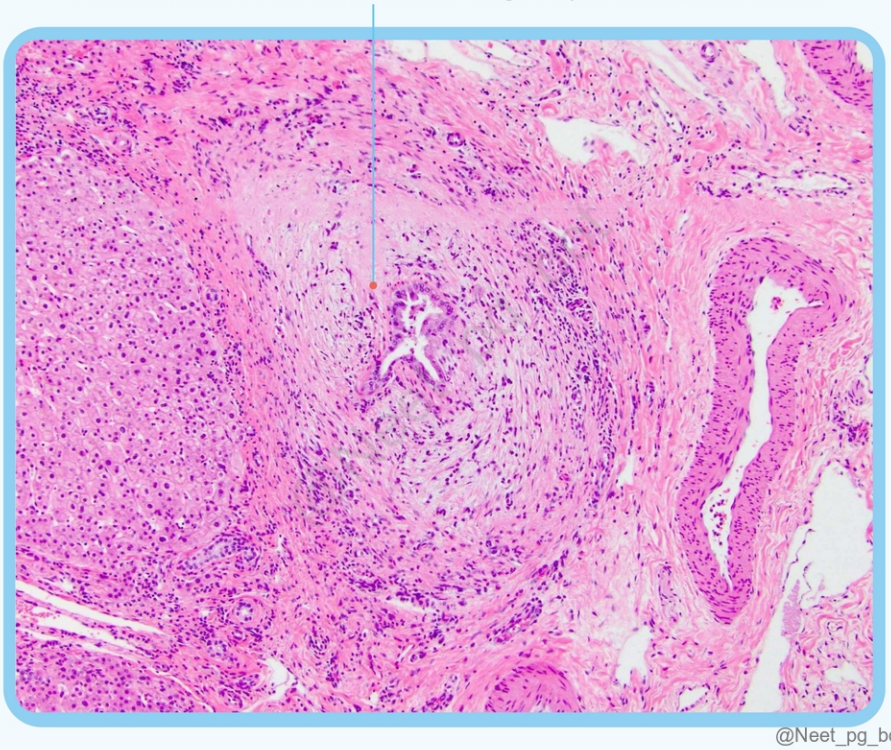
Q21: A 45 year old male with a history of ulcerative colitis presents with jaundice, right upper quadrant pain, and intermittent fever. Laboratory tests reveal elevated serum ALP and gamma-glutamyl transpeptidase (GGTP). MRCP shows stricturing and beading of the bile ducts. What is the most likely diagnosis? (Q843540)

A. Primary sclerosing cholangitis

B. Acute cholangitis

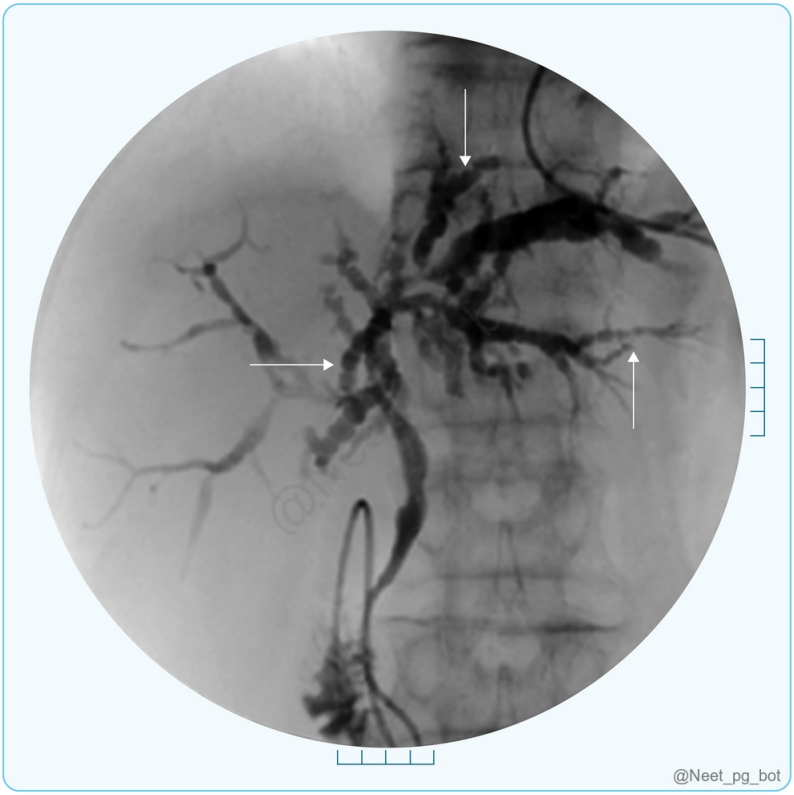
C. Choledocholithiasis

D. Hepatocellular carcinoma



Correct Answer: A. Primary sclerosing cholangitis

■ *Listen (English)*



■ *Listen (Hindi)*

Explanation: The clinical presentation of jaundice, right upper quadrant pain, and intermittent fever, along with elevated serum ALP and GGTP, and,MRCP findings of bile duct stricture and beading, are highly suggestive of Primary sclerosing cholangitis (PSC). PSC is a chronic liver disease characterized by inflammation and scarring of the bile ducts, often associated with inflammatory bowel disease (IBD), especially ulcerative colitis. Primary Sclerosing Cholangitis Etiology: unknown Risk factors : Diseases: Ulcerative colitis, Crohn's disease, Sjogren’s syndrome, Graves disease Gender: Male predominance Age: 30-60 years of age Pathophysiology : It causes diffuse inflammation, sclerosis, and obliteration of the intra- and extrahepatic biliary systems Resulting in multiple areas of stricture and dilatations of the bile duct (beaded appearance) These bile ducts, on the cut section, give an onion skin appearance due to fibrosis. The selective destruction of terminal intra-hepatic ducts gives a Pruned tree appearance. A) Beaded appearance B) Pruned tree appearance C) Band-like strictures Acute cholangitis (Option B) : While the symptoms can be similar, acute cholangitis is an acute condition and does not show the characteristic beading and stricturing of the bile ducts seen in PSC. Choledocholithiasis (Option C) : In choledocholithiasis, imaging usually reveals stones or a dilated bile duct rather than the beading and stricturing characteristic of PSC. Hepatocellular carcinoma (HCC) (Option D) typically presents with weight loss, abdominal pain, jaundice, a liver mass on imaging, elevated alpha-fetoprotein (AFP) levels, and is not associated with bile duct stricturing or beading.

Periductal “onion skin” fibrosis surrounding an injured but intact bile duct

Pruned Tree Appearance

Onion skin appearance

↑ *Back to this question in Part A*

@Neet_pg_bot

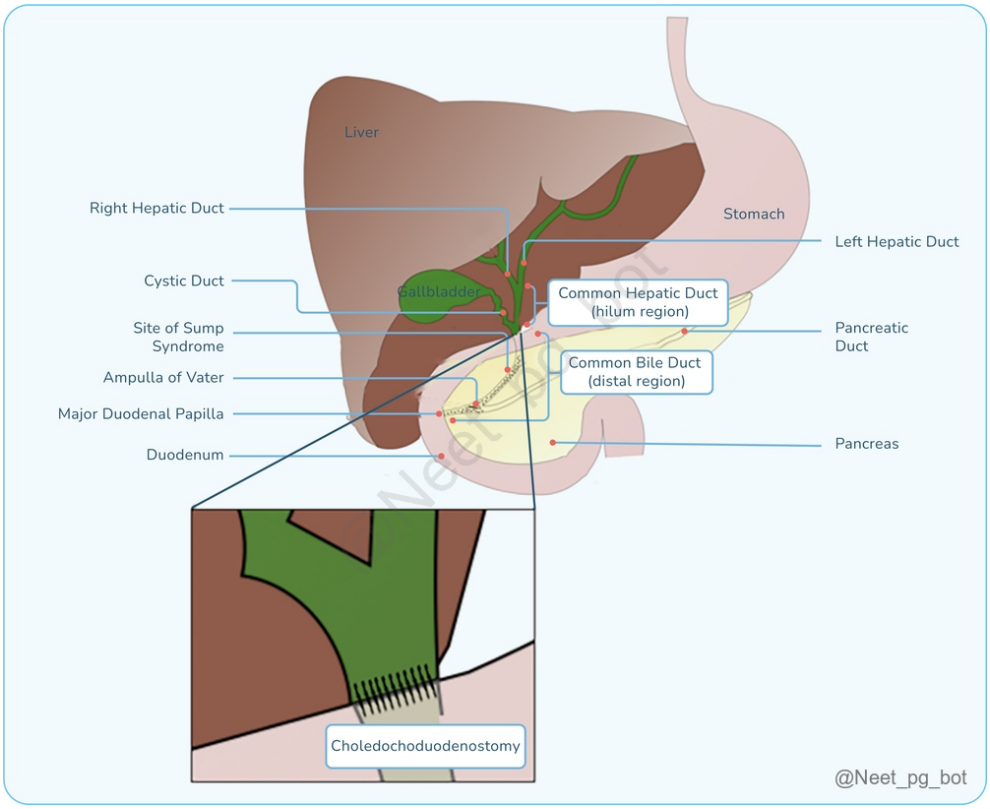
Q22: A 70 year old female presents with signs of severe cholangitis. Despite initial treatment with broad-spectrum antibiotics and an unsuccessful ERCP attempt, her condition continues to worsen. An ultrasound shows multiple stones and a severely dilated common bile duct. What is the next best step in management? (Q843495)

A. Repeat ERCP

B. Percutaneous transhepatic cholangiography (PTC)

C. Open biliary decompression

D. Continued observation and supportive care



Correct Answer: C. Open biliary decompression

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Open biliary decompression is the correct answer. Given the patient’s deteriorating condition, complex biliary anatomy, and failure of ERCP, open biliary decompression is necessary. This procedure directly addresses the severe obstruction and infection, providing a more definitive solution. Management of cholangitis: Antibiotic Therapy: Broad-spectrum IV antibiotics targeting common pathogens like E. coli, Klebsiella, and Enterobacter. Biliary Drainage: Essential to relieve obstruction. Methods include ERCP, PTC, or open surgical intervention. Surgical Intervention: Needed in severe cases, complex strictures, or failure of less invasive methods. Techniques include: Choledochotomy: Incision in the common bile duct to remove the blockage, often with T-tube placement. Choledochoduodenostomy: Connecting the common bile duct to the duodenum to bypass the obstruction. Choledochojejunostomy: Connecting the common bile duct to the jejunum, often using a Roux-en-Y configuration to prevent bile reflux. Supportive Care: IV fluids, pain management, blood pressure support, and monitoring of vital signs and organ function. Repeat ERCP (Option A): Repeating ERCP may be considered in some cases. However, given the severity of the patient’s condition and the previous failure, it is unlikely to be effective. Persistent symptoms and hypotension indicate a need for a more definitive intervention. Percutaneous transhepatic cholangiography (PTC) (Option B): PTC is another less invasive option that involves accessing the biliary system through the liver. While it can be useful in some cases, it may not be sufficient for a severely ill patient with complex stones and failed initial endoscopic treatment. Continued observation and supportive care

(Option D): This option is incorrect as it fails to address the worsening biliary obstruction and severe infection. Delaying intervention can lead to life-threatening complications like sepsis and multi-organ failure.

References:

Bailey and Love's Short Practice of Surgery, 28th Edition, Page 1237, 1238 Sabiston Textbook of Surgery, 21st Edition, Page 1515 SRB's Manual of Surgery, 6th Edition, Page 643

↑ *Back to this question in Part A*

@Neet_pg_bot

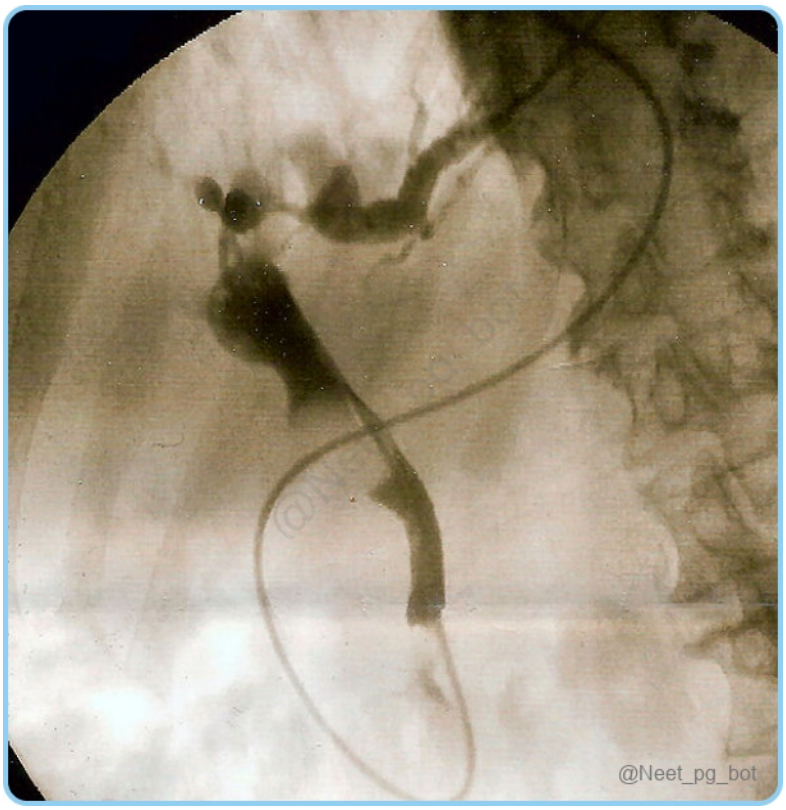
Q23: A 62 year old male presents with jaundice and severe abdominal pain in the right upper quadrant that started abruptly after a heavy meal. He also reports dark urine, pale stools, and intermittent fever with chills. An ultrasound shows a dilated common bile duct. ERCP is planned for stone removal. What is the maximum size of the stone that can typically be removed by ERCP without additional procedures? (Q843491)

A. 17 mm

B. 15 mm

C. 20 mm

D. 25 mm



Correct Answer: B. 15 mm

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Stones up to 15 mm can usually be removed by Endoscopic Retrograde Cholangiopancreatography - ERCP without requiring additional procedures. Options A, C and D are incorrect as stones of these sizes typically require additional procedures like mechanical lithotripsy or balloon sphincteroplasty. MRCP of CBD stone ERCP of a distal CBD stone

@Neet_pg_bot

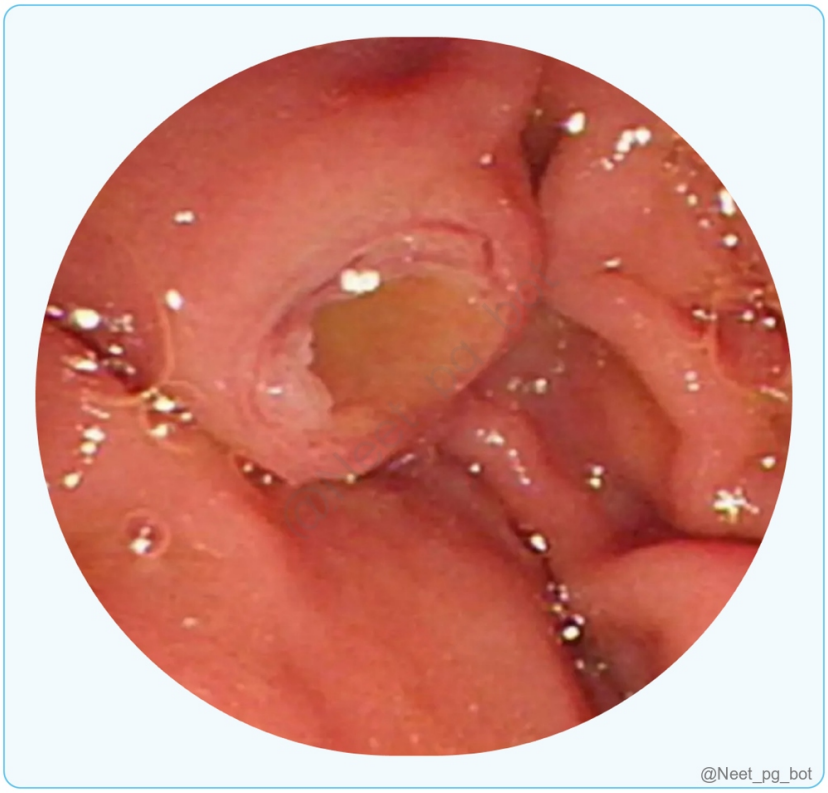
Q2: A 60-year-old male presents with recurrent episodes of abdominal pain and is found to have jaundice. An ERCP is performed, revealing thick mucus extruding through the ampulla of Vater. Which of the following is the most likely diagnosis? (Q848974)

A. Pseudocyst

B. Main duct IPMN



C. Chronic pancreatitis

D. Pancreatic adenocarcinoma

Correct Answer: B. Main duct IPMN

- *Listen (English)*
- *Listen (Hindi)*

Explanation: The presence of thick mucus extruding through the ampulla of Vater during an ERCP is diagnostic of a main duct IPMN, a mucinous tumor that produces large amounts of mucus. Diagnostic significance of thick mucus during ERCP Finding: Thick mucus extruding through the ampulla of Vater during ERCP Diagnostic of: Main duct IPMN (intraductal papillary mucinous neoplasm) Pseudocyst (Option A): While pseudocysts can be associated with mucus, they do not typically cause mucus extrusion through the ampulla of Vater during ERCP. Chronic pancreatitis (Option C): It is characterized by inflammation and fibrosis, not mucus production. Pancreatic adenocarcinoma (Option D): These are solid, scirrhous tumors, characterized by neoplastic tubular glands, which do not produce thick mucus that extrudes through the ampulla of Vater during an ERCP.

@Neet_pg_bot

Q3: What is the most common complication and common cause of death in a patient post pancreaticoduodenectomy? (Q848927)

A. Delayed gastric emptying, Pulmonary complication

B. Anastomosis leak, Pulmonary complication

C. Delayed gastric emptying, Perforated bowel obstruction

D. Anastomosis leak, Perforated bowel obstruction

Correct Answer: A. Delayed gastric emptying, Pulmonary complication

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The most common complication of pancreatoduodenectomy is delayed gastric emptying, while the most common cause of death is pulmonary complications. Pancreatoduodenectomy: Also known as Whipple's procedure, involves the excision of the pancreatic head, duodenum, distal stomach, gallbladder, and distal bile duct. The most common complication of pancreatoduodenectomy is delayed gastric emptying. The most common cause of death is pulmonary complications. Anastomosis leak is another common complication of pancreatoduodenectomy and can result in the formation of pancreatic fistula severely affecting the mortality and morbidity of the patient Complication Frequency (%) Delayed gastric emptying (Option A) 18 Pancreas fistula 12 Wound infection 7 Intraabdominal abscess 6 Cardiac events 3 Bile leak 2 Overall reoperation 3

References:

Sabiston Textbook of Surgery, 21st Edition, Page 1558 https://www.nature.com/articles/s41598-022-26814-7 Postoperative morbidity following Whipple's procedure

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 48-year-old perimenopausal woman presents with abdominal discomfort. Imaging reveals a multilocular cyst with thick walls located in the pancreatic tail. Fine-needle aspiration of the cyst fluid shows high carcinoembryonic antigen levels exceeding 400 ng/mL, with normal amylase levels. What is the most likely diagnosis? (Q848965)

A. Pancreatic pseudocyst

B. Serous cystadenoma

C. Mucinous cystic neoplasm

D. Adenoma of the Ampulla of Vater

Correct Answer: C. Mucinous cystic neoplasm

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Cyst characteristics (multilocular cyst with thick walls in the pancreatic tail), and high CEA levels strongly point towards the diagnosis of MCN. It is commonly seen in perimenopausal women. Mucinous cystic neoplasms (MCNs) and adenomas represent distinct types of cystic pancreatic tumors with varying malignant potential. Factor MCNs Adenomas (Option D) Pseudocysts (Option A) Serous cystadenoma (Option B) Demographics Perimenopausal women Varied History of pancreatitis Older woman Location Pancreatic body or tail Ampulla of Vater Anywhere in the pancreas Tail of pancreas Characteristics Multilocular cysts, thick walls Polypoid submucosal masses Cysts with elevated amylase Lobular, hypodense lesion with multiple small cysts

Key Diagnostic Tool CEA levels (>400 ng/mL) Endoscopy History, imaging, amylase levels CECT: Central stellate scar, central sunburst calcification

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1276, 1281, 1282

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 45-year-old male has a history of recurrent peptic ulcers and severe abdominal pain. Despite the use of proton pump inhibitors, his symptoms persist. Endoscopic examination reveals small nodules in the medial wall of the duodenum. His family history is significant for multiple endocrine neoplasia type I. Which of the following statements is most likely true regarding his condition? (Q848952)

A. The tumors are most commonly found in the tail of the pancreas.

B. The condition is curable with surgical removal of the primary tumor.

C. The patient's gastrinoma is likely located within the gastrinoma triangle.

D. The use of proton pump inhibitors has made diagnosis of this condition easier

Correct Answer: C. The patient's gastrinoma is likely located within the gastrinoma triangle.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Recurrent peptic ulcers, nodules in the duodenal wall, and MEN 1 family history point to a diagnosis of Zollinger- Ellison syndrome, in which gastrinomas are predominant. Gastrinomas are often located within the gastrinoma triangle, defined by cystic duct/common bile duct, duodenum, and pancreas. Zollinger-Ellison syndrome: Aspect Details Tumor Location Duodenal loop (Option A) , Pancreas (head) Causes Persistent peptic ulceration Historical Recognition Severe peptic ulcers unresponsive to surgery pre-PPI era. The use of proton pump inhibitors (Option D) has made the condition controllable but harder to recognize. Types Sporadic, MEN type I (with parathyroid adenoma) Common Locations Gastrinoma Triangle (Option C) (cystic duct/common bile duct, duodenum, pancreas) 90% located in Gastrinoma triangle/ Passaro's triangle Detection Small nodules in duodenal wall, endoscopic and surgical inspection needed Course Indolent for some malignant gastrinomas Treatment Palliative liver resection, liver transplantation, surgical removal for palliation in MEN type I as they are incurable. (Option B) Prognosis Worse for tumors outside gastrinoma triangle

References:

Bailey and Love Short Practice of Surgery, 28th Edition, Page 1179, 1180

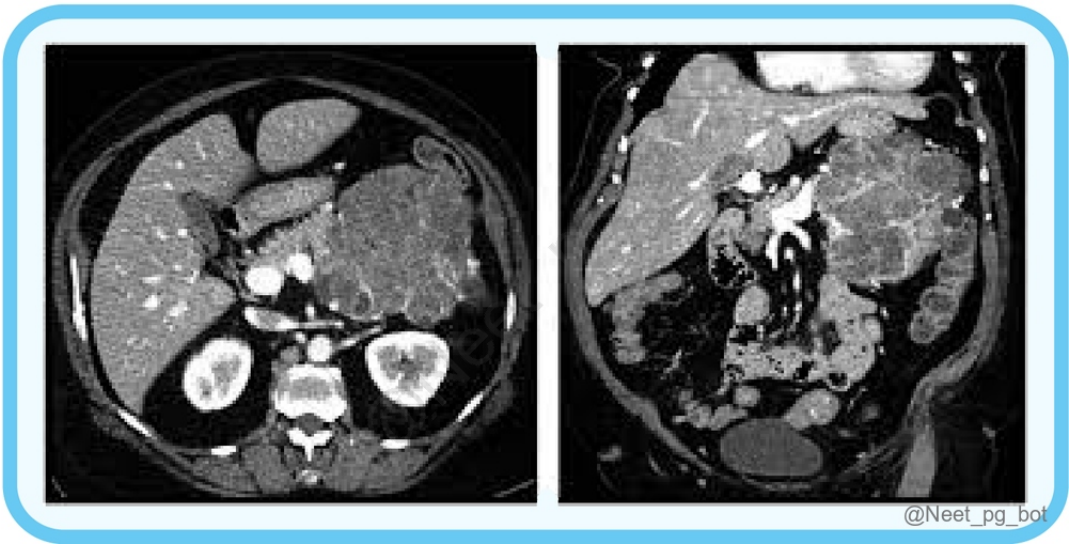
↑ *Back to this question in Part A*

Q6: A 70-year-old female patient is evaluated for a pancreatic cystic mass. The CT scan shows a lobular, hypodense lesion with multiple small cysts, a central hyperdense scar, and scattered "sunburst" calcifications. Based on these findings, what is the most likely diagnosis? (Q848962)

A. Mucinous cystic neoplasm

B. Pancreatic pseudocyst

C. Serous cystadenoma



D. Intraductal papillary mucinous neoplasm

Correct Answer: C. Serous cystadenoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The CT features described, lobular hypodense lesion with a central hyperdense scar and "sunburst" calcifications , are characteristic of a serous cystadenoma. Serous Cystic Neoplasms (SCNs): Characteristics : Benign tumors with multiple small cysts resembling bubble wrap. Commonly found in older women. Management : Surgery : Consider if a solid mass is present or if surgical intervention is indicated. Monitoring : For patients unfit for surgery or without surgical indications, use clinical evaluations, serum CA 19-9 tests, MRCP, and EUS. CT Findings of Serous Cystadenomas: Feature Description Shape and Density Lobular shape; hypodense due to high water content. Calcifications Present in up to 30%; can show a " sunburst " pattern. Central Fibrous Scar Hyperdense, stellate pattern, enhances with contrast. Enhancement Patterns Hypervascular; fibrous portions enhance post-contrast fluid density in less fibrous areas. Oligocystic and Macrocystic Variants Oligocystic patterns may mimic mucinous neoplasms; macrocystic variants may resemble pseudocysts or mucinous cysts. Differentiation Challenging to distinguish from other cystic pancreatic neoplasms; an MRI may be needed. Mucinous cystic neoplasms (Option A): MCNs are seen in perimenopausal women, as multilocular thick-walled cysts in the pancreatic body or tail, and histologically, contain an ovarian-type stroma. They can turn malignant. Pancreatic pseudocysts (Option B): Usually lack central scarring and specific calcification. Intraductal papillary mucinous neoplasm (IPMN) (Option D): IPMNs are more common in older men and mostly involve the pancreatic head. Thick mucus is seen extruding from the ampulla on ERCP, which is diagnostic of IPMN. It has a greater tendency to prove malignant.

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1281, 1282

https://www.ncbi.nlm.nih.gov/books/NBK557432/

↑ *Back to this question in Part A*

@Neet_pg_bot

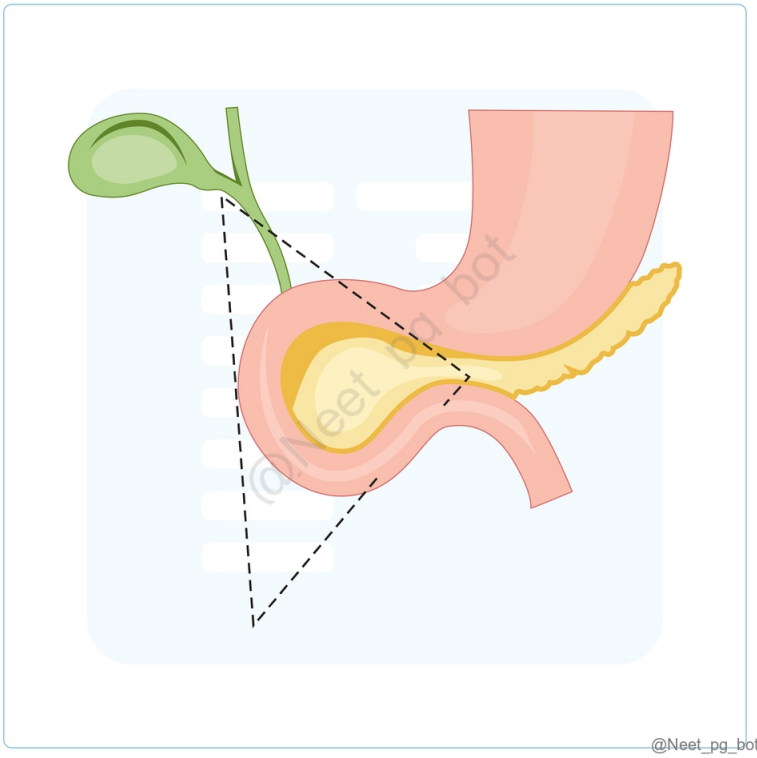
Q7: What is the most common site of gastrinoma in patients with Zollinger–Ellison syndrome (Q848953)

A. Stomach

B. Pancreas

C. Duodenum

D. Liver



Correct Answer: C. Duodenum

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Majority of gastrinomas are located in the duodenum in both sporadic cases (50% to 88% of cases) and those associated with MEN 1 (70% to 100% of cases). Gastrinoma Pathology Sporadic Disease: Tumors mainly in duodenum (50% to 88%) Small (<5 mm) and multiple MEN 1: Tumors in the duodenum 90% occur within the 'gastrinoma triangle': Bounded by the pancreas neck/body junction, second/third parts of the duodenum, and cystic/common bile ducts junction. Gastrinoma Overview: Category Details Definition

Fulminating ulcer diathesis, recurrent ulceration, non-β islet cell tumors (gastrinoma) Incidence 0.5-4 per million, 0.1% of duodenal ulcers, 20-25% associated with MEN Rarely occur in the stomach, peripancreatic lymph nodes, liver, bile duct, ovary, and heart Pancreatic gastrinoma comprises 25% of the cases Pathology Sporadic (duodenum, small, multiple), MEN 1 (duodenum, gastrinoma triangle) Clinical Peptic ulcers, diarrhea, abdominal pain, high alcohol use history Diagnosis Elevated FSG (fasting serum gastrin), gastric pH <2, secretin provocation test, MEN 1 screening, localization studies Treatment Surgery (sporadic without metastases, MEN 1 >2 cm) Medical (PPI, SSA, locoregional therapy)

@Neet_pg_bot

Q8: Among the following, which option correctly describes the most common location of origin of insulinoma in the pancreas? (Q848984)

A. Head > Body > Tail

B. Body = Tail > Head

C. Tail > Body > Head

D. Head = Body = Tail

Correct Answer: D. Head = Body = Tail

■ *Listen to Audio 1*

Explanation: Common sites for origin of insulinoma in pancreas are the head, body and tail of the pancreas equally. Location Tumors Head Carcinoma pancreas Serous cystadenoma Intraductal Papillary Mucinous neoplasm Somatostatinoma PPOMA (Pancreatic Polypeptide cell tumor) Body and tail Glucagonoma Mucinous cystadenoma Tail VIPOMA (Vasoactive Intestinal Peptide tumor) Equal distribution in body, head and tail. Insulinoma

@Neet_pg_bot

Q10: A 55-year-old male presents with jaundice, weight loss, and epigastric pain. Imaging reveals a mass in the head of the pancreas. Which of the following conditions is most likely responsible for these symptoms? (Q848976)

A. Chronic Pancreatitis

B. Ductal Adenocarcinoma

C. Solid Pseudopapillary Neoplasm

D. Intraductal Papillary Mucinous Neoplasm

Correct Answer: B. Ductal Adenocarcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Ductal Adenocarcinoma is the most common malignancy of the pancreas, most commonly occurring in the head region. It typically presents with symptoms like jaundice (due to bile duct obstruction), weight loss, and epigastric pain. Imaging often reveals a mass in the head of the pancreas, making it the most likely diagnosis in this clinical scenario. Common Conditions in the Head of the Pancreas: Ductal Adenocarcinomas Most prevalent condition in the head of the pancreas. Can occur throughout the pancreas but predominantly originates in the head. Other Conditions Commonly Found in the Head of the Pancreas: Chronic Pancreatitis (Option A) Affects the entire pancreas, but pain is often concentrated in the head if it is the primary disease site. Intraductal Papillary Mucinous Neoplasms (IPMNs) (Option D) Frequently found in the head of the pancreas. Characterized by mucus production, observable during ERCP. Solid Pseudopapillary Neoplasms (Option C) Rare malignant lesions, more common in the head of the pancreas. More commonly seen in women of childbearing age. Ampullary Tumors Originate from the ampulla of Vater or the distal common bile duct. Present as a mass in the head of the pancreas due to the ampulla of Vater's location. Include adenomas and adenocarcinomas, often mistaken for pancreatic head tumors due to proximity.

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1281

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A patient with a suspected intraductal papillary mucinous neoplasm (IPMN) has elevated serum CA 19-9 levels. What does this finding most likely suggest? (Q848971)

A. The IPMN is benign and does not require surgical intervention

B. The IPMN is likely malignant or has high-grade dysplasia

C. The IPMN is a branch duct type and requires conservative management

D. The IPMN is likely malignant and surgery is contraindicated

Correct Answer: B. The IPMN is likely malignant or has high-grade dysplasia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Elevated CA 19-9 levels are often associated with malignancy or high-grade dysplasia in IPMNs, suggesting a need for further evaluation and potentially surgery. Intraductal Papillary Mucinous Neoplasms (IPMNs) Location: Predominantly in the head of the pancreas . More common in older men . Pathology: The whole pancreatic duct is distended with the mucin secreted and may cause obstruction Types: Main duct IPMN (High risk of malignancy) Side branch IPMN (Low risk of malignancy) Mixed IPMN Investigations: MRCP is the first line and investigation of choice. CT in MRI contraindicated patients. EUS (endoscopic ultrasound) with FNA (Fine needle aspiration) of the cyst fluid for analysis: Mucinous content Increased CEA and amylase levels On endoscopy, visualization of thick mucus extruding from the ampulla is diagnostic of a main duct IPMN. Risk of malignant transformation IN IPMN: Main duct 5–9 mm Enhancing mural nodule <5 mm Thickened, enhancing cyst wall BD-IPMN >3 cm Lymphadenopathy Pancreatitis Increased serum CA 19–9 Cyst growth >5 mm over 2 years Management Algorithm: Aspect Details Management Pathways Surgical Indications : Confirmed carcinoma/high-grade dysplasia, solid mass, jaundice, mural nodules, significant duct dilation. Non-Surgical Management : For unsuitable candidates or non-surgical criteria, with regular monitoring (clinical, CA 19-9, imaging). Surgical Options Pylorus-Preserving Pancreatoduodenectomy (PPPD) : For pancreatic head tumors. Distal Pancreatectomy : For body/tail tumors. Total Pancreatectomy : For multifocal tumors, unsafe bowel anastomosis and whole duct involvement.

↑ *Back to this question in Part A*

Q12: In a patient with a pancreatic cyst, peripheral eggshell calcification on CT is: (Q848967)

A. Common in benign cysts and easily detected.

B. Easily detected and a definitive marker of malignancy.

C. Difficult to detect but highly indicative of malignancy in mucinous cystic neoplasms.

D. Exclusively associated with pancreatic pseudocysts, not with malignancy.

Correct Answer: C. Difficult to detect but highly indicative of malignancy in mucinous cystic neoplasms.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Peripheral eggshell calcification is subtle on CT but a strong indicator of malignancy in mucinous cystic neoplasms. Peripheral Eggshell Calcification in Mucinous Cystic Neoplasms (MCNs) of the Pancreas: Aspect Details Calcification Type Peripheral eggshell Imaging Modality CT scan (challenging to detect) Predictive Value High for malignancy Typical Patient Middle-aged females Cyst Characteristics Unilocular or multilocular macrocysts Possible Imaging Findings Thickened wall, vascular involvement Clinical Action Further assessment and potential surgery

References:

Sabiston Textbook of Surgery, 21st Edition, Page 1547 https://www.ncbi.nlm.nih.gov/pmc/articles/PMC5051074/

↑ *Back to this question in Part A*

@Neet_pg_bot

Q13: A 45-year-old patient presents with chronic watery diarrhea. Laboratory tests reveal elevated levels of vasoactive intestinal peptide (VIP) > 150 pg/ml, achlorhydria, and hypokalemia. Imaging studies show a solitary mass in the body of the pancreas. What is the treatment of choice in this condition? (Q848960)

A. Initiate high-dose corticosteroid therapy with Prednisolone

B. Start treatment with Octreotide

C. Perform a distal pancreatectomy

D. Begin broad-spectrum antibiotic therapy

Correct Answer: C. Perform a distal pancreatectomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The described scenario is that of VIPOMA . Distal pancreatectomy is the treatment of choice for VIPOMA, especially when the tumor is solitary and located in the body or tail of the pancreas. VIPOMA Source: D2 cells of the pancreas. Alternative Names: Pancreatic cholera, Verner-Morrison syndrome, weak-tea syndrome. Nature: Usually malignant. Clinical Features (WDHA Syndrome) Watery diarrhea. Hypokalemia. Achlorhydria. Biochemical Markers Vasoactive Intestinal Peptide (VIP): Secretion > 150 pg/ml. Location Typically found in the body and tail of the pancreas. Treatment Surgical: Distal pancreatectomy is the treatment of choice when the tumor is solitary and located in the body or tail of the pancreas Medications: Prednisolone (Option A) : Controls diarrhea. Octreotide (Option B) : Useful in managing symptoms. Begin broad-spectrum antibiotic therapy (Option D): Antibiotics are not indicated in the management of VIPOMA, as the condition is related to a tumor rather than an infection.

References:

SRB Manual of Surgery, 6th Edition, Page 704

↑ *Back to this question in Part A*

@Neet_pg_bot

Q14: A 58-year-old female presents with diarrhea, weight loss, and itchy lesions around the mouth and vagina. Physical examination reveals a rash as shown in the image below. On evaluation, she has diabetes, and imaging studies indicate a large pancreatic mass. Which of the following is the most likely diagnosis? (Q848956)

A. Gastrinoma

B. Insulinoma

C. Glucagonoma

D. VIPoma

Correct Answer: C. Glucagonoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The above symptoms of weight loss, diarrhea, stomatitis and vulvovaginitis with the characteristic rash suggestive of necrolytic migratory erythema , along with large pancreatic mass points towards the diagnosis of glucagonoma. Aspect Details Origin Alpha cells of the pancreas Common Locations Body and tail of the pancreas Size 5-10 cm Prevalence Sporadic; 17% with MEN type II syndrome Gender More common in females Malignancy 80% malignant; 80% spread to liver Symptoms Necrolytic migratory erythema, diabetes, diarrhea, weight loss, stomatitis, anemia, amino acid deficiency, vulvovaginitis Diagnostic Tests MRI, CT scan, Endosonography, Angiogram, Serum glucagon levels (>50 pmol/L) Treatment Anemia and deficiency correction, IV amino acids, DVT prevention, Distal pancreatectomy, Whipple's/total pancreatectomy, Enucleation, Dacarbazine Gastrinoma (Option A): Typically associated with Zollinger-Ellison syndrome, presenting with recurrent peptic ulcers rather than necrolytic migratory erythema. Insulinoma (Option B): Characterized by hypoglycemia and hyperinsulinemia, not typically associated with necrolytic migratory erythema. VIPoma (Option D): Associated with WDHA syndrome (Watery Diarrhea, Hypokalemia, Achlorhydria) and not with necrolytic migratory erythema.

@Neet_pg_bot

Q15: A 45-year-old woman with a family history of cancer presents for a routine check-up. Her mother and maternal aunt both had pancreatic cancer. Genetic testing reveals a gain-of-function mutation in the PRSS1 gene. Which of the following factors contributes the most to her increased risk of developing pancreatic cancer? (Q848920)

A. Chronic pancreatitis

B. Germline BRCA2 mutation

C. Lynch syndrome

D. Hereditary pancreatitis

Correct Answer: D. Hereditary pancreatitis

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hereditary pancreatitis is associated with a gain-of-function mutation in the PRSS1 gene and increases the risk of pancreatic cancer by 50-70 times. Genetic Risk Factors for Pancreatic Cancer: Family History

: Two first-degree relatives with pancreatic cancer increase risk by 18-57 times. Germline BRCA2 Mutations : Present in some rare high-risk families. Hereditary Pancreatitis : 50-70 times increased risk. Chronic Pancreatitis : 5-15 times increased risk. Other Syndromes : Lynch Syndrome (HNPCC) Ataxia Telangiectasia Peutz-Jeghers Syndrome Familial Breast-Ovarian Cancer Syndrome Familial Atypical Multiple Mole Melanoma Familial Adenomatous Polyposis (risk of ampullary/duodenal carcinoma) Hereditary Pancreatitis: Inheritance : Autosomal dominant with 80% penetrance. Mutations : PRSS1 : Gain-of-function mutation on chromosome 7, producing degradation-resistant trypsin. SPINK1 : Loss-of-function mutation predisposes to idiopathic pancreatitis. CFTR : Mutations linked to idiopathic chronic pancreatitis. Cancer Risk : Significantly increased, especially with tobacco use. Other Risk Factors: Demographic factors Environmental/Lifestyle factors Genetic Factor Relative Risk Increase Family History (two first-degree relatives) 18-57 times Germline BRCA2 Mutations High-risk families Hereditary Pancreatitis 50-70 times Chronic Pancreatitis 5-15 times

@Neet_pg_bot

Q16: Which diagnostic finding is most indicative of an insulinoma? (Q848951)

A. Elevated serum glucose levels

B. Low C-peptide levels

C. Elevated serum insulin levels during hypoglycemia

D. Hyperinsulinemic response to oral glucose tolerance test

Correct Answer: C. Elevated serum insulin levels during hypoglycemia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The most indicative diagnostic finding for an insulinoma is elevated serum insulin levels during hypoglycemia. This confirms that hypoglycemia is due to endogenous insulin production, which is characteristic of insulinoma. Category Details Definition A rare, typically benign tumor of the pancreatic islet cells that produces excess insulin. Clinical Features Whipple's Triad- Documented low blood glucose levels during symptomatic episodes Relief of symptoms upon administration of glucose Symptoms often occur during fasting or after exercise Symptoms of hypoglycemia (e.g., sweating, palpitations, confusion, visual disturbances, seizures) Diagnosis Gold-standard test for diagnosing insulinoma is a 72-hour fast. (Option C) Combination of plasma glucose < 55 mg/dL + insulin level ≥ 3 microUnits/mL + C peptide level ≥ to 0.6 ng/mL + proinsulin ≥ 5 pmol/L, + negative sulfonylurea level indicates that the hypoglycemia induction is by hyperinsulinemia Insulin/glucose ratio > 0.4 is diagnostic Imaging: CT, MRI, EUS Management Surgical resection is the treatment of choice Medical management with diazoxide or octreotide for non-surgical candidates or unresectable tumors Elevated serum glucose levels (Option A) : Insulinomas cause hypoglycemia, not elevated glucose levels. Low C-peptide levels

(Option B) : Insulinomas typically show elevated C-peptide levels, indicating endogenous insulin production. Low C-peptide levels would suggest exogenous insulin administration. Hyperinsulinemic response to oral glucose tolerance test (Option D) : While insulinomas cause excessive insulin production, the diagnosis is confirmed by measuring insulin levels during hypoglycemic episodes, not after an oral glucose load.

@Neet_pg_bot

Q17: Which of the following statements is true regarding neuroendocrine tumors of the pancreas? (Q848928)

A. The most common non-functional neuroendocrine tumor of the pancreas is insulinoma

B. Somatostatin receptor scintigraphy is used for the localization of NETs

C. The most common site of metastasis is the lungs

D. Functional NETs are diagnosed at a later stage and have poor prognosis

Correct Answer: B. Somatostatin receptor scintigraphy is used for the localization of NETs

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Neuroendocrine tumors of the pancreas (NETs): Type Description Examples Key Features Functional NETs Secrete hormones causing clinical syndrome Insulinoma(MC), Gastrinoma, Glucagonoma, VIPoma, Somatostatinoma Present early due to symptoms Non-functional NETs Do not produce active hormones Polypeptide cell tumor (PPOMA) - Most common type Present late with mass effect The most common functional and malignant neuroendocrine tumor of the pancreas is a gastrinoma. It is also the most common in MEN syndrome. The most common site of metastasis is the liver. Neuroendocrine tumors are symptomatic due to the secretion of active substances. Consequently, patients are: Symptomatic at an early stage and diagnosed at an early stage Early diagnosis improves outcomes Diagnosis: Laboratory measurement of active substances or their by-products. Somatostatin receptor scintigraphy (SRS) is used for the localization of NETs.

@Neet_pg_bot

Q18: Which surgical procedure is characterized by the resection of the pancreatic head while preserving the stomach and pylorus? (Q848926)

A. Whipple procedure

B. Distal pancreatectomy

C. Longmire Traverso procedure

D. Total pancreatectomy

Correct Answer: C. Longmire Traverso procedure

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Longmire Traverso procedure is also called Pylorus Preserving Pancreaticoduodenectomy. Pylorus-Preserving Pancreaticoduodenectomy (PPPD) Preserves the gastric antrum, pylorus, and proximal duodenum, anastomosing the duodenum to the jejunum to maintain gastrointestinal continuity. Indications: Malignant or premalignant neoplasms in the pancreatic head or periampullary structures (bile duct, ampulla, or duodenum) Advantages of PPPD compared to conventional pancreaticoduodenectomy are: Reduced incidence of postoperative complications like dumping syndrome, marginal ulceration, and bile reflux gastritis. Improved gastrointestinal function due to preservation of the gastric antrum and pylorus in PPPD leading to more physiological gastric emptying. Reduced operative time and blood Loss Lower perioperative mortality In pylorus-preserving pancreaticoduodenectomy (PPPD), the sequence of anastomoses typically follows these steps: 1st - Pancreaticojejunostomy 2nd - Hepaticojejunostomy 3rd - Duodenojejunostomy

References:

www.uptodate.com/contents/pylorus-preserving-pancreaticoduodenectomy?search=whipple%20procedure&source=search_result&selectedTitle=1~60&usage_type=default&display_rank=1

↑ *Back to this question in Part A*

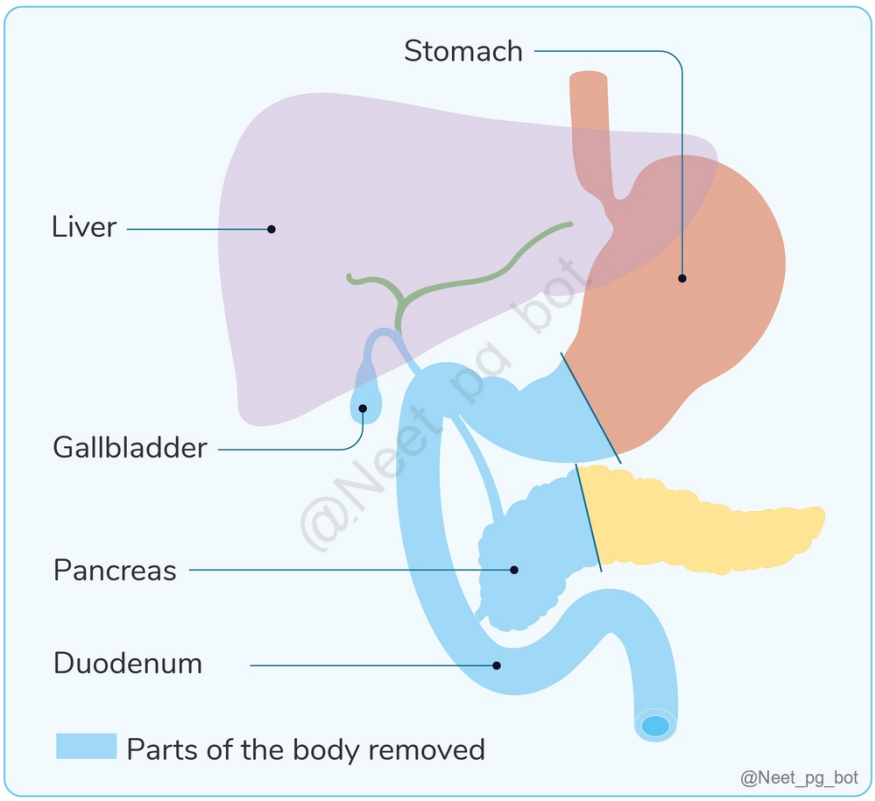
@Neet_pg_bot

Q19: A patient is scheduled to undergo a Whipple procedure for the treatment of pancreatic cancer. The surgeon needs to perform anastomosis to reconstruct the digestive tract after removing the affected tissues. In which sequence are the anastomoses typically performed during a Whipple procedure? (Q848925)

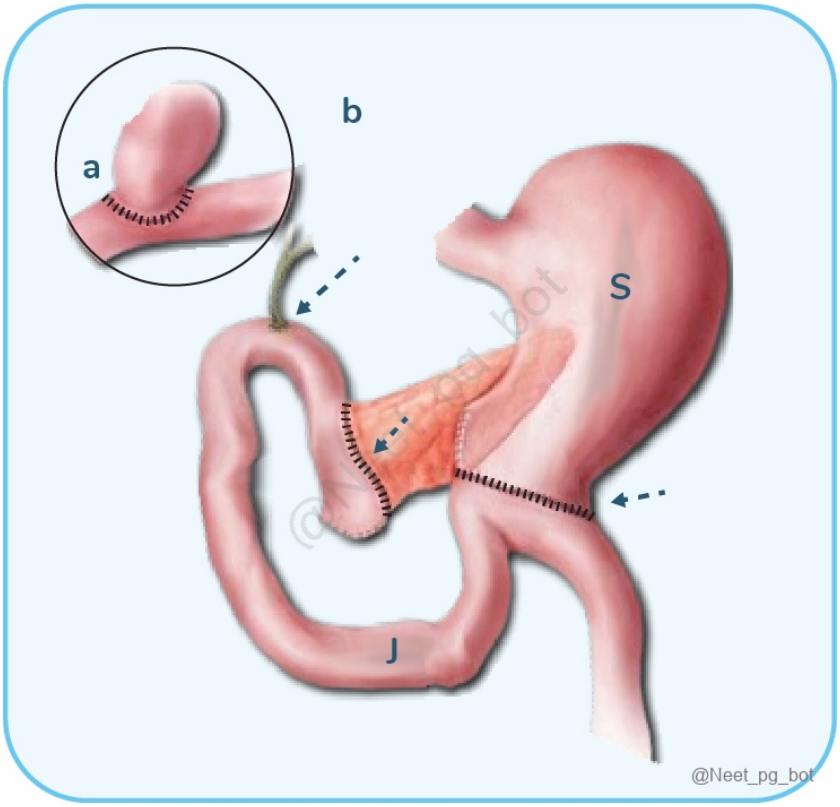
A. Hepaticojejunostomy → Pancreaticojejunostomy → Gastrojejunostomy

B. Pancreaticojejunostomy → Hepaticojejunostomy → Gastrojejunostomy

C. Gastrojejunostomy → Pancreaticojejunostomy → Hepaticojejunostomy



D. Pancreaticojejunostomy → Gastrojejunostomy → Hepaticojejunostomy



Correct Answer: B. Pancreaticojejunostomy → Hepaticojejunostomy → Gastrojejunostomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The typical sequence for performing anastomosis in a Whipple procedure is to start with the pancreaticojejunostomy, followed by the hepaticojejunostomy, and finally the gastrojejunostomy. This order allows for proper reconstruction of the digestive system following the removal of the affected tissues. Whipple's procedure (Pancreaticoduodenectomy) Structures removed: Head of the pancreas, the first part of the small intestine (duodenum), the gallbladder, and a portion of the bile duct. Types: Pylorus-Preserving Whipple Procedure (Preferred) Non–Pylorus-Preserving Whipple Procedure Indications Pancreatic Cancer: Commonly treated with Whipple if cancer is localized to the head of the pancreas. Chronic Pancreatitis: when uncontrolled by medical management. Tumors in Pancreas/Surrounding Areas: Includes duodenum, distal bile duct, and ampulla of Vater. Procedure Steps Tumor Assessment: Explore abdomen to assess tumor size, location, and spread. Resection: Remove head of pancreas, duodenum, gallbladder, and part of bile duct; this may include partial stomach resection. Lymph Node Dissection: Remove and examine nearby lymph nodes. Reconstruction Pancreaticojejunostomy: Connect remaining pancreas to jejunum. Hepaticojejunostomy: Connect common bile duct to jejunum. Gastrojejunostomy: Connect stomach to jejunum. Anastomosis Principles Tension-Free Connection: Achieve mucosa-to-mucosa connection for healing. Order of Anastomoses: Pancreaticojejunostomy → Hepaticojejunostomy → Gastrojejunostomy Stent Placement: May use internal/external stents for small ducts. Complications Pancreatic Fistula: Major issue; managed with somatostatin analogues. Delayed Gastric Emptying Bleeding, wound infection Reoperation, increased mortality Dumping/Bile Reflux: Common after non-pylorus-preserving Whipple; pylorus-preserving method has uncertain benefits. Other options: Option A: Hepaticojejunostomy → Pancreaticojejunostomy → Gastrojejunostomy Biliary anastomosis is not performed before the pancreatic one because pancreatic stump handling becomes more difficult due to edema. Option C: Gastrojejunostomy → Pancreaticojejunostomy → Hepaticojejunostomy Gastric reconstruction is always performed last, not first. Option D: Pancreaticojejunostomy → Gastrojejunostomy → Hepaticojejunostomy The bile duct anastomosis should precede gastric reconstruction; this order is not surgical standard.

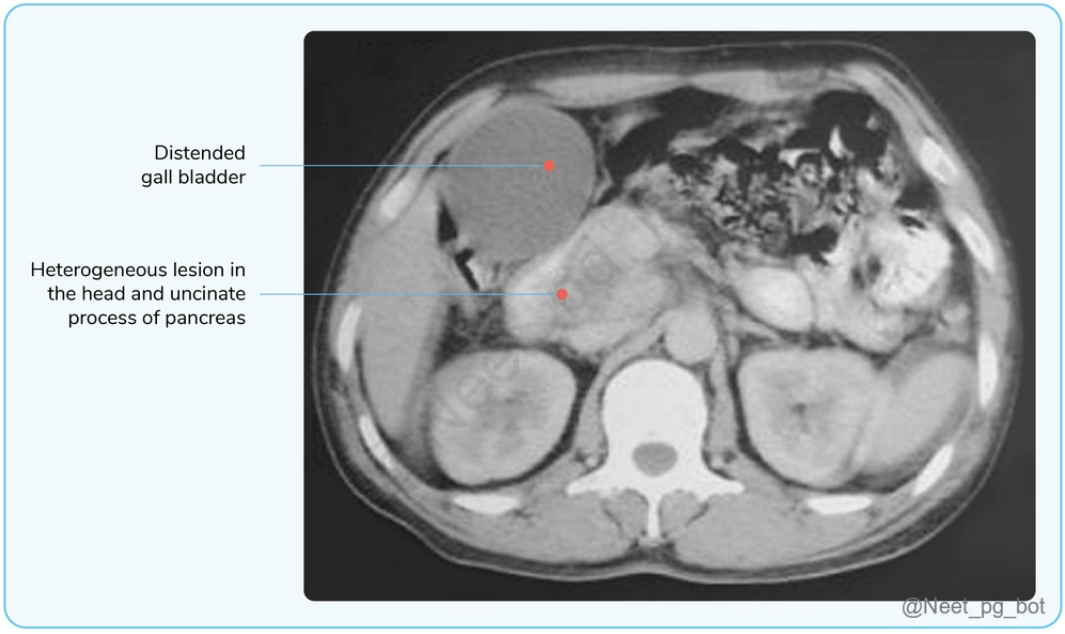
@Neet_pg_bot

Q20: A 65-year-old male presents with jaundice, dark urine, and weight loss over the past two months. Courvoisier's Sign is positive on physical examination. What is the next best step in the management of this patient to both visualize pancreatic and biliary ducts, and tissue sampling? (Q848924)

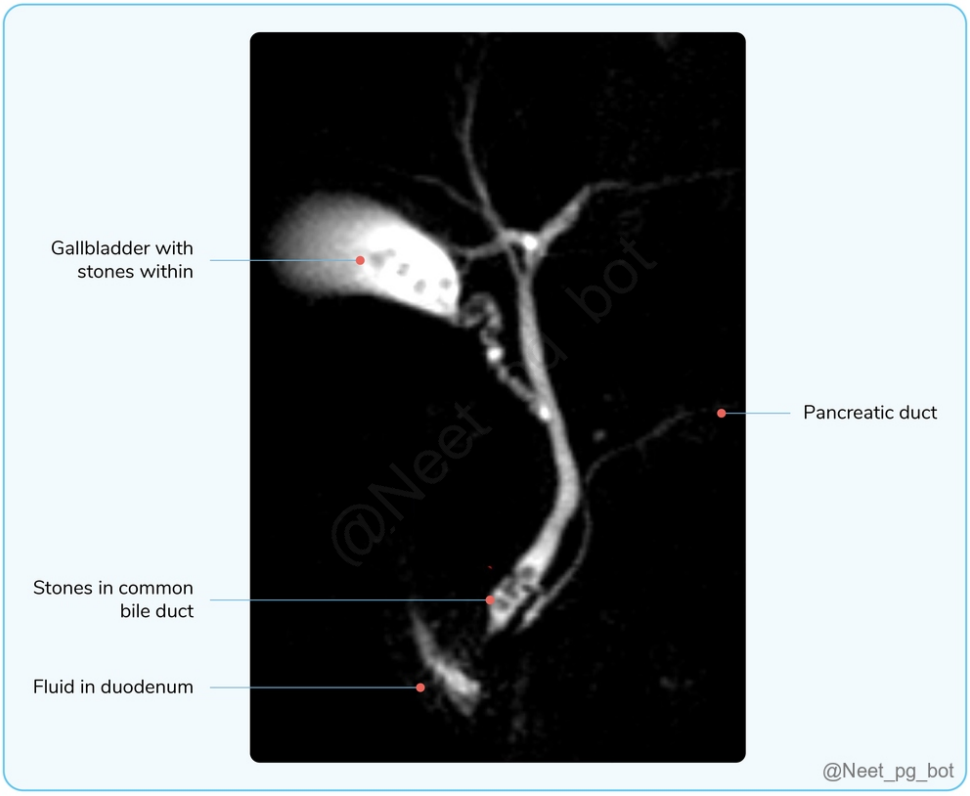
A. Computed Tomography

B. Endoscopic Ultrasonography

C. Endoscopic Retrograde Cholangiopancreatography

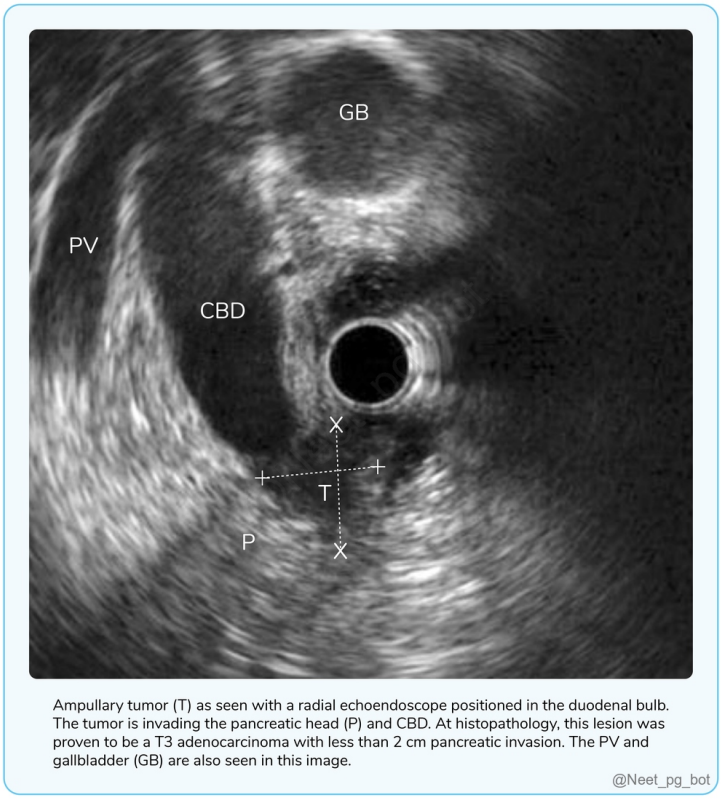


D. Diagnostic Laparoscopy



Correct Answer: C. Endoscopic Retrograde Cholangiopancreatography

■ *Listen (English)*



■ *Listen (Hindi)*

Explanation: The presence of jaundice, dark urine, weight loss, and Courvoisier's sign is positive on physical examination is suggestive of pancreatic cancer. ERCP is used for visualizing bile and pancreatic ducts and can obtain brush cytology or biopsy samples but is less effective at detecting small pancreatic tumors compared to EUS. Imaging techniques and their usefulness: Technique Uses and key features CT Scan (Option A) First choice for diagnosing pancreatic cancer. Detects mass, duct dilation, and pancreatic atrophy. Detection of metastasis. MRI/MRCP (Magnetic Resonance Cholangiopancreatography) Complementary to CT for additional information. MRCP identifies biliary obstruction and pancreatic duct issues. Does not show calcification visible on CT. ERCP (Endoscopic Retrograde Cholangiopancreatography) Visualizes pancreatic and biliary ducts. Allows for tissue sampling. Key signs: Narrowing of ducts, double duct sign. EUS (Endoscopic Ultrasound) (Option B) Useful when CT does not show a tumor. Assesses vascular invasion and differentiates cystic tumors from pseudocyst Additional Procedures: Diagnostic Laparoscopy : (Option D) Uses: Identifies small peritoneal and liver metastases to assess resectability Not suitable for visualisation of the pancreatic and biliary ducts.

Distended gall bladder

Bailey and Love Short Practice of Surgery, 28th Edition, Page 1263- 1267, 1283

↑ *Back to this question in Part A*

@Neet_pg_bot

Q21: A 55-year-old man with no history of obesity or a family history of diabetes is recently diagnosed with diabetes mellitus. He also reports vague upper abdominal discomfort, significant weight loss, and mild jaundice. Which of the following findings on physical examination would most likely suggest a diagnosis of pancreatic cancer? (Q848923)

A. Tender and enlarged gallbladder

B. Hepatomegaly with jaundice

C. Courvoisier's sign

D. Murphy’s sign

Correct Answer: C. Courvoisier's sign

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Courvoisier's sign is the presence of a palpable, non-tender gallbladder , which strongly suggests malignant obstruction of the bile duct , typically from a pancreatic head tumor. This is a classic sign associated with pancreatic cancer. Pancreatic carcinomas are highly aggressive tumors, more than 85% of it being ductal adenocarcinomas. Symptoms: Jaundice secondary to obstruction is the most common symptom Characteristically painless, but may be associated with nausea and epigastric discomfort Pruritus, dark urine and pale stools with steatorrhea Weight loss Signs: Courvoisier’s sign - palpable, non-tender gallbladder Palpable liver and ascites Diabetes mellitus depending on the location of tumor Tender and enlarged gallbladder (Option A): A tender gallbladder is more suggestive of acute cholecystitis or gallstone disease rather than pancreatic cancer. Hepatomegaly with jaundice (Option B): While hepatomegaly and jaundice can be present in pancreatic cancer, they are less specific. Hepatomegaly can occur due to a variety of other conditions, including liver metastasis. Murphy’s sign (Option D) is said to be positive when there is pain in right upper abdomen with deep palpation, classically seen in acute cholecystitis.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q22: A 56-year-old patient with pancreatic cancer has completed initial treatment. To monitor for potential recurrence, the oncologist decides to check a tumor marker. Which of the following tumor markers is commonly used for establishing a baseline and monitoring for recurrence in pancreatic cancer? (Q848922)

A. Alpha-fetoprotein

B. Carbohydrate Antigen 19-9

C. Carcinoembryonic Antigen

D. Human Chorionic Gonadotropin

Correct Answer: B. Carbohydrate Antigen 19-9

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Carbohydrate Antigen 19-9 (CA19-9) is commonly used to establish a baseline level and monitoring for recurrence in pancreatic cancer. Pancreatic cancer tumor marker: Carbohydrate Antigen 19-9 (CA19-9) Usage : Establish a baseline level for monitoring. Characteristics : Not highly specific or sensitive. Useful for detecting recurrence if initial levels are raised Alpha-fetoprotein (AFP) (Option A) : Primarily useful for liver cancer and germ cell tumors, not specific to pancreatic cancer. Carcinoembryonic Antigen (CEA) (Option C) : More commonly used for colorectal cancer, not specifically for pancreatic cancer. Human Chorionic Gonadotropin (hCG) (Option D) : Primarily used in the context of trophoblastic diseases and certain germ cell tumors, not for pancreatic cancer.

Bailey and Love Short Practice of Surgery, 28th Edition, Page 1283,1284, 1571, 1572, 1364, 1618

↑ *Back to this question in Part A*

@Neet_pg_bot

Q23: A 65-year-old man presents with symptoms of jaundice and abdominal pain. Imaging studies reveal a solid mass in the pancreatic head. Histological examination shows a dense fibrous stroma with neoplastic tubular glands. The tumor is characterized by local spread along nerves, lymphatics, and blood vessels, and has metastasized to the liver. What is the most likely diagnosis? (Q848921)

A. Serous cystadenoma

B. Mucinous cystic neoplasm

C. Ductal adenocarcinoma

D. Solid pseudopapillary neoplasm

Correct Answer: C. Ductal adenocarcinoma

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Ductal adenocarcinoma type of pancreatic cancer is characterized by a solid mass with neoplastic tubular glands in a dense fibrous stroma, local spread, and metastasis, as described in the given scenario. Ductal Adenocarcinoma: Prevalence : >85% of pancreatic cancer cases (most common) Origin : Ductal cells of the pancreas. Characteristics : Solid tumors with neoplastic tubular glands in dense fibrous stroma. Spread : Locally along nerves, lymphatics, and blood vessels; metastasis often to the liver and peritoneum. Challenges : Histological differentiation can be difficult due to similarities with chronic pancreatitis. Tumor Type Characteristics Common Locations Typical Patients Ductal Adenocarcinoma Solid tumors with neoplastic tubular glands Pancreas (general) - Serous Cystadenomas (Option A) Large clusters of small cysts Pancreas Older women Mucinous Cystic Neoplasms (Option B) Thick-walled, multilocular cysts Pancreatic body or tail Perimenopausal women Intraductal Papillary Mucinous Neoplasms (IPMNs) Multifocal, more likely malignant Pancreatic head Older men Solid Pseudopapillary Neoplasms (Option D) Large, partially solid, partially cystic masses Pancreas Women of childbearing age Adenomas of the Ampulla of Vater Smooth, polypoid submucosal masses Ampulla of Vater - Ampullary Adenocarcinomas Early presentation with biliary obstruction Ampulla of Vater -

Q73 (p. 1822)					

Q1: What is the most probable diagnosis for a 42-year-old woman who came with symptoms of fever, vomiting, and right hypochondriac pain, which radiates to the neck? She has experienced similar episodes in the past, and a positive Murphy's sign was observed during the examination. (Q857521)

A. Acute cholecystitis

B. Carcinoma gallbladder

C. Peptic ulcer

D. Acute appendicitis

Correct Answer: A. Acute cholecystitis

Explanation: Murphy's sign : when we place the fingers on the right hypochondrium and ask the patient to take deep inspiration. At the height of inspiration, there is a sudden catch. This catch is due to an inflamed gallbladder coming in contact with the abdominal wall. This produces pain. In the case of acute cholecystitis, there is inflammation of the gallbladder, and Murphy's sign is positive. Murphy’s sign is not positive in carcinoma of the

gallbladder (Option B), peptic ulcer (Option C), or acute appendicitis (Option D), as it is specifically associated with acute cholecystitis.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1235, 1236, 1244

↑ *Back to this question in Part A*

@Neet_pg_bot

Q2: ERCP is least useful in the diagnosis of: (Q856781)

A. Recurrent pancreatitis

B. Unexplained jaundice

C. Periampullary mass

D. Acute Pancreatitis without choledocholithiasis

Correct Answer: D. Acute Pancreatitis without choledocholithiasis

Explanation: Acute pancreatitis is inflammation of the pancreas, often linked to biliary causes like gallstones or choledocholithiasis; however, when choledocholithiasis is absent, and no bile duct obstruction is present, ERCP is not typically recommended. ERCP (Endoscopic Retrograde Cholangiopancreatography) is an invasive diagnostic and therapeutic procedure used to examine and treat disorders of the bile ducts , pancreatic ducts , and gallbladder . In the given case, non-invasive imaging like abdominal ultrasound, CT scan, or MRI is sufficient to assess the pancreas and biliary tree, and ERCP is reserved for patients with evidence of bile duct obstruction . Recurrent pancreatitis (Option A) can be caused by bile duct stones, pancreatic duct abnormalities, or strictures. ERCP helps by identifying obstructions, structural changes, and stones in the bile duct or pancreatic duct . It also allows therapeutic interventions such as stone removal or stenting of the bile duct. Therefore, ERCP is often used in recurrent pancreatitis if there is suspicion of biliary causes. Unexplained jaundice (Option B) can arise from a variety of causes, but one of the most common is obstruction of the bile duct, often by stones, tumours, or strictures. ERCP is an excellent diagnostic tool for identifying the cause of jaundice. Periampullary mass (Option C) is a growth near the Ampulla of Vater, and ERCP is particularly useful in the diagnosis of these as it provides detailed imaging of the ampulla of Vater and helps identify the location, extent, and nature of the mass, aiding in further management decisions.

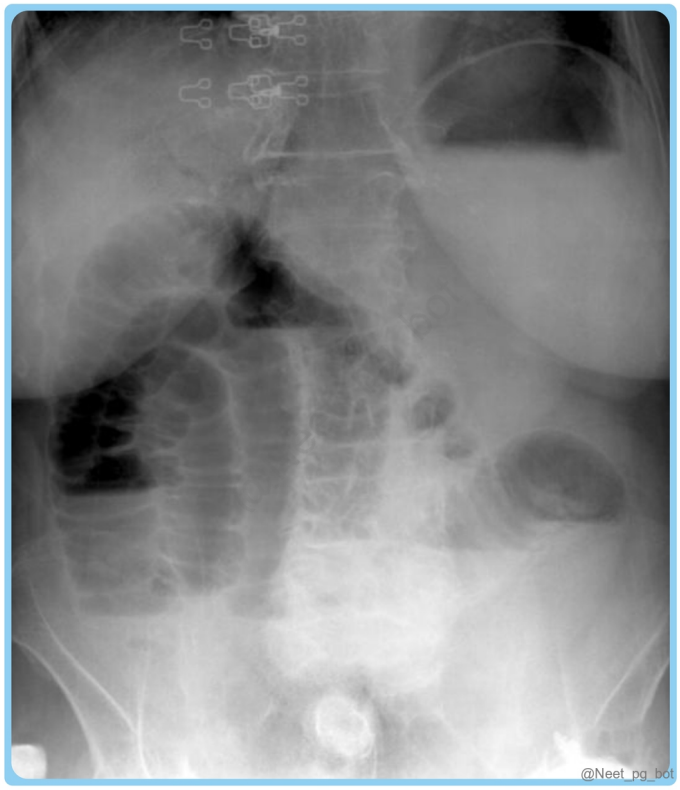
↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 54-year-old female patient presents with abdominal pain and bilious vomiting. She had a history of abdominal hysterectomy 2 years back. On examination, abdomen auscultation revealed high-pitched bowel sounds. Investigations showed air within the biliary tree. What is the most likely diagnosis? (Q856242)

A. Gallstone ileus



B. Adhesive intestinal obstruction

C. Ischemic enterocolitis

D. Diverticulitis

Correct Answer: A. Gallstone ileus

Explanation: The patient, with a history of abdominal hysterectomy 2 years ago, presents with abdominal pain, bilious vomiting, high-pitched bowel sounds on auscultation, and investigations revealing air within the biliary tree, indicating Gallstone ileus. A rare complication of cholelithiasis (0.4%) caused by the impaction of one or more gallstones within the gastrointestinal tract, is more common in the elderly and women. Pathophysiology: Acute cholecystitis→ erosion of inflamed tissues → Formation of a cholecystointestinal fistula→ Gallstone ileus Small gallstones typically pass through the intestines, but stones 2–5 cm in size can become impacted, usually in the terminal ileum or at the ileocecal valve. Clinical Manifestations: Acute, intermittent, or chronic episodes of partial or complete gastrointestinal obstruction. Signs of obstruction include dehydration, abdominal distension and tenderness, high-pitched bowel sounds, and obstructive jaundice. (Option A) Diagnosis: Plain Abdominal Radiograph: Partial or complete intestinal obstruction Pneumobilia or contrast material in the biliary tree Calcified gallstone with position changes on serial films (tumbling sign) {{caption_text}} CT Scan: Superior sensitivity (up to 93%) Shows abnormal gallbladder with air, air-fluid level, or fluid accumulation with an irregular wall (Option A) {{caption_text}} Management: Management of intestinal obstruction Enterolithotomy: The most common surgical procedure A longitudinal incision on the antimesenteric border proximal to the site of impaction Gallstone is brought to a non-edematous bowel segment by gentle manipulation and extraction. Cholecystoenteric fistula resection only if the patient is stable and there are residual gallstones that may cause infection or recurrent ileus. Adhesive intestinal obstruction (Option B) occurs when scar tissue from previous abdominal surgery causes bowel loops to stick together, leading to obstruction. It typically presents with symptoms of bowel obstruction (pain, vomiting, distention) but would not show air in the biliary tree. Ischemic enterocolitis (Option C) results from reduced blood flow to the intestines, often due to arterial blockage or low blood pressure. It causes diffuse abdominal pain, tenderness, and sometimes bloody diarrhoea, but does not cause the air in the biliary tree. Diverticulitis (Option D) is inflammation or infection of small pouches (diverticula) in the colon. It usually presents with lower abdominal pain, fever, and changes in bowel habits, and does not cause air in the biliary tree.

Textbook of SRB’s Surgical Operations, 6th Edition, Page 633-634.

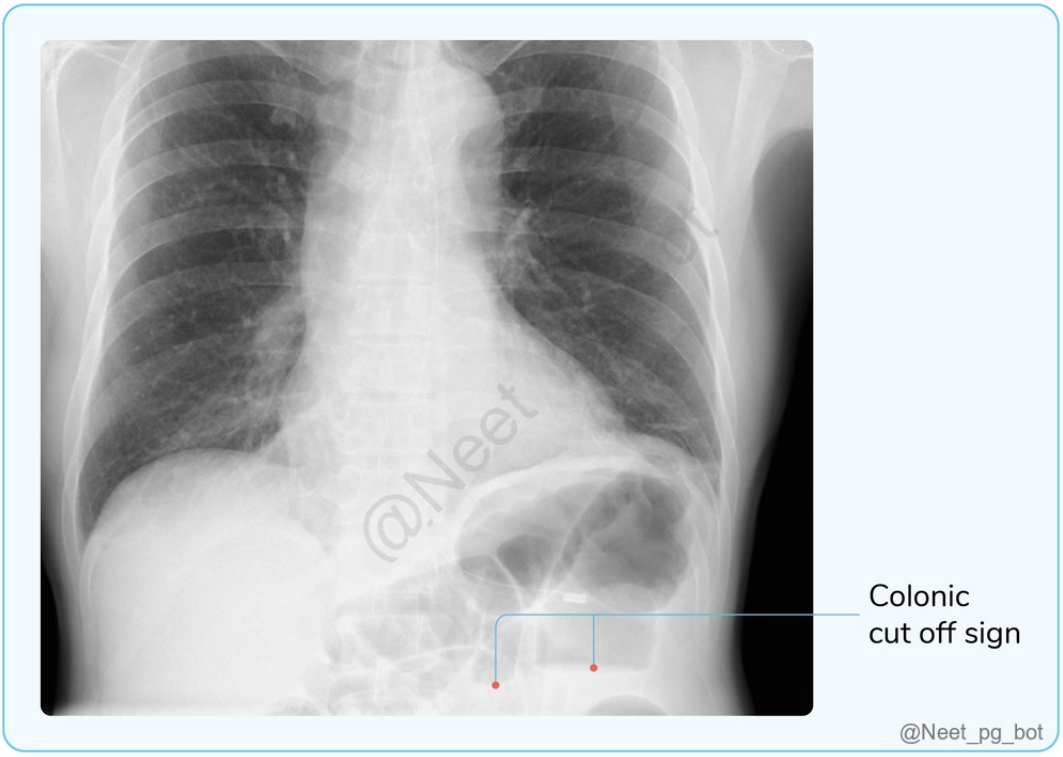
↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: An alcoholic patient presented with severe abdominal pain. Pancreatitis was suspected, and a CT scan revealed lesions with fluid collected near the body of the pancreas. Which of the following enzymes is most likely to be elevated? (Q856230)

A. Serum GGT

B. CEA



C. Serum lipase

D. Serum bilirubin

Correct Answer: C. Serum lipase

Explanation: The patient's severe abdominal pain and CT scan showing fluid-filled lesions near the body of the pancreas suggest an inflammatory process, diagnosed as Pancreatitis , with elevated serum lipase levels. Clinical Diagnosis (Requires 2 of 3): Abdominal pain is strongly suggestive of acute pancreatitis. Serum amylase and/or lipase (more specific) level at least 3 times the upper limit of normal. Imaging findings characteristic of acute pancreatitis. X-ray Features Sentinel loop sign : Dilated loop of small intestine near the inflamed pancreas due to localised ileus. Significance : Early indicator of acute pancreatitis on X-ray. Sentinel loop sign {{caption_text}} Colon cut-off sign : Abrupt termination of gas in the colon at the splenic flexure, with collapsed distal colon loops. Significance : Suggests localised pancreatic inflammation, causing colonic spasm as an indirect sign of acute pancreatitis {{caption_text}} Investigations of Choice: Contrast-enhanced CT (CECT) : Primary tool for assessing pancreatic necrosis, peripancreatic inflammation, fluid collections, and complications. Most reliable for staging and detecting complications. It may underestimate necrosis if done in the first 24 hours. Morphological Types (Revised Atlanta Classification 2008): Interstitial oedematous pancreatitis : Mild form with pancreatic oedema and swelling but no necrosis. Necrotising pancreatitis : Severe form involving pancreatic parenchymal necrosis, associated with higher morbidity and mortality. Serum GGT (Gamma-Glutamyl Transferase) (Option A) is elevated in liver disease, especially in cases of alcohol abuse, but it's not specific to pancreatitis. CEA (Option B) , carcinoembryonic antigen, is a tumour marker not typically elevated in pancreatitis. Serum bilirubin (Option D) may be elevated in biliary obstruction or liver disease; it is not a primary marker for pancreatitis.

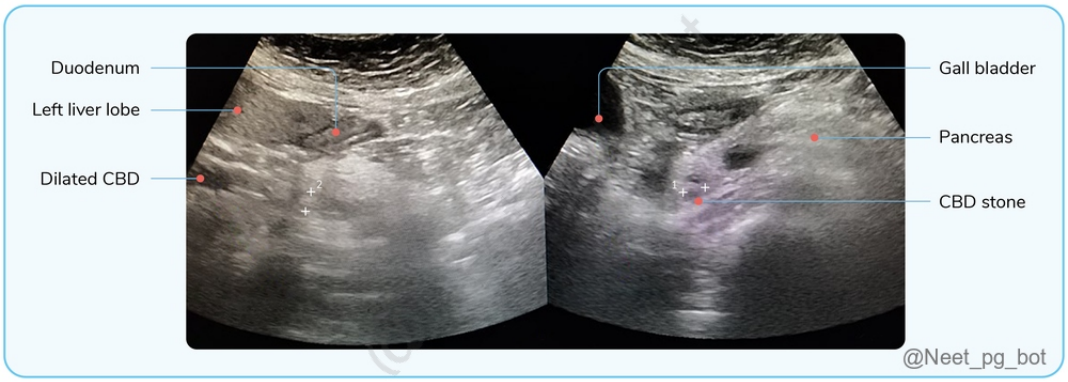
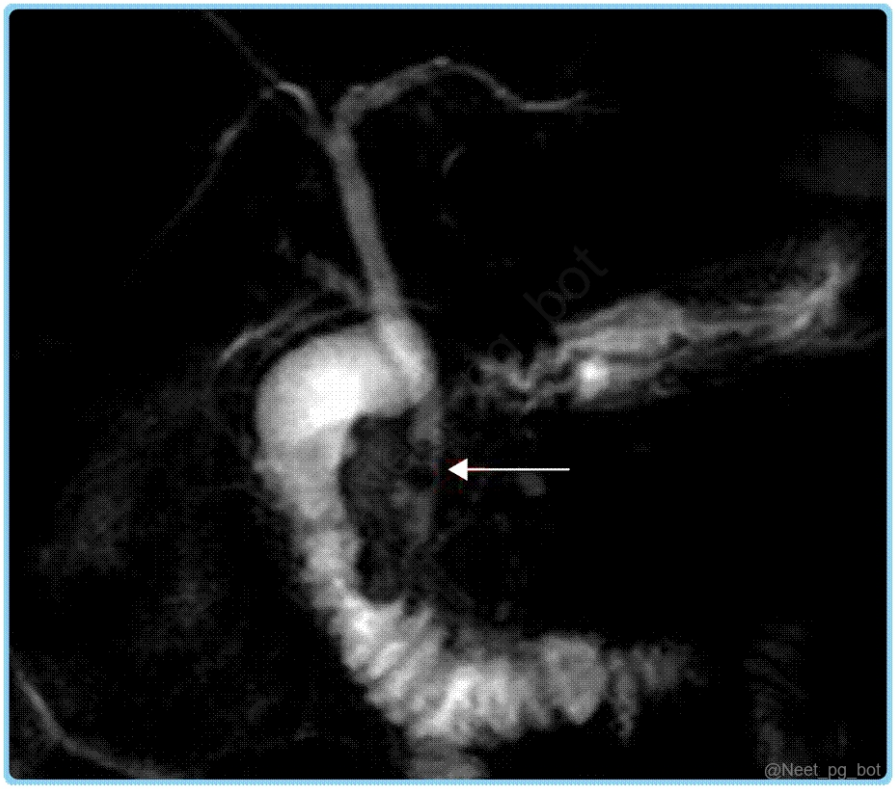
@Neet_pg_bot

Q5: A patient underwent cholecystectomy for gallstones 2.5 years ago. She now presents with symptoms of obstructive jaundice. Investigation reveals a stone in the common bile duct. What is the stone most likely to be? (Q856204)

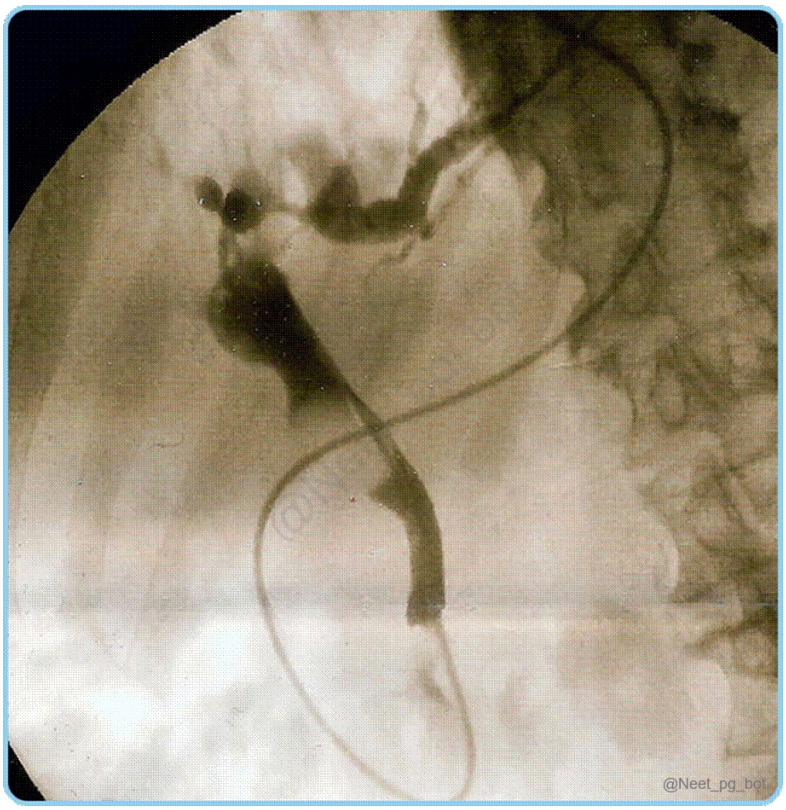
A. Primary



B. Secondary



C. Tertiary



D. Recurrent

Correct Answer: D. Recurrent

Explanation: The given scenario, where a patient has a history of cholecystectomy (gallbladder removal) for gallstones 2.5 years ago and is now presenting with obstructive jaundice and a gallstone in the common bile duct (CBD), indicates a case of recurrent type of Common Bile Duct Stones (Choledocholithiasis) . Types Retained common bile duct stones Detected within 2 years of cholecystectomy Recurrent common bile duct stones Detected after 2 years of cholecystectomy (Option D) Clinical features Charcot's triad : Pain + Fever + Jaundice Reynauld's pentad: Mental status changes + Hypotension + Charcot's triad Biliary colic: A sudden, severe, colicky pain in the right upper quadrant that radiates to the back and shoulder, precipitated by a fatty or heavy meal, and can last for a few hours. Darkening of the urine and lightening of the stools. Steatorrhea, or fatty stools Pruritus (itching), loss of appetite, weight loss, nausea, and vomiting Investigation Ultrasound: Useful for detecting gallstones and CBD dilation but has limited sensitivity for CBD stones. {{caption_text}} MRCP: Non-invasive, excellent for visualising biliary tree anatomy and pathology. ERCP: Highly sensitive, both diagnostic and therapeutic for CBD stones. PTC: Used when ERCP is not feasible, such as post-gastrectomy patients or unsuccessful ERCP attempts. EUS: Invasive but accurate for diagnosing choledocholithiasis. Blood Tests: ↑ bilirubin, ↑alkaline phosphatase, and ↑white blood cell count indicate choledocholithiasis and possible complications like cholangitis. Treatment Endoscopic Management: ERCP with sphincterotomy and stone extraction; stenting if necessary. Percutaneous Removal: Used when endoscopic access is difficult. Surgery: Options include laparoscopic and open choledocholithotomy, choledochoduodenostomy, and choledochojejunostomy. Complications Cholangitis Pancreatitis Liver Damage Biliary Stricture Gallstone Ileus {{caption_text}} MRCP of CBD stone {{caption_text}} ERCP of a distal CBD stone Primary (Option A) forms inside the common bile duct (CBD), with brownstones being the most common type. These stones are often associated with underlying conditions such as primary sclerosing cholangitis or Caroli disease. Secondary (Option B) are those that form in the gallbladder and later migrate into the common bile duct (CBD). The most common type is cholesterol stones, which can subsequently move into the CBD. Tertiary (Option C) are formed within the bile ducts as a result of bacterial or parasitic infection.

Duodenum
Left liver lobe
Dilated CBD
Gall bladder
Pancreas
CBD stone

@Neet_pg_bot

Q6: What should be the subsequent course of action in the management of a female patient who experienced abdominal pain and increased heart rate three days after cholecystectomy? Her white blood cell count is 11000 cells / mm^3, and an ultrasound examination revealed a 5x5 cm accumulation of fluid in the sub-hepatic space on the right side. (Q856532)

A. Antibiotics and send home

B. USG-guided pigtail catheter drainage

C. Laparoscopy and re-exploration

D. ERCP and T-tube placement

Correct Answer: B. USG-guided pigtail catheter drainage

Explanation: The next step in managing a woman who presented with abdominal pain and tachycardia, with a fluid collection in the right sub-hepatic space seen on ultrasound, is USG-guided pigtail catheter drainage as this is a case of bile duct injury following cholecystectomy. Ultrasound-guided pigtail catheter drainage offers several advantages, including improved accuracy in locating the fluid collection and minimizing the risk of complications. Antibiotics and send home (Option A) The presence of a fluid collection and symptoms suggestive of postoperative complications necessitates intervention rather than sending the patient home with antibiotics alone. Laparoscopy and re-exploration (Option C) are not the first-line management options for a fluid collection in the subhepatic space. Less invasive measures like drainage should be attempted first. ERCP and T-tube placement (Option D) are indicated in biliary tract-related issues, which may not be the primary cause of the fluid collection in this scenario.

Bailey & Love's Short Practice of Surgery (28th Edition) page 1252

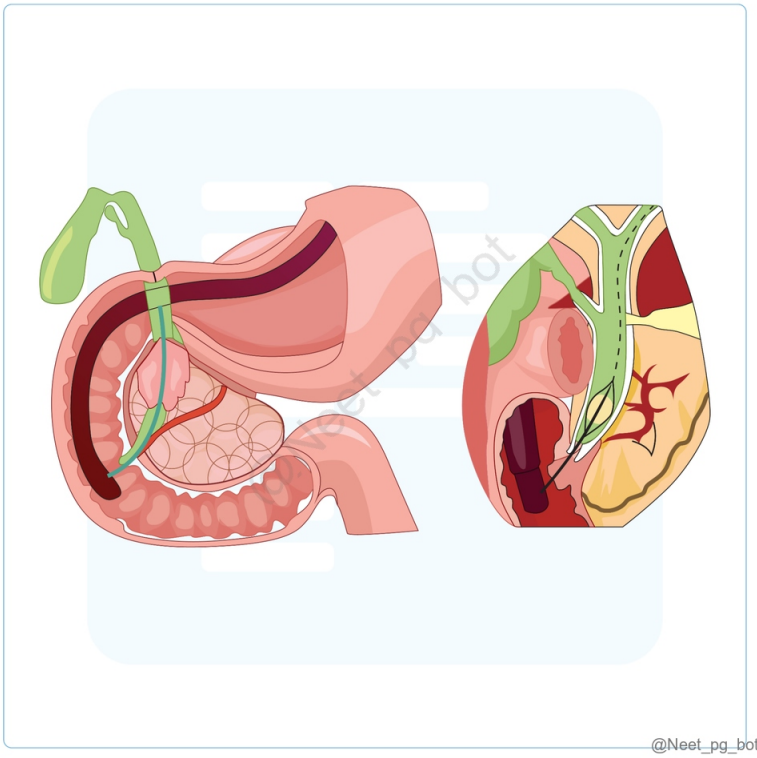
↑ *Back to this question in Part A*

@Neet_pg_bot

Q7: A 16-year-old female with recurrent jaundice and abdominal pain is found to have a fusiform cystic dilatation of the common bile duct on ultrasound. Which investigation is best to fully delineate the biliary anatomy and confirm the diagnosis before surgery? (Q858369)

A. Magnetic Resonance Cholangiopancreatography

B. Endoscopic ultrasound



C. Percutaneous transhepatic cholangiography

D. Endoscopic retrograde cholangiopancreatography

Correct Answer: A. Magnetic Resonance Cholangiopancreatography

Explanation: Magnetic Resonance Cholangiopancreatography (MRCP) is: A non-invasive imaging modality. Excellent for visualising the biliary tree and pancreatic ducts . Particularly useful in obstructive jaundice to evaluate: Site of obstruction Cause (e.g., stones, strictures, tumours) Extent of biliary dilatation It does not require contrast injection into the ducts and has no risk of pancreatitis or infection , unlike ERCP. {{caption_text}} INVESTIGATIONS Endoscopic Ultrasound (Option B ruled out) The first imaging test that is performed. Confirms the presence of the cyst. Reveals anatomical details, including bile duct and pancreatic duct relationship. Magnetic Resonance Cholangiopancreatography (MRCP) Non-invasive imaging technique. Provides detailed

images of the gallbladder and biliary system. Highly sensitive (>90%) and specific (>99%) for identifying common bile duct stones. Visualizes biliary anatomy and the extent of dilatation. Endoscopic Retrograde Cholangiopancreatography (ERCP): (Option D ruled out) Invasive procedure with endoscope and contrast material. Diagnostic and therapeutic capabilities (tissue sampling, decompression, treatment of choledocholithiasis). Effective but has a complication rate of up to 10%. Percutaneous Transhepatic Cholangiography (PTC) Invasive procedure with a needle directly into the liver. Useful for intrahepatic biliary disease or when ERCP is not feasible. (Option C ruled out) Helps delineate surgical anatomy and enables drainage catheter and stent placement. CT SCAN Mainly to see the intrahepatic biliary system Other Tests Hepatobiliary nuclide Scanning Liver Function Tests

↑ *Back to this question in Part A*

@Neet_pg_bot

Q9: A 40 year old woman presented with jaundice, fever, and abdominal pain. She is suspected to have cholangitis. Which of the following apart from abdominal pain makes up Reynold pentad? 1. Fever 2. Jaundice 3. Hypotension 4. Altered sensorium 5. Hematemesis 6. Melena (Q858359)

A. 1, 2, 3, 4

B. 2, 3, 4, 5

C. 1, 3, 4, 5

D. 1, 2, 4, 5

Correct Answer: A. 1, 2, 3, 4

Explanation: Reynold's Pentad is seen in severe (suppurative) cholangitis , which includes: 1. Fever with chills 2. Jaundice 3. Hypotension (Shock) 4. Altered mental status (Confusion, delirium) 5. Right upper quadrant (RUQ) pain Cholangitis Aetiology Often due to obstruction in the biliary tree, leading to bacterial infection by organisms like Klebsiella, E. coli, Enterobacter, Pseudomonas, and Citrobacter species. Symptoms Charcot's triad - pain, jaundice, fever Additional tenderness in the epigastrium and right hypochondrium is common. Severe Form: Reynolds pentad - persistent pain, fever, jaundice, shock, and altered mental status Indicates acute obstructive

suppurative cholangitis. Lab Findings Elevated white blood cell count, bilirubin, and alkaline phosphatase levels. Chronic cases may show lobar or segmental atrophy or hypertrophy. Recurrent Pyogenic Cholangitis More common in East Asian populations, caused by intrahepatic stones and infections Risk factors include parasitic infections like Clonorchis sinensis and Ascaris lumbricoides. 2, 3, 4, 5 (Option B) Includes hematemesis , which is NOT a feature of Reynold's Pentad. 1, 3, 4, 5 (Option C) Misses jaundice and includes hematemesis , which is NOT a feature of Reynold's Pentad 1, 2, 4, 5) (Option D) Includes hematemesis , which is unrelated to cholangitis. I

@Neet_pg_bot

Q10: What is the most appropriate next step in the management of a female patient who has abdominal pain, multiple gallstones with no thickening of the gallbladder wall as seen on ultrasound, a common bile duct diameter of 12mm, serum bilirubin level of 0.8, alkaline phosphatase level of 380, and a 5-fold increase in GGT? (Q858345)

A. MRCP

B. ERCP

C. Endoscopic ultrasound

D. Laparoscopic cholecystectomy

Correct Answer: A. MRCP

Explanation: The patient has multiple gallstones, and the CBD diameter is increased at 12mm, which suggests the possibility of choledocholithiasis (stones in the common bile duct). The elevated alkaline phosphatase and significantly raised GGT levels also indicate some degree of biliary obstruction. MRCP can accurately assess the CBD and help identify the presence, location, and size of any stones within the duct. It can also evaluate the pancreatic duct for any associated pathology. By obtaining this information, MRCP can guide further management decisions and determine the most appropriate intervention, whether it's endoscopic or surgical. ERCP (Endoscopic Retrograde Cholangiopancreatography) (Option B) ERCP can be therapeutic and used for stone removal, it is typically reserved for cases where there is a clear indication for intervention, such as symptomatic choledocholithiasis or evidence of biliary obstruction with significant symptoms or abnormal liver function tests. Endoscopic ultrasound (Option C) EUS can be useful for evaluating certain conditions, such as pancreatic tumours or staging of gastrointestinal malignancies, it is not the primary modality for assessing gallstones or the biliary

system. Laparoscopic cholecystectomy (Option D) in this case, the focus is primarily on the evaluation of the biliary system. Therefore, performing a cholecystectomy without further assessment and identification of possible choledocholithiasis would be premature.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1237- 1242

↑ *Back to this question in Part A*

@Neet_pg_bot

Q11: A patient presents with pain in the right upper quadrant on the second postoperative day following a cholecystectomy. Evaluation reveals a collection in the subhepatic space. A bile leak is suspected. What is the best next step in management? (Q856233)

A. MRCP

B. ERCP

C. HIDA

D. CECT

Correct Answer: B. ERCP

Explanation: In the context of a postoperative cholecystectomy patient where imaging has already confirmed a bile leak , the best next step in management is ERCP (Endoscopic Retrograde Cholangiopancreatography) . ERCP not only helps confirm and localise the leak but, more importantly, allows therapeutic intervention , such as placement of a biliary stent, which reduces intraductal pressure and promotes closure of the leak. Endoscopic Retrograde Cholangiopancreatography (ERCP) Definition It is an invasive diagnostic and therapeutic procedure used to examine and treat disorders of the bile ducts , pancreatic ducts , and gallbladder . Indications It allows for visual assessment of the duodenum and ampulla of Vater. Allows biopsies, stone extraction, and other Interventional procedures like sphincterotomy, biliary stenting, and biliary stricture dilation. In Jaundice Less suitable for jaundiced patients as it is invasive Imaging Type Provides dynamic information during contrast introduction Image {{caption_text}} MRCP (Option A) is a non-invasive imaging technique that can help visualise bile ducts, but it doesn't provide the same ability for therapeutic intervention as ERCP . HIDA (Option C) (Hepatobiliary Iminodiacetic Acid scan) is useful for evaluating biliary patency and assessing bile flow . Though it can be used for detecting bile flow abnormalities, it cannot be used for therapeutic management, hence ERCP is generally considered the best for diagnosing and managing bile leaks. CECT (Option D) can be used to detect collections or fluid accumulation and its evaluation but it lacks the therapeutic intervention that ERCP can offer. Additionally, CECT involves radiation exposure and may not be the optimal choice when a more specific investigation like ERCP is available.

@Neet_pg_bot

Q12: A 36-year-old man presents with dull aching epigastric pain. He gives a history of acute abdominal pain following a binge of alcohol 5 weeks back, which was managed conservatively. On examination, he appeared icteric, and a firm mass was palpable in the epigastrium. His CT scan is given below. Which of the following is the most likely diagnosis? (Q857497)

A. Pancreatic pseudocyst

B. Large choledochal cyst

C. Gastric duplication cyst

D. Mesenteric cyst

Correct Answer: A. Pancreatic pseudocyst

Explanation: Pancreatic pseudocyst is a complication seen after 2 weeks of an acute pancreatitis attack. It is commonly seen in alcoholism. The cyst is usually located between the stomach and transverse colon, between the stomach and liver or Behind or below the transverse colon. Clinically a tense cystic mass in the epigastrium, umbilical region or left hypochondrium can be seen. Large choledochal cyst (Option B) Choledochal cyst is a congenital cyst and is not caused due to alcoholism. It is not seen as a tense mass in the epigastrium. Gastric duplication cyst (Option C) It is a congenital cyst and is not caused by alcoholism. It is seen usually in relation to the distal region of the greater curvature. There is no clinically evident tense mass near the epigastrium. Mesenteric cyst (Option D) This cyst is congenital

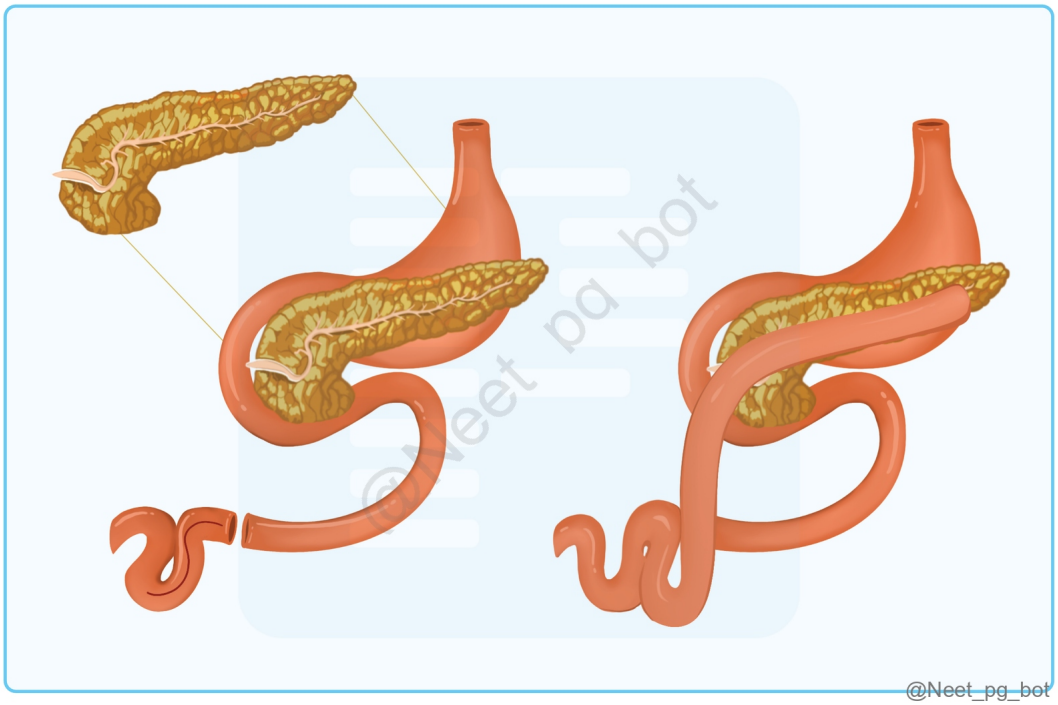
@Neet_pg_bot



Q13: Identify the procedure shown in the image below. (Q857478)

A. Gastrojejunostomy

B. Pancreaticojejunostomy

C. Pancreatic Ileostomy

D. Duodenojejunostomy

Correct Answer: B. Pancreaticojejunostomy

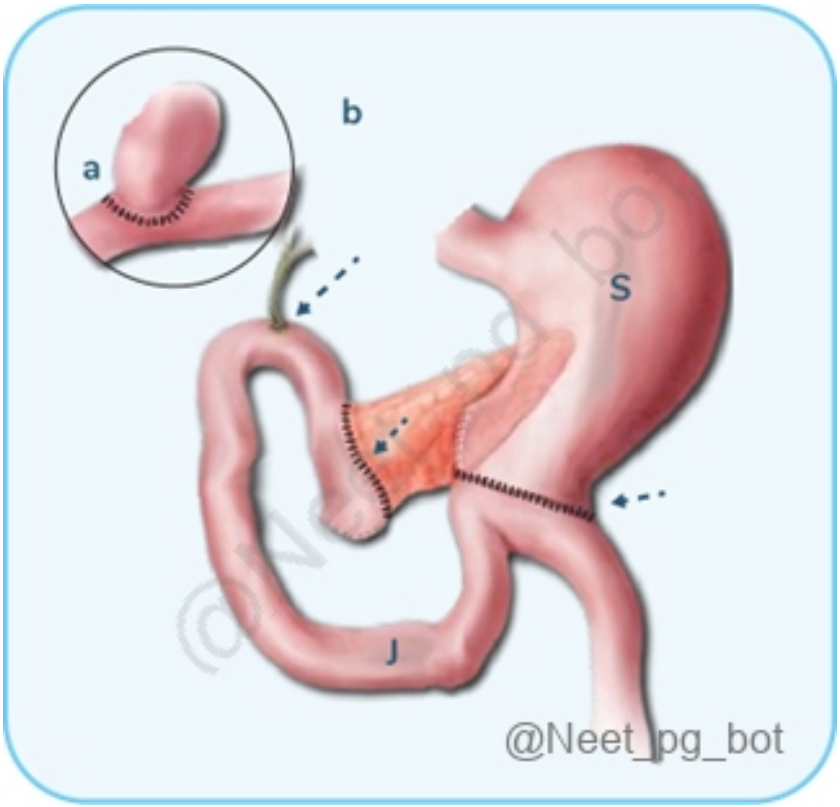
Explanation: The procedure shown in the above image is pancreaticojejunostomy. Puestow's operation is indicated for diffuse chronic pancreatitis and dilated pancreatic duct. The duct is opened wide, strictures are cut open, stones are removed, and it is anastomosed to one of the loops of jejunum. This is a by-pass procedure. It preserves both endocrine and exocrine functions. Gastrojejunostomy (Option A) It is the anastomosis of the body of the stomach to the first loop of the jejunum, by passing the duodenum. This procedure does not include the pancreas. Pancreatic Ileostomy (Option C) is done in case of pancreatic duct obstruction, and the pancreas is anastomosed to the ileum. This procedure is not indicated in the image. Duodenojejunostomy (Option D) It is a procedure done to anastomose a part of the duodenum to the jejunum to bypass an obstruction in the duodenum. This procedure is not indicated in the image.

References:

https://www.researchgate.net/publication/318295858_Longitudinal_Pancreaticojejunostomy_Puestow_Procedure

↑ *Back to this question in Part A*

@Neet_pg_bot



Q14: Identify the procedure shown in the image: (Q857473)

A. Beger’s procedure

B. Whipple’s procedure

C. Frey’s procedure

D. Pancreatic redivision

Correct Answer: B. Whipple’s procedure

Explanation: Correct answer B) Whipple’s procedure Explaantion: The procedure shown in the image is Whipple’s procedure or pancreaticoduodenectomy. It is the primary surgical treatment for pancreatic cancer. The head of the pancreas, most of the duodenum, a portion of the bile duct, the gallbladder, and associated lymph nodes are removed. Whipple's pancreaticoduodenectomy involves resecting the tumour along with the 'C' loop of duodenum up to DJ flexure, proximal jejunum, head of the pancreas up to the neck, and partial gastrectomy, followed by three anastomoses: Pancreaticojejunostomy, Hepaticojejunostomy and Gastrojejunostomy typically performed for a mobile growth without metastasis. Berger’s procedure (Option A) In Beger’s procedure all of the head of the pancreas is removed but the bile duct, stomach and duodenum are preserved. Frey’s procedure (Option C) This procedure includes head coring (a portion of the head of the pancreas is incised). The Duodenum is spared. Pancreatic division (Option D) The image shown indicates Pancreaticoduodenectomy and not pancreatic division.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q15: A 40-year-old man is brought to the casualty with severe abdominal pain radiating to the back for the past 1 day and has had 3 episodes of vomiting. The pain radiates to the back and is slightly relieved in the sitting forward position. The following signs are seen on examination and lab investigations reveal elevated lipase and amylase. Which of the following is the most likely diagnosis? (Q857470)

A. Acute appendicitis

B. Acute cholecystitis

C. Acute pancreatitis

D. Acute ischemic colitis

Correct Answer: C. Acute pancreatitis

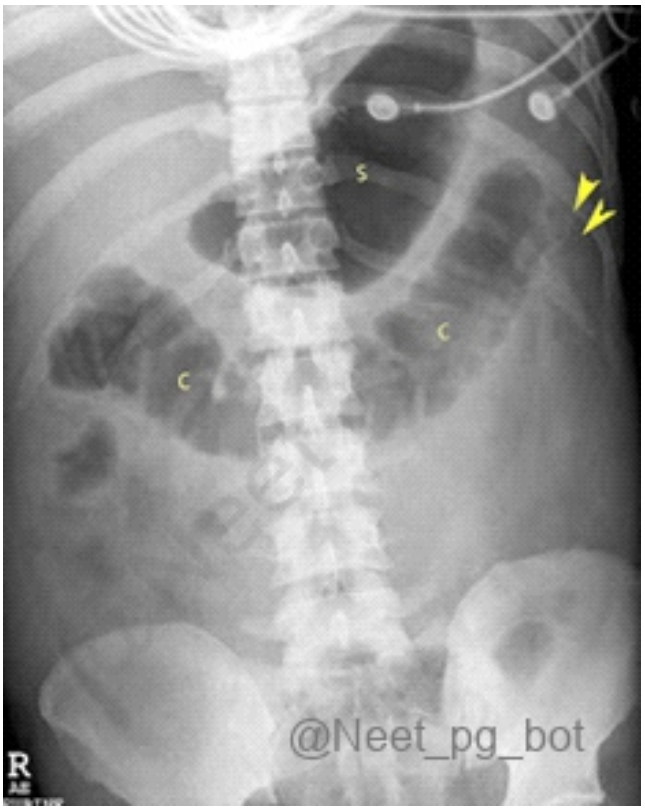
Explanation: The image shows Cullen’s sign , which is superficial edema with bruising in the subcutaneous fatty tissue around the peri-umbilical region, as well as the Grey Turner sign, which is flank ecchymosis. These signs are indicative of acute pancreatitis . Acute pancreatitis is characterised by pain in the abdomen that radiates to the back and is relieved in the sitting forward position. Elevated lipase and amylase are seen in acute pancreatitis. Acute Appendicitis (Option A) Pain typically starts as periumbilical and later localizes to the right lower quadrant (RLQ) (McBurney’s point). No back radiation or elevated lipase/amylase . Acute Cholecystitis (Option B) presents with RUQ pain , Murphy’s sign (+) , and fever. No back radiation or lipase elevation unless complicated by gallstone pancreatitis. Acute Ischemic Colitis (Option D) presents sudden severe abdominal pain (out of proportion to clinical findings) , often in elderly patients with vascular disease . No elevated lipase/amylase or back radiation.

References:

Bailey and Love Short Practice of Surgery, 28th Edition, Pages 139, 140

↑ *Back to this question in Part A*

@Neet_pg_bot



Q16: A young man presents to the emergency department with complaints of severe abdominal pain and 3 episodes of vomiting in the past 9 hours. He says that the pain radiates to the back and is partially relieved by bending forwards. The abdominal radiograph of the patient is given below which shows a ‘colon cut-off sign ’. What is the most likely diagnosis? (Q857194)

A. Acute hepatitis

B. Acute pancreatitis

C. Acute colitis

D. Intestinal obstruction

Correct Answer: B. Acute pancreatitis

Explanation: Acute Pancreatitis Feature Description Definition Acute inflammation of the pancreas due to premature enzyme activation , leads to autodigestion. Common Causes (Mnemonic: "I GET SMASHED") I diopathic, G allstones (most common), E thanol, T rauma, S teroids, M umps, A utoimmune, S corpion sting, H yperlipidemia/hypercalcemia, E RCP, D rugs (thiazides, azathioprine). Clinical Features Severe epigastric pain (radiates to back, worsens after food), nausea, vomiting, fever . Severe cases: Cullen's Sign (periumbilical bruising), Grey Turner's Sign (flank bruising), Colon Cutoff Sign (gas-filled, distended transverse colon with abrupt cut-off at splenic flexure due to inflammation). (Option B) Diagnosis (Atlanta Criteria) ≥2 of 3 criteria : (1) Lipase >3x ULN (more specific than amylase), (2) Epigastric pain , (3) Imaging (CT/USG/MRI) evidence . CT scan (best for complications), Ultrasound (detects gallstones). Severity Classification Mild: No organ failure, Moderate: <48 hrs organ failure, Severe: >48 hrs organ failure. Management IV Fluids (Ringer's lactate), NPO (Bowel Rest), Pain Control (IV opioids), and Enteral feeding are preferred over TPN. ERCP only if gallstone pancreatitis with cholangitis. No routine antibiotics unless infected necrosis. Complications Early (<1 week): SIRS, Shock, ARDS, Renal failure, DIC, Hypocalcemia. Late (>1 week): Necrosis (sterile/infected), Pseudocyst, Abscess, Chronic Pancreatitis, Biliary obstruction. Acute hepatitis (Option A) Symptoms of acute hepatitis are fever, fatigue, loss of appetite, nausea, vomiting, abdominal pain, dark urine, light-coloured stools, joint pain, and jaundice. Acute colitis (Option C) In colitis, the mucosal lining of the colon becomes acutely or chronically inflamed. Symptoms of patients with colitis include watery diarrhoea, abdominal pain, tenesmus, urgency, fever, subjective fatigue, or blood in the stool. Intestinal obstruction (Option D) Intestinal obstructions present with dilated bowel loops with multiple air-fluid levels on abdominal x-ray.

Bailey and Love Short Practice of Surgery, 28th Edition, Pages 1270- 1273

↑ *Back to this question in Part A*

@Neet_pg_bot

Q17: Which of the following is the most common side effect of cholecystectomy? (Q857190)

A. Acute kidney injury

B. Osteoporosis

C. Steatorrhea

D. Colorectal cancer

Correct Answer: C. Steatorrhea

Explanation: Complications of Cholecystectomy Category Complication Description/Features Early (Intraoperative & Immediate Postoperative) Bile Duct Injury Accidental damage to the common bile duct (CBD) leads to bile leakage or strictures (More common in laparoscopic cholecystectomy). Hemorrhage Bleeding from the cystic artery or liver bed; managed with hemostasis or blood transfusion if severe. Bowel Injury Unintended injury to the duodenum or colon , is rare but serious. Anesthesia-related Complications Aspiration, respiratory depression, hypotension , and arrhythmias. Early Postoperative (0–7 Days) Infection (Wound/Port-Site Abscess) Fever, erythema, tenderness at the incision site. More common in diabetics or immunocompromised patients. Bile Leak (Biloma) Fever, abdominal pain, nausea , and localized fluid collection on imaging. Often from cystic duct stump or accessory bile duct injury . Subhepatic Collection (Abscess) Fever, RUQ pain, and tachycardia ; requires percutaneous drainage . Retained Gallstones Residual gallstones in the bile duct can cause biliary colic or cholangitis postoperatively. Deep Vein Thrombosis (DVT) & Pulmonary Embolism (PE) Due to prolonged immobilization , leading to leg swelling or sudden dyspnea (Prevent with early ambulation, anticoagulation). Late Postoperative (>7 Days – Months/Years) Steatorrhea (Fatty Stools) (Option C) Most common long-term issue due to continuous bile secretion , leading to fat malabsorption . Post-Cholecystectomy Syndrome (PCS) Persistent dyspepsia, bloating, diarrhea, or RUQ pain due to bile reflux or remnant stones. Biliary Strictures Chronic narrowing of the CBD , leading to jaundice and cholangitis . Chronic Diarrhea Related to altered bile acid metabolism , may require bile acid sequestrants (e.g., cholestyramine). Increased Risk of Colorectal Cancer (Debatable) Some studies suggest a mild increase in colon cancer risk due to altered bile acid metabolism , but evidence is weak . Acute Kidney Injury (AKI) (Option A) Not a common direct complication of cholecystectomy; it could occur due to severe infection or intraoperative hypotension, but it is rare. Osteoporosis (Option B) No direct link; chronic fat malabsorption (as in severe bile acid diarrhoea) can lead to vitamin D deficiency, but this is uncommon in routine cholecystectomy cases. Colorectal Cancer (Option D) Some studies suggest a mild increase in colon cancer risk due to altered bile acid metabolism, but it is not a direct or common consequence of cholecystectomy.

Bailey and Love Short Practice of Surgery, 28th Edition, Pages 1251, 1254

↑ *Back to this question in Part A*

@Neet_pg_bot

Q18: What would be your approach in managing a patient who is a 40-year-old woman with a 5 mm gallbladder polyp detected on abdominal ultrasound, but no gallbladder stones? The patient is overall healthy and shows no symptoms. (Q857186)

A. Regular follow-up every 2 months

B. Polypectomy

C. Laparoscopic cholecystectomy

D. Open cholecystectomy

Correct Answer: A. Regular follow-up every 2 months

Explanation: Management Approach for Gallbladder Polyps Polyp Size Management <6 mm Regular follow-up (USG every 6–12 months for 2 years) 6–9 mm Follow-up every 3–6 months , consider cholecystectomy if growth or risk factors ≥10 mm Laparoscopic cholecystectomy (higher malignancy risk) Any size + symptoms or high-risk features Laparoscopic cholecystectomy Polypectomy (Option B) Not feasible since the gallbladder lacks mucosal resection capability like the colon. Laparoscopic Cholecystectomy (Option C) Only indicated if: Polyp ≥10 mm Rapid growth (>2 mm/year) High-risk features (PSC, age >50, sessile polyp, associated gallstones) Open Cholecystectomy (Option D) Only needed if there’s suspicion of malignancy or difficult laparoscopic access .

References:

Bailey and Love Short Practice of Surgery, 28th Edition, Pages 1247, 1248.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q19: A patient underwent laparoscopic cholecystectomy and was discharged after removing the drain tube on the first postoperative day. On day two, the patient came back to the hospital with complaints of increasing abdominal pain with tachycardia and was febrile on examination. On ultrasound examination, there was a 5 x 5 cm collection in the subhepatic space. What is the most likely cause of this condition? (Q857185)

A. Infection

B. Surgical site pain

C. Bile leak

D. Retained gallstones

Correct Answer: C. Bile leak

Explanation: The given findings are highly suggestive of a bile leak , which is one of the most common early complications of laparoscopic cholecystectomy , occurring when bile escapes from an injured cystic duct stump or accessory bile duct . Infection (Option A) Would take more time (5–7 days post-op) to develop and is less likely to cause localized fluid collection early . Surgical Site Pain (Option B) Would not cause fever, tachycardia, or fluid collection on imaging. Retained Gallstones (Option D) Can cause biliary colic or cholangitis , but does not usually present this early with localized fluid collection ; more common after weeks to months .

References:

Bailey and Love short practice of surgery, 28th Edition, Pages 1252, 1253

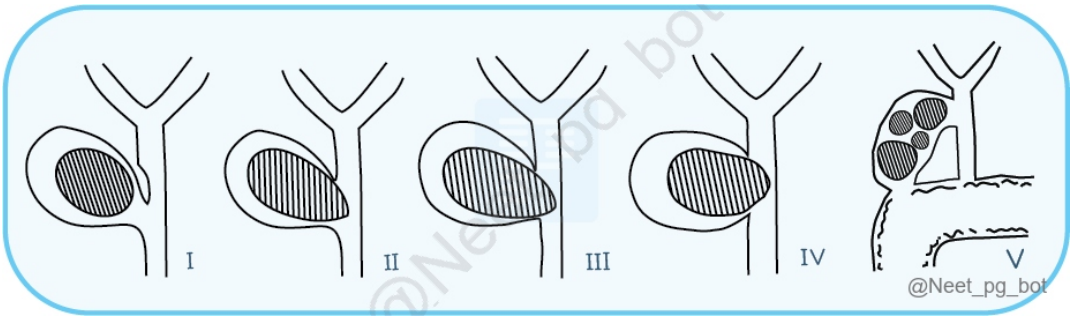
↑ *Back to this question in Part A*

@Neet_pg_bot

Q20: What is the term for a stone obstructing the cystic duct, causing dilation of the common hepatic duct, resulting in CBD obstruction and jaundice? (Q859850)

A. Acute cholecystitis

B. Porcelain gallbladder



C. Cholesterolosis

D. Mirizzi’s syndrome

Correct Answer: D. Mirizzi’s syndrome

Explanation: The condition described in the question is known as Mirizzi’s syndrome . Mirizzi's syndrome is seen in 1% of all cholecystectomies, where a gallstone impacts the gallbladder wall, leading to compression and pressure necrosis. This often results in adherence to the common hepatic duct (CHD) or common bile duct (CBD) wall and can occasionally lead to a cholecystocholedochal fistula. It leads to biliary obstruction , which can result in jaundice and dilation of the bile ducts (CHD and CBD). Mirizzi’s syndrome Pathophysiology The gallstone usually impacts from the Hartmann's pouch, leading to compression of the CHD/CBD. Can also occur from the fundus of the gallbladder into the CBD. Clinical features Fever Abdominal pain Obstructive jaundice Upper abdominal tenderness on the right side Possible palpable soft, enlarged liver Csendes Classification Type I - Extrinsic compression of the CBD/CHD by a large impacted stone in Hartmann's pouch; IA- the presence of cystic duct IB- is obliterated cystic duct Type II - The stone has eroded the CBD/CHD less than 1/3rd of the

circumference of the CBD/CHD, forming a fistula Type III - Involving up to 2/3rd of the circumference of CBD/ CHD Type IV - Cholecystocholedochal fistula (>2/3rd) involving the entire circumference of the CBD/CHD Type V - Cholecystocholedochal fistula with cholecystoenteric fistula without gallstone ileus (VA) or with gallstone ileus (VB) {{caption_text}} Investigations Ultrasonography (USG): Initial imaging to assess gallbladder and ducts. CT Scan: Provides detailed imaging of the biliary system. ERCP/ MRCP: Essential for delineating duct anatomy and identifying the site of obstruction. HIDA Scan: Useful for functional assessment of the biliary system. Findings: Dilatation of the intrahepatic biliary system with a block at the common hepatic duct (CHD). Acute cholecystitis (Option A) is inflammation of the gallbladder, typically due to gallstone obstruction of the cystic duct. While this condition can cause pain and tenderness in the right upper quadrant , it does not commonly cause dilation of the common hepatic duct or jaundice unless there is a secondary obstruction of the CBD or cystic duct. Porcelain gallbladder (Option B) refers to calcification of the gallbladder wall, usually due to chronic cholecystitis . This condition is associated with an increased risk of gallbladder cancer but does not cause biliary obstruction or jaundice due to stone impaction in the cystic duct. Cholesterolosis (Option C), also called strawberry gallbladder, involves lipid deposits in the gallbladder mucosa, leading to a characteristic appearance on imaging. It is often asymptomatic and does not typically cause biliary obstruction or jaundice .

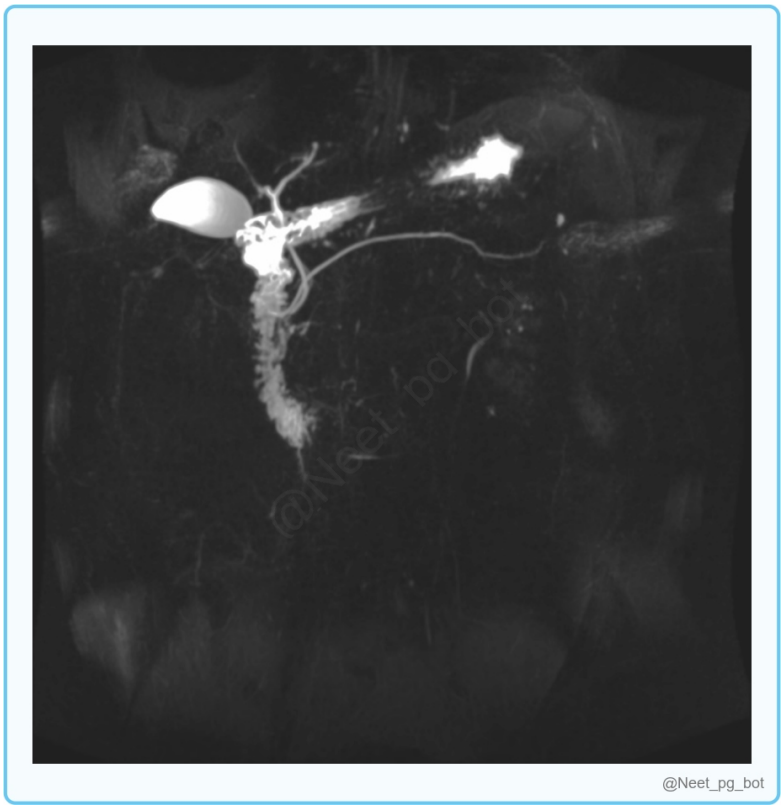
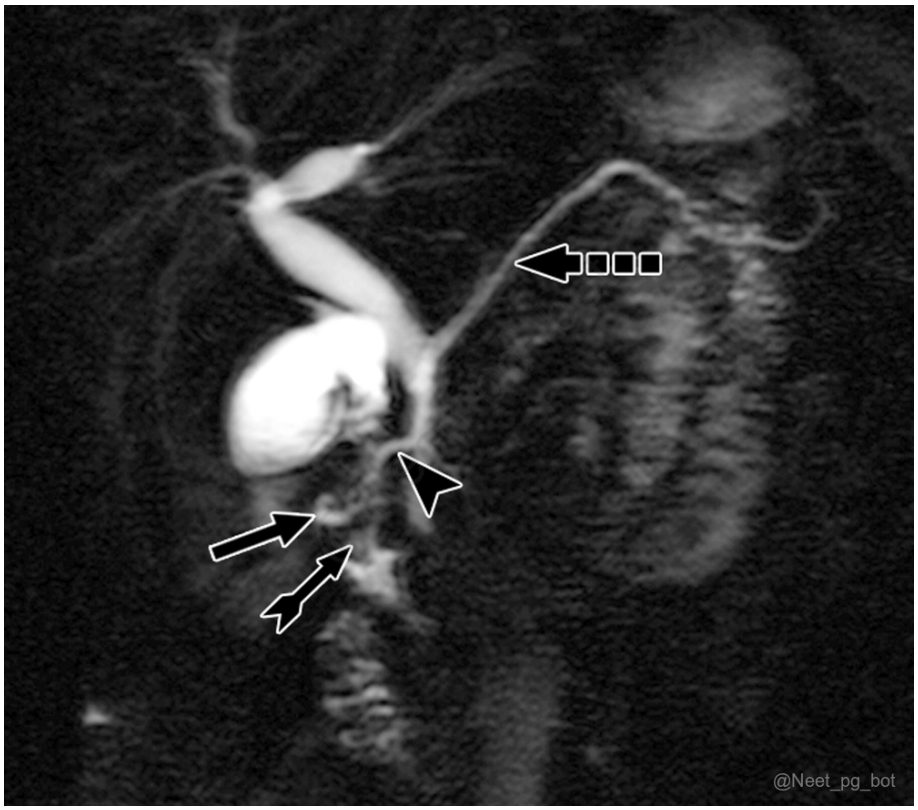
@Neet_pg_bot



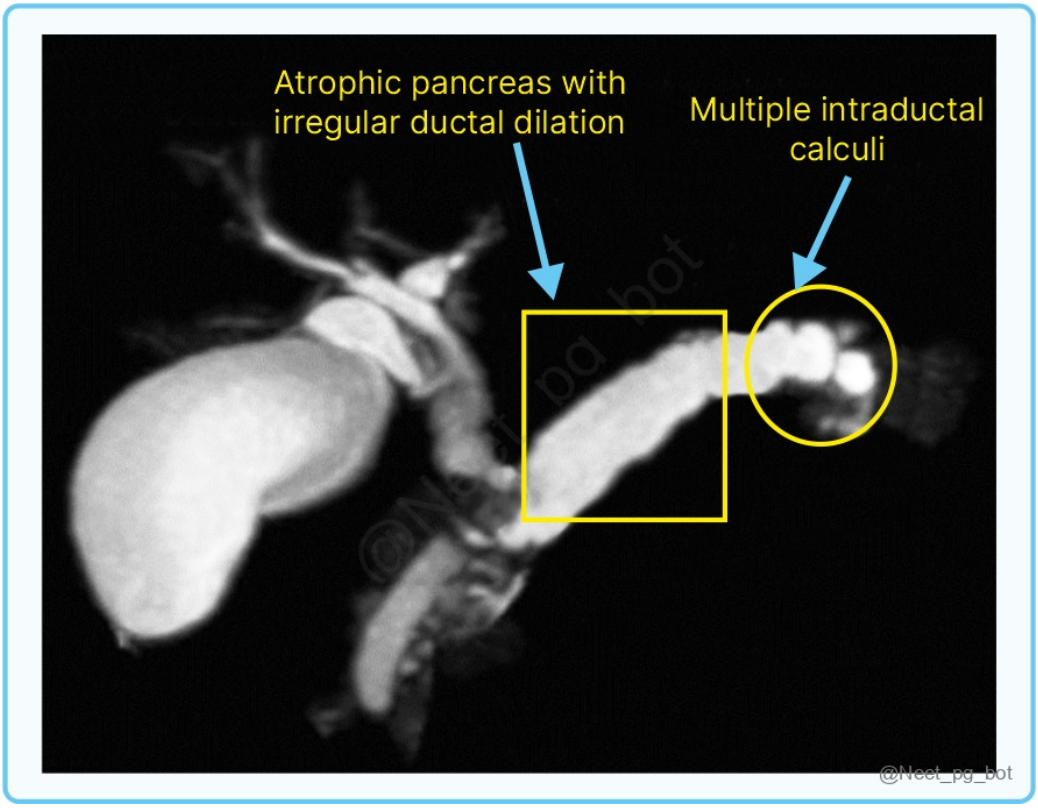
Q21: A 17-year-old boy presents with recurrent episodes of abdominal pain. Serum amylase and lipase are elevated on two occasions, but exocrine pancreatic function is normal. An MRCP image is shown below. Which of the following is the most likely diagnosis? (Q879143)

A. Annular pancreas

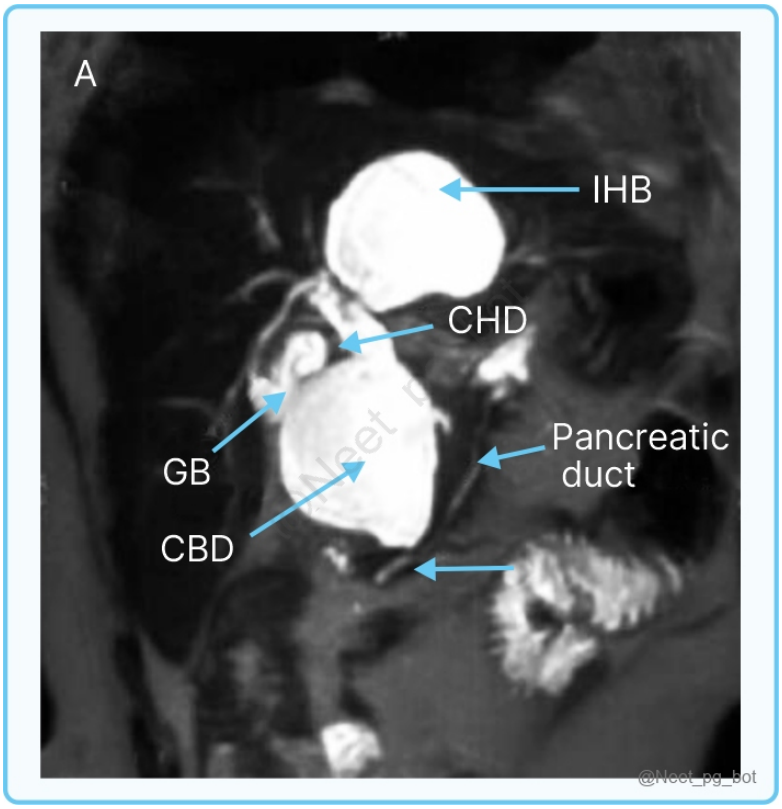
B. Chronic pancreatitis



C. Pancreas divisum



D. Choledochal cyst



Correct Answer: C. Pancreas divisum

Explanation: The patient has recurrent episodes of acute pancreatitis (elevated amylase & lipase on multiple occasions) with normal exocrine pancreatic function, meaning the pancreas is not chronically damaged, which rules out chronic pancreatitis. On MRCP, the presence of two distinct pancreatic ducts, dorsal and ventral, without any junction between them, is characteristic of pancreatic divisum, a congenital anomaly resulting from the failure of these ducts to fuse during embryologic development, which presents as recurrent episodes of acute pancreatitis with elevated amylase/lipase, normal fecal elastase (normal exocrine function) in adolescents or young adults. Annular pancreas (Option A): It presents as duodenal obstruction and shows a ring of pancreatic tissue around the duodenum on MRCP. MRCP shows an annular duct (solid arrow) joining the duct of Santorini (arrowhead). The main pancreatic duct (dashed arrow) does not have a stricture. The duodenal lumen (winged arrow) is narrow. Chronic pancreatitis (Option B): Presents as abnormal exocrine function , ductal irregularity, or calcifications presenting as “chain of lakes” on MRCP. Choledochal cyst (Option D): A bile duct dilation, presenting with jaundice/cholangitis, appearing on MRCP as T2-bright (hyperintense) fluid-filled structures demonstrating cystic dilatation of bile ducts. Type IV-A choledochal cyst with anomalous pancreaticobiliary duct junction (blue arrow)

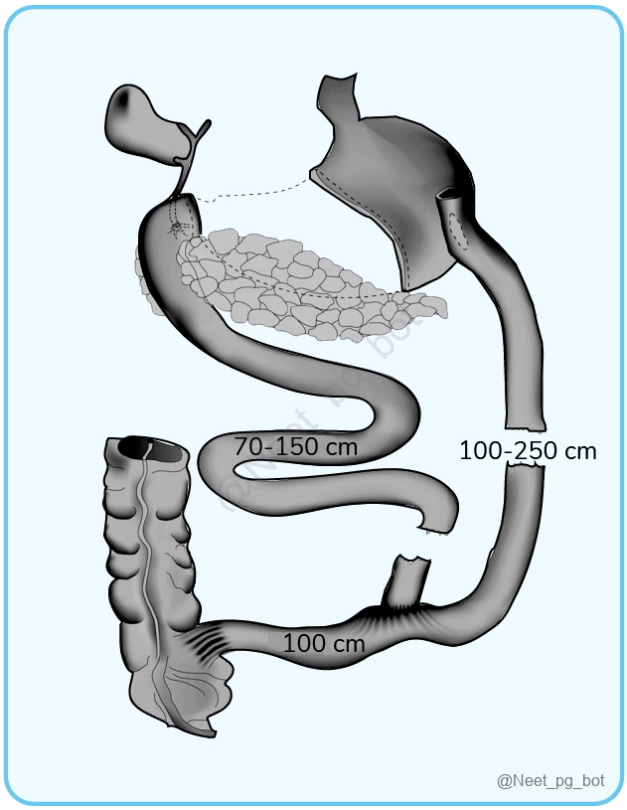
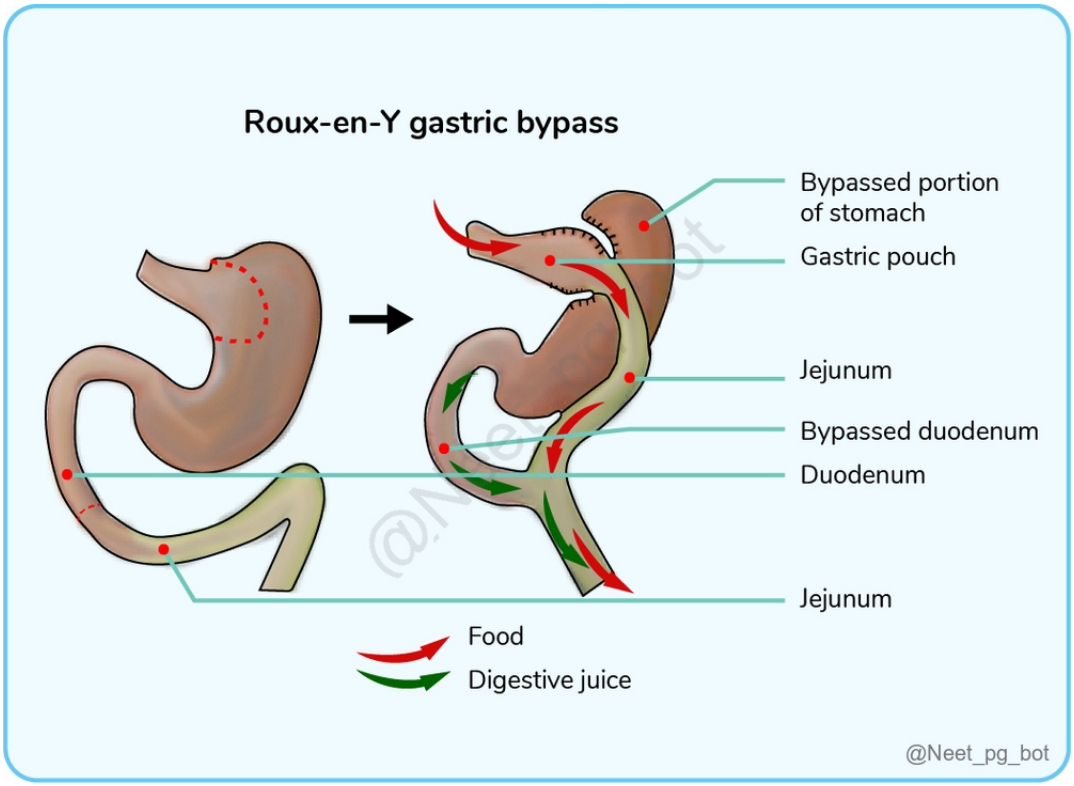
Q22: Identify the procedure: (Q879138)

A. Biliopancreatic diversion

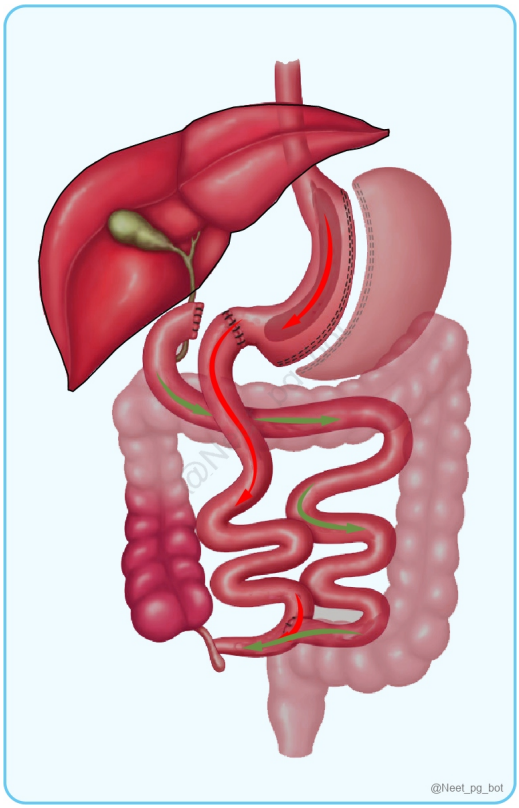
B. Roux -en Y procedure



C. Sleeve gastrectomy



D. Duodenal switch



Correct Answer: A. Biliopancreatic diversion

Explanation: Correct Option A - Biliopancreatic diversion: The image shows Biliopancreatic Diversion (BPD). A partial gastrectomy with gastroileostomy A very long Roux limb (~200 cm) A short common channel (~50 cm) A distal jejunoileostomy A disconnected duodenum (duodenal stump) ■Incorrect Options: Roux-en-Y procedure (Option B): Has a short Roux limb and does not have a short 50 cm common channel. Sleeve gastrectomy (Option C): No intestinal bypass at all; only tubular stomach resection. ■■■■■■■ Duodenal switch■ (Option D): Almost the entire stomach is resected except a narrow lesser curvature, the duodenum is divided, and its end is anastomosed to the distal 250 cm of ileum. Classic BPD differs because the duodenum is not preserved or connected to the ileum.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q24: A patient has undergone a laparoscopic cholecystectomy. A drain was inserted because of a difficult gallbladder dissection. Day 7 drain output is 300 ml. The patient is afebrile, and MRCP shows cystic duct stump leak. What is the next best management? (Q879124)

A. ERCP with or without a stent

B. USG-guided pigtail catheter insertion

C. Re – do laparoscopic ligation of the bile stump

D. Follow up as it will heal on its own

Correct Answer: A. ERCP with or without a stent

Explanation: Correct Option A - ERCP with or without a stent: The patient is stable, afebrile , and the leak is confirmed → Endoscopic management is first-line . A post-cholecystectomy bile leak from the cystic duct stump is best managed by ERCP with sphincterotomy and/or biliary stent placement . This reduces intraductal pressure and allows the leak to seal. Bile Duct Injuries Diagnosis USG: Collections, CBD dilatation. CT: Collections, obstruction, vascular injury. MRCP (gold standard): Defines level/type of injury. HIDA: Confirms leak/obstruction. ERCP: Diagnostic + therapeutic (stent for cystic duct stump leak). Management Stabilize + drain collections. ERCP stenting = first choice for cystic duct leaks/early strictures. Percutaneous drainage if unstable/debilitated. Definitive surgery: Roux-en-Y hepaticojejunostomy for benign strictures or duct transection. Incorrect Options: USG-guided pigtail catheter insertion (Option B): This is used for biloma or localized collection , but here the drain output is already externalized and MRCP shows stump leak, so definitive ductal management is needed. Re-do laparoscopic ligation of cystic stump (Option C): Re-exploration is reserved for major duct injuries, uncontrolled sepsis, or failed ERCP. Not required in a classic cystic duct stump leak. Follow-up and expectant management (Option D): Persistent leak (>50–100 mL/day after 48 hours) requires intervention. It will not reliably close on its own.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1252

↑ *Back to this question in Part A*

@Neet_pg_bot

Q25: Arrange the following steps of surgery in order: A. Creating pneumoperitoneum B. Dissection of hepatocystic triangle C. Ligation of cystic duct and artery D. Separation of the gallbladder from the liver bed (Q879106)

A. A-B-C-D

B. A-C-B-D

C. B-A-C-D

D. D-A-B-C

Correct Answer: A. A-B-C-D

Explanation: Correct Option A - A-B-C-D: The standard sequence for laparoscopic cholecystectomy is: A – Creating pneumoperitoneum B – Dissection of hepatocystic triangle (Calot’s triangle) C – Ligation of cystic duct and artery D – Separation of the gallbladder from the liver bed

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1250

↑ *Back to this question in Part A*

@Neet_pg_bot

Q26: On day 3 after laparoscopic cholecystectomy, a stable patient develops worsening RUQ pain and low-grade fever. Imaging shows a 6-cm biloma and a small cystic duct stump leak. Symptoms persist despite antibiotics and observation. What is the next best step in management? (Q879097)

A. Observation

B. IV antibiotics

C. Image-guided pigtail drainage

D. ERCP with stenting

Correct Answer: C. Image-guided pigtail drainage

Explanation: Correct Option C - Image-guided pigtail drainage: The best next step for a stable patient with a symptomatic 6-cm biloma due to a small cystic duct stump leak is image-guided pigtail drainage , followed by ERCP with stenting if required. The biloma is large and symptomatic, with increasing pain and low-grade fever → indicating inflammation or early infection (6-cm collection will not resolve with observation or antibiotics alone). (Option A, B ruled out) Percutaneous drainage under USG/CT guidance: The standard first step to relieve symptoms, control infection risk, and prevent bile peritonitis. (Option C) After drainage, ERCP with biliary stenting lowers ductal pressure, diverts bile into the duodenum, and more effectively promotes closure of the small cystic duct stump leak than sphincterotomy alone. (Option D ruled out)

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 1089.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q27: What is the most frequently occurring location for an intraperitoneal abscess to develop? (Q855584)

A. Suprahepatic

B. Subhepatic

C. Left lobe of the liver

D. Left side below diaphragm

Correct Answer: B. Subhepatic

Explanation: The most common site for an intraperitoneal abscess to develop is the subhepatic area, typically located beneath the liver. This location is prone to abscess formation due to its proximity to the biliary system and gastrointestinal tract, where infections can easily spread. Most common site of intraperitoneal abscess: In recumbent or lying down position: Morrison pouch/subhepatic space In upright posture: Pelvis (Pouch of Douglas) MC site (Overall): Pelvis (Pouch of Douglas) Suprahepatic (Option A) refers to the area above the liver . While abscesses like subphrenic abscesses can occasionally form in this region, it is not the most common site for intraperitoneal abscesses. Left lobe of the liver (Option C) is not the most common location for general intraperitoneal abscess formation. Left side below the diaphragm (Option D) is not as commonly associated with intraperitoneal abscesses as the subhepatic space. The left side of the diaphragm area can have abscesses like subphrenic abscesses.

Sabiston, Text Book of Surgery, 21st Edition, Page 229.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q28: A 70-year-old woman had her routine follow-up, and her USG is shown below. She is asymptomatic at present but has a history of mild right hypochondriac pain, which is relieved by taking analgesics. What is the most likely diagnosis? (Q859867)

A. Gallstones

B. Amoebic liver abscess

C. Hydatid cyst

D. Acute cholecystitis

Correct Answer: A. Gallstones

Explanation: The most likely diagnosis is Gallstones , based on the USG findings of a thickened gallbladder wall with biliary sludge, acoustic shadowing and the patient's history of mild right hypochondriac pain that responds to analgesics. Gallstones can sometimes be asymptomatic or present with mild right upper quadrant pain , which is relieved by analgesics. This suggests biliary colic rather than an acute infection. Biliary sludge, often seen on imaging, is a precursor to gallstones and can occur due to stagnation of bile in the gallbladder, often in the presence of gallstones. Amoebic liver abscess (Option B) presents with fever , right upper quadrant pain , and liver enlargement . It is often seen in patients with a history of amoebic dysentery (entamoeba histolytica infection). The USG would show a hypoechoic mass in the liver, which is not consistent with the findings in this case. {{caption_text}} Hydatid cyst (Option C) is caused by Echinococcus tapeworm infection and is usually found in the liver. The USG appearance of a hydatid cyst typically shows water-lily signs multilocular cysts, or honeycomb patterns, which is not seen here. Symptoms include abdominal pain, nausea, vomiting, and jaundice. {{caption_text}} Acute cholecystitis (Option D) presents with severe right upper quadrant pain , fever , and Murphy's sign (pain on palpation of the right upper quadrant). It generally presents more acutely and is associated with inflammation and infection , leading to more severe symptoms .

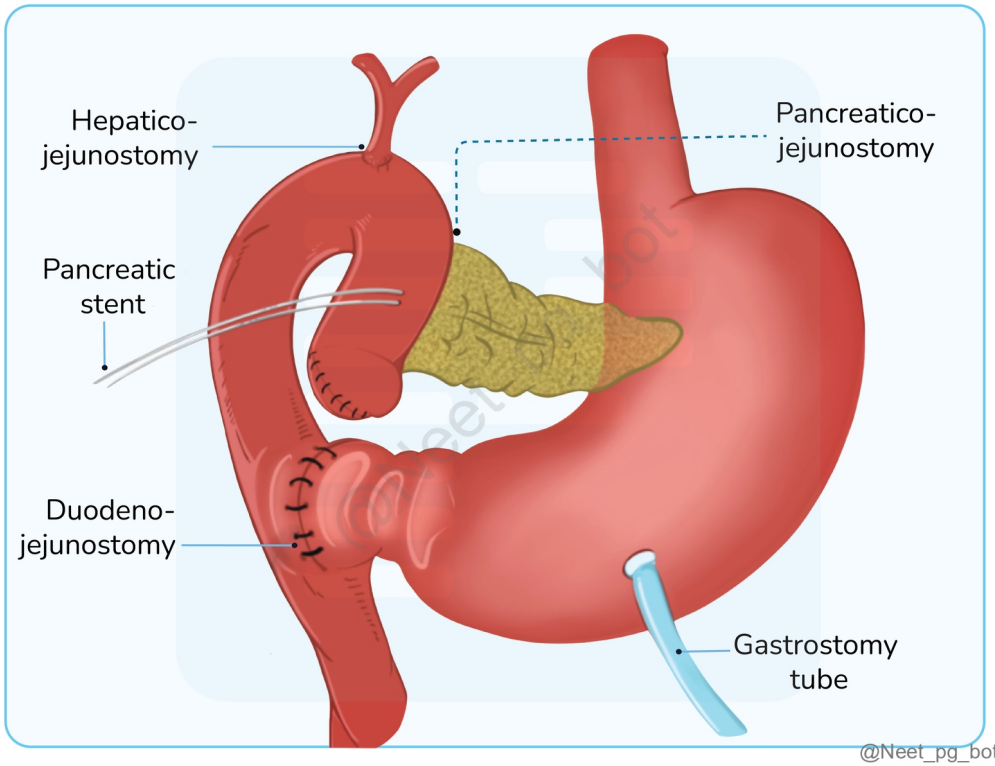
Bailey and Love's Short Practice of Surgery, 28th Edition, Page 1244

SRB’s Manual of Surgery, 6th Edition, Pages 634, 636.

↑ *Back to this question in Part A*

@Neet_pg_bot

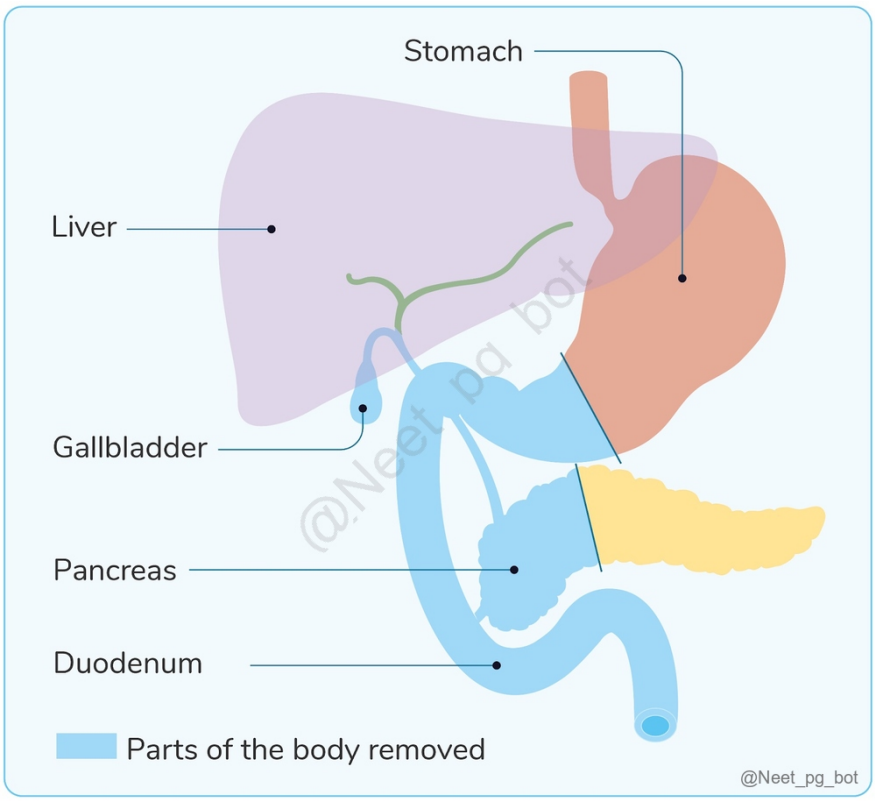


Q29: The following procedure is performed for the management of? (Q855692)

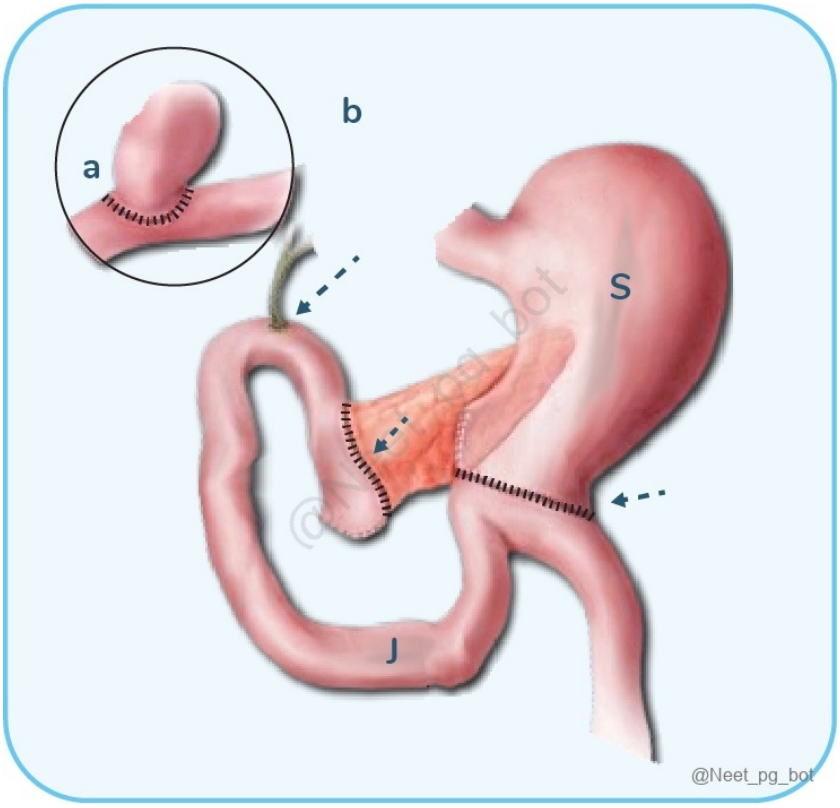
A. Advanced gastric carcinoma

B. Gallbladder carcinoma

C. Distal cholangiocarinoma



D. Chronic calcific pancreatitis



Correct Answer: C. Distal cholangiocarinoma

Explanation: The given image depicts the Pylorus Preserving Whipple’s Procedure (Pancreaticoduodenectomy) , which is used in the management of distal cholangiocarcinoma. Structures removed Head of the pancreas, the first part of the small intestine (duodenum), the gallbladder, and a portion of the bile duct. Types • Pylorus-Preserving Whipple Procedure • Non–Pylorus-Preserving Whipple Procedure Indications Pancreatic Cancer: Commonly treated with Whipple if cancer is localised to the head of the pancreas. Chronic Pancreatitis: when uncontrolled by medical management. Tumors in Pancreas/Surrounding Areas: Includes duodenum, distal bile duct (distal

cholangiocarcinoma), and ampulla of Vater. (Option C) Procedure Steps Tumor Assessment: Explore the abdomen to assess tumor size, location, and spread. Resection: Remove the head of the pancreas, duodenum, gallbladder, and part of the bile duct; this may include partial stomach resection. Lymph Node Dissection: Remove and examine nearby lymph nodes. {{caption_text}} Reconstruction Pancreaticojejunostomy: Connect the remaining pancreas to the jejunum. Hepaticojejunostomy: Connect common bile duct to the jejunum. Gastrojejunostomy: Connect stomach to jejunum. Anastomosis Principles Tension-Free Connection: Achieve mucosa-to-mucosa connection for healing. Order of Anastomoses: Pancreaticojejunostomy → Hepaticojejunostomy → Gastrojejunostomy Stent Placement: May use internal/external stents for small ducts. {{caption_text}} Complications • Pancreatic Fistula: Major issue; managed with somatostatin analogues. • Delayed Gastric Emptying • Bleeding, wound infection • Reoperation, increased mortality • Dumping/Bile Reflux: Common after non-pylorus-preserving Whipple, the pylorus-preserving method has uncertain benefits. Advanced gastric carcinoma (Option A): Treatment depends on tumour location. For proximal tumours, extended gastrectomy with D2 lymphadenectomy is done; for middle tumours, total gastrectomy; and for distal tumours, subtotal gastrectomy. The Whipple procedure is specific to pancreaticoduodenal cancers, not gastric carcinoma. Gallbladder carcinoma (Option B): Treatment involves an extended cholecystectomy, which includes removal of the liver segments, gallbladder, and surrounding lymph nodes. The Whipple procedure is not typically used unless the tumour invades the bile duct or pancreas. Chronic calcific pancreatitis (Option D): Treatment involves enzyme supplementation, pain management with NSAIDs and opioids, and procedures like ERCP with stenting or drainage. The Whipple procedure is not the first choice; instead, pancreaticojejunostomy or drainage surgeries are preferred based on the extent of the damage.

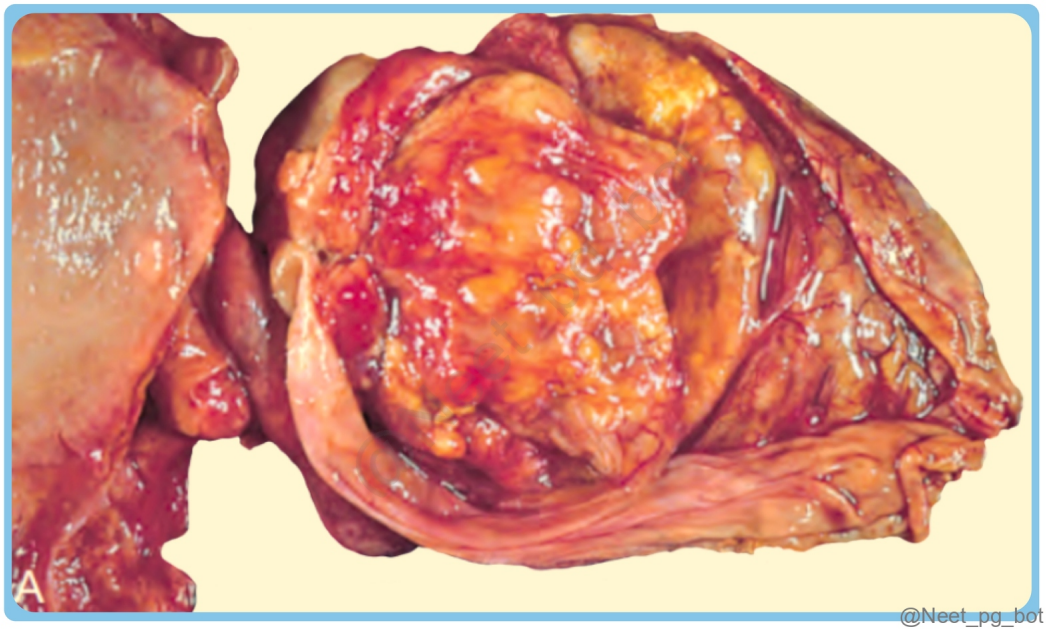
@Neet_pg_bot



Q30: A patient underwent a laparoscopic cholecystectomy for cholelithiasis. A picture of the resected gall bladder is shown below. What is the diagnosis? (Q859620)

A. Gall bladder carcinoma

B. Mixed stone in gallbladder

C. Cholecystitis

D. Choledocholithiasis

Correct Answer: A. Gall bladder carcinoma

Explanation: The given image shows a resected gall bladder with features suggestive of carcinoma, it is typically nodular and infiltrative , causing thickening of the gall bladder wall, which may extend to the entire gall bladder. It is often difficult to differentiate from chronic cholecystitis. Gall bladder carcinoma Risk factors Gallstones, (The risk of developing carcinoma in gallstone disease is 7-10 times higher than in the general population) Porcelain gallbladder, PSC, Abnormal pancreatic-biliary junction Presentation Often indistinguishable from benign gallbladder diseases Symptoms include: Biliary colic Cholecystitis (especially in older individuals) Jaundice (late-stage) Loss of appetite (late-stage) Palpable mass (late-stage) Lab investigation Non-specific indicators: Anemia Leukocytosis Slight increase in transaminases Tumor markers: Elevated CA19-9 Elevated carcinoembryonic antigen (in ~80% of patients) Diagnosis Ultrasonography (USG): Initial diagnosis CT Scans: Thorax, abdomen, and pelvis for confirmation and staging MRI/MRCP: For accurate preoperative staging PET Scans: To identify metastatic disease Staging & Biopsy Preoperative Staging: Crucial to assess local disease extent and rule out distant metastases Percutaneous Biopsy: Guided by radiological imaging for unresectable tumours Laparoscopic Examination: Detects peritoneal or liver metastases that preclude surgery Mixed stone in gall bladder (Option B) refers to gallstones composed of a mixture of cholesterol, bilirubin, and calcium salts. They are normally identified through imaging methods such as ultrasound and may not appear visibly as a carcinoma. Cholecystitis (Option C) refers to inflammation of the gall bladder, often due to gallstones or infection. It can present with acute symptoms like pain, fever, and nausea. Imaging shows gallbladder wall thickening (>3 mm), pericholecystic fluid, & ultrasonographic Murphy's sign. Choledocholithiasis (Option D) refers to the presence of stones in the common bile duct, and its diagnosis typically requires imaging to show stones in the bile duct.

Bailey & Love’s Short Practice of Surgery, 28th Edition, Page 1258

↑ *Back to this question in Part A*

@Neet_pg_bot

Q31: Which of the following is a tumour marker of pancreatic cancer? (Q859616)

A. NSE

B. Alpha-Fetoprotein

C. Ca 15-3

D. CA 19-9

Correct Answer: D. CA 19-9

Explanation: CA 19-9 is a tumour marker that is commonly associated with pancreatic cancer . Pancreatic cancer tumor marker: Carbohydrate Antigen 19-9 (CA19-9) Usage : Establish a baseline level for monitoring. Characteristics : Not highly specific or sensitive. Useful for detecting recurrence if initial levels are raised Tumor markers Tumor marker Associated conditions Alpha-fetoprotein (AFP) (Option B ruled out) Hepatocellular carcinoma (HCC) Hepatoblastoma Yolk sac tumour (endodermal sinus tumour) Nonseminomatous germ cell tumour of testis ↑ AFP: abdominal wall defects, neural tube defects ↓ AFP: associated with trisomy 21, 18, and 13 β-HCG Nonseminomatous testicular germ cell tumours (choriocarcinoma, embryonal cell carcinoma, mixed germ cell tumour, seminoma) Ovarian cancer: choriocarcinoma (gestational trophoblastic disease) Carcinoembryonic antigen (CEA) Colorectal cancer Pancreatic cancer Breast cancer Lung cancer (especially in non-small cell cancers) Gastric cancer Prostate-specific antigen (PSA) Prostate cancer Benign prostatic hyperplasia Prostatitis Calcitonin Medullary thyroid cancer (both sporadic and associated with MEN 1 and MEN 2) Alkaline phosphatase Metastases to bone or liver Paget disease of the bone Placental alkaline phosphatase Seminoma Lactate dehydrogenase Ovarian cancer (dysgerminoma) Testicular germ cell tumours (both seminoma and nonseminoma) Lymphomas Ewing's sarcoma Neuron specific enolase (NSE) (Option A ruled out) Neuroendocrine tumors Small cell lung cancer Carcinoid tumour Neuroblastoma CA 19–9 (Option D) Pancreatic adenocarcinoma Colon cancer Cholangiocarcinoma CA 15–3 and CA 27–29 (Option C ruled out) Breast cancer CA 125 Ovarian carcinoma Other gynecologic malignancies S-100 protein (S100A) and (S100B) Malignant melanoma SMRP Mesothelioma

@Neet_pg_bot

Q32: A young sheep farmer presents to the OPD with pain in the right upper part of the abdomen. Upon examination, there was tenderness and enlargement of the liver. Blood investigations show eosinophilia, elevated liver enzymes, and abdominal ultrasound, as shown below. Which of the following is the most likely diagnosis?

(Q859613)

A. Amoebic liver abscess

B. Hydatid cyst

C. Pyogenic liver abscess

D. Hepatocellular carcinoma

Correct Answer: B. Hydatid cyst

Explanation: The clinical presentation described, along with the ultrasound provided her,e suggests Hydatid disease . The given ultrasound shows a characteristic waterlily sign, indicating a cyst with a detached membrane floating within the cyst cavity, which is a hallmark of stage CE 3. Hydatid cyst Causative agent Echinococcus granulosus Commonly Affected Organs Liver (most common site, about 60-70% of cases) Lungs (second most common site) Other organs (rare but possible): Brain, spleen, kidneys, bones, and peritoneum Clinical Features Asymptomatic Phase: Common due to slow cyst growth. Symptomatic Phase: Liver Involvement: Mostly right lobe; Abdominal pain, hepatomegaly, obstructive jaundice, portal hypertension. Lung Involvement: Cough, chest pain, dyspnea, hemoptysis, pneumothorax. Investigations Imaging Studies: USG is the first-line imaging modality, particularly for liver involvement. Features: Echinococcal cyst wall shows double echogenic lines separated by a hypoechoic layer (double contour) CT Scan MRI Serological Tests: ELISA Immunoblotting Other tests: Casoni Intradermal Test ARC5 Immunoelectrophoresis Amoebic liver abscess (Option A) can cause pain and liver enlargement, they are more common in individuals who have a history of travel to endemic areas and typically present with an abscess in the liver, not a cyst. Pyogenic liver abscess (Option C) are mostly caused by bacterial

infections and are more likely to present with fever, chills, and more localized pain. They would not typically cause the marked eosinophilia seen in this case. Hepatocellular carcinoma (Option D) can cause liver enlargement; it is a malignant tumour and generally doesn't present with the eosinophilia or characteristic ultrasound findings seen in parasitic infections.

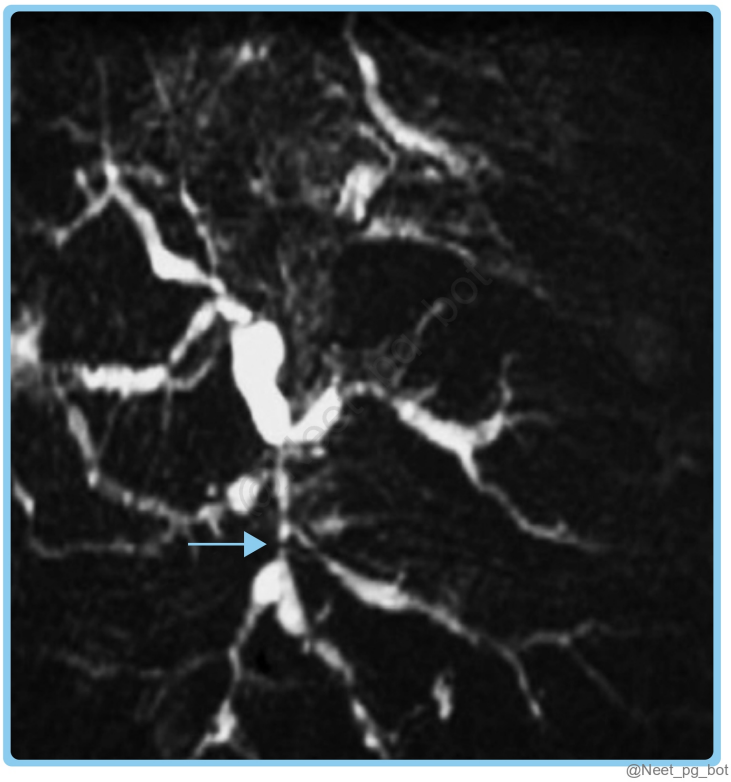
@Neet_pg_bot

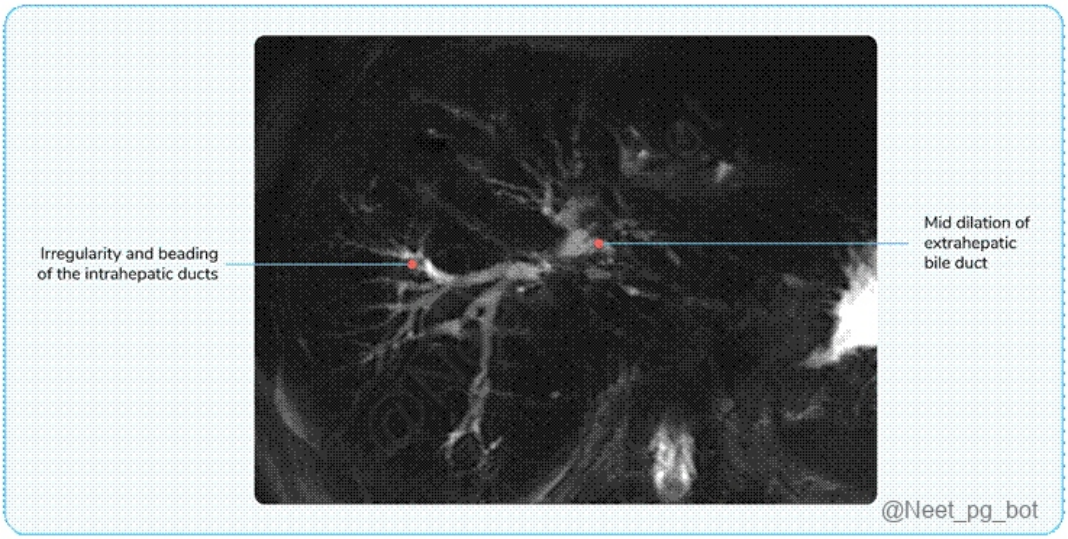


Q33: A 35-year-old man presented with recurrent episodes of fever with chills. The MRCP image is shown below. What is the most likely diagnosis? (Q858489)

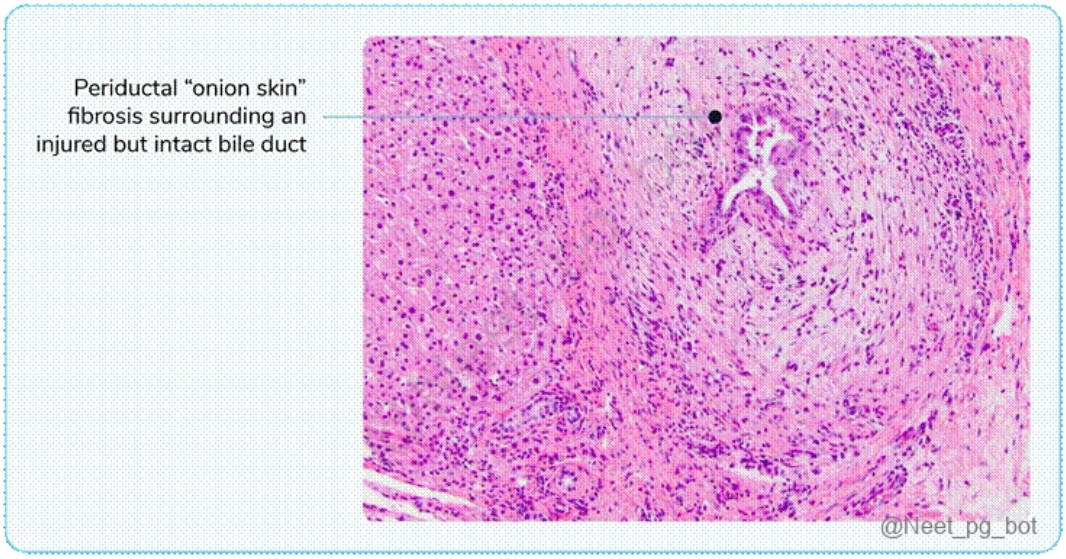
A. Primary sclerosing cholangitis

B. Caroli disease

C. Oriental cholangitis



D. Primary biliary carcinoma



Correct Answer: A. Primary sclerosing cholangitis

Explanation: The patient's age, male predominance, along with MRCP findings of (beading) multiple irregular stricturing and dilatations of the bile duct, suggest Primary Sclerosing Cholangitis . Primary Sclerosing Cholangitis (PSC) PSC is characterised by inflammation and obliterative fibrosis of extrahepatic and large intrahepatic bile ducts, with dilation of preserved segments. Demographics It commonly occurs in individuals aged 30-50 years. Has a male predominance of 2:1. Pathogenesis It suggests an immunologically mediated process supported by circulating autoantibodies and T lymphocytes in the periductal stroma, as well as associations with HLA-B8 and ulcerative colitis . A mix of environmental & genetic factors may trigger bile duct injury. Increased risk of PSC in first-degree relatives indicates a genetic component. Activated T cells from ulcerative colitis mucosa may migrate to the liver, targeting bile duct antigens. Changes in the intestinal microbiome or infections may alter cholangiocytes, causing inflammation. Atypical perinuclear antineutrophil cytoplasmic antibodies (pANCA) are Clinical features Common symptoms include fatigue, pruritus, and jaundice. Nearly 50% of patients are asymptomatic at diagnosis, often identified through elevated serum alkaline phosphatase. Ascending cholangitis, chronic pancreatitis, and chronic cholecystitis may also occur. Fibrosis can progress to cirrhosis over 10-15 years. Characteristic findings ERCP/MRCP shows the beaded appearance of bile ducts {{caption_text}} Biopsy, Early features: Periductal "onion skin" fibrosis & inflammation Portal edema & bile ductular proliferation Later stages show progressive fibrosis leading to biliary cirrhosis and obliterative cholangitis, resulting in "vanishing bile duct syndrome" {{caption_text}} Associated conditions Ulcerative colitis, risk of developing cholangiocarcinoma Complication Lifetime risk of developing cholangiocarcinoma is about 20%. Caroli disease (Option B) is a rare congenital condition characterised by cystic dilatation of the intrahepatic bile ducts . On MRCP, it shows diffuse bile duct dilation with saccular and fusiform features, along with a peripheral funnel-shaped sign. Unlike PSC, Caroli disease typically involves only the intrahepatic ducts, without extrahepatic duct involvement. Oriental cholangitis (Option C) is seen in Asian populations and is often related to hepatolithiasis and biliary tract infections . It doesn’t normally show the beaded appearance on MRCP, which is

more characteristic of primary sclerosing cholangitis . Primary biliary carcinoma (Option D) is also known as Cholangiocarcinoma and presents with obstructive jaundice , but it doesn't usually cause recurrent fever and chills as cholangitis does. On MRCP, it shows focal or diffuse bile duct strictures or mass lesions rather than the beaded appearance.

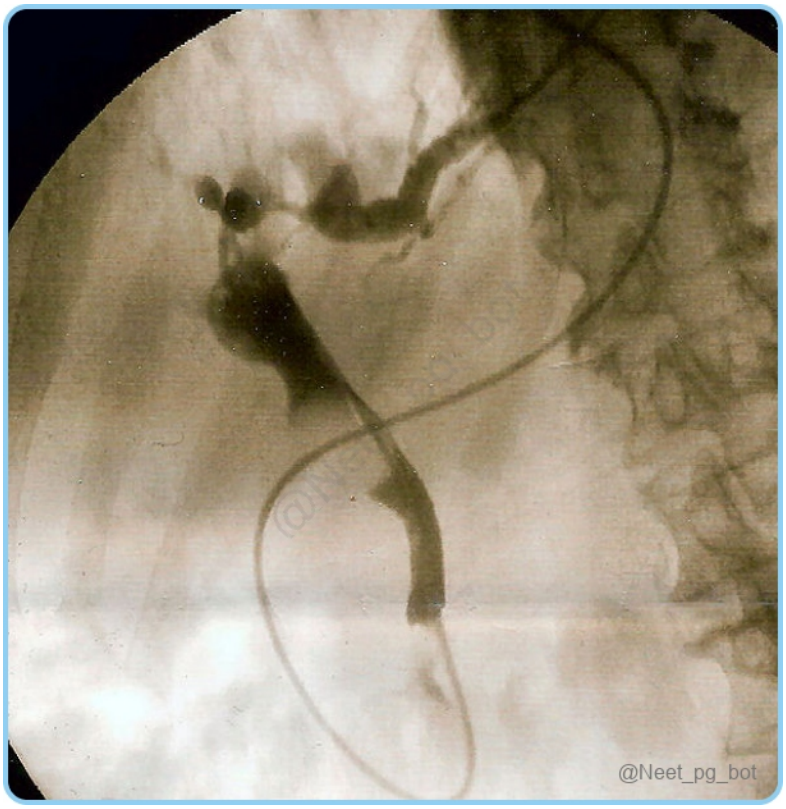
@Neet_pg_bot

Q34: An 80-year-old woman presented with fatigue. Imaging revealed a scleroatrophic gallbladder with impacted stones and a large stone in the common bile duct, causing dilation of the biliary tree. What is the next step in management? (Q855020)

A. Immediately take up the patient for cholecystectomy



B. Endoscopic retrograde cholangiopancreatography

C. Wait and watch

D. CT scan

Correct Answer: B. Endoscopic retrograde cholangiopancreatography

Explanation: The next step in the management of this patient is ERCP , which is used to relieve biliary obstruction caused by the stone in the common bile duct. It is a procedure that combines endoscopy and fluoroscopy to visualise and treat conditions affecting the bile ducts and pancreatic ducts. It allows for the removal of common bile duct stones, dilation of strictures, and placement of stents to relieve biliary obstruction. It has both diagnostic and therapeutic capabilities. Stones up to 12 mm can usually be removed by Endoscopic Retrograde. Choledocholithiasis Investigation Ultrasound: Useful for detecting gallstones and CBD dilation but has limited sensitivity for CBD stones. MRCP: Non-invasive, excellent for visualising biliary tree anatomy and pathology. ERCP: Highly sensitive, both diagnostic and therapeutic for CBD stones. PTC: Used when ERCP is not feasible, such as post-gastrectomy patients or unsuccessful ERCP attempts. EUS: Invasive but accurate for diagnosing choledocholithiasis. Blood Tests: ↑ bilirubin, ↑alkaline phosphatase, and ↑white blood cell count indicate choledocholithiasis and possible complications like cholangitis. Treatment Endoscopic Management: ERCP with sphincterotomy and stone extraction; stenting if necessary. {{caption_text}} Percutaneous Removal: Used when endoscopic access is difficult. Surgery: Options include laparoscopic and open choledocholithotomy, choledochoduodenostomy, and choledochojejunostomy. Complications Cholangitis: Bacterial infection due to obstructed bile flow, leading to fever, chills, right upper quadrant pain, and jaundice. Pancreatitis: Inflammation of the pancreas due to obstruction at the ampulla of Vater. Liver Damage: Prolonged obstruction can cause biliary cirrhosis and liver failure. Biliary Stricture: Chronic inflammation can lead to the narrowing of the bile ducts. Gallstone Ileus: Large gallstone eroding into the intestine, causing mechanical obstruction. Immediately take up the patient for cholecystectomy (Option A): Cholecystectomy is the surgical removal of the gall bladder. When there is an active obstruction of the bile duct, the focus should first be on relieving the biliary obstruction before considering cholecystectomy. Once the obstruction is addressed, the patient can undergo cholecystectomy to prevent future complications. Wait and watch (Option C) is not appropriate in this case because the patient has an impacted stone in the common bile duct with associated dilation of the biliary tree and is symptomatic. If left management is delayed, it could lead to complications. CT scan (Option D) may provide additional information about the extent of the biliary tree dilatation and the presence of other abnormalities, but it does not address the immediate need for intervention to relieve the biliary obstruction.

@Neet_pg_bot

Q35: A 5-year-old child with Wilson's disease is being considered for liver transplantation. Which of the following is not a parameter in the selection criteria for transplantation? (Q855014)

A. Age < 10 years

B. Bilirubin > 300µmol/L

C. AST > 300 IU/L

D. PT > 100 s

Correct Answer: A. Age < 10 years

Explanation: The Nazer score (Wilson Prognostic Index) evaluates prognosis in Wilson's disease–related liver failure using three biochemical parameters only : 1. Serum Bilirubin µmol/L) 2. AST(IU/L) 3. Prothrombin time (seconds) Each parameter is scored from 0–4 , and a total score ≥7 indicates poor prognosis , warranting liver transplantation . Age is not a component of this score. Parameter 0 1 2 3 4 Serum bilirubin (µmol/L) <100 100-149 150-199 200-299 ≥ 300 AST (IU/L) <100 100-149 150- 199 200-299 ≥ 300 PT (s) <20 20-39 40-59 60-79 ≥ 80

Harrison's Principles of Internal Medicine, 21st Edition, Pages 648, 2552.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q36: A patient with recurrent pain in the right hypochondrium, nausea, and vomiting is diagnosed with biliary dyskinesia. Which of the following is least useful in the diagnosis of this condition? (Q856301)

A. CT scan

B. HIDA scan

C. ERCP

D. Endoscopy

Correct Answer: C. ERCP

Explanation: Biliary dyskinesia is a functional disorder of the gallbladder, characterised by abnormal motility, and diagnosis is typically made through tests that evaluate gallbladder function rather than its structure. Diagnosis: It is a diagnosis of exclusion CT Scan is used for detecting structural abnormalities, and can help rule out other non-biliary causes of abdominal pain if the diagnosis is unclear. (Option A ruled out) Endoscopy: It is essential to rule out peptic ulcer disease or common upper GI conditions. (Option D ruled out) A HIDA scan is useful in diagnosis, as it evaluates gallbladder function using a radioactive tracer. (Option B ruled out) ERCP is an invasive and high-risk therapeutic procedure , not a primary diagnostic tool for gallbladder function. It is used with sphincterotomy in non-responders to cholecystectomy.

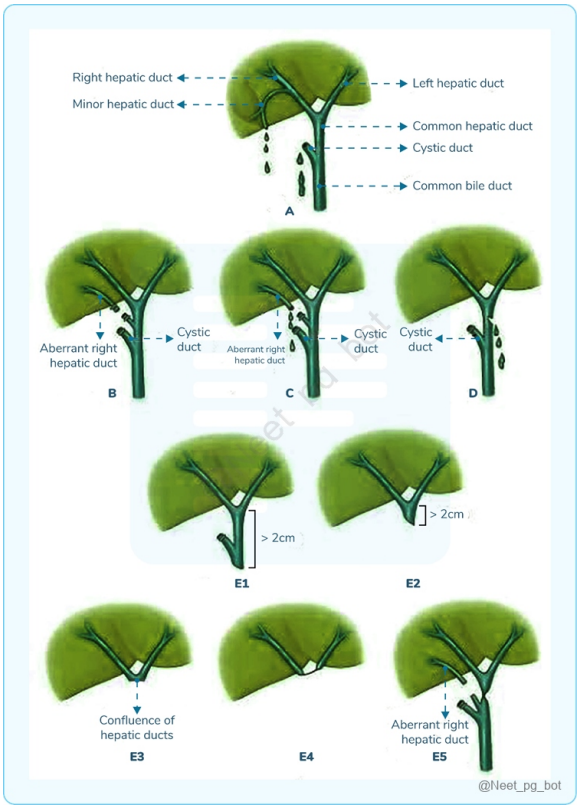
@Neet_pg_bot

Q37: According to Strasberg's classification of bile duct injuries, a bile leak from the cystic duct stump or a minor duct in the gallbladder fossa with continuity to the common bile duct is classified as: (Q856250)

A. Type A

B. Type B



C. Type C

D. Type D

Correct Answer: A. Type A

Explanation: Strasberg Type A bile duct injury refers to a bile leak from the cystic duct stump or a minor accessory bile duct that remains connected to the common bile duct. This is usually a minor injury causing bile leakage without disruption of the main bile duct continuity. It is often managed conservatively or with endoscopic procedures. The Strasberg classification of bile duct injuries Type A (M/C) (Option A) Cystic duct stump leak or leak from sub-vesical duct of Luschka Type B (Option B ruled out) Ligation or occlusion of aberrant right sectoral duct Type C (Option C ruled out) Transection without occlusion of the aberrant right sectoral duct Type D (Option D ruled out) Injury to the lateral wall of the Common hepatic duct Type E E1 to E5 Bismuth classification

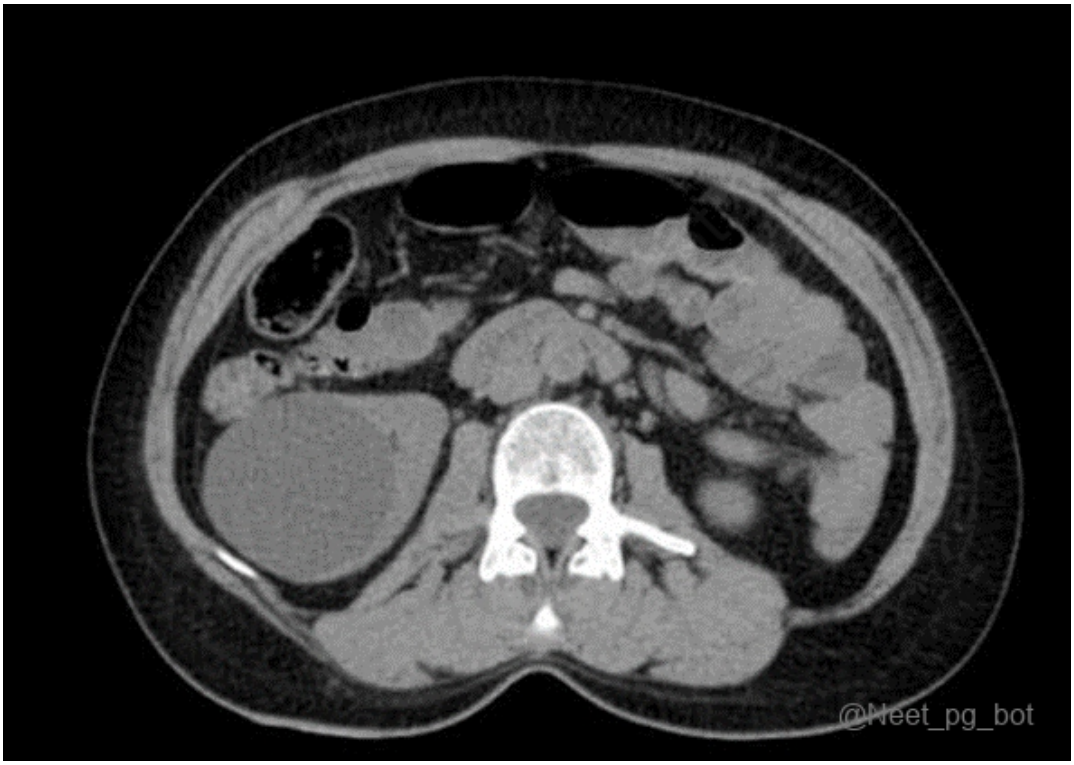
Sabiston Textbook of Surgery, 21st edition, Page 1511

↑ *Back to this question in Part A*

@Neet_pg_bot



Q38: A 62-year-old female undergoes a contrast-enhanced abdominal CT scan for unrelated mild abdominal discomfort. The scan reveals a solitary, 4 cm, round, dark, fluid-filled lesion in the right kidney as shown in the image. The lesion does not change in appearance or become brighter after the administration of intravenous contrast. Based on these findings, what is the most likely diagnosis? (Q844294)

A. Renal cyst

B. Renal tumor

C. ADPKD

D. Hydatid cyst

Correct Answer: A. Renal cyst

Explanation: Correct Option A - Renal cyst: The most likely diagnosis is a Simple Renal Cyst . The CT findings of a solitary, fluid-filled lesion with a paper-thin wall and no internal complexity (septations or calcifications) are classic for this benign condition. Most importantly, the lack of enhancement after contrast administration definitively rules out a solid renal tumor, which would be vascular and become brighter. Incorrect Options: Option B - Renal tumor: A solid renal tumor would appear as a dense mass (not dark and fluid-filled) and would significantly enhance (become brighter) with contrast due to its rich blood supply. A cystic tumor would have thick, irregular walls or enhancing internal septa. Option C - Autosomal Dominant Polycystic Kidney Disease (ADPKD): his condition is characterized by multiple cysts in both kidneys , often causing the kidneys to be enlarged and distorted. The question describes a solitary lesion. Option D - Hydatid cyst: This would typically appear as a complex cyst with a thick, well-defined wall (not paper-thin) and classic internal daughter cysts giving it a multiseptated appearance.

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1469

↑ *Back to this question in Part A*

@Neet_pg_bot

Q39: A patient underwent cholecystectomy, and the histopathology reveals carcinoma with invasion into the muscular layer. What is the next best step? (Q857249)

A. Radiotherapy

B. Chemotherapy

C. Excision of the stump

D. Extended Cholecystectomy

Correct Answer: D. Extended Cholecystectomy

Explanation: T1b lesions refer to gallbladder cancer that invades the muscular layer but not beyond the deeper layers. The next best step is extended cholecystectomy to ensure an R0 resection , which includes removal of the surrounding lymph nodes (e.g., hepatoduodenal, gastrohepatic) and possibly part of the hepatic parenchyma to achieve clear margins. TNM Staging of Gall bladder Carcinoma: Category Description Tis Carcinoma in situ T1 Tumor invades lamina propria or muscle layer T1a Tumor invades lamina propria T1b Tumor invades muscle layer T2 Tumor invades perimuscular connective tissue T2a Tumor does not extend to serosa T2b Tumor extends to serosa, but does not invade the liver T3 Tumor perforates serosa and/or invades liver/adjacent organs T4 Tumor invades main portal vein/hepatic artery/multiple extrahepatic organs Lymph node N0 No regional lymph node metastasis N1 Metastases to 1-3 regional lymph nodes N2 Metastases to >3 regional lymph nodes Metastasis M0 No distant metastasis M1 Distant metastasis Gallbladder Cancer Treatment: Gallbladder Polyp: Adenomatous polyps have malignant potential. Risk factors for malignancy: Single polyp, size >1 cm, age >50 years. Management: Cholecystectomy is recommended for polyps >1 cm. Polyps <1 cm may undergo surveillance, except in PSC (where earlier cholecystectomy is advised). Gallbladder Cancer Post-Cholecystectomy: T1a Lesions (mucosa, lamina propria): Cholecystectomy T1b Lesions (muscular invasion) : Extended cholecystectomy is recommended, especially with vascular, perineural, or lymphatic invasion. T2 Lesions (past muscularis): Radical cholecystectomy with lymph node removal as more than 40% have nodal metastasis. T3/T4 Lesions (extensive): Extended surgery, including liver resection, may be needed for R0 margins.

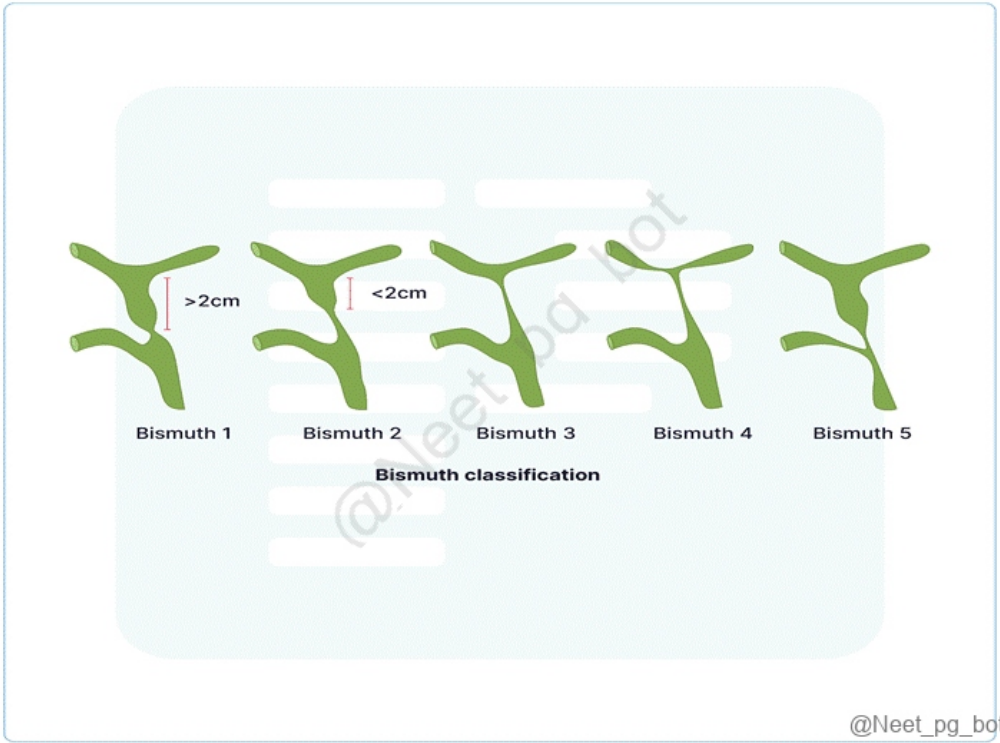
Sabiston Textbook of Surgery, 21st Edition, Page 1518,1519

↑ *Back to this question in Part A*

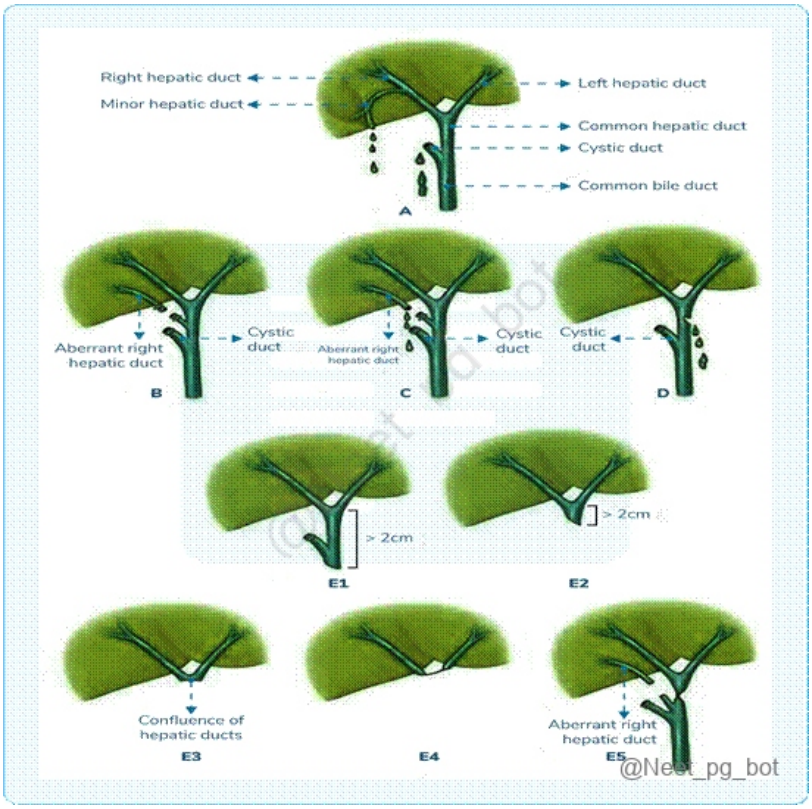
@Neet_pg_bot

Q40: Which classification system is used for bile duct injury, taking location, injury to the duct, and vessel involvement into account? (Q857247)

A. Bismuth



B. Strasberg



C. Stewart Way

D. Hannover

Correct Answer: D. Hannover

Explanation: The Hannover classification is a comprehensive system for bile duct injuries , particularly post-cholecystectomy, that accounts for: Location of injury Type of duct injury (partial or complete) Presence of vascular injury (e.g., to the right hepatic artery) It provides a more detailed description compared to older systems and is especially useful in surgical planning. Type A : Cystic duct or gallbladder bed leak. Type B : Incomplete or complete stenosis. Type C : Lateral tangential injuries. Type D : Complete bile duct injury with vascular injuries. Type E : Late bile duct stenosis. Bismuth Classification: (Option A) Describes strictures of the biliary system , particularly benign biliary strictures after surgery. It is based solely on the location of the stricture relative to the hepatic duct confluence. Bismuth classification for biliary strictures Type I Common hepatic duct stump >2cm Stricture is Low Type II Common hepatic duct stump <2cm Stricture is mid Type III Hilar stricture with intact confluence Stricture is high Type IV Hilar stricture with destroyed confluence Type V Stricture involving aberrant right sectoral duct with or without stricture of common hepatic duct Strasberg classification (Option B) divides bile duct injuries into five main classes: Type A (M/C) Cystic duct stump leak or leak from sub-vesical duct of Luschka Type B Ligation or occlusion of aberrant right sectoral duct Type C Transection without occlusion of the aberrant right sectoral duct Type D Injury to the lateral wall of the Common hepatic duct Type E E1 to E5 Bismuth classification {{caption_text}} Stewart-Way Classification (Option C): Focuses on mechanisms of injury and surgeon-related errors , useful for root cause analysis rather than guiding surgical repair. Stewart-Way Classification: Class I : Incomplete injury. Class II : Lateral injury with bile leak and stenosis. Class III : Complete transection of the common bile duct (most common, 60%). Class IV : Duct branch injuries with involvement of the right hepatic artery.

@Neet_pg_bot

Q41: Which of the following is not a risk factor for gallbladder cancer? (Q857241)

A. Porcelain Gall Bladder

B. Primary Sclerosing Cholangitis

C. Polyp <10 mm

D. Gallstone >3 cm

Correct Answer: C. Polyp <10 mm

Explanation: Gallbladder polyps smaller than 10 mm are generally not considered a significant risk factor for gallbladder cancer, while other conditions like porcelain gallbladder, primary sclerosing cholangitis, and large

gallstones are associated with an increased risk. Risk Factors For Carcinoma GB Gallstones : 90% of carcinoma cases are associated with gallstones. The risk of developing carcinoma in gallstone disease is 7-10 times higher than in the general population. Relative risk based on stone size: Less than 2 cm: Lower risk 2-3 cm: Relative risk of 2.5 More than 3 cm (Option D) : Relative risk of 10 or more Other Conditions : Choledochal cyst Anomalous pancreaticobiliary duct junction (20%) Gallbladder polyps (more than 1 cm in size, more than 3 in number, or adenomatous polyps) Porcelain gallbladder (Option A): 25% risk of malignant transformation, with 90% being inoperable tumours Primary Sclerosing Cholangitis (Option B) Infections and Inflammatory Conditions : Chronic typhoid carriers Inflammatory bowel disease Hepatitis B and hepatitis C virus infections Other factors: Polypoid lesions (GB polyp) Xanthogranulomatous cholecystitis Nitrosamines Carcinogens

↑ *Back to this question in Part A*

@Neet_pg_bot

Q42: A 45-year-old male presents to the emergency department with severe abdominal pain radiating to the back. Laboratory investigations reveal elevated serum amylase and lipase levels. Which of the following should be avoided in the management of the given condition? (Q860175)

A. Nil per oral

B. Administration of 5% dextrose

C. Parenteral nutrition

D. Early initiation of oral feedings

Correct Answer: B. Administration of 5% dextrose

Explanation: The clinical presentation suggests acute pancreatitis. In managing acute pancreatitis , administration of 5% dextrose should be avoided in the initial phase because it can excessively increase blood glucose levels. Elevated glucose can stimulate the pancreas and worsen the condition by increasing pancreatic activity. This can exacerbate inflammation and further damage the pancreas. Acute pancreatitis: Clinical features: Pain (severe , constant , and often resistant to common analgesics) . In about 50% of patients , the pain radiates to the back , and some patients may find relief by sitting or leaning forward . Nausea and vomiting are usually prominent, and retching may persist even with nasogastric aspiration. Examination findings: Patient's condition: well to severely ill with signs of shock and toxicity . Tachypnea , tachycardia , and hypotension are commonly observed. Mild icterus may suggest biliary obstruction (in gallstone pancreatitis). SIRS may be present Bluish discolouration (Grey Turner’s sign or Cullen’s sign). Abdominal distension due to ileus or ascites is common, and muscle guarding is often present. Diagnosis: Serum amylase level > 3x the normal value is strongly indicative. Serum

lipase is more sensitive and specific than amylase. CECT scan is the gold standard for confirming the diagnosis. Management: Mild cases may be managed with IV fluids (Option C) , analgesics , and antiemetics . Nil per oral: (NPO) is typically advised initially to avoid stimulating the pancreas. Antibiotics are not generally indicated unless there is suspicion of infection Management of severe cases: Admit to intensive care or a high-dependency unit for close monitoring. Aggressive fluid resuscitation is critical, guided by vital signs, urine output, and central venous pressure. Oxygen supplementation and serial blood gas analysis . If nutritional support is necessary, enteral feeding via nasogastric tube is preferred over parenteral nutrition. (Option D) Management of specific complications: Antibiotics may be indicated if cholangitis or other infections are suspected. Prophylactic antibiotics should not exceed 14 days . If gallstone pancreatitis is suspected and there is biliary obstruction , ERCP should be performed within 72 hours . Complications: Shock , arrhythmias , ARDS (acute respiratory distress syndrome), renal failure , and DIC (disseminated intravascular coagulation) . Metabolic derangements like hypocalcemia , hyperglycemia , and hyperlipidemia may occur. Peripancreatic fluid collection , pancreatic abscess , pseudocyst , and pancreatic necrosis . Pleural effusion , pancreatic ascites , and pancreatic haemorrhage (pseudoaneurysm) are also common.

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1272-1274

↑ *Back to this question in Part A*

@Neet_pg_bot

Q43: What is the most common complication of ERCP? (Q860172)

A. Duodenal perforation

B. Cholangitis

C. Hemorrhage

D. Pancreatitis

Correct Answer: D. Pancreatitis

Explanation: Pancreatitis is the most common complication of ERCP, with an incidence of approximately 4.3%. While post-ERCP pancreatitis is typically mild, it can become severe with extensive pancreatic necrosis in some cases. Complications of ERCP: Pancreatitis (Most Common) It can be severe, with extensive pancreatic necrosis Associated with a significant mortality rate Use of per-rectal indometacin/diclofenac to reduce risk Duodenal perforation (Option A) Haemorrhage post-sphincterotomy (Option C) Sepsis Cholangitis (Option B) Sphincter stenosis

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 156

SRB's Manual of Surgery, 6th Edition, Page 625

↑ *Back to this question in Part A*

@Neet_pg_bot

Q44: A newborn presents with jaundice. Biliary atresia is suspected when jaundice is persistent and exceeds? (Q860450)

A. 2 days

B. 2 weeks

C. 2 months

D. 2 years

Correct Answer: B. 2 weeks

Explanation: Biliary atresia is a serious condition that causes bile ducts to become obstructed or absent, leading to cholestasis and liver damage. In newborns, jaundice that persists beyond 2 weeks is a key clinical sign of biliary atresia, as physiological jaundice typically resolves within the first 1-2 weeks of life. Extra-Hepatic Biliary Atresia: Also known as Non-Cystic Obliterative Cholangiopathy. Characterised by complete obliteration of extrahepatic bile ducts and intrahepatic ducts at the hilum. Typically appear by 2 to 6 weeks of age Jaundice (yellowish coloration of skin and sclera) Abnormally pale stools Dark urine Commonly associated with polysplenia or asplenia Investigations: Liver Function Tests: Increased conjugated bilirubin. Markers of cholestasis: 5' nucleotidase Alkaline phosphatase (ALP) GGT (Gamma-glutamyl transferase): Normal: Up to 40 U/L 4x elevation: Intrahepatic causes 10x elevation: Extrahepatic causes Exception: Low in PFIC type I and II Ultrasound: High-frequency USG (HUS) for neonatal cholestasis. Fasting USG is the gold standard when biliary atresia is suspected. Characteristic findings: Triangular cord sign (hyperechoic areas indicating fibrous/atretic bile duct) Non-visualized gallbladder/micro gallbladder/gallbladder ghost Radionucleotide Study: HIDA Scan (Hepatobiliary scan with Tc labelled imino-di-acetic acid): Used as a screening test. Decreased tracer excretion due to obstruction Phenobarbitone loading/priming (5 days) to improve tracer uptake Used as a screening test, not specific Best Investigation: Liver biopsy: IOC for confirming diagnosis. Surgical Management: Temporary procedure: Kasai procedure/hepaticojejunostomy Definitive management: Liver transplantation Kasai Procedure: Temporary procedure Creates communication between the liver and jejunum for bile drainage Should be performed within 8 weeks after birth

@Neet_pg_bot

Q45: A 45-year-old alcoholic patient presents to the ER with severe abdominal pain radiating to the back. Blood investigations reveal increased serum amylase and lipase levels. What is the most likely diagnosis? (Q860443)

A. Peptic ulcer disease

B. Acute pancreatitis

C. Acute cholecystitis

D. Pyogenic liver abscess

Correct Answer: B. Acute pancreatitis

Explanation: The patient's history of alcohol consumption, along with severe abdominal pain radiating to the back and significantly elevated serum amylase and lipase levels , points strongly toward acute pancreatitis. Acute pancreatitis: Clinical features: Pain (severe , constant , and often resistant to common analgesics) . In about 50% of patients , the pain radiates to the back , and some patients may find relief by sitting or leaning forward . Nausea and vomiting are usually prominent, and retching may persist even with nasogastric aspiration. Examination findings: Patient's condition: well to severely ill with signs of shock and toxicity . Tachypnea , tachycardia , and hypotension are commonly observed. Mild icterus may suggest biliary obstruction (in gallstone pancreatitis). SIRS may be present Bluish discolouration (Grey Turner’s sign or Cullen’s sign). Abdominal distension due to ileus or ascites is common, and muscle guarding is often present. Diagnosis: Serum amylase level > 3x the normal value is strongly indicative. Serum lipase is more sensitive and specific than amylase. CECT scan is the gold standard for confirming the diagnosis. Management: Mild cases may be managed with IV fluids , analgesics , and antiemetics . Nil per os (NPO) is typically advised initially to avoid stimulating the pancreas. Antibiotics are not generally indicated unless there is suspicion of infection Management of severe cases: Admit to intensive care or a high-dependency unit for close monitoring. Aggressive fluid resuscitation is critical, guided by vital signs, urine output, and central venous pressure. Oxygen supplementation and serial blood gas analysis . If nutritional support is necessary, enteral feeding via nasogastric tube is preferred over parenteral nutrition. Management of specific complications: Antibiotics may be indicated if cholangitis or other infections are suspected. Prophylactic antibiotics should not exceed 14 days . If gallstone pancreatitis is suspected and there is biliary obstruction , ERCP should be performed within 72 hours . Complications: Shock , arrhythmias , ARDS (acute respiratory distress syndrome), renal failure , and DIC (disseminated intravascular coagulation) . Metabolic derangements like hypocalcemia , hyperglycemia , and hyperlipidemia may occur. Peripancreatic fluid collection , pancreatic abscess , pseudocyst , and pancreatic necrosis . Pleural effusion , pancreatic ascites , and pancreatic haemorrhage (pseudoaneurysm) are also common. Incorrect Options: Peptic ulcer disease (Option A) typically presents with epigastric pain, but it doesn't radiate to the back & does not cause elevated amylase and lipase levels. Acute cholecystitis (Option C) presents with right upper quadrant abdominal pain, often with fever and nausea, but it is not typically associated with marked increases in amylase and lipase. This condition would usually show elevated liver enzymes and bilirubin. Pyogenic liver abscess (Option D) can present with fever and abdominal pain, but it does not typically cause significant increases in amylase and lipase. This condition would be more likely to show abnormal liver function tests and may be associated with other findings like fever or jaundice.

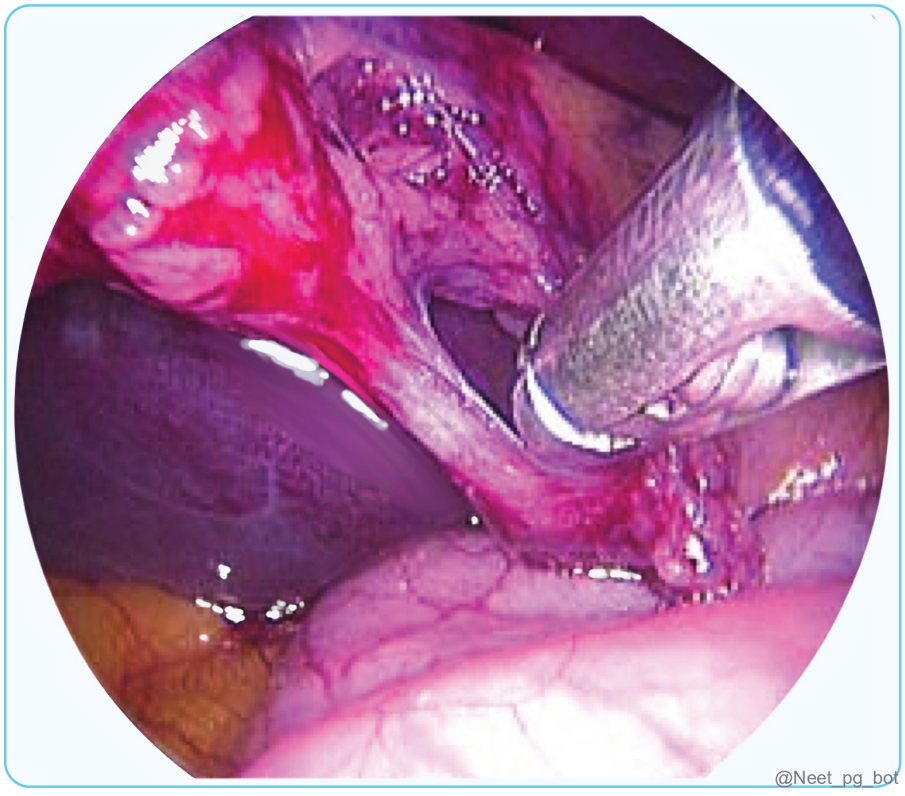
@Neet_pg_bot

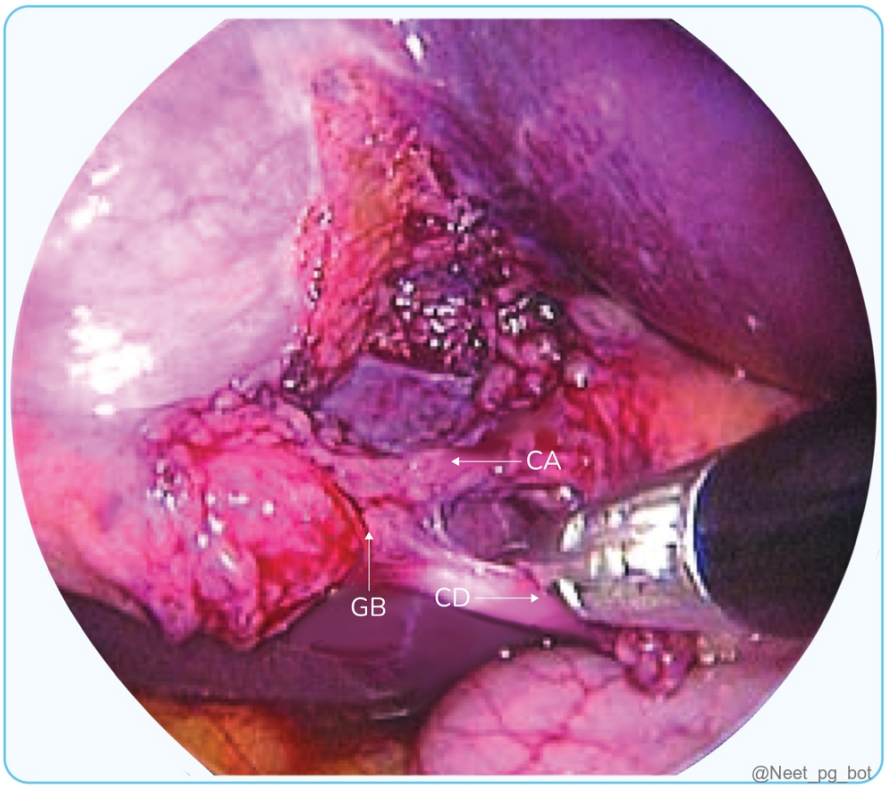


Q46: A patient underwent laparoscopic cholecystectomy. Identify the marked structure in the image. (Q860420)

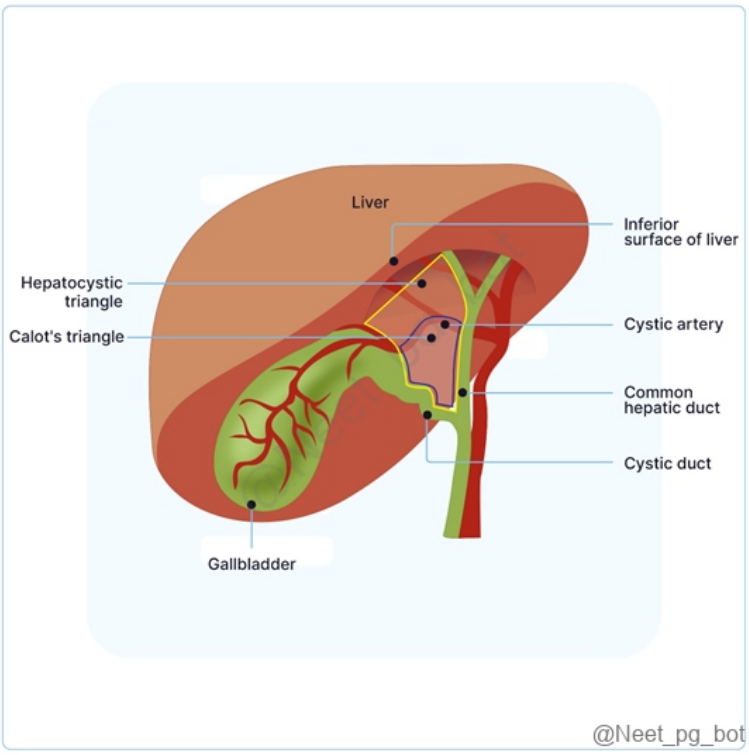
A. Cystic artery

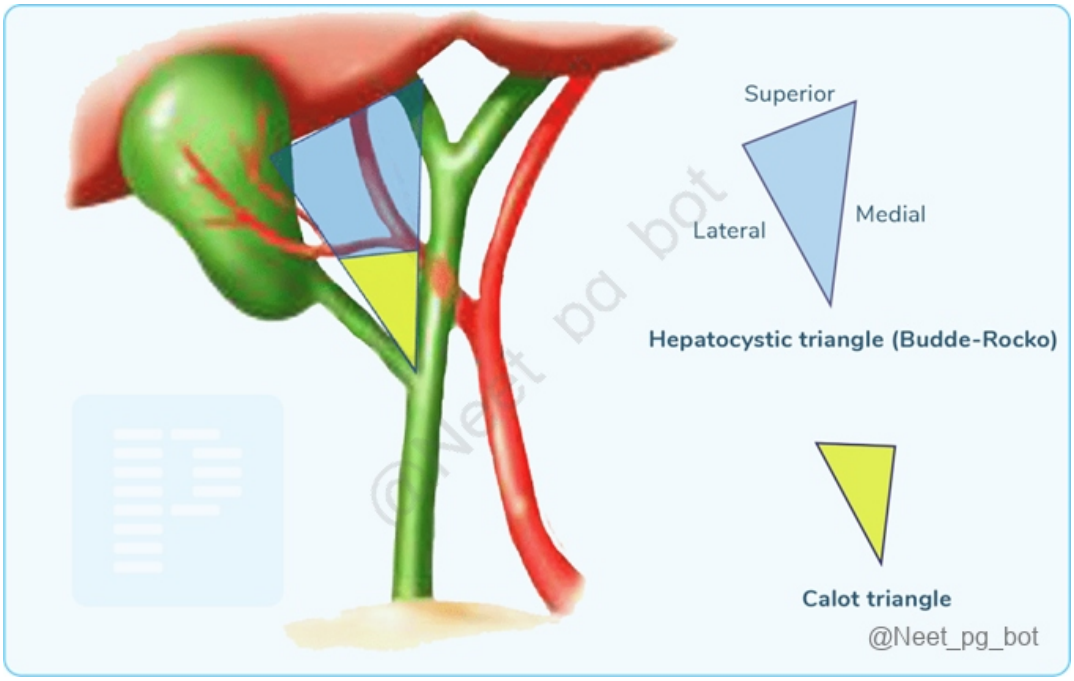
B. Cystic duct

C. Right hepatic artery

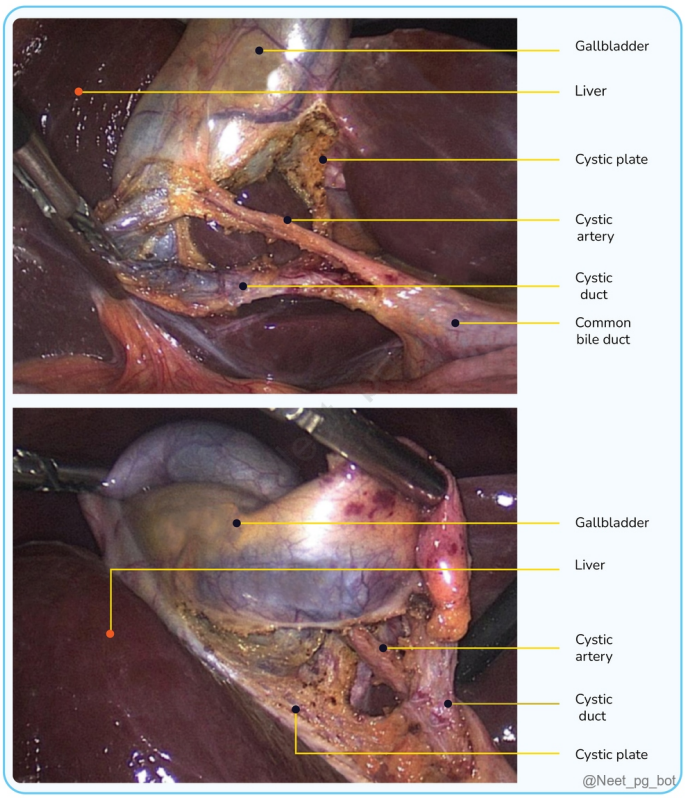


D. Hepatic duct





Correct Answer: B. Cystic duct



Explanation: The marked structure is a Cystic duct. {{caption_text}} GB - Gall Bladder CA - Cystic Artery CD - Cystic Duct Calot's triangle, also known as the cystohepatic triangle, is an important anatomical area during gallbladder surgery. The boundaries of Calot's triangle are defined by: Cystic duct (lateral boundary) Common

hepatic duct (medial boundary) The inferior surface of the liver (superior boundary) The contents of Calot's triangle typically include the cystic artery, which supplies blood to the gallbladder, and the cystic lymph node (Lund’s node). Identification of these structures is crucial during a cholecystectomy to avoid accidental injury to the biliary or vascular systems. Note: The term "hepatocystic triangle" is often used interchangeably with Calot's triangle. It emphasizes the inclusion of the liver's inferior surface as part of the boundaries, along with the cystic duct and the common hepatic duct. {{caption_text}}

@Neet_pg_bot

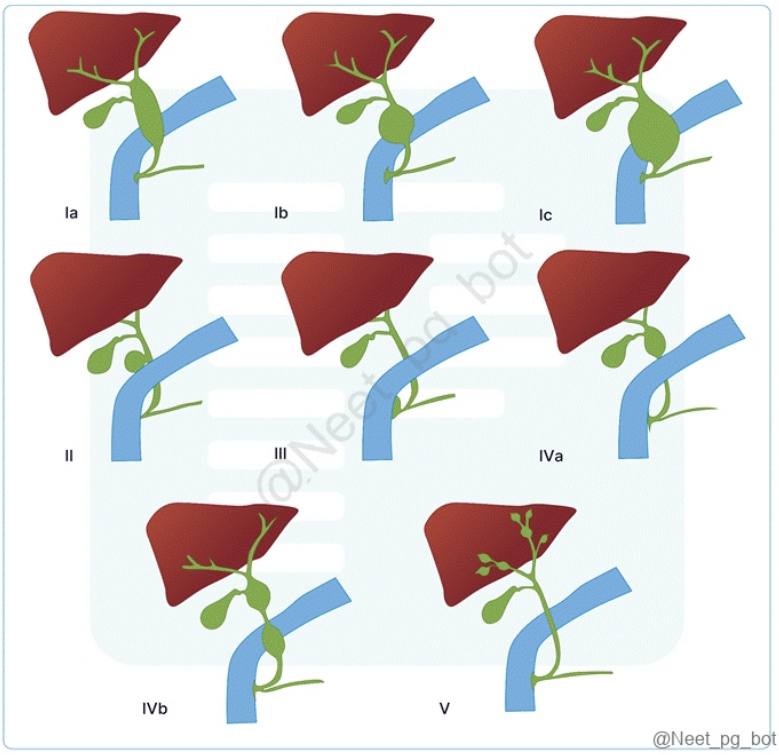
Q47: Which of the following statements about Choledochal Cyst is incorrect? (Q857250)

A. Increased risk of cholangiocarcinoma



B. The cyst can be opened directly and drained

C. Todani classification is used for grading

D. Associated with abnormal Bilio-Pancreatic Junction

Correct Answer: B. The cyst can be opened directly and drained

Explanation: Choledochal cysts should not be simply drained. Direct drainage can lead to complications, including infection and further dilation. The proper treatment usually involves surgical resection of the cyst and reconstruction of the bile duct. Choledochal Cyst: Congenital dilatations of the intra- and/or extrahepatic biliary system can present at any age. In choledochal cysts, there is an abnormal junction between the bile duct and the pancreatic duct (Option D) , leading to the reflux of pancreatic enzymes into the common bile duct (CBD). The presence of these enzymes in the CBD causes its dilation. Clinical features : Patients may present with jaundice, fever, abdominal pain, and a right upper quadrant mass. Pancreatitis is a frequent presentation in adults. Approximately 60% of cases are diagnosed before the age of 10 years. The classical triad of jaundice, right upper quadrant mass, and abdominal pain is present in only a minority of patients (0–17%) Patients have an increased risk of developing malignancies like: Cholangiocarcinoma (Option A) Squamous cell carcinoma Bile duct sarcoma Hepatoma Pancreatic carcinoma Gallbladder carcinoma Todani modification of Alonso- Lej classification (Option C) Type I Ia Cystic dilation of the extrahepatic bile duct (Most common) Ib Focal segmental dilation of extrahepatic bile duct Ic Fusiform dilation of extrahepatic bile duct Type II Diverticular dilation of extrahepatic bile duct Type III Dilatation of intraduodenal part of bile duct (choledochocele) Type IV IV a Dilatation of both intra and extrahepatic bile duct IV b Multiple cysts involving extrahepatic bile duct only Type V Multiple cysts involving intrahepatic bile duct only (Caroli's disease) Type Treatment Type I Complete excision, cholecystectomy, Roux-en-Y hepaticojejunostomy Type II Complete excision Type III Transduodenal excision or sphincteroplasty, endoscopic drainage may suffice Type IVa Tailored to anatomy: extrahepatic cysts treated like Type I; partial hepatectomy and reconstruction for localised intrahepatic involvement Type IVb Managed like Type I Type V (Caroli disease) Resection for unilobar disease; liver transplantation for diffuse disease

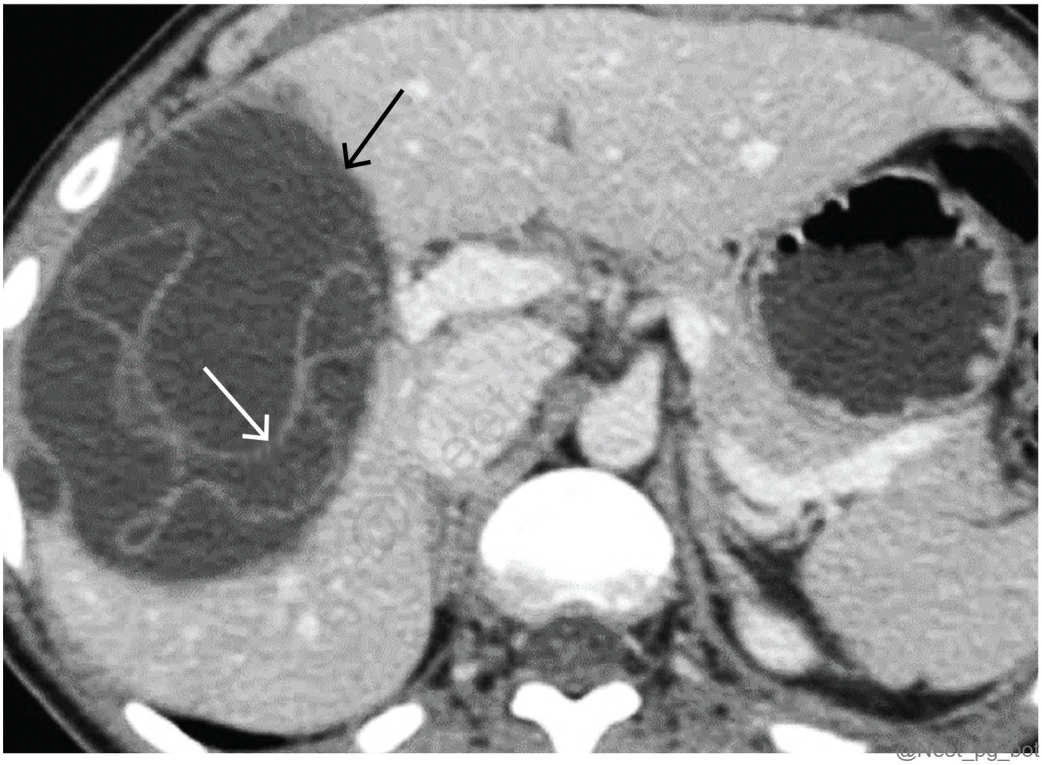
@Neet_pg_bot



Q48: Identify the stage of disease given in the image. (Q844272)

A. Type 1

B. Type 2

C. Type 3

D. Type 4

Correct Answer: B. Type 2

Explanation: Correct Option B - Type 2: The cyst becomes more complex, often with the presence of daughter cysts, membranes, or debris. The cyst wall may show signs of rupture or detachment. Imaging Characteristics: A mixed pattern with daughter cysts, floating membranes ("water lily sign"), or internal debris. This stage indicates an ongoing degenerative process of the cyst, with possible partial rupture. WHO-IWGE staging Gharbi classification Description Stage CE1 Type I Unilocular anechoic cystic lesion with double line sign Active CE2 Type III Multiseptated, "rosette-like" "honeycomb" cyst Active CE3 A Type II Cyst with detached membranes

(water-lily sign) Transitional CE3 B Type III Cyst with daughter cysts in solid matrix Transitional CE4 Type IV Cyst with heterogenous hypoechoic/hyperechoic contents. No daughter cysts Inactive CE5 Type V Solid cyst with calcified wall Inactive Incorrect Options: Option A - Type 1: The cyst is small and filled with clear fluid, with no visible daughter cysts or debris. This represents the early, uncomplicated stage. Imaging Characteristics: A purely cystic lesion with smooth walls, no internal septations, or calcifications. Option C - Type 3: The cyst begins to mature, showing internal septations or a "honeycomb" appearance as daughter cysts start forming within the main cyst. Imaging Characteristics: Multiple small cysts within the main cyst, leading to a multilocular appearance. The cyst walls remain intact, and the fluid is still clear. Option D - Type 4: The cyst shows evidence of complete degeneration, with a solidified appearance. The cyst is often calcified and may no longer be active. Imaging Characteristics: A dense, calcified mass with no visible fluid or daughter cysts. The cyst is inactive or dead.

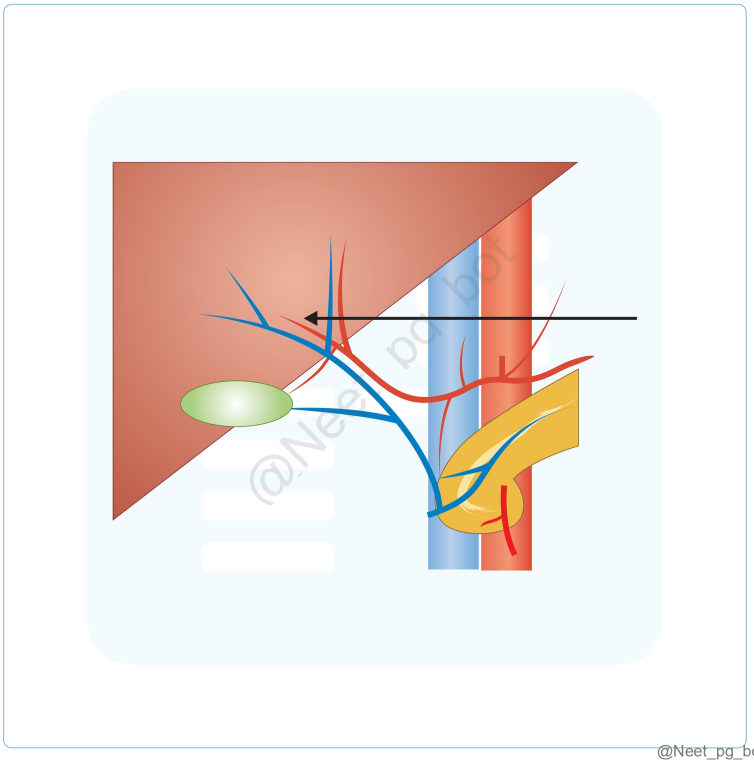
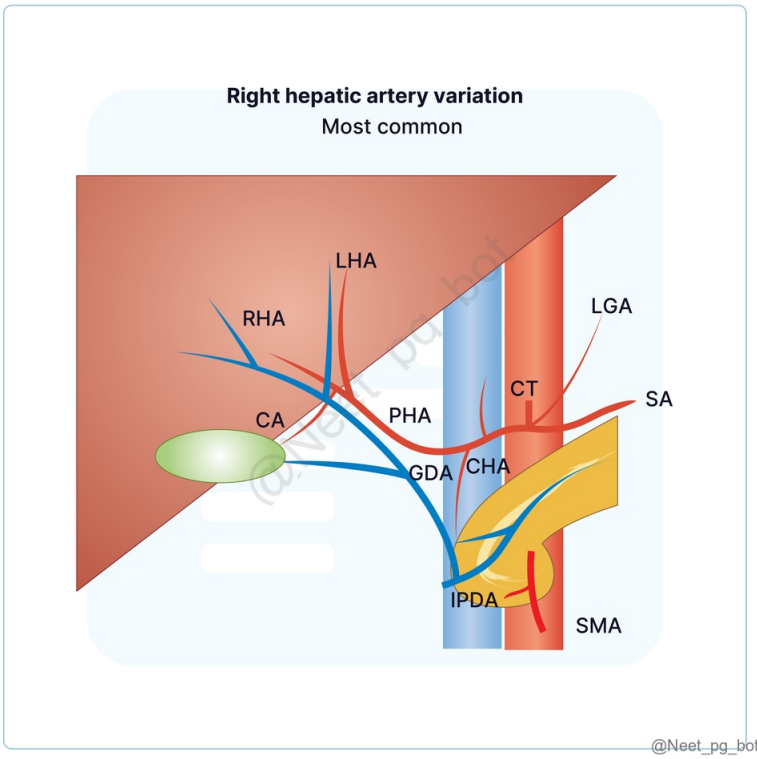
@Neet_pg_bot



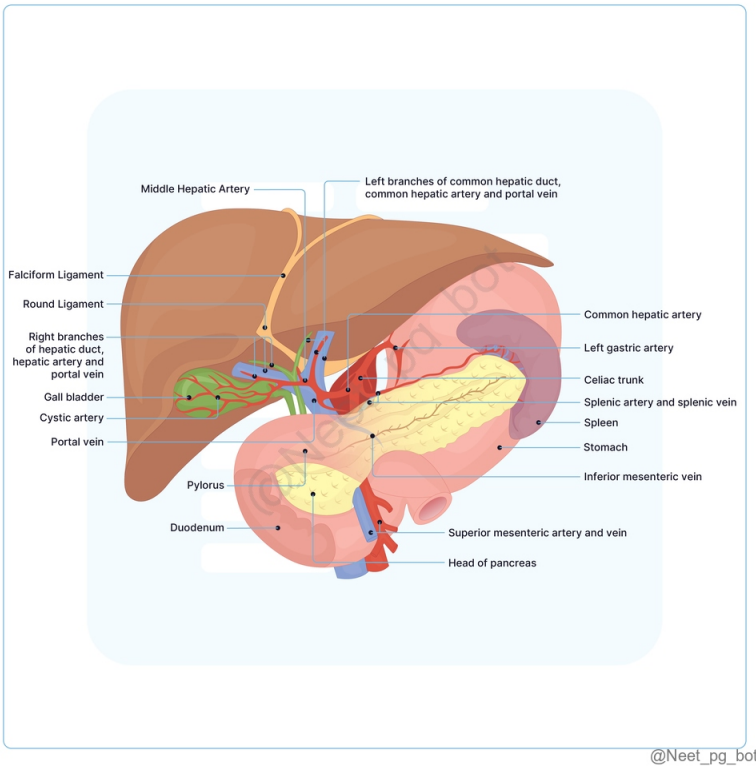
Q49: Identify the marked structure? (Q852723)

A. Cystic artery

B. Right Hepatic artery



C. Hepatic duct



D. Cystic duct

Correct Answer: B. Right Hepatic artery

Explanation: Course and Branching: The Right Hepatic Artery (RHA) originates from the Proper Hepatic Artery and courses toward the right lobe of the liver . It runs behind the common hepatic duct and gives rise to the Cystic Artery , which supplies the gallbladder. Image-Based Identification: The marked structure is seen branching toward the right lobe of the liver , which aligns with the usual anatomical location of the Right Hepatic Artery . Its size and direction distinguish it from smaller branches such as the Cystic Artery . Right Hepatic Artery Feature Description Origin Proper Hepatic Artery (branch of Common Hepatic Artery) Course Runs behind the common hepatic duct and ascends toward the right lobe of the liver Branches Cystic artery (to gallbladder), Segmental branches to liver Function Supplies the right lobe of the liver and gallbladder Clinical Importance Injury during cholecystectomy can lead to hemorrhage or hepatic ischemia Cystic Artery (Option A): Incorrect because the cystic artery is a smaller branch of the RHA that supplies the gallbladder, whereas the marked structure is larger and directed toward the liver. Hepatic Duct (Option C): Incorrect because the hepatic duct is a biliary structure that transports bile, not an artery. Cystic Duct (Option D): Incorrect because the cystic duct connects the gallbladder to the bile duct system and does not match the marked arterial structure.

@Neet_pg_bot

Q50: Which of the following is the classical triad of acute cholangitis? (Q852707)

A. Pain, jaundice, fever

B. Pain, jaundice, shock

C. Fever, jaundice, ↑WBC

D. Pain, ↑WBC, ↑Bilirubin

Correct Answer: A. Pain, jaundice, fever

Explanation: Pain, jaundice, fever - this triad, known as Charcot's triad- indicates cholangitis. Cholangitis Aetiology Often due to obstruction in the biliary tree, leading to bacterial infection by organisms like Klebsiella, E. coli, Enterobacter, Pseudomonas, and Citrobacter species. Symptoms Charcot's triad - pain, jaundice, fever Additional tenderness in the epigastrium and right hypochondrium is common. Severe Form: Reynolds pentad - persistent pain, fever, jaundice, shock, and altered mental status Indicates acute obstructive suppurative cholangitis. Lab Findings Elevated white blood cell count, bilirubin, and alkaline phosphatase levels. Chronic cases may show lobar or segmental atrophy or hypertrophy. Recurrent Pyogenic Cholangitis More common in East Asian populations, caused by intrahepatic stones and infections Risk factors include parasitic infections like Clonorchis sinensis and Ascaris lumbricoides. Pain, jaundice, shock (Option B): This option is incorrect as shock is not part of Charcot's triad but is part of Reynolds's pentad. Fever, jaundice, ↑WBC (Option C): ↑WBC, although it does occur in cholangitis, is not a component of Charcot's triad. Pain, ↑WBC, ↑Bilirubin (Option D): ↑Bilirubin, although it does occur in cholangitis, is not a component of Charcot's triad.

@Neet_pg_bot

Q51: A 20-year-old male presents with acute epigastric pain and fever. He has a history of cholelithiasis. On examination, abdominal guarding and rigidity are noted. Laboratory results show elevated serum amylase and lipase levels, along with leukocytosis. What is the most likely diagnosis for his condition? (Q853061)

A. Serum amylase remains elevated even after 30 days of resolution of acute pancreatitis

B. ■■■> 75 per cent of patients present with hypercalcemia

C. Serum lipase is more specific than serum amylase

D. Increase in the level of serum lipase is directly proportional to the severity

Correct Answer: C. Serum lipase is more specific than serum amylase

Explanation: The most likely diagnosis here is acute pancreatitis , given the acute epigastric pain, fever, history of cholelithiasis, abdominal guarding, rigidity, & elevated serum amylase and lipase levels along with leukocytosis. Serum lipase is indeed more specific than amylase for diagnosing acute pancreatitis. While both enzymes are elevated in pancreatitis, lipase tends to remain elevated longer and is more directly associated with pancreatic damage. (Option A ruled out) Serum amylase levels can also be elevated in other acute abdominal conditions such as perforation, volvulus, and torsion. If amylase remains elevated for more than a few weeks, it could indicate a chronic condition or other non-pancreatic diseases. > 75 per cent of patients present with hypercalcemia (Option B) : Hypercalcemia is not a common feature of acute pancreatitis. In fact, hypocalcemia is more commonly observed in acute pancreatitis, which happens due to the precipitation of calcium salts in the pancreatic tissue because of the saponification of fat. Increase in the level of serum lipase is directly proportional to the severity (Option D) : Lipase and amylase do not directly correlate with the severity of the disease, and n one of the commonly used scoring systems for grading pancreatitis directly rely on the values of amylase or lipase to assess the severity of the condition.

SRB’s Manual of Surgery, 6th Edition, Pages 675 - 680

↑ *Back to this question in Part A*

@Neet_pg_bot

Q52: A patient presents with a 2-year history of anorexia, epigastric pain, jaundice, and itching (pruritis). On examination, the gallbladder is palpable. What is the most likely diagnosis? (Q866482)

A. Gallbladder carcinoma

B. Hepatocellular carcinoma (HCC)

C. Cholelithiasis (gallstones)

D. Ca of the head of the pancreas

Correct Answer: D. Ca of the head of the pancreas

Explanation: Prolonged anorexia, epigastric pain, jaundice, and pruritis with a palpable gallbladder (Courvoisier's sign) indicate chronic biliary obstruction, most commonly caused by carcinoma of the head of the pancreas. CA Pancreas Symptoms: Jaundice secondary to obstruction is the most common symptom Characteristically painless, but may be associated with nausea and epigastric discomfort Pruritus, dark urine and pale stools with steatorrhea Weight loss Signs: Courvoisier's sign - palpable, non-tender gallbladder (Option D) Palpable liver and ascites Diabetes mellitus depending on the location of tumor Gallbladder carcinoma (Option A): Although gallbladder carcinoma can cause jaundice and a palpable gallbladder, it is less common and usually presents with more localized symptoms. Hepatocellular carcinoma (HCC) (Option B) rarely causes biliary obstruction or a palpable gallbladder. Cholelithiasis (gallstones) (Option C) usually causes episodic pain and does not present with a palpable gallbladder or chronic jaundice.

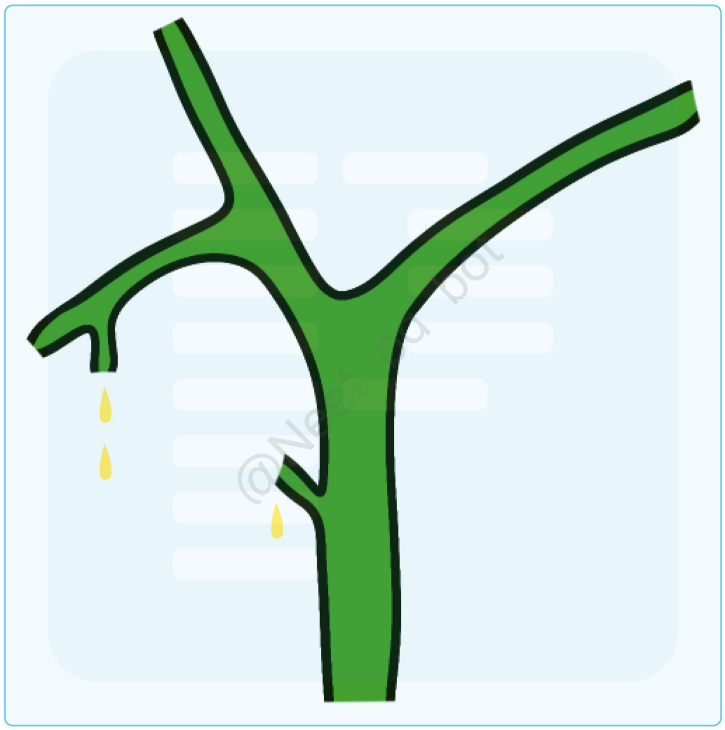
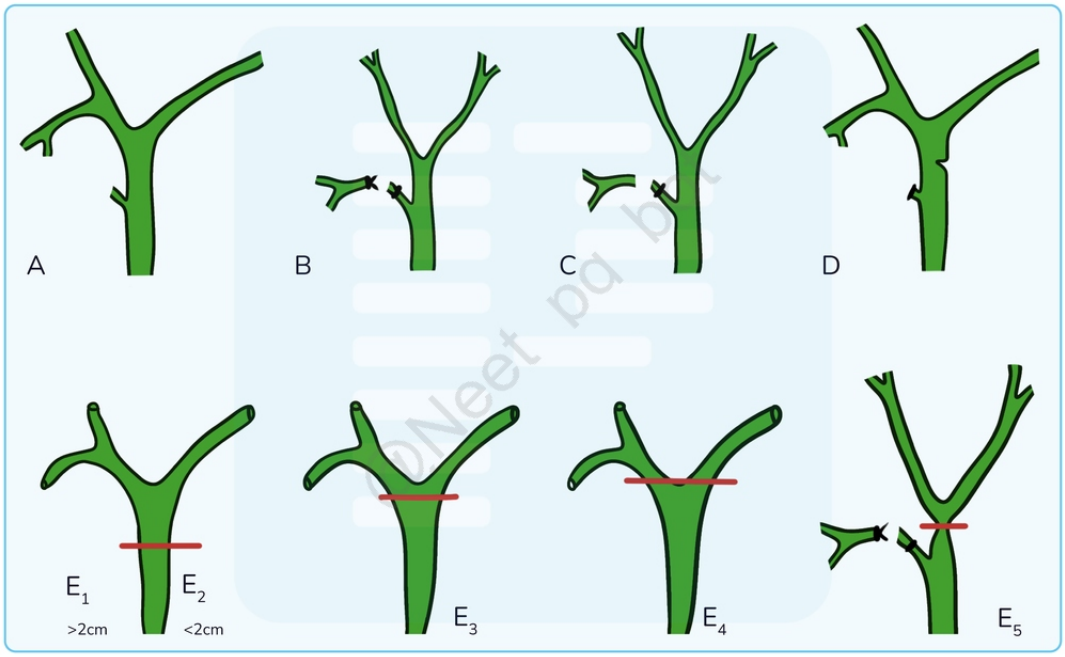
@Neet_pg_bot



Q53: Based on the given image, which type of injury is shown according to the Bismuth-Strasberg classification: (Q866466)

A. Type A

B. Type B



C. Type C

D. Type D

Correct Answer: A. Type A

Explanation: According to the Bismuth-Strasberg classification, the image shows a Type A injury, which involves a cystic duct stump leak or leakage from small ducts in the liver bed, and is the most common type, typically occurring without damage to the major bile ducts. Bismuth classification for biliary strictures Type A Bile leak from cystic duct or liver bed (Option A) Type B Occlusion of the right segmental duct (Option B ruled out) Type C Bile leak from divided right segmental duct (Option C ruled out) Type D Lateral injury to the common hepatic duct (Option D ruled out) Type E E1: Main bile duct injury, more than 2 cm from the confluence E2: Main bile duct injury, less than 2 cm from the confluence E3: Hilar injury with intact confluence E4: Injury involving the confluence; right and left hepatic ducts are separated E5: Injury of aberrant right sectoral duct with simultaneous injury of the main bile duct.

@Neet_pg_bot

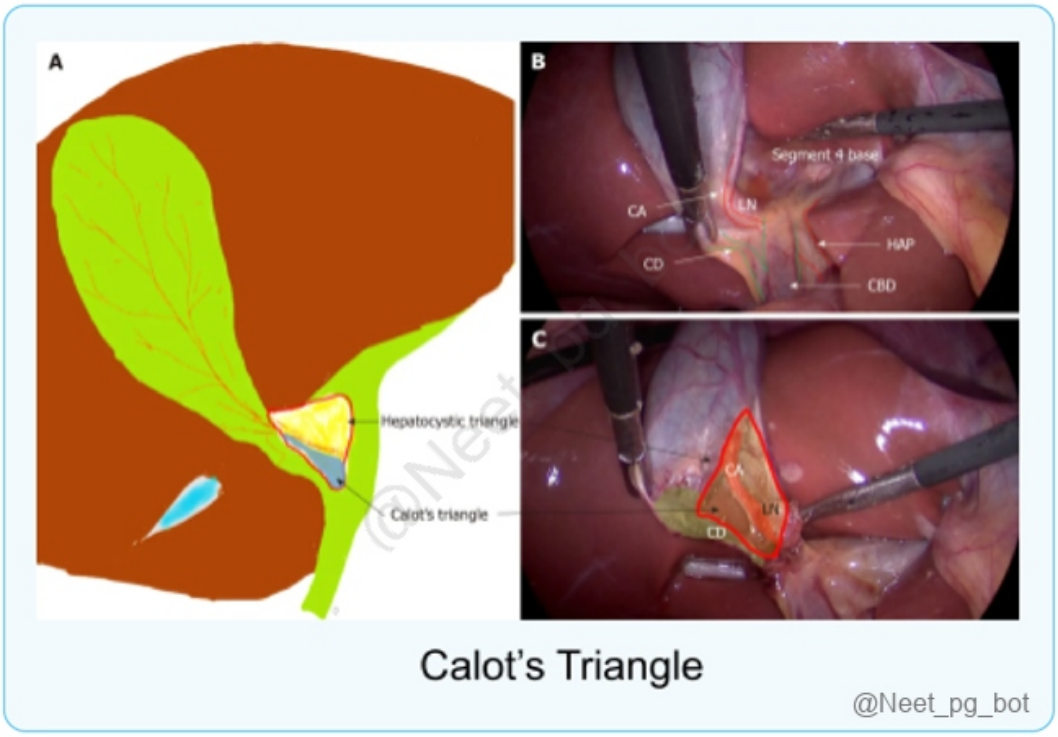
Q54: During a laparoscopic cholecystectomy, the surgeon carefully identifies the boundaries of the hepatocystic triangle to avoid injury to important structures. Which of the following is not a boundary of the hepatocystic triangle? (Q865336)

A. Cystic duct

B. Common hepatic duct



C. Inferior border of the liver

D. Cystic artery

Correct Answer: D. Cystic artery

Explanation: The hepatocystic triangle (also called Calot's triangle) is an important anatomical area identified during laparoscopic cholecystectomy to prevent injury to the common bile duct and other vital structures. The Cystic artery (D) is not a boundary; rather, it is the most important content of the triangle. Boundaries of Hepatocystic (Calot's) triangle: Medially: The Common hepatic duct (Option B) Laterally: The Cystic duct (Option A) Superiorly: The Inferior border of the liver (Option C) Contents of Hepatocystic (Calot's) triangle: Cystic artery (Option D) (supplies blood to the gallbladder) Cystic lymph node (Lund's node) Autonomic fibers reaching the gallbladder

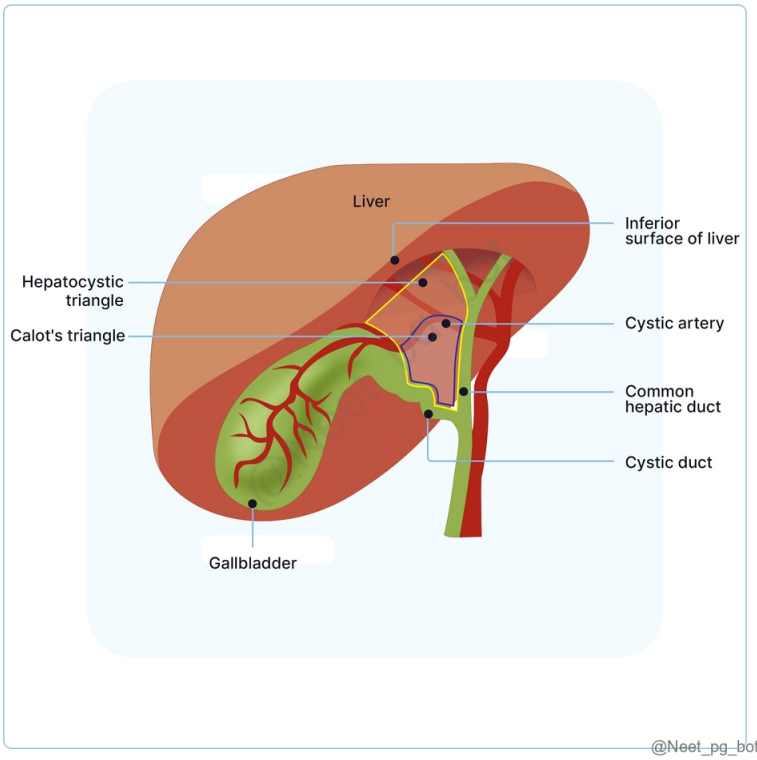
↑ *Back to this question in Part A*

@Neet_pg_bot

Q55: A 30-year-old female presented with pain in the right upper quadrant of the abdomen after 4 days of cholecystectomy. On USG, it showed a significant collection in RUQ. What will you do further? (Q866916)

A. Re-explore laparoscopically



B. Higher antibiotics

C. MRCP

D. USG guided aspiration of content

Correct Answer: D. USG guided aspiration of content

Explanation: The patient presents 4 days post-cholecystectomy with a localized collection in the right upper quadrant on ultrasound. The immediate priority here is diagnosis and therapeutic drainage — aspiration will relieve symptoms, confirm the nature of the fluid (bile, pus, blood), and guide further management. If the aspirated content is bile → further evaluation with MRCP or ERCP can be planned to localize and treat the leak. Aspiration is minimally invasive and avoids unnecessary re-exploration in a stable patient. Post-Cholecystectomy Collections: Causes: Bile leak (cystic duct stump leak, accessory duct injury), intra-abdominal abscess, hematoma, seroma. Symptoms: Fever, abdominal pain, localized tenderness, distension, jaundice (if major duct injury). Diagnosis: USG: Detects and localizes fluid collection. Aspiration: Confirms content type. MRCP: Maps biliary anatomy if a bile leak is suspected. ERCP: Diagnostic + therapeutic (stenting, sphincterotomy). Surgical anatomy: Calot's triangle boundaries → Cystic duct (medial), common hepatic duct (lateral), inferior surface of liver (superior). Contents: Cystic artery, cystic lymph node of Lund, connective tissue. Management pathway: USG-guided aspiration. If bile leak → MRCP/ERCP. Persistent leak or large duct injury → surgical repair. Re-explore laparoscopically (Option A) – Too invasive without knowing the nature of the collection. Higher antibiotics (Option B) – Won't resolve a large collection; drainage is required. MRCP (Option C) – Useful after confirming bile in the aspirate, but here aspiration is the first step.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q56: A 55-year-old alcoholic patient presents with sudden and unintentional weight loss. Lab investigations revealed serum alkaline phosphatase (ALP) of 240 IU/L, alpha-fetoprotein (AFP) of 600 ng/ml, and normal serum AST and ALT levels. What

is the most likely diagnosis? (Q855185)

A. Hepatic adenoma

B. Cholangiocarcinoma

C. Hepatocellular carcinoma

D. Alcoholic hepatitis

Correct Answer: C. Hepatocellular carcinoma

Explanation: The patient's normal AST and ALT, along with the raised ALP, are consistent with cholestasis or hepatic malignancy. Hepatocellular carcinoma (HCC) is a primary liver cancer often seen in patients with chronic liver disease, including those with alcoholism. The elevated alpha-fetoprotein (AFP) is a marker commonly associated with HCC. Tumor Markers: Elevated Alpha-fetoprotein (AFP) levels above 20 ng/ml are observed in approximately 70% of cases of hepatocellular carcinoma. An increase in PIVKA-II (Protein Induced by Vitamin K Absence or Antagonism-II) is also noted. Risk factors for HCC: Cirrhosis Metabolic disorders Environmental factors HBV infection HCV infection Alcohol NAFLD Primary biliary cirrhosis Chronic active hepatitis Hemochromatosis Wilson's Disease Glycogen Storage Disorder α1AT-deficiency Porphyria cutanea tarda Citrullinemia Orotic aciduria Alagille's syndrome Cigarette Smoking Anabolic steroids Aflatoxin Thorotrast Other options: Option A: Hepatic adenoma Typically occurs in young women on OCPs. AFP does not rise in hepatic adenoma. ALP elevation is not characteristic. Option B: Cholangiocarcinoma Causes marked ALP elevation but AFP is not elevated; CA19-9 may rise instead. Option D: Alcoholic hepatitis Characteristically shows AST : ALT ratio >2, both elevated. AFP does not rise significantly. ALP is not disproportionately elevated compared to transaminases.

@Neet_pg_bot

Q57: A 50-year-old alcoholic patient presents with a history of waxing and waning jaundice for the past 2 months. His CT examination reveals dilatation of the common bile duct and pancreatic duct. What is the most probable diagnosis in the patient? (Q855691)

A. Cholangiocarcinoma

B. Periampullary carcinoma

C. Common bile duct stone

D. Head of the pancreas carcinoma

Correct Answer: B. Periampullary carcinoma

Explanation: The scenario of an alcoholic patient experiencing fluctuating jaundice, with a CT scan showing dilation of both the common bile duct and pancreatic duct, is most likely indicative of Periampullary Carcinoma . It originates in the pancreas, bile duct, or intestines close to the ampulla of Vater (the region where the common bile duct and pancreatic duct converge and enter the duodenum). They can cause obstruction of both the common bile duct and pancreatic duct. Clinical features: Jaundice (waxing and waning) (most common) A palpable, non-tender gallbladder Weight loss Abdominal pain Nausea/vomiting Pruritus Fever Gastrointestinal bleeding Cholangiocarcinoma (Option A) arises from the bile ducts and can cause common bile duct dilatation. However, the waxing and waning jaundice and dilatation of the pancreatic duct, in this case, are more indicative of periampullary carcinoma. Cholangiocarcinoma usually presents with more progressive jaundice. Common bile duct stone (Option C) can cause ductal dilatation, but the waxing and waning jaundice and pancreatic duct involvement make periampullary carcinoma more likely. Bile duct stones typically cause acute, not fluctuating, jaundice. Head of the pancreas carcinoma (Option D) can cause ductal dilatation, but periampullary carcinoma is a more specific diagnosis given the involvement of both the common bile duct and pancreatic duct. Pancreatic cancer typically presents with continuous jaundice, not fluctuating.

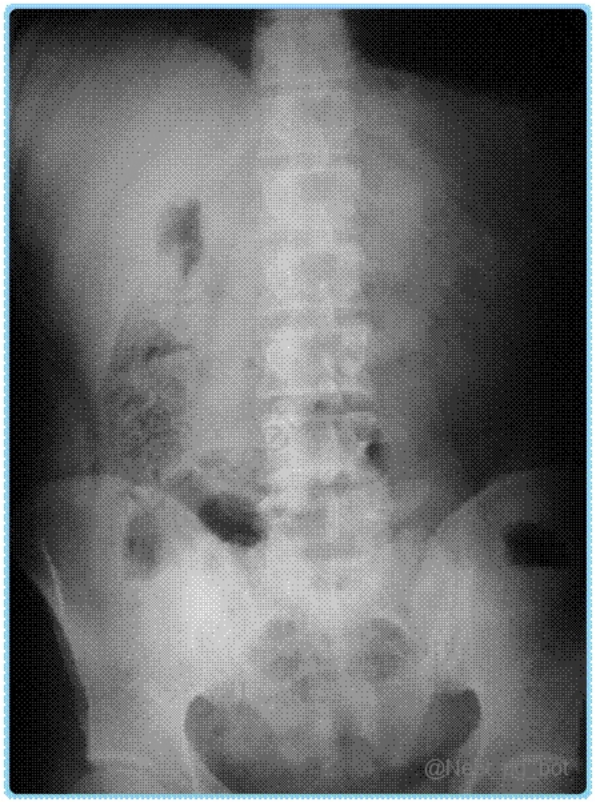
↑ *Back to this question in Part A*

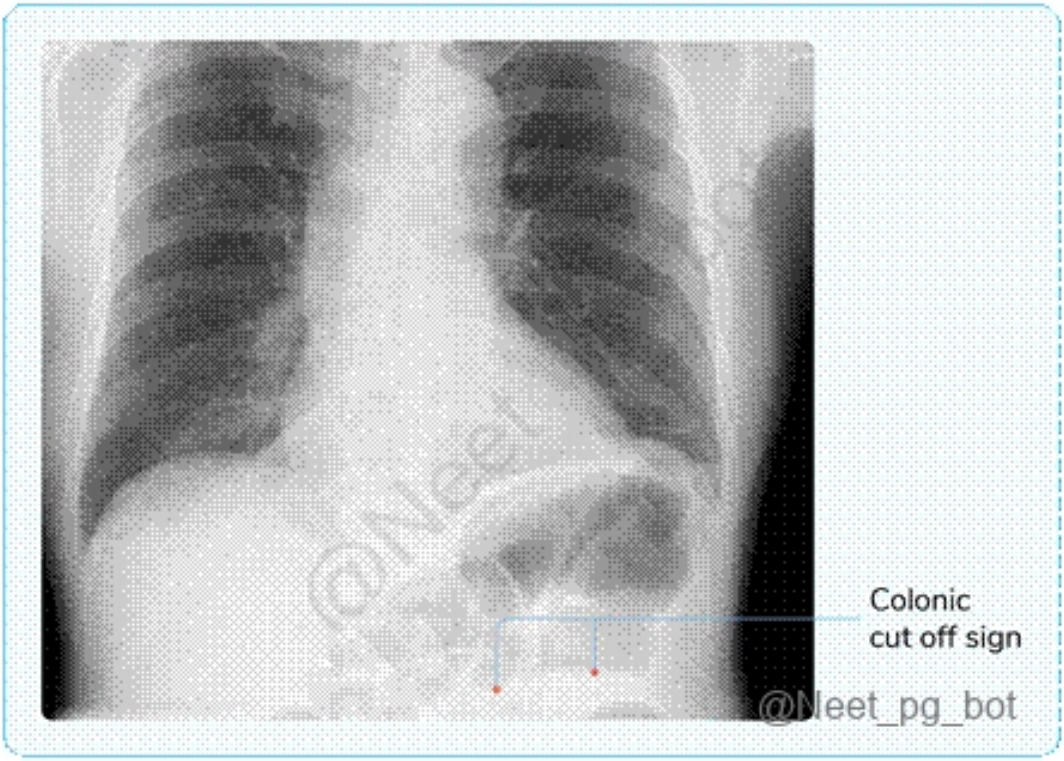
@Neet_pg_bot

Q58: A chronic-alcoholic presents to the emergency room with acute pain in the abdomen in the epigastric region radiating to the back with nausea, anorexia, and occasional vomiting. Investigations showed elevated amylase levels (3 times) and total count. Likely diagnosis is: (Q857788)

A. Acute hepatitis



B. Acute pancreatitis



C. Acute cholecystitis

D. Acute appendicitis

Correct Answer: B. Acute pancreatitis

Explanation: The scenario of a chronic alcoholic presenting with epigastric abdominal pain radiating to the back, along with nausea, anorexia, occasional vomiting, and elevated amylase levels and total count, is indicative of Acute Pancreatitis. Clinical Diagnosis (Requires 2 of 3): Abdominal pain is strongly suggestive of acute pancreatitis. (Option B) Serum amylase and/or lipase (more specific) level at least 3 times the upper limit of normal. (Option B) Imaging findings characteristic of acute pancreatitis. X-ray Features Sentinel loop sign : Dilated loop of small intestine near the inflamed pancreas due to localized ileus. Significance : Early indicator of acute pancreatitis on X-ray. {{caption_text}} Sentinel loop sign Colon cut-off sign : Abrupt termination of gas in the colon at the splenic flexure, with collapsed distal colon loops. Significance : Suggests localized pancreatic inflammation, causing colonic spasm as an indirect sign of acute pancreatitis {{caption_text}} Investigations of Choice: Contrast-enhanced CT (CECT) : Primary tool for assessing pancreatic necrosis, peripancreatic inflammation, fluid collections, and complications. Most reliable for staging and detecting complications. May underestimate necrosis if done in the first 24 hours. Morphological Types (Revised Atlanta Classification 2008): Interstitial oedematous pancreatitis : Mild form with pancreatic oedema and swelling but no necrosis. Necrotising pancreatitis: Severe form involving pancreatic parenchymal necrosis, associated with higher morbidity and mortality. Acute hepatitis (Option A) is liver inflammation, often caused by viral infections, alcohol, or toxins, with symptoms like jaundice, fatigue, dark urine, and elevated liver enzymes (ALT, AST). This diagnosis is unlikely for the patient, as her symptoms of epigastric pain, elevated amylase, and the absence of jaundice or liver enzyme elevation point more toward pancreatitis. Acute Cholecystitis (Option C) , caused by gallstones, presents with right upper quadrant pain, fever, and nausea, with ultrasound showing gallstones or thickened walls. However, the patient's epigastric pain and elevated amylase suggest pancreatitis, not cholecystitis. Acute appendicitis (Option D) presents with right lower quadrant pain, fever, elevated white blood cell count, and pain that starts around the umbilicus, shifting to the lower right abdomen. In this case, the patient has epigastric pain and elevated amylase, making appendicitis unlikely, as it doesn’t typically affect amylase levels.

Sabiston Textbook of Surgery, 21st Edition, Page 1533-1535.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q59: Which of the following is the best preferred investigation for Neuroendocrine Tumors (NETs)? (Q857777)

A. USG

B. SRS

C. MRI

D. PET

Correct Answer: D. PET

Explanation: Pancreatic Neuroendocrine Tumors (PNETs) are derived from pluripotent stem cells. Classified as functional and non-functional PNETs Subtypes: Insulinoma (most common functional PNET) Gastrinoma (most common functional and malignant PNET) Non-functional tumors VIPoma Glucagonoma Somatostatinoma Carcinoid ACTHoma GRFoma It is symptomatic and diagnosed at an early stage. Diagnosis: Laboratory measurement of active substances or its by products. PET (Positron Emission Tomography)/CT: Preferred investigation for NETs nowadays. (Option D) Tracer: 68Gallium (68Ga)-labeled somatostatin analogs Somatostatin receptor scintigraphy (SRS) is used for the localization of NETs. (IOC). All Neuroendocrine tumors express Somatostatin receptors except Insulinoma. It is not used nowadays. (Option B ruled out) USG (ultrasound) (Option A) is not the best choice for pancreatic NETs because the pancreas is deep in the abdomen, making it hard to visualize. It is useful for detecting large masses but is less sensitive for smaller tumors or those without distinct features. MRI (Option C) is useful for pancreatic tumors and liver metastases but lacks the functional detail of SRS. SRS is the gold standard for detecting somatostatin receptor-positive NETs.

@Neet_pg_bot

Q60: A patient arrives with pain in the right upper abdomen. One week ago, the patient experienced a bout of diarrhoea. Abdominal CT scan results indicate the presence of a liver abscess measuring approximately 25 cubic centimetres. What should be the subsequent course of action in treating this patient? (Q855205)

A. PAIR

B. Surgery

C. Medical therapy

D. Percutaneous drainage

Correct Answer: C. Medical therapy

Explanation: The key feature in the patient's history is the bout of diarrhea one week prior . This strongly suggests an enteric pathogen as the cause. Entamoeba histolytica, the protozoan that causes amebiasis, infects the colon (causing diarrhea/dysentery) and can then travel via the portal vein to the liver, forming an abscess. The initial treatment for a liver abscess typically involves medical therapy with broad-spectrum antibiotics. Percutaneous drainage or PAIR may be considered if the abscess does not improve with antibiotics or if it grows in size or

becomes symptomatic. Surgery is reserved for more complicated or non-drainable abscesses. Management of Hepatic Pyogenic Abscess: Initial Management: Broad-Spectrum Antibiotics: Start immediately to control bacteremia and prevent complications. Antibiotics should cover gram-negative, gram-positive, and anaerobic organisms (e.g., ampicillin, aminoglycoside, metronidazole). Typically 2 weeks or more, depending on infection resolution and drainage success. Drainage Techniques: Percutaneous Drainage: First-line treatment with success rates of 66% to 90% . Advantages: Simpler, avoids general anaesthesia. Contraindications: Ascites, coagulopathy, proximity to vital structures. Percutaneous drainage should be attempted first, reserving surgery for failures. Percutaneous Aspiration: Less effective than percutaneous catheter drainage but reasonable for initial treatment. Surgical drainage: Reserved for cases where percutaneous drainage fails or when surgery is needed for underlying conditions (e.g., appendicitis). Feature Amebic Abscess Pyogenic Abscess Age 20–40 years >50 years Male-to-Female Ratio ≥10:1 1.5:1 Solitary vs Multiple Solitary 80% Solitary 50% Location Usually right liver Usually right liver Travel in Endemic Area Yes No Diabetes Uncommon (~2%) More common (~27%) Alcohol Use Common Common Jaundice Uncommon Common Elevated Bilirubin Uncommon Common Elevated Alkaline Phosphatase Common Common Positive Blood Culture No Common Positive Amebic Serology Yes No

↑ *Back to this question in Part A*

@Neet_pg_bot

Q61: A patient presents with features of chronic pancreatitis, including recurrent attacks, and has a 10 mm dilatation of the pancreatic duct with intraductal calculi present. Which of the following is the surgery of choice? (Q855189)

A. Pancreaticoduodenectomy

B. Longitudinal pancreaticojejunostomy

C. ERCP and sphincterotomy

D. Coring of the pancreas head

Correct Answer: B. Longitudinal pancreaticojejunostomy

Explanation: In chronic pancreatitis, a main pancreatic duct dilatation ≥7 mm with intraductal stones indicates an obstructive form of the disease. The Puestow procedure (Longitudinal pancreaticojejunostomy) decompresses the duct by opening it along its length and anastomosing it to a Roux-en-Y jejunal loop. It effectively relieves pain by reducing intraductal pressure and facilitates drainage of calculi. It is the procedure of choice when dilation is significant (like 10 mm). Incorrect Options: Option A) Pancreaticoduodenectomy (Whipple) : Reserved for head mass, suspicion of malignancy, or unrelieved obstruction- not for a dilated duct alone. Option C) ERCP and sphincterotomy : Useful for small stones or strictures; not effective for diffuse pancreatic duct stones in a markedly dilated duct. Option D) Coring of the pancreas head (Frey procedure) : Indicated when inflammatory mass in the pancreatic head coexists; not needed here if only duct dilation + stones are present.

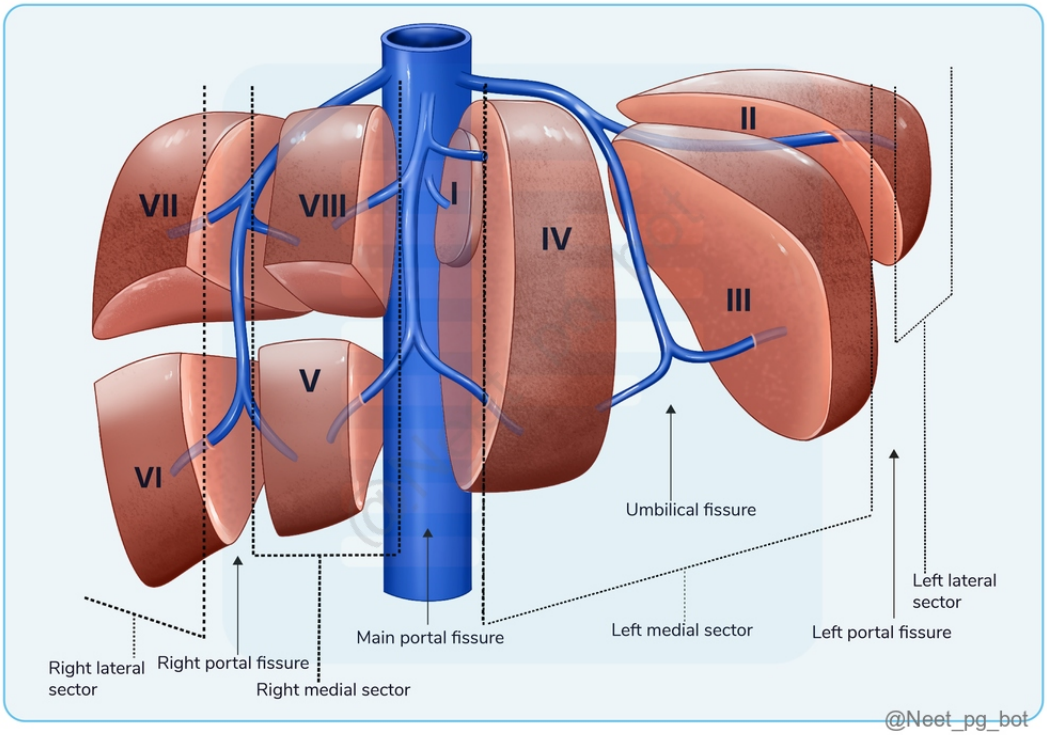
Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1279,1280

↑ *Back to this question in Part A*

@Neet_pg_bot

Q62: A 46 year male had a tumor in his left lobe of liver, so left sided hemi hepatectomy was planned, which of the following lobes of liver will be resected in this procedure? (Q866907)

A. 2,3 and 4



B. 1,2 & 3

C. 5, 6, 7 & 8

D. 2, 3, 4 & 5

Correct Answer: A. 2,3 and 4

Explanation: Liver lobes are defined surgically based on Couinaud's segmental anatomy (functional anatomy), which follows the portal vein and hepatic vein divisions rather than the classical anatomical right/left lobes. In a left hemihepatectomy , the left functional lobe is removed. This includes segments II, III, and IV : Segment II & III: Left lateral section Segment IV: Left medial section Segments of the liver Segment VIII: The superior part of the right anterior sector. Drainage: Drains into the right and middle hepatic veins. Segment I (Caudate Lobe): Posterior to segment IV, straddles the inferior vena cava. Drainage: Multiple small veins drain directly into the inferior vena cava. Bile Ducts: Related to the confluence of the right and left hepatic ducts. Segment II: Posterolateral to the left portal fissure. Drainage: Drains into the left hepatic vein; rarely directly into the inferior vena cava. Segment VII: The superior part of the right posterior sector, posterior to the right hepatic vein. Drainage: Primarily into the right hepatic vein; occasionally directly into the inferior vena cava. Segment III: Between the umbilical and left portal fissures. Drainage: Primarily into the left hepatic vein; alternative drainage via falciform ligament veins. Segment VI: Inferior part of the right posterior sector, posterior to the right portal fissure. Drainage: Usually into the right hepatic vein; may drain directly into the inferior vena cava. Segment V: Inferior segment of the right anterior sector. Drainage: Typically into the right and middle hepatic veins; can drain directly into the inferior vena cava. Segment IV: Between the umbilical fissure and main portal fissure, anterior to segment I. Drainage: Usually into the middle hepatic vein; can also drain into the left hepatic vein. 1, 2 & 3 (Option B): Segment I is the caudate lobe, which is functionally separate and not routinely removed in a left hemihepatectomy. 5, 6, 7 & 8 (Option C): These are part of the right functional lobe. 2, 3, 4 & 5 (Option D): Segment 5 belongs to the right lobe.

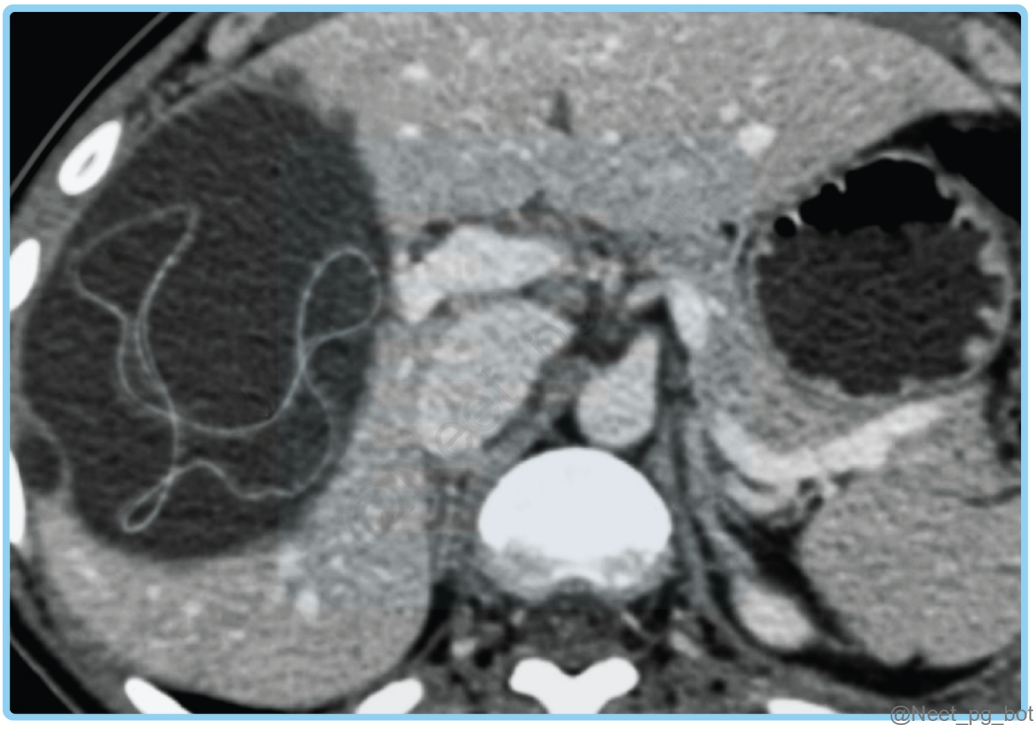
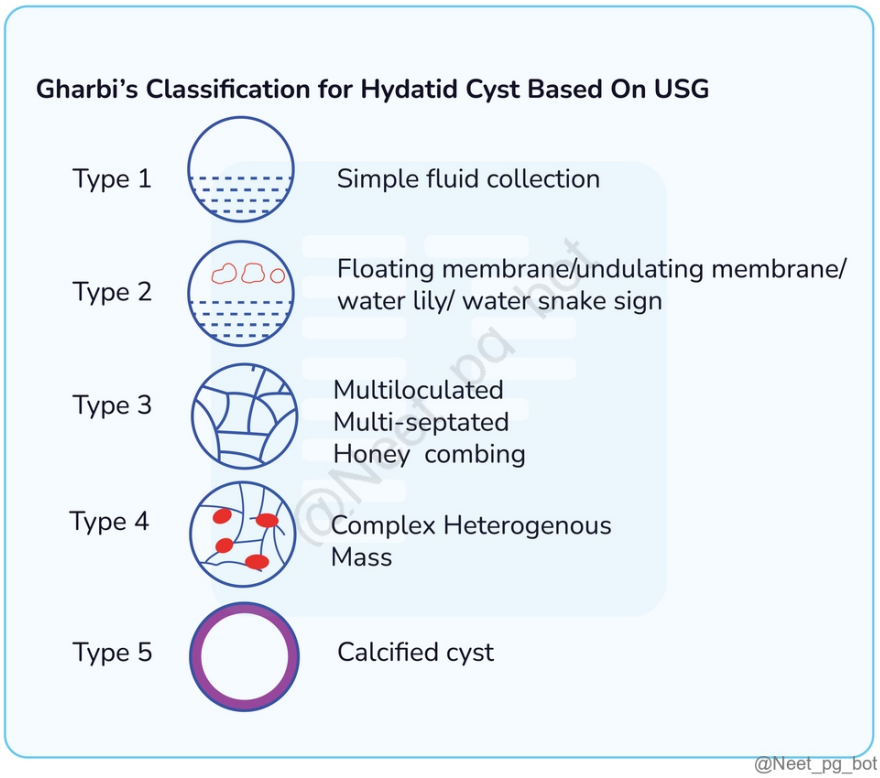
@Neet_pg_bot



Q63: A patient presents with fever, abdominal pain, and jaundice. Investigations show the given findings. Which of the following statements is true regarding this condition? (Q855184)

A. Surgery is mandatory

B. Fine-needle aspiration cytology is diagnostic



C. Angioembolization is the treatment of choice

D. Echinococcus species is involved in etiology

Correct Answer: D. Echinococcus species is involved in etiology

Explanation: The patient's symptoms of fever, abdominal pain, and jaundice, along with the provided findings of a serpentine linear membrane (a wavy membrane within the cyst), suggest a diagnosis of hydatid disease or echinococcosis . This condition is caused by infection with the Echinococcus species of tapeworm, typically transmitted through contact with dogs or livestock. Hydatid disease: Caused by Echinococcus granulosus (dog tapeworm). Humans are intermediate hosts, infected through oral ingestion of eggs from dogs. Clinical features: Common organs affected : Liver (most common), lungs, brain. Symptoms: Abdominal pain, jaundice, dysphagia, dyspnea, neurological signs (headache, ICP). It can present after trauma or with anaphylactic shock. Diagnosis: Eosinophilia , positive serology (ELISA, immunoelectrophoresis). Imaging : Ultrasound, CT, MRCP (for biliary involvement). {{caption_text}} Treatment: PAIR technique (Puncture, Aspiration, Injection, Reaspiration) after albendazole or praziquantel. Radical pericystectomy or segmentectomy for hepatic cases. Omentoplasty or laparoscopic marsupialization for cysts. Scolicidal agents : Hypertonic saline, ethanol, or povidone-iodine used during surgery. Laparoscopic marsupialization (deroofing) for cysts. Cyst aspiration, followed by scolicidal agent application and sealing biliary communications. Surgery is mandatory (Option A) : While surgery is often an effective treatment for hydatid cysts, it is not always required. In some cases, non-surgical options such as antiparasitic medications or percutaneous drainage may be more suitable. Fine-needle aspiration cytology is diagnostic (Option B) : Fine-needle aspiration (FNA) is generally avoided in the diagnosis of echinococcosis due to the risk of triggering anaphylaxis and the potential to spread the infection. Angioembolization is the treatment of choice (Option C) : Angioembolization is not typically the first-line treatment for hydatid disease and is not commonly used as a primary approach.

@Neet_pg_bot

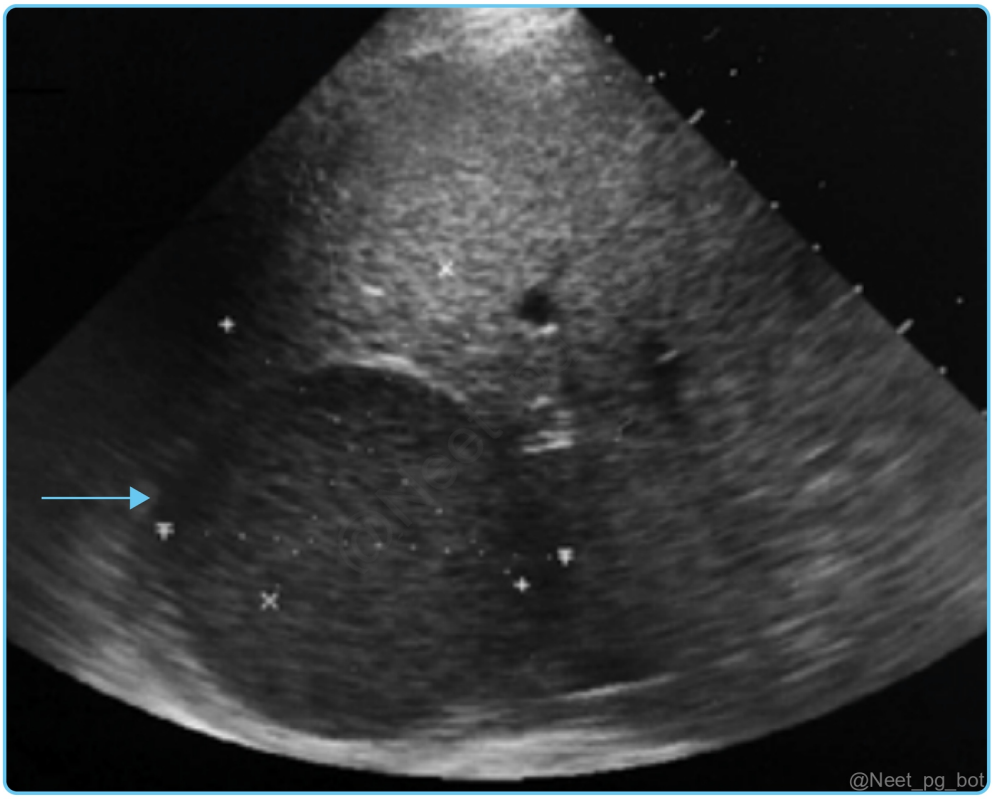
Bailey & Love's Short Practice of Surgery, 28th Edition, Page 73-76

↑ *Back to this question in Part A*

@Neet_pg_bot



Q64: A 35-year-old patient with a history of dysentery for 6 weeks complains of pain in the right upper abdomen. On ultrasound, a hypoechoic hyperdense lesion is seen in the liver. Based on the given image, identify the condition. (Q854784)

A. Amoebic liver abscess

B. Pyogenic liver abscess

C. Hydatid cyst

D. Hemangioma

Correct Answer: A. Amoebic liver abscess

Explanation: The ultrasound image shows a hypoechoic hyperdense lesion in the liver. Given the patient's clinical history of dysentery, the most likely diagnosis is an amoebic liver abscess . Amoebic liver abscess is caused by the protozoan parasite Entamoeba histolytica , typically contracted through the ingestion of contaminated food or water. On ultrasound, the abscess appears as a well-defined, hypoechoic lesion with variable internal echoes . Mild to moderate oedema in the surrounding liver parenchyma may also be seen. Feature Amebic Abscess Pyogenic Abscess Age 20–40 years >50 years Male-to-Female Ratio ≥10:1 1.5:1 Solitary vs Multiple Solitary 80% Solitary 50% Location Usually right liver Usually right liver Travel in Endemic Area Yes No Diabetes Uncommon (~2%) More common (~27%) Alcohol Use Common Common Jaundice Uncommon Common Elevated Bilirubin Uncommon Common Elevated Alkaline Phosphatase Common Common Positive Blood Culture No Common Positive Amebic Serology Yes No Incorrect Options: Pyogenic liver abscess (Option B) : A pyogenic liver abscess, caused by bacterial infections like Escherichia coli or Klebsiella pneumoniae , usually presents as multiple hypoechoic lesions on ultrasound, rather than the single lesion shown here. Inflammation in the surrounding liver parenchyma may also be evident. Hydatid cyst (Option C) : Caused by the larval stage of Echinococcus granulosus , hydatid cysts typically appear as well-defined, anechoic, or hypoechoic lesions, often with multiple daughter cysts inside. The provided image shows a single hypoechoic hyperdense lesion, which is inconsistent with a hydatid cyst. Hemangioma (Option D) : Hemangiomas are benign vascular tumours that commonly occur in the liver. They usually appear as hyperechoic lesions with posterior acoustic enhancement on ultrasound. The lesion in the provided image, being hypoechoic and hyperdense, does not fit the typical characteristics of a hemangioma.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q65: After laparoscopic cholecystectomy, what should the expected urine output be in a patient with normal renal function? (Q854780)

A. 500 ml/day

B. 0.5 ml/min

C. 0.5-1.5 ml/kg/hour

D. 1 ml/kg/min

Correct Answer: C. 0.5-1.5 ml/kg/hour

Explanation: The normal urine output is around 1500 ml/day for a healthy adult, which roughly translates to 0.5-1.5 ml/kg/hour . (1x70(kg)x24(hours) ~ 1700 ml). Minimum urine output to excrete end products of protein metabolism: 500ml/day Ideal urine output in a normal 70kg adult: 1500 ml

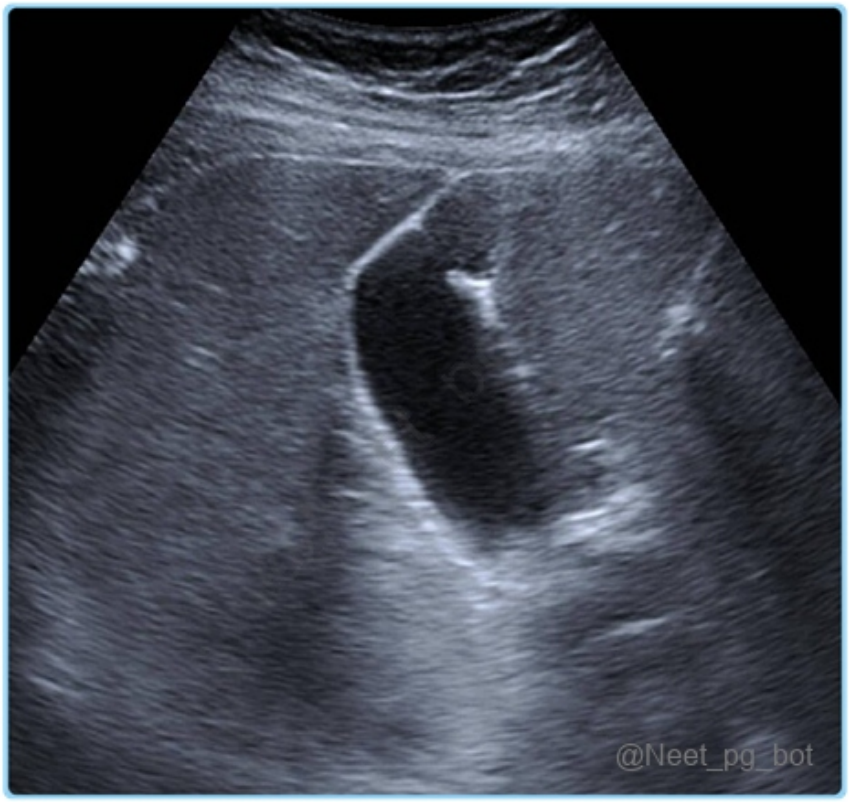
@Neet_pg_bot

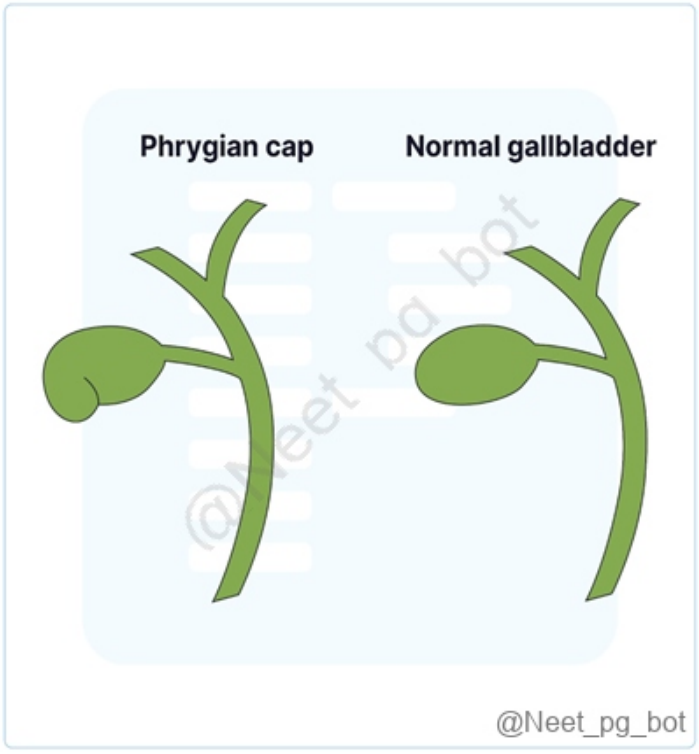
Q66: What is the sign of the gallbladder seen in this USG? (Q854768)

A. Phrygian cap sign

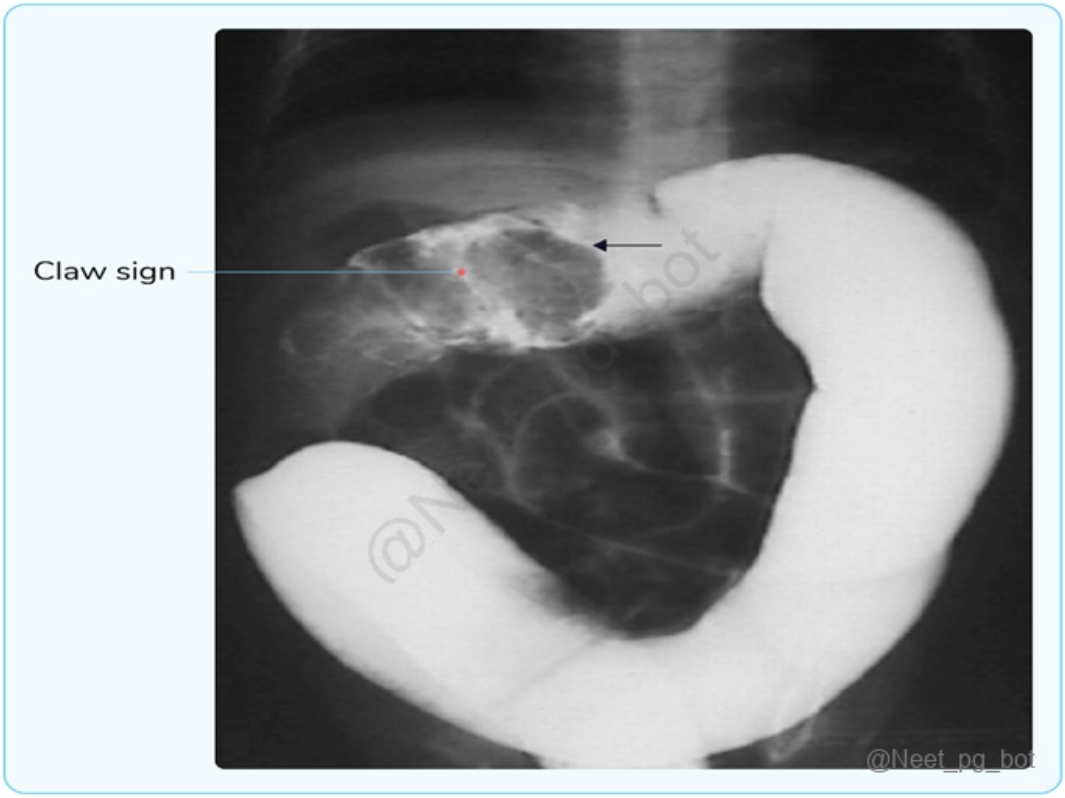
B. Murphy sign



C. Claw sign



D. Omega sign



Correct Answer: A. Phrygian cap sign

Explanation: The image on the ultrasound (USG) shows the Phrygian cap sign , which is a common anatomical variation of the gallbladder. A Phrygian cap is a congenital variant of the gallbladder characterised by a fold at the fundus that resembles a cap. It is a benign condition and is typically asymptomatic, with its appearance being consistent with a cap-like structure on ultrasound. It has no pathological significance and does not affect gallbladder function. {{caption_text}} Incorrect Options: Murphy sign (Option B) is a clinical finding seen in acute cholecystitis, where pain and inspiratory arrest occur upon palpation of the gallbladder. It is not related to the anatomical variation seen in the USG image. Claw sign (Option C) is a radiological feature seen in intussusception , not related to the gallbladder. {{caption_text}} Omega sign (Option D) is a radiological finding observed in choledochal cysts , where the dilated common bile duct forms an "omega" or "figure-of-8" shape. It does not relate to the anomaly shown in the USG image.

@Neet_pg_bot

Q67: Which condition is most likely based on the image findings? {{caption_text}} (Q854742)

A. Stricture

B. Choledocholithiasis

C. Cholecystitis

D. Cholangiocarcinoma

Correct Answer: B. Choledocholithiasis

Explanation: The MRCP (Magnetic Resonance Cholangiopancreatography) image reveals dilation of the common bile duct (CBD) along with filling defects, representing gallstones within the duct. Filling defects on MRCP indicate an obstruction in the bile ducts, commonly caused by gallstones (choledocholithiasis) or other blockages. These defects appear as areas where the bile duct does not fill properly or has reduced signal intensity. Symptoms of choledocholithiasis typically include jaundice, abdominal pain, nausea, and vomiting. Treatment often involves endoscopic retrograde cholangiopancreatography (ERCP) with sphincterotomy and stone extraction. Incorrect Options: Stricture (Option A) : A bile duct stricture appears as narrowing or constriction of the bile duct caused by inflammation, scarring, or tumours obstructing the duct. While it can mimic choledocholithiasis on imaging, it does not show the characteristic filling defects seen in choledocholithiasis. Cholecystitis (Option C) is the inflammation of the gallbladder, usually due to gallstones blocking the cystic duct. MRCP typically shows gallbladder wall thickening, pericholecystic fluid, and gallstones in the gallbladder but not changes in the bile ducts, so it wouldn't cause CBD dilation or filling defects. Cholangiocarcinoma (Option D) is a malignant tumour of the bile duct epithelium. On MRCP, it can cause bile duct dilation and strictures and may also show intraductal masses or nodules. However, the pattern of obstruction caused by a tumour differs from the filling defects seen with choledocholithiasis, as these defects are caused by gallstones, not a mass.

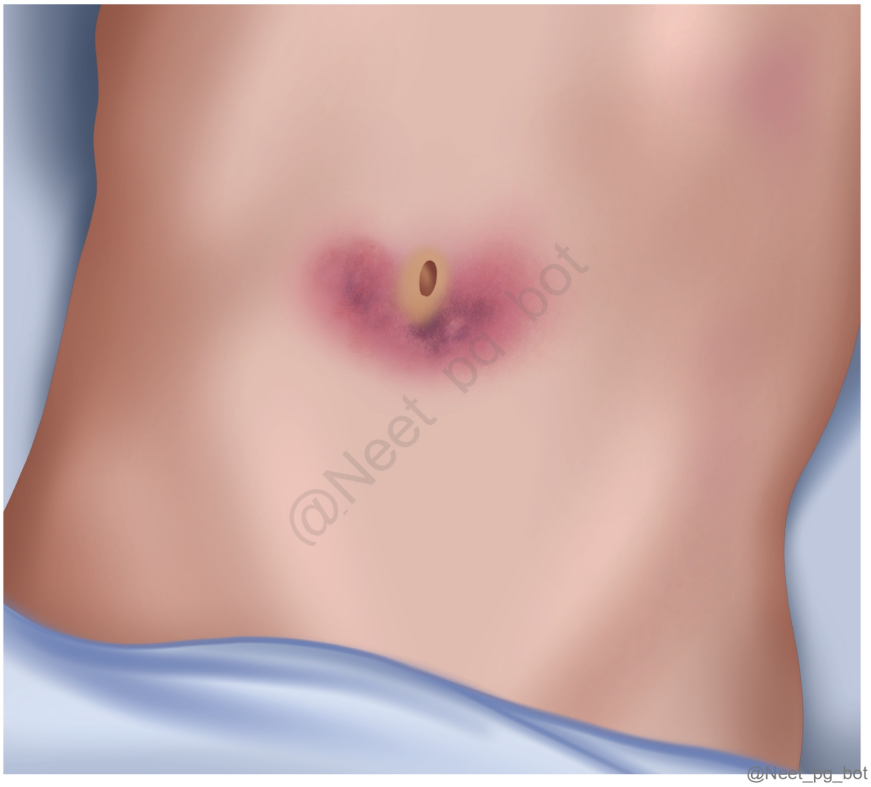
Sabiston’s Textbook of Surgery, 21st Edition, Page 1501.

↑ *Back to this question in Part A*

@Neet_pg_bot

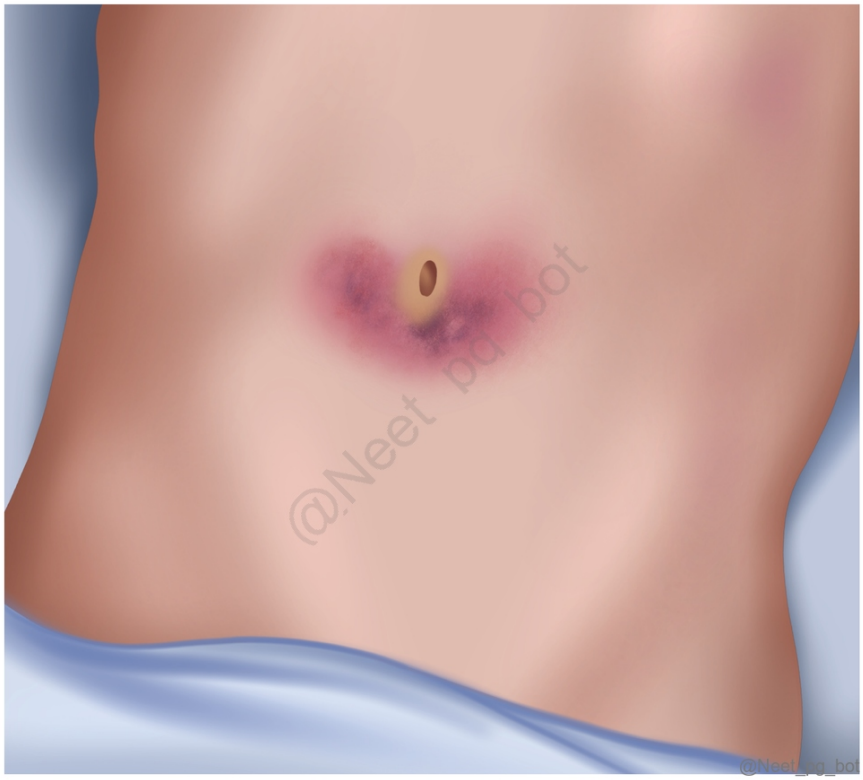


Q68: A 45-year-old male presents with abdominal pain in the emergency room. . On examination, there is blackish discoloration involving the periumbilical skin . What is the most likely diagnosis for this presentation? (Q820153)

A. Acute pancreatitis

B. Necrotizing fasciitis

C. Chronic pancreatitis



D. Traumatic fat necrosis

Correct Answer: A. Acute pancreatitis

Explanation: Option A - Acute Pancreatitis: Acute pancreatitis is characterized by inflammation of the pancreas and can cause severe abdominal pain. However, it typically doesn't lead to blackish discoloration of the perineal skin. Hypotension may occur in severe cases due to systemic inflammation and fluid shifts, but the perineal discoloration is not a common feature of acute pancreatitis. Presents with cullens sign Incorrect Options: Option B - Necrotizing Fasciitis: Deeper tissue injury, usually from anaerobic bacteria or S pyogenes . Pain may be out of proportion to exam findings. Results in crepitus from methane and CO2 production. “Flesh-eating bacteria.” Causes bullae and skin necrosis causing violaceous color of bullae, surrounding skin . Surgical emergency Option C - Chronic Pancreatitis: Chronic pancreatitis is a long-standing inflammation of the pancreas, often due to alcohol abuse or other underlying factors. It leads to persistent abdominal pain, digestive issues, and potentially

complications over time. However, it is unlikely to cause the rapid onset of perineal skin discoloration and hypotension as seen in the given presentation. Option D - Traumatic Fat Necrosis: Traumatic fat necrosis can occur as a result of physical trauma to fatty tissues, leading to localized inflammation and tissue damage. While it can cause skin discoloration, it typically presents as a localized issue rather than involving the perineal skin. It's also less likely to cause the severe systemic symptoms, including hypotension, seen in this case.

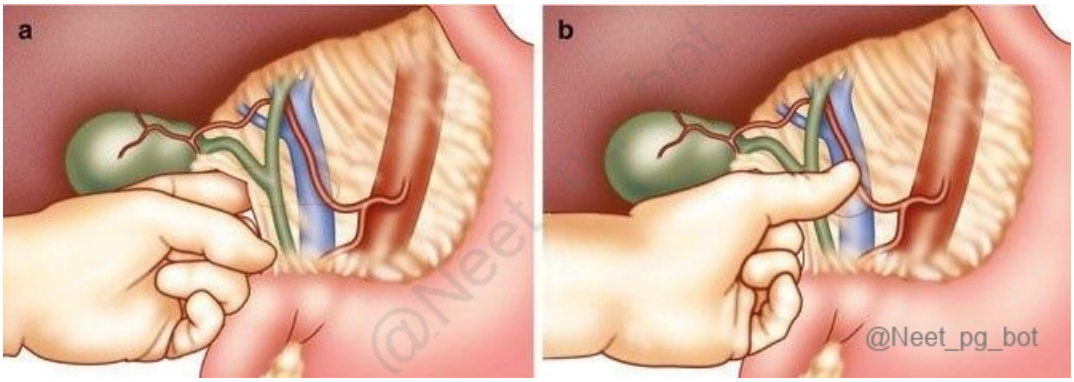
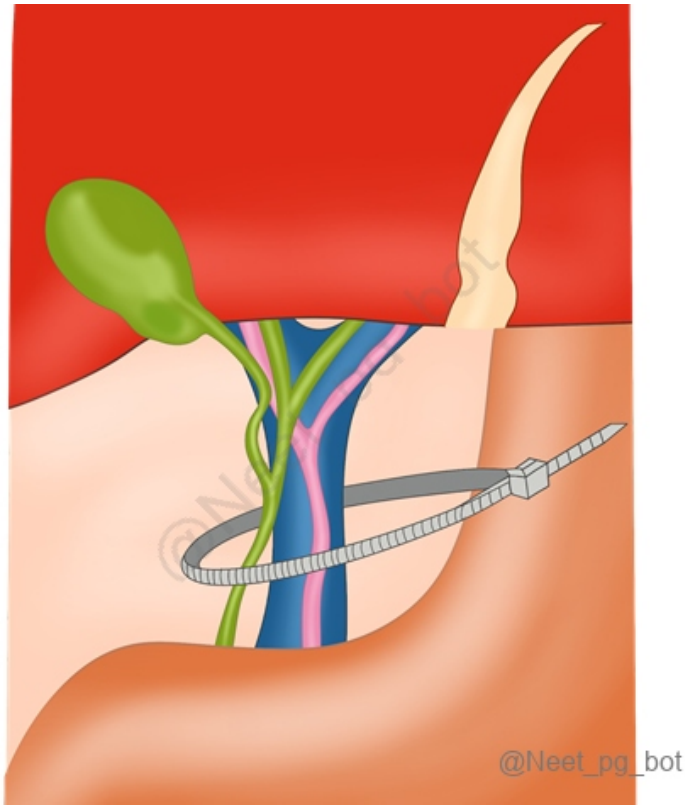
@Neet_pg_bot



Q69: A 39-year-old patient presented with RTA and is brought to ER with a pulse rate of 120/min, and SBP of <80mmHg. Despite intravenous fluid resuscitation and BT, the patient's condition deteriorates with ongoing profuse bleeding from the liver . Identify the procedure shown in the image done to control massive liver bleed. (Q820112)



A. Kocher maneuver

B. Pringle’s maneuver

C. Cattell-Braasch maneuver

D. Mattox maneuver

Correct Answer: B. Pringle’s maneuver

Explanation: Correct option B - Pringle's maneuver Pringle's maneuver involves temporarily clamping the hepatoduodenal ligament, which contains the portal vein, hepatic artery, and common bile duct. This maneuver is used to control bleeding from the liver by temporarily interrupting blood flow to the liver. It is a common technique used during liver surgery or to manage traumatic liver bleeding. Incorrect options: Option A - Kocher maneuver: Kocher maneuver is a surgical technique used during cholecystectomy to mobilize the duodenum and improve access to the gallbladder. It is not relevant to controlling liver bleeding. Option C - Cattell-Braasch maneuver: Cattell-Braasch maneuver is a mobilization surgical technique that allows good access to the retroperitoneal structures. The inferior vena cava, abdominal aorta below the superior mesenteric artery, and retroperitoneal organs of the right side are exposed when it is completed. Option D - Mattox maneuver: Mattox

maneuver, also known as a left medial visceral rotation, is a surgical step to explore and handle Zone 1 and 2 retroperitoneal injuries (aorta, left iliac and pelvic vessels). It starts with incising the parietal peritoneum at the white line of Toldt from the sigmoid colon to the splenic flexure.

Q70: What is the optimal management approach for a patient presenting with fever and abdominal pain five days after experiencing a common bile duct injury resulting in a leak ? (Q793377)

A. Ultrasound–guided aspiration

B. ERCP and stenting

C. Re-exploration and hepaticojejunostomy

D. Re-exploration and primary repair

Correct Answer: B. ERCP and stenting

Explanation: Correct Option B - ERCP and stenting: ERCP (Endoscopic Retrograde Cholangiopancreatography) with stenting is the optimal management approach for a patient presenting with fever and abdominal pain five days after experiencing a common bile duct injury resulting in a leak. ERCP : This procedure allows direct visualization of the bile ducts and enables interventions such as stent placement to address the bile duct injury. ERCP is a minimally invasive procedure performed by passing an endoscope through the mouth, esophagus, and stomach into the duodenum to access the bile ducts. Stenting : Stents are inserted during ERCP to facilitate bile drainage and promote healing of the bile duct injury. They also help maintain the patency of the duct and prevent further complications such as bile leakage and bile peritonitis. Incorrect Options: Option A - Ultrasound-guided aspiration: While ultrasound-guided aspiration may be useful for draining a biloma (collection of bile outside the biliary system), it does not address the underlying bile duct injury. Therefore, it is not the definitive management approach for this condition. Option C - Re-exploration and hepaticojejunostomy: Re-exploration and hepaticojejunostomy involve surgical intervention to repair the bile duct injury by creating a new connection between the bile duct and the jejunum. While this approach may be necessary in some cases, it is usually reserved for more complex or severe injuries. In the presented case, less invasive options such as ERCP with stenting are preferred before resorting to surgical intervention. Option D - Re-exploration and primary repair: Similar to option C, re-exploration and primary repair involve surgical intervention to directly repair the bile duct injury. This approach may be considered if less invasive options fail or if the injury is severe. However, it is not the initial management approach for a patient presenting with fever and abdominal pain after a common bile duct injury.

Q71: Which of the following represents a type III choledochal cyst from the given image ? (Q793411)

A. A

B. B

C. C

D. D

Correct Answer: C. C

Explanation: Correct Option C - C: Choledochal cysts are rare congenital anomalies that involve dilation of the biliary tree. These cysts can occur anywhere along the biliary tree, from the intrahepatic bile ducts to the common bile duct. Based on the location and extent of the dilation, choledochal cysts are classified into five types. Image C shows a Dilatation of the intraduodenal part of the bile duct (choledochocele); it represents a type III choledochal cyst. Incorrect Options: Option A - A: Type II cyst is Diverticular dilatation of the extrahepatic bile duct. Option B - B: Type I cyst is Cystic dilatation of extrahepatic bile duct (most common) Option D - D: Type V cyst involves multiple dilations of the intrahepatic and/or extrahepatic bile ducts.

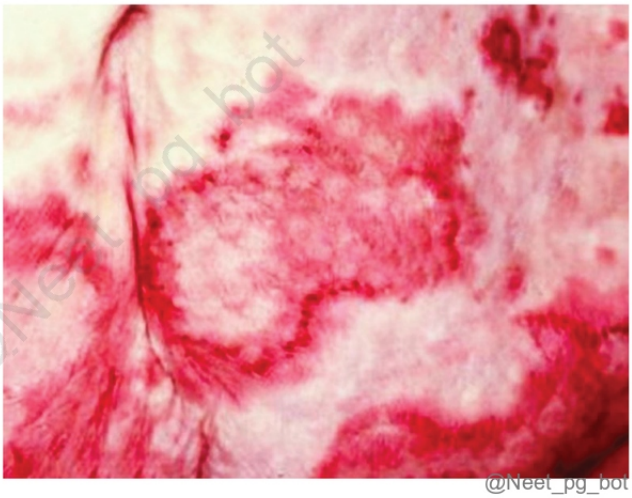
@Neet_pg_bot

Q72: Which neuroendocrine tumor of the pancreas is commonly linked with necrolytic erythema migrans ? (Q793855)

A. Insulinoma

B. Glucagonoma



C. Somatostatinoma

D. VIPoma

Correct Answer: B. Glucagonoma

Explanation: Correct Option B - Glucagonoma: Necrolytic Erythema Migrans (NEM): This is a characteristic skin manifestation associated with glucagonoma, also known as the hyperglycemic cutaneous syndrome. NEM presents as a rash with erythema and necrosis, typically affecting the lower extremities and perineum. It's considered the most common symptom of glucagonoma. "4D" Syndrome: Glucagonoma is associated with a set of symptoms known as the "4D" syndrome: Diabetes Mellitus: Glucagonoma can lead to elevated blood glucose levels due to the excess release of glucagon, which opposes insulin action, contributing to the development of diabetes mellitus. Dermatitis: NEM, as described earlier, is the dermatological manifestation characterized by erythema and necrosis. Deep Vein Thrombosis (DVT): Glucagonoma can increase the risk of DVT formation due to various factors such as hypercoagulability. Depression: Patients with glucagonoma may experience depression, which could be attributed to various physiological and psychological factors associated with the disease. Incorrect Options: Option A - Insulinoma: Insulinomas are neuroendocrine tumors of the pancreas that primarily secrete insulin. While hypoglycemia is a hallmark symptom of insulinoma due to excess insulin secretion, it is not associated with necrolytic erythema migrans. Option C - Somatostatinoma: Somatostatinomas are rare neuroendocrine tumors that overproduce somatostatin. Dermatological manifestations associated with somatostatinoma typically include acanthosis nigricans and diabetes mellitus, but not necrolytic erythema migrans. Option D - VIPoma: VIPomas are neuroendocrine tumors that secrete vasoactive intestinal peptide (VIP), leading to profuse watery diarrhea, hypokalemia, and achlorhydria (WDHA syndrome). While VIPomas can lead to skin flushing, diarrhea is the prominent symptom, and necrolytic erythema migrans is not associated with VIPomas.

Q73: A 40-year-old man is brought to the casualty with severe abdominal pain radiating to the back for the past 1 day and has had 3 episodes of vomiting. The pain radiates to the back and is slightly relieved in the sitting forward position . The following signs are seen on examination and lab investigations reveal elevated lipase and amylase . Which of the following is the most likely diagnosis? (Q805008)

A. Acute appendicitis

B. Acute cholecystitis

C. Acute pancreatitis

D. Acute ischemic colitis

Correct Answer: C. Acute pancreatitis

Explanation: of correct answer.

Q25 (p. 1855)					

Q1: A 45-year-old male presents to the emergency department with severe chest pain following forceful vomiting. Physical examination reveals subcutaneous emphysema. What is the most likely diagnosis? (Q849134)

A. Myocardial Infarction

B. Boerhaave's Syndrome

C. Acute Pancreatitis

D. Gastric Ulcer Perforation

Correct Answer: B. Boerhaave's Syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Boerhaave's syndrome is characterized by spontaneous esophageal perforation due to forceful vomiting. Key features include severe chest pain and subcutaneous emphysema. Boerhaave's syndrome Definition Spontaneous full-thickness tear of the esophagus, usually due to sudden increase in intraesophageal pressure against a closed glottis (forceful vomiting) Common Site Lower third of the esophagus, posterolateral aspect, usually toward the left pleural cavity Etiology / Causes Spontaneous emetogenic perforation (Boerhaave); iatrogenic perforation from endoscopy, dilation, EMR/ESD/POEM; direct trauma (rare); foreign body ingestion; corrosive ingestion; advanced esophageal cancer Classic Presentation Sudden severe chest pain, vomiting, subcutaneous emphysema; may have hematemesis; rapid accumulation of left pleural effusion Other Clinical Signs Shock, fever, tachycardia, tachypnea; Hamman’s sign (crunching sound over heart due to mediastinal air) Investigations Chest X-ray: pneumomediastinum, widened mediastinum, left pleural effusion; CT/MRI chest with IV/oral contrast; contrast swallow with Gastrografin (if patient stable); endoscopy (diagnostic and therapeutic) Complications Mediastinitis (most common cause of mortality), sepsis, pleural contamination, shock, high morbidity and mortality if untreated

@Neet_pg_bot

Q2: A 45-year-old woman presents with fatigue, difficulty swallowing and pale skin. Investigation reveals a cervical esophageal web. Which of the following conditions is most likely? (Q849131)

A. Achalasia

B. Barrett’s Esophagus

C. Plummer-Vinson Syndrome

D. Esophageal Carcinoma

Correct Answer: C. Plummer-Vinson Syndrome

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Plummer-Vinson Syndrome is characterized by a cervical esophageal web, iron deficiency anemia, and dysphagia, fitting the patient’s symptoms. Plummer Vinson Syndrome Overview A rare condition affecting middle-aged women. Characterized by a triad of: Cervical esophageal web Iron deficiency anemia Dysphagia. Causes Iron/nutritional deficiencies Genetic factors Autoimmune conditions Risks Increased risk of post-cricoid and cervical esophageal cancer Treatment Iron supplements Dietary modifications, Endoscopic dilatation if necessary Achalasia (Option A) : Achalasia is due to failure of LES relaxation and presents with progressive dysphagia to both solids and liquids . It shows bird-beak appearance on barium swallow, not an esophageal web. It is not associated with iron deficiency anemia or cervical webs. Barrett’s Esophagus (Option B) : Barrett’s esophagus is a complication of chronic GERD , characterized by intestinal metaplasia of the lower esophagus . It presents with heartburn and reflux symptoms , not cervical dysphagia. It does not cause esophageal webs or iron deficiency anemia . Esophageal Carcinoma (Option D): Typically presents with progressive dysphagia (first solids, then liquids) , weight loss, and anorexia. It is seen in older patients , not classically associated with esophageal webs. Although Plummer–Vinson syndrome is a risk factor for carcinoma, the given presentation is of the syndrome itself , not malignancy.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q3: A 70-year-old male with a history of smoking presents with progressive dysphagia and weight loss. Endoscopy reveals a mass in the mid-esophagus. Biopsy confirms squamous cell carcinoma. Imaging shows the tumor invading the muscularis propria and metastasis to three regional lymph nodes. What is the TNM classification for this patient? (Q849128)

A. T2 N1 M0

B. T2 N2 M0

C. T3 N2 M0

D. T2 N3 M1

Correct Answer: B. T2 N2 M0

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: T2 N2 M0 indicates tumor invasion of the muscularis propria (T2), metastasis to 3-6 regional lymph nodes (N2), and no distant metastasis (M0). TNM Staging- Carcinoma Esophagus T Tx Tumor cannot be assessed T0 No primary tumor Tis High-grade dysplasia (malignant cells confined by basement membrane) T1 Tumor invades lamina propria, muscularis mucosae, or submucosa T1a Invades lamina propria or muscularis mucosae T1b Invades submucosa T2 Invades muscularis propria T3 Invades adventitia T4 Invades adjacent structures T4a Invades pleura, pericardium, azygos vein, diaphragm, or peritoneum T4b Invades aorta, vertebral body, or airway N Nx Nodes cannot be assessed N0 No regional node metastasis N1 Metastasis in 1-2 regional nodes N2 Metastasis in 3-6 regional nodes N3 Metastasis in 7+ regional nodes M M0 No distant metastasis M1 Distant metastasis

Bailey & Love's Short Practice of Surgery (28th Edition), Page: 1138

↑ *Back to this question in Part A*

@Neet_pg_bot

Q4: A 45-year-old man presents with progressive dysphagia for both solids and liquids over the past year. He also reports occasional chest pain, especially after eating. Manometry is performed and analyzed using the Chicago Classification. The results show spastic contractions in the distal esophagus. Based on these findings, what type of achalasia is most likely? (Q849117)

A. Type I Achalasia

B. Type II Achalasia

C. Type III Achalasia

D. Diffuse Esophageal Spasm

Correct Answer: C. Type III Achalasia

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Chicago Classification 4.0 Revised Criteria for Esophageal Disorders: Esophageal Disorder Description Values Achalasia Type I Minimal contractility (Option A ruled out) IRP ≥ 15 mmHg, 100% failed peristalsis Type II Esophageal pan-pressurization (Option B ruled out) IRP ≥ 15 mmHg, 100% failed peristalsis with ≥ 20% pan-esophageal pressurization Type III Spastic contractions (Option C) IRP ≥ 15 mmHg, ≥ 20% spastic contractions (DCI > 8,000 mmHg·s·cm) IRP: Integrated Relaxation Pressure DCI: Distal Contractile Integral DL: Distal Latency

References:

Bailey & Love's Short Practice of Surgery, 28th Edition, Page 1122.

Chicago Classification

↑ *Back to this question in Part A*

@Neet_pg_bot

Q5: A 40-year-old man complains of a burning sensation in his chest and regurgitation after meals. Symptoms improve with antacids and have no significant weight loss. What is the most likely diagnosis? (Q849123)

A. Peptic ulcer disease

B. Gastroesophageal reflux disease (GERD)

C. Gastritis

D. Esophageal spasm

Correct Answer: B. Gastroesophageal reflux disease (GERD)

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: GERD is a condition where stomach contents, including acid, reflux into the esophagus, causing symptoms like heartburn, regurgitation, difficulty swallowing and sometimes chest pain. The burning sensation behind the sternum after meals, improvement with antacids, and the absence of significant weight loss are classic signs of GERD, making it the most likely diagnosis in this case. The most important pathophysiological factor implicated in GERD is frequent transient LES relaxation. Diagnosis: Endoscopy: To visualize the esophagus and identify inflammation, ulcers, or Barrett's esophagus. 24-hour pH Monitoring: Gold standard for diagnosis of GERD which measures acid exposure in the esophagus over a day. Esophageal Manometry: Assesses esophageal motility and LES function. Barium Swallow: An X-ray test that evaluates swallowing and reflux patterns.

Bailey & Love's short practice of surgery, Edition 28,page 1112, 1113&1114

GERD

↑ *Back to this question in Part A*

@Neet_pg_bot

Q6: Which of the following findings are diagnostic of nutcracker esophagus? Distal esophageal contraction amplitude > 180 mmHg Distal esophageal contraction amplitude > 45 mmHg Distal esophageal peristaltic wave duration > 6 cm Distal esophageal contraction amplitude < 30 mmHg Distal esophageal contraction duration > 6 seconds Multiple simultaneous contractions with an amplitude of > 30 mmHg. (Q849125)

A. 1 and 5

B. 2 and 3

C. 1, 3, and 5

D. 2 and 6

Correct Answer: A. 1 and 5

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Hypercontractile motility disorder Nutcracker/ Jackhammer Esophagus Definition Excessively intense, coordinated esophageal contractions with normal LES function. Investigations Esophageal Manometry High amplitude contractions (>180 mmHg) Prolonged contraction duration (>6 seconds) Normal LES pressure and relaxation Barium Swallow (Esophagram) "Corkscrew" or "rosary bead" appearance due to intense contractions Endoscopy Typically normal mucosa Used to rule out structural abnormalities

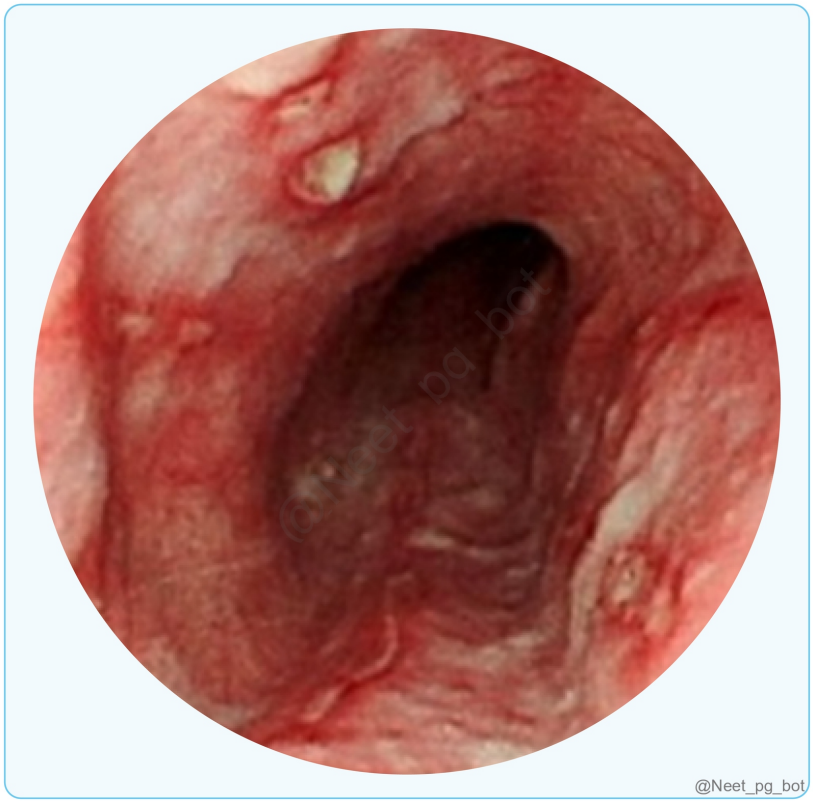
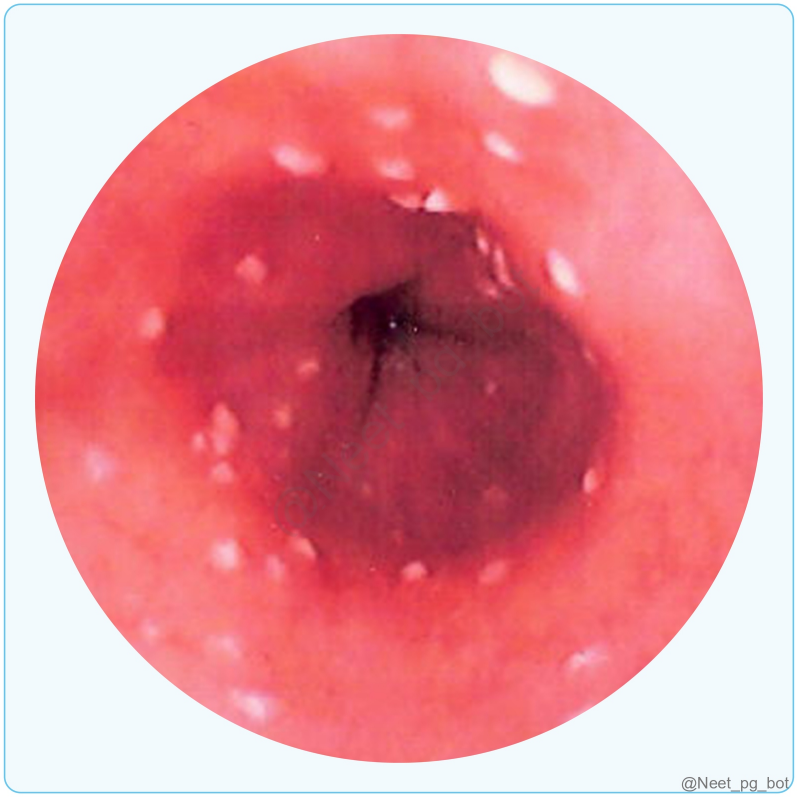
@Neet_pg_bot

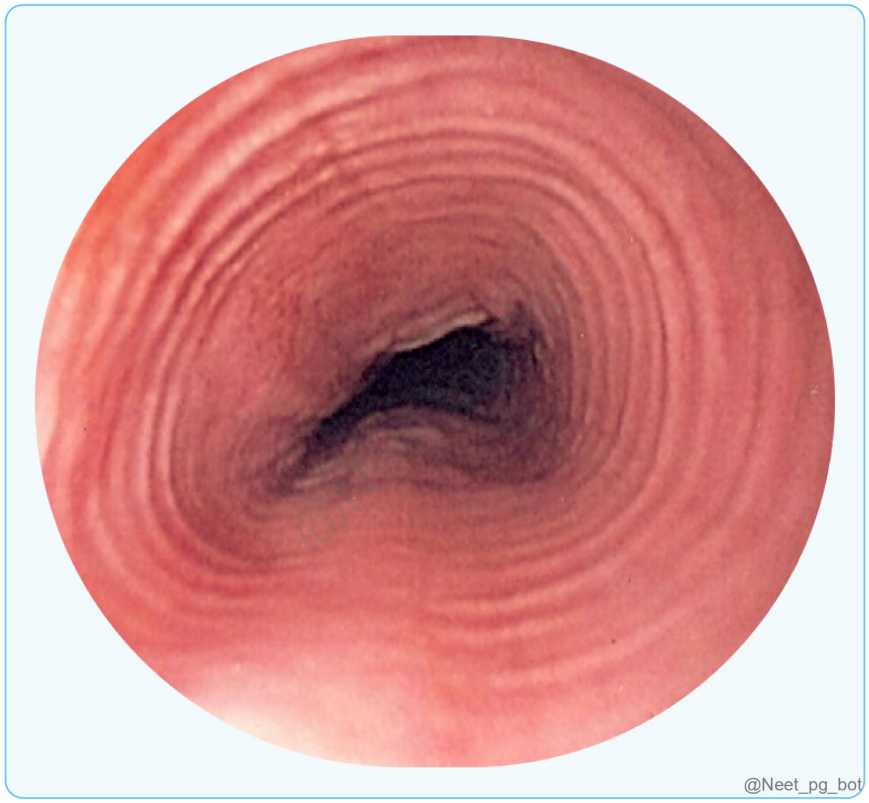
Q7: Match the following conditions with its endoscopy images A) Esophageal candidiasis 1) B) Feline esophagitis 2) C)Herpes simplex esophagitis 3) D)CMV esophagitis 4) (Q849135)



A. A-2, B-4, C-1, D-3



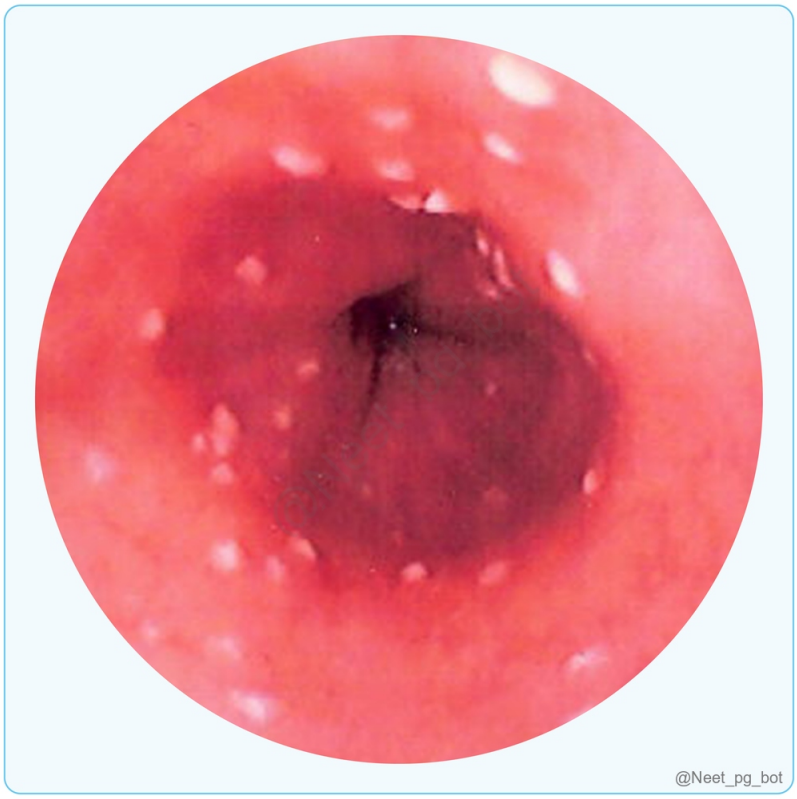
B. A-3, B-4, C-1, D-2



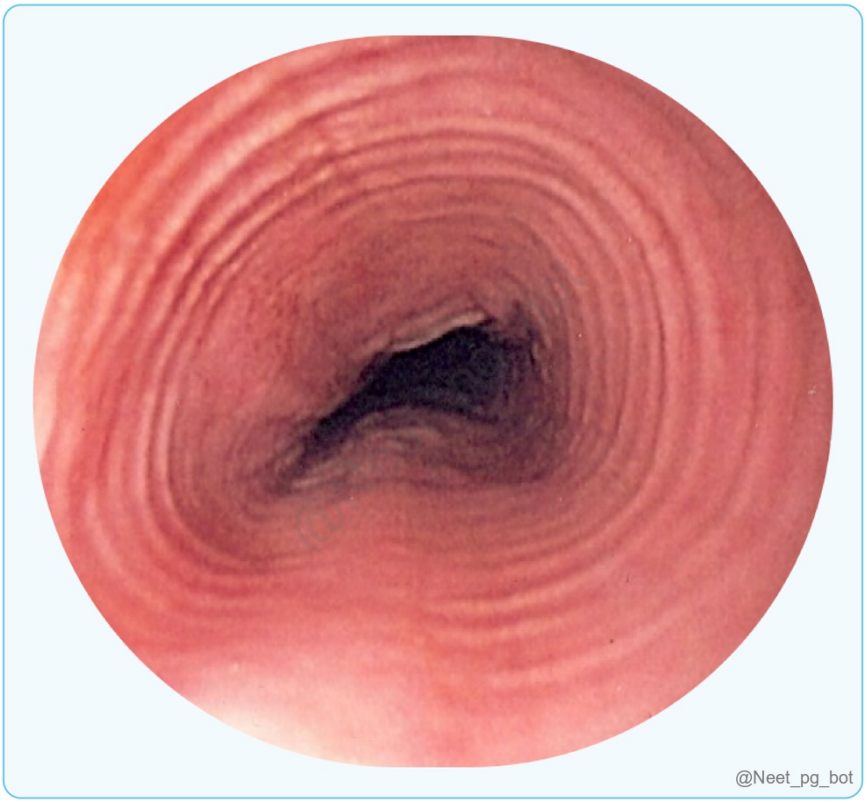
C. A-4, B-3, C-2, D-1

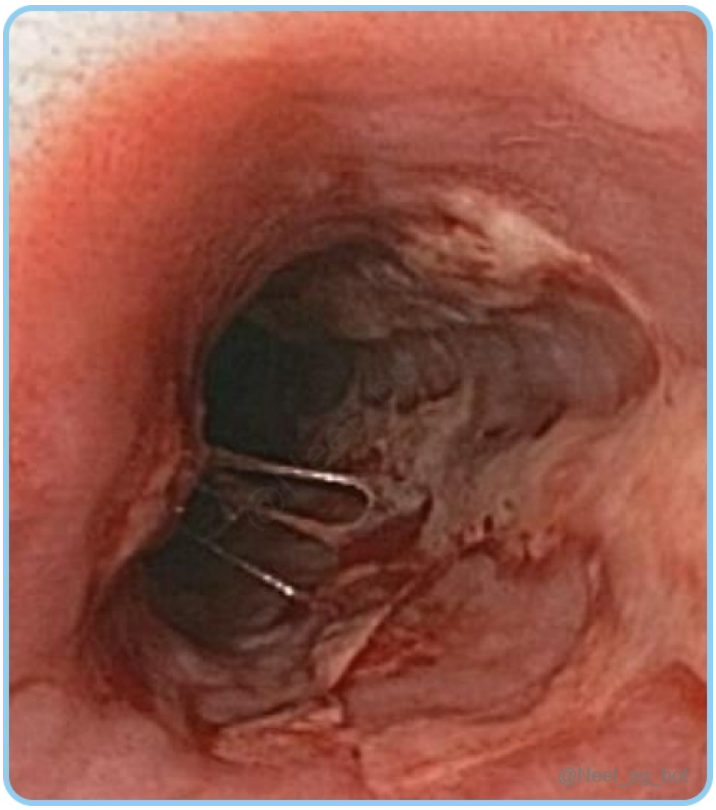
D. A-1, B-4, C-2, D-3

@Neet_pg_bot

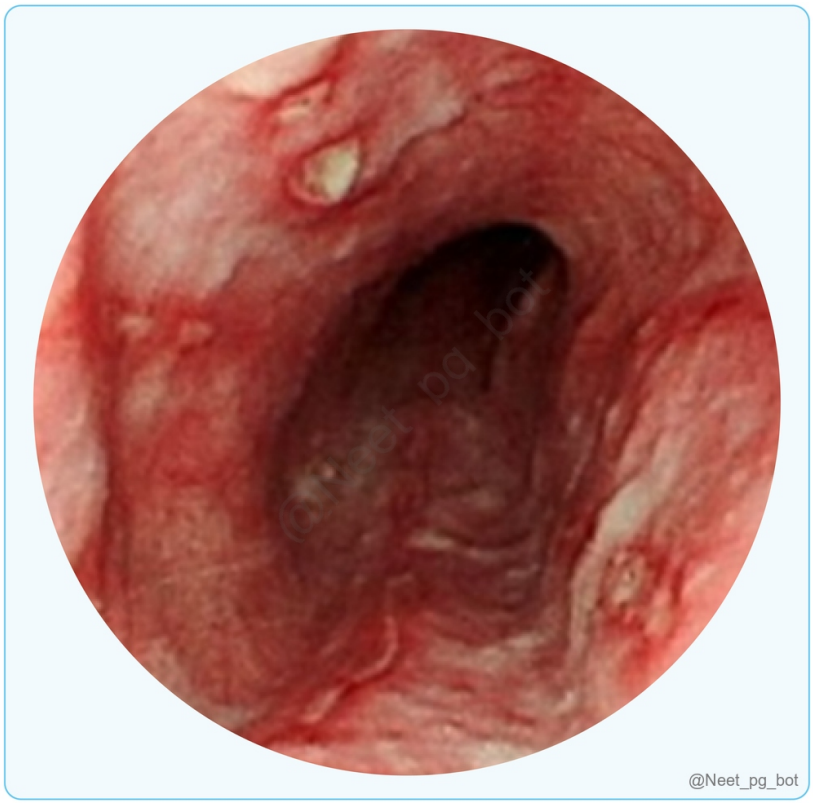


@Neet_pg_bot





Correct Answer: B. A-3, B-4, C-1, D-2



■ *Listen to Audio 1*

Explanation: A-3, B-4, C-1, D-2 Esophageal candidiasis Characterized by white, raised plaques that resemble cottage cheese or curd. These plaques are adherent and often found along the entire length of the esophagus. The surrounding mucosa may appear erythematous and friable. Feline esophagitis Often presents with concentric rings, giving the esophagus a "feline" appearance, Herpes simplex esophagitis Typically presents with multiple small, well-circumscribed, punched-out ulcers. These ulcers are often located in the mid-to-distal esophagus. The surrounding mucosa may be erythematous. CMV esophagitis Characterized by large, solitary or linear ulcers, often located in the mid-to-distal esophagus. The ulcers may have a well-defined border and are surrounded by relatively normal mucosa.

↑ *Back to this question in Part A*

@Neet_pg_bot

Q8: Which of the following is true regarding the esophagus? (Q849108)

A. The upper esophageal sphincter is composed of the thyropharyngeus and cricopharyngeus muscles

B. The lower esophageal sphincter is a physiological entity

C. The cervical esophagus is supplied by the inferior thyroid artery

D. All are true

Correct Answer: D. All are true

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Upper esophageal sphincter (UES): Feature Details Location The inlet of the esophagus, at the neck Muscle Composition Inferior pharyngeal constrictor composed of the thyropharyngeus and cricopharyngeus muscles (Option A) Weakness Point The transition between the thyropharyngeus (oblique fibers) and cricopharyngeus (horizontal fibers) creates the Killian triangle (site of Zenker diverticulum) Lower esophageal sphincter (LES): Feature Details Location The lower end of the esophagus, in the terminal 4 cm Function Prevents reflux of gastric and duodenal contents Specialty A physiological zone of high pressure (Option B) Vasculature: Segment Arterial Supply Venous Drainage Cervical Esophagus Inferior thyroid arteries (Option C) Inferior thyroid veins Thoracic Esophagus Descending thoracic aorta, bronchial arteries Azygos and hemiazygos veins Abdominal Esophagus Left gastric artery, paired inferior phrenic arteries Drains into systemic and portal venous systems via left and right phrenic veins, left gastric (coronary) vein, and short gastric veins

@Neet_pg_bot

Q9: A 60-year-old male patient complains of intermittent dysphagia and episodes of food obstruction. Endoscopy reveals a fibrous band at the gastroesophageal junction. Which of the following is the most likely diagnosis? (Q849133)

A. Esophageal Web

B. Zenker's Diverticulum

C. Barrett's Esophagus

D. Schatzki Ring

Correct Answer: D. Schatzki Ring

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Schatzki ring is identified as a benign constricting band of fibrous tissue at the gastroesophageal junction, causing symptoms such as dysphagia and food obstruction. Schatzki Ring Overview A benign constricting band of fibrous tissue located at the gastroesophageal junction (GEJ). Characteristics Proximal side lined with squamous epithelium The distal side lined with columnar epithelium Causes Exact cause unclear Linked to gastroesophageal reflux disease (GERD) Often associated with hiatal hernia Symptoms Dysphagia (difficulty swallowing) Food obstruction Diagnosis Barium esophagram Endoscopy Treatment Endoscopic dilation using bougie or balloon Biopsy to rule out malignancy Repeated dilation may be necessary for symptomatic relief Esophageal Web (Option A): Esophageal webs are thin mucosal membranes located in the upper (cervical) esophagus , not at the GEJ. They are associated with iron deficiency anemia (Plummer–Vinson syndrome) . Zenker’s Diverticulum (Option B): Zenker’s diverticulum is a pharyngoesophageal pouch occurring at Killian’s dehiscence (upper esophagus). It presents with: Regurgitation of undigested food Halitosis Neck swelling Barrett’s Esophagus (Option C): Barrett’s esophagus involves intestinal metaplasia of distal esophagus due to GERD . It presents with chronic reflux symptoms , not intermittent obstruction. There is no fibrous ring formation .

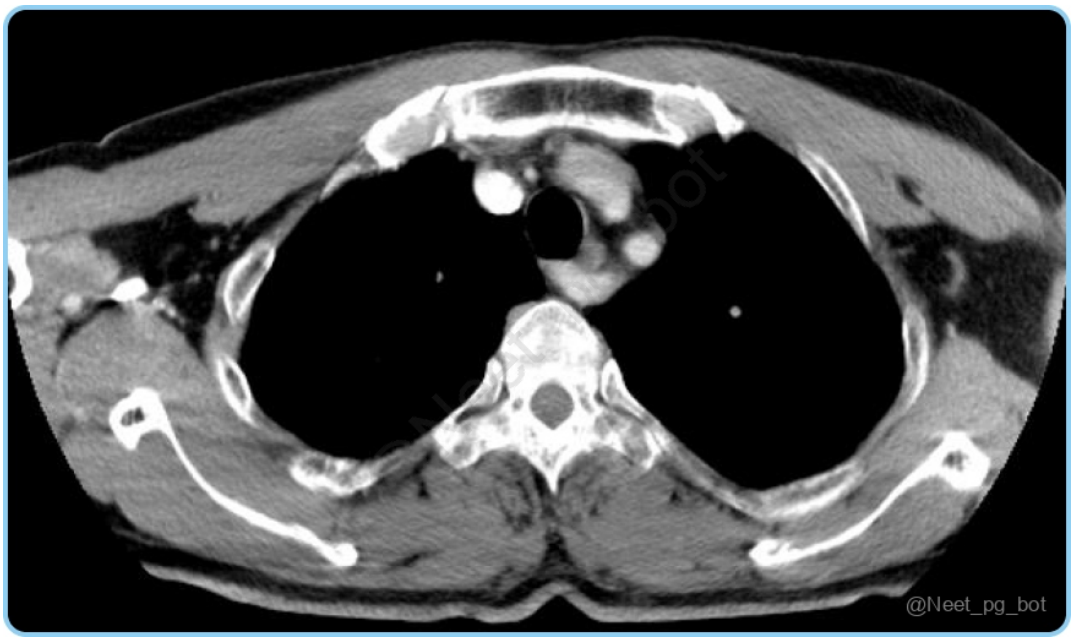
↑ *Back to this question in Part A*

@Neet_pg_bot



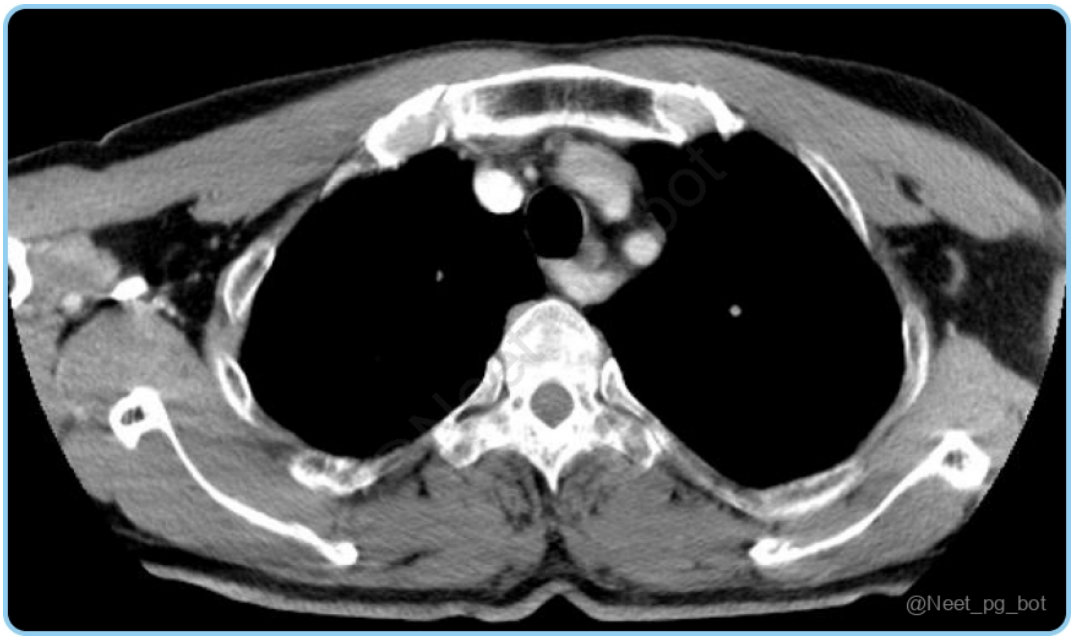
Q10: A 60-year-old patient presents with late-onset difficulty swallowing and significant weight loss. Imaging reveals an aberrant right subclavian artery compressing the esophagus. What is the most likely diagnosis? (Q849132)

A. Achalasia

B. Esophageal Cancer

C. Dysphagia Lusoria

D. Schatzki's Ring



Correct Answer: C. Dysphagia Lusoria

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Dysphagia lusoria is caused by vascular compression of the esophagus due to an aberrant right subclavian artery, fitting the patient's symptoms and imaging findings. The CT scan shows an aberrant right subclavian artery (visible as a vessel passing behind the esophagus) causing esophageal compression Dysphagia Lusoria Definition Rare swallowing disorder due to vascular compression of the esophagus, mainly by an aberrant right subclavian artery (ARSA) Pathophysiology ARSA from the left aortic arch passes behind/in front of the esophagus, causing compression Symptoms Difficulty swallowing worsens with age, possible weight loss and nutritional deficiencies Diagnosis Imaging studies (barium swallow, chest CT) Manometric studies are not typically helpful Management Based on symptom severity Dietary modifications for mild cases. Surgical intervention for severe cases. Other options: Option A: Achalasia: Wouldn't show vascular abnormality; would show dilated esophagus with bird's beak appearance on barium swallow Option B: Esophageal Cancer : Would show a mass lesion, not just vascular compression Option D: Schatzki's Ring: Intermittent dysphagia to solids only; no weight loss or vascular findings

@Neet_pg_bot

Q11: A 45-year-old man undergoes an endoscopy for evaluation of dysphagia and an incidental mass is discovered in the esophagus. An endoscopic ultrasound (EUS) shows a hypoechoic mass originating from the muscularis propria. Which of the following statements regarding the esophageal lesion is most accurate? (Q849130)

A. Immediate biopsy and fine-needle aspiration (FNA) should be performed to confirm the diagnosis.

B. If the lesion is asymptomatic and small, it can be observed without biopsy.

C. The preferred treatment for small, symptomatic lesions is chemotherapy.

D. Large lesions (>5 cm) are best managed with radiofrequency ablation (RFA)

Correct Answer: B. If the lesion is asymptomatic and small, it can be observed without biopsy.

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: The clinical scenario is suggestive of leiomyoma. Small, asymptomatic leiomyomas can be safely observed without biopsy. Esophageal Leiomyomas Overview Hypoechoic masses beneath the mucosa, typically found in the middle to distal esophagus Most common benign tumor in the esophagus Often found incidentally during endoscopies Origin Arise from the muscularis propria or submucosal layer Symptoms Usually asymptomatic, but large tumors can cause dysphagia or discomfort Imaging Barium esophagram: Smooth filling defect Endoscopy: Round protrusion with smooth overlying mucosa Endoscopic ultrasound (EUS): Hypoechoic with regular borders, originating from the fourth endosonographic layer Malignant Transformation Rare, resection is recommended if enlargement is observed during follow-up Biopsy Biopsies or FNAs are relatively contraindicated due to risk of scarring, which complicates enucleation (Option A ruled out) Surgical Approaches Enucleation: Thoracoscopic approach for smaller tumors. Chemotherapy is not indicated (Option C ruled out) Submucosal Tunneling Endoscopic Resection (STER): Minimally invasive, involves creating a submucosal tunnel for resection Thoracoscopy: Suitable for larger tumors (>5 cm) (Option D ruled out)

References:

Bailey & Love's Short Practice of Surgery (28th Edition), Page: 1134

Sabiston Textbook Of Surgery, 21st edition, page: 1037, 1038

↑ *Back to this question in Part A*

@Neet_pg_bot

Q12: A 62-year-old male presents with progressive dysphagia and weight loss over the past 3 months. An endoscopy reveals a tumor in the lower third of the esophagus. Biopsy confirms adenocarcinoma. Further investigation reveals, the tumor has invaded the muscularis propria but no distant metastasis is detected. Which treatment option is most appropriate for this patient? (Q849129)

A. Endoscopic Mucosal Resection (EMR)

B. Endoscopic Submucosal Dissection (ESD)

C. Esophagectomy

D. Radiofrequency Ablation (RFA)

Correct Answer: C. Esophagectomy

■ *Listen (English)*

■ *Listen (Hindi)*

Explanation: Esophagectomy is the primary treatment for locally advanced esophageal cancer where the tumor has invaded the muscularis propria. Carcinoma Esophagus- Management Staging Accurate staging is essential for treatment planning. Early-Stage Disease Endoscopic Mucosal Resection (EMR): Removes superficial cancers (T1a) and early cancers with minimal submucosal invasion (T1b). (Option A ruled out) Endoscopic Submucosal Dissection (ESD): Removes larger lesions with en bloc resection. (Option B ruled out) Radiofrequency Ablation (RFA) : Treats early Barrett's esophagus-associated cancers. Uses heat to destroy cancer cells. No surgical specimen for pathological assessment. (Option D ruled out) Locally Advanced Disease Esophagectomy: Primary treatment for locally advanced cancer. Removes esophagus and reconstructs the digestive tract using the stomach, jejunum, or colon. Surgical approaches: transhiatal, transthoracic, minimally invasive (MIE). (Option C) Multimodality Therapy: Combines chemotherapy, radiation therapy, and surgery. Neoadjuvant Chemoradiation: Shrinks the tumor before surgery. CROSS trial showed survival benefit for neoadjuvant chemoradiation followed by surgery. Palliative Treatment Endoscopic Stenting: Maintains esophageal patency, helps with swallowing difficulties. Chemotherapy: Slows cancer progression, shrinks the tumor. Radiotherapy: Shrinks tumors, controls bleeding. Brachytherapy: Internal radiation therapy targeting the tumor.
